Package ‘clinDataReview’

February 23, 2022

Type Package

Title Clinical Data Review Tool

Version 1.2.2

Date 2022-02-23

Description Creation of interactive tables, listings and figures (‘TLFs’) and associated report for exploratory analysis of data in a clinical trial, e.g. for clinical oversight activities.
Interactive figures include sunburst, treemap, scatterplot, line plot and barplot of counts data.
Interactive tables include table of summary statistics (as counts of adverse events, enrollment table) and listings.
Possibility to compare data (summary table or listing) across two data batches/sets.
A clinical data review report is created via study-specific configuration files and template ‘R Markdown’ reports contained in the package.

Imports bookdown, clinUtils (>= 0.1.0), crosstalk, data.table,
 ggplot2, haven, htmltools, htmlwidgets, knitr, jsonlite,
 jsonvalidate, methods, plotly, plyr, rmarkdown, stats, stringr,
 utils, tools, yaml

Suggests countrycode, inTextSummaryTable (>= 3.1.0), pander,
 patientProfilesVis (>= 0.12.0), reshape2, testthat, xml2, DT

SystemRequirements pandoc (to create a clinical data review report)

**addDateOfReportRun**  
*Add date of report running*

**Description**
Add the today's date of when the report runs to the info of the metadata.

**Usage**
```r
addDateOfReportRun(summaryInfo)
```

**Arguments**
- `summaryInfo` matrix, see output from `getMetadata`.

**Value**
A matrix, same as input `summaryInfo` with an extra row with the date of today.

---

**addFacetPanel**  
*Add facet-panel to single plotly plot.*

**Description**
Add facet-panel to single plotly plot.

**Usage**
```r
addFacetPanel(
  pl,  
  panelLab,  
  panelWidth = 20,  
  fontSize = 15,  
  side = c("top", "right")
)
```

**Arguments**
- `pl` a plotly object to which to add a single facet panel
- `panelLab` text to be shown in the facet panel
- `panelWidth` thickness of the panel in pixels.
- `fontSize` fontsize of `facetText`
- `side` the side of the plot to show the panel (currently only right panels are implemented.)
addReferenceLinesClinDataPlot

Details

plot title clipping.
In case case side = 'top', the plot title (eg. layout(title = "title")) will clip with the top panel.
Resolve this with the following configurations: (once all the subplots have already been combined)
layout( title = list(text = "title",yref = "container",y = 1)) # place the title at absolute top of the page
margin = list(t = panelWidth + heightTitleTextInPixels) # If font size = 15 roughly equal to 20 pixels.

Value

plotly object with the facet panel added.

addReferenceLinesClinDataPlot

Add reference (horizontal/vertical/diagonal) lines to a clinical data plot

Description

Add reference (horizontal/vertical/diagonal) lines to a clinical data plot

Usage

addReferenceLinesClinDataPlot(
  gg,
  data,
  xVar,
  yVar,
  xLim = NULL,
  yLim = NULL,
  refLinePars = NULL,
  facetPars = NULL
)

Arguments

- **gg**: ggplot object.
- **data**: Data.frame with data.
- **xVar**: String with column of data containing x-variable.
- **yVar**: String with column of data containing y-variable.
- **xLim**: Numeric vector of length 2 with limits for the x/y axes.
annotateData

**yLim**

Numeric vector of length 2 with limits for the x/y axes.

**refLinePars**

(optional) Nested list, with parameters for each reference line(s). Each sublist (a.k.a reference line) contains:

- aesthetic value(s) or variable(s) for the lines (in this case column names of data) for reference lines. The line position is controlled by the aesthetics supported in `geom_vline`, `geom_hline` and `geom_abline`.
- 'label': (optional) Logical specifying if the line should be annotated (FALSE to not annotate the line) or string with annotation label. By default, the value of the position of the horizontal/vertical line or the equation of the diagonal line is displayed.

**facetPars**

List with facetting parameters, passed to the facetting function. Variables should be specified as character or formula. For ‘wrap’ facetting (`facetType` is ‘wrap’), if the layout is not specified via `nrow/ncol`, 2 columns are used by default.

**Value**

Updated ggplot object.

**Author(s)**

Laure Cougnaud

---

**annotateData**

*Annotate a SDTM dataset.*

**Description**

Standard annotation variables are available via the parameter `annotType`. Custom dataset/variables of interest are specified via the `annotDataset/annotVar` parameters.

**Usage**

```r
annotateData(
  data,
  dataPath = ".",
  annotations,
  subjectVar = "USUBJID",
  verbose = FALSE,
  labelVars = NULL,
  labelData = "data"
)
```
**Arguments**

- **data**: Data.frame with input data to annotate.
- **dataPath**: String with path to the data.
- **annotations**: Annotations (or list of those) either as a:
  - string with standard annotation type, among:
    - demographics: standard variables from the demographics data (DM or ADSL) are extracted
    - exposed_subjects: a logical variable: EXFL is added to data, identifying exposed subjects, i.e. subjects included in the exposure dataset (EX/ADEX) dataset and with non empty and non missing start date (’EXSTDTC’, ’STDY’ or ’ASTDY’)
    - functional_groups_lab: a character variable: ’LBFCTGRP’ is added to data based on standard naming of the parameter code (’PARAMCD’ or ’LBFTESTCD’ variable)
  - list of custom annotation, with:
    - (optional) annotation dataset, either:
      * ’dataset’: String with name of the annotation dataset, e.g. ’ex’ to import data from the file: ’[dataset].sas7bdat’ in dataPath
      * ’data’: Data.frame with annotation dataset
      The input data is used if ’data’ and ’dataset’ are not specified.
    - ’vars’: Either:
      * Character vector with variables of interest from annotation dataset. If not specified, all variables of the dataset are considered.
      * String with new variable name computed from varFct
    - ’varFct’: (optional) Either:
      * function of data or string containing such function (e.g. ’function(data) ’)
      * string containing manipulations from column names of data (e.g. ’col1 + col2’) used to create a new variable specified in vars.
    - ’filters’: (optional) Filters for the annotation dataset, see filters parameter of filterData.
      The annotation dataset is first filtered, before being combined to the input data, such as only the records retained in the annotation dataset will be annotated in the output data. Other records will have missing values in the annotated variables.
    - ’varLabel’: (optional) label for new variable in case varFct is specified.
    - ’varsBy’: (optional) Character vector with variables used to merge input data and the annotation dataset. If not specified:
      * if an external dataset (dataset/data) is specified: subjectVar is used
      * otherwise: annotation dataset and input data are merged by rows IDs
- **subjectVar**: String with subject ID variable, ’USUBJID’ by default.
annotateData

verbose Logical, if TRUE (FALSE by default) progress messages are printed in the current console. For the visualizations, progress messages during download of subject-specific report are displayed in the browser console.

labelVars Named character vector containing variable labels of data. This will be updated with the labels of the extra annotation variables (in attr(output, 'labelVars')).

labelData (optional) String with label for input data, that will be included in progress messages.

Value

Annotated data. If labelVars is specified, the output contains an extra attribute: 'labelVars' containing updated labelVars (accessible via: in attr(output, 'labelVars')).

Examples

library(clinUtils)

data(dataADaMCDISCP01)

dataLB <- dataADaMCDISCP01$ADLBC
dataDM <- dataADaMCDISCP01$ADSL
dataAE <- dataADaMCDISCP01$ADAE

labelVars <- attr(dataADaMCDISCP01, "labelVars")

# standard annotations:
# path to dataset should be specified via: 'pathData'
## Not run:
annotateData(dataLB, annotations = "demographics", pathData = ...)
## End(Not run)

# add all variables in annotation data (if not already available)
head(annotateData(dataLB, annotations = list(data = dataDM)), 1)

# only variables of interest
head(annotateData(dataLB, annotations = list(data = dataDM, vars = c("ARM", "ETHNIC"))), 1)

# filter annotation dataset
dataAnnotated <- annotateData(dataLB,
annations = list(
data = dataDM,
vars = c("ARM", "ETHNIC"),
filters = list(var = "ARM", value = "Placebo")
)
)
head(subset(dataAnnotated, ARM == "Placebo"), 1)
head(subset(dataAnnotated, is.na(ARM)), 1)

# worst-case scenario: add a new variable based on filtering condition
dataAE$AESEV <- factor(dataAE$AESEV, levels = c("MILD", "MODERATE", "SEVERE"))
dataAEWC <- annotateData(
data = dataAE,
annotations = list(
  vars = "WORSTINT",
  # create new variable: 'WORSTINT'
  # with TRUE if maximum toxicity grade per subject/test
  # (if multiple, they are all retained)
  filters = list(
    var = "AESEV",
    # max will take latest level in a factor
    # (so 'MODERATE' if 'MILD'/"MODERATE" are available)
    valueFct = function(x) x[which.max(as.numeric(x))],
    varsBy = c("USUBJID", "AEDECOD"),
    keepNA = FALSE,
    varNew = "WORSTINT",
    labelNew = "worst-case"
  ),
  labelVars = labelVars,
  verbose = TRUE
)
attr(dataAEWC, "labelVars")["WORSTINT"]

# add a new variable based on a combination of variables:
dataLB <- annotateData(dataLB,
  annotations = list(vars = "HILORATIO", varFct = "A1HI / A1LO")
)

# add a new variable based on extraction of a existing variable
# Note: slash should be doubled when the function is specified as text
dataLB <- annotateData(dataLB,
  annotations = list(vars = "PERIOD", varFct = "sub(".* Week (.+)", 'Week \d\d\d', AVISIT)"
)

# multiple annotations:
dataAnnotated <- annotateData(dataLB,
  annotations = list(
    list(data = dataDM, vars = c("ARM", "ETHNIC")),
    list(data = dataAE, vars = c("AESEV"))
  )
)
head(dataAnnotated, 1)

# Barplot interactive plot.

barplotClinData Barplot interactive plot.

Description

Barplot interactive plot.
barplotClinData

Usage

barplotClinData(
  data,
  xVar,
  yVar,
  xLab = getLabelVar(xVar, labelVars = labelVars),
  yLab = getLabelVar(yVar, labelVars = labelVars),
  colorVar = NULL,
  colorLab = getLabelVar(colorVar, labelVars = labelVars),
  colorPalette = NULL,
  barmode = "group",
  titleExtra = NULL,
  title = paste(paste(yLab, "vs", xLab, titleExtra), collapse = "<br>")
)

Arguments

data Data.frame with data.
xVar String with column of data containing x-variable.
yVar String with column of data containing y-variable.
xLab String with label for xVar.
yLab String with label for xVar.
colorVar (optional) String with color variable.
colorLab (optional) String with label for colorVar.
colorPalette (optional) Named character vector with color palette. If not specified, the viridis color palette is used. See clinColors.
barmode String with type of barplot, either: 'group' or 'stack' (see parameter in layout).
titleExtra String with extra title for the plot (appended after title).
barplotClinData

title String with title for the plot.
caption String with caption.  
The caption is included at the bottom right of the plot. Please note that this  
might overlap with vertical or rotated x-axis labels.
subtitle String with subtitle.  
The subtitle is included at the top left of the plot, below the title.
labelVars Named character vector containing variable labels.
width Numeric, width of the plot in pixels, 700 by default.
height Numeric, height of the plot in pixels, 700 by default.
hoverVars Character vector with variable(s) to be displayed in the hover, by default any  
position and aesthetic variables displayed in the plot.
hoverLab Named character vector with labels for hoverVars.
textVar (optional) String with a text variable, that will be displayed outside of each bar.
pathVar String with variable of data containing hyperlinks with path to the subject-  
specific report, formatted as:

<a href="/path-to-report">label</a>

If multiple, they should be separated by ‘,’.
The report(s) will be:
• compressed to a zip file and downloaded if the user clicks on the ‘p’ (a.k.a  
 ‘profile’) key when hovering on a point of the plot
• included in a collapsible row, and clickable with hyperlinks in the table
pathLab String with label for pathVar, included in the collapsible row in the table.
table Logical, if TRUE (FALSE by default) returns also a datatable containing the  
plot data. (The plot and the table are not linked.)
tableVars Character vector with variables to be included in the table.
tableLab Named character vector with labels for each tableVars.
tableButton Logical, if TRUE (by default) the table is included within an HTML button.
tablePars List with parameters passed to the getClinDT function.
id String with general id for the plot:
• ’id’ is used as group for the SharedData
• ’button:[id]’ is used as button ID if table is TRUE
If not specified, a random id, as ’plotClinData[X]’ is used.
verbose Logical, if TRUE (FALSE by default) progress messages are printed in the current console. For the visualizations, progress messages during download of subject-specific report are displayed in the browser console.

Value

Either:
• if a table is requested: a clinDataReview object, a.k.a a list with the ’plot’ (plotly object)  
 and ’table’ (datatable object)
• otherwise: a plotly object
Author(s)

barplotClinData(
data = dataPlot,
xVar = "AEDECOD",
yVar = "n", yLab = "Number of patients with adverse events",
labelVars = lblVars
)
boxplotClinData

Boxplot interactive plot.

Description

Boxplot interactive plot.

Usage

boxplotClinData(
  data,
boxplotClinData

Arguments

data: Data.frame with data.
xVar: String with column of data containing x-variable.
yVar: String with column of data containing y-variable.
xLab: String with label for xVar.
yLab: String with label for xVar.
colorVar: (optional) String with color variable.
colorLab: String with label for colorVar.
colorPalette: (optional) Named character vector with color palette. If not specified, the viridis color palette is used. See clinColors.
facetVar: (optional) String with facet variable.
facetLab: String with label for facetVar.
ncol  single-length integer denoting the number of columns for the facetting.
titleExtra  String with extra title for the plot (appended after title).
title  String with title for the plot.
subtitle  String with subtitle.
The subtitle is included at the top left of the plot, below the title.
caption  String with caption.
The caption is included at the bottom right of the plot. Please note that this
might overlap with vertical or rotated x-axis labels.
labelVars  Named character vector containing variable labels.
width  Numeric, width of the plot in pixels, 700 by default.
height  Numeric, height of the plot in pixels, 700 by default.
hoverVars  Character vector with variable(s) to be displayed in the hover, by default any
position and aesthetic variables displayed in the plot.
hoverLab  Named character vector with labels for hoverVars.
pathVar  String with variable of data containing hyperlinks with path to the subject-specific report, formatted as:

  \(<a\ href="/path-to-report">label</a>\)

  If multiple, they should be separated by: ', '.
The report(s) will be:
  • compressed to a zip file and downloaded if the user clicks on the 'p' (a.k.a
    'profile') key when hovering on a point of the plot
  • included in a collapsible row, and clickable with hyperlinks in the table
pathLab  String with label for pathVar, included in the collapsible row in the table.
idVar  String with variable containing subject ID.
idLab  String with label for idVar.
table  Logical, if TRUE (FALSE by default) returns also a datatable containing the
plot data. (The plot and the table are not linked.)
tableVars  Character vector with variables to be included in the table.
tableLab  Named character vector with labels for each tableVars.
tableButton  Logical, if TRUE (by default) the table is included within an HTML button.
tablePars  List with parameters passed to the getClinDT function.
id  String with general id for the plot:
  • 'id' is used as group for the SharedData
  • 'button:[id]' is used as button ID if table is TRUE
If not specified, a random id, as 'plotClinData[X]' is used.
verbose  Logical, if TRUE (FALSE by default) progress messages are printed in the current
console. For the visualizations, progress messages during download of
subject-specific report are displayed in the browser console.
Value

Either:

- if a table is requested: a clinDataReview object, a.k.a a list with the ‘plot’ (plotly object) and ‘table’ (datatable object)
- otherwise: a plotly object

yVar = "AVAL",
facetVar = "ATPT", ncol = 2,
colorVar = "TRTA",
title = "Diastolic Blood Pressure distribution",
subtitle = "By actual visit and analysis timepoint",
yLab = "Actual value of the Diastolic Blood Pressure parameter (mmHg)"
, caption = "Summary statistics are computed internally. ",
labelVars = labelVars
)

## End(Not run)

---

checkAvailabilityMetadata

*Check availability of arguments in list*

**Description**

Check availability of arguments in list

**Usage**

checkAvailabilityMetadata(paramsList, subListName)
checkConfigFile

Arguments

paramsList   A named list.
subListName  String indicating which of the sublist names to check for exisitance.

Value

The content of the sublist. If not available, returns "Not Available".

cHECK CONFIG FILE

Description

Check a configuration file (in _YAML_ format) based on a requirement file in JSON Schema format.

Usage

checkConfigFile(configFile, configSpecFile)

Arguments

configFile     String with name of the config file of interest in YAML format.
configSpecFile String with name of the config file containing requirements in JSON Schema format.

Value

No returned value, an error message is printed in the console if the configuration file doesn’t comply to the specified specifications.

Author(s)

Laure Cougnaud
checkReportTitles  

Check report titles

Description

Check uniqueness of report titles across the config files. If not unique titles are provided, an error is returned.

Usage

```r
checkReportTitles(
  configFiles,
  configDir = file.path(inputDir, "config"),
  inputDir = "."
)
```

Arguments

- **configFiles**: Character vector with config file names
- **configDir**: String with directory with config files, ('config' by default)
- **inputDir**: String with input directory, working directory by default.

Value

A named vector with the report titles and the corresponding config file

Author(s)

Michela Pasetto

See Also

Other clinical data reporting: `convertMdToHtml()`, `forceParams()`, `getMdHeader()`, `getParamsFromConfig()`, `gitbook_clinDataReview_report()`, `html_clinDataReview_report()`, `knitPrintClinDataReview()`, `render_clinDataReviewReport()`

checkTemplatesName  

Checks of config files template.

Description

Check if the templates specified in the input config files don’t originate from multiple sources (e.g. custom and R package via the parameter templatePackage). If so, the corresponding config files are not considered.
checkValueType

Usage

checkTemplatesName(
  configFiles,
  configDir = file.path(inputDir, "config"),
  inputDir = "."
)

Arguments

cfgFiles: Character vector with name or path of the config file(s).
configDir: String with directory with config files, by default a 'config' folder in inputDir. It should contain a general 'config.yml' file and dedicated 'config-[X].yml' for each chapter. The order of each chapter is specified in the 'config' slot in the general general 'config.yml'.
inputDir: String with input directory, working directory by default.

Value

Updated configFiles

Author(s)

Laure Cougnaud

checkValueType(data, vars, valueVar, valueType = "total", labelVars = NULL)

Arguments

data: Data.frame with data.
vars: Character vector with variables of data containing plot nodes. If multiple, they should be specified in hierarchical order (from parent to child node).
valueVar: String with numeric variable of data containing node value, and associated label.

Description

Check if the specified valueType parameter can be passed to the branchvalues of the plot_ly treemap/sunburst visualizations.

Usage

checkValueType(data, vars, valueVar, valueType = "total", labelVars = NULL)
valueType               String with type of values in valueVar (branchvalues of the plot_ly function), among others: 'total' (default, only if sum(child) <= to parent) or 'relative'.

labelVars               Named character vector containing variable labels.

Value

If the condition is fullfilled: updated valueType and warning; otherwise input valueType.

Author(s)

Laure Cougnaud
hoverLab

Named character vector with labels for hoverVars.

pathExpand

Logical, should the variable in pathExpand be included in a collapsible row or as hyperlink in the table? Should be TRUE for if multiple paths are included for each idVar, FALSE otherwise (by default).

table

Logical, if TRUE (FALSE by default) returns also a datatable containing the plot data. The plot and table are linked when included in a Rmarkdown document: when clicking on an plot element, only the corresponding records are retained in the associated table; when some records are selected in the table, they are highlighted in the associated table.

refLinePars

(optional) Nested list, with parameters for each reference line(s). Each sublist (a.k.a reference line) contains:

• aesthetic value(s) or variable(s) for the lines (in this case column names of data) for reference lines. The line position is controlled by the aesthetics supported in geom_vline, geom_hline and geom_abline.

• 'label': (optional) Logical specifying if the line should be annotated (FALSE to not annotate the line) or string with annotation label. By default, the value of the position of the horizontal/vertical line or the equation of the diagonal line is displayed.

labelVars

Named character vector containing variable labels.

id

String with general id for the plot:

• 'id' is used as group for the SharedData

• 'button:[id]' is used as button ID if table is TRUE

If not specified, a random id, as 'plotClinData[X]' is used.

title

String with title for the plot.

titleExtra

String with extra title for the plot (appended after title).
caption

String with caption.
The caption is included at the bottom right of the plot. Please note that this might overlap with vertical or rotated x-axis labels.

subtitle

String with subtitle.
The subtitle is included at the top left of the plot, below the title.
colorVar

(optional) String with color variable.
colorLab

String with label for colorVar.
colorPalette

(optional) Named character vector with color palette. If not specified, the viridis color palette is used. See clinColors.

Value

No return value, used for the documentation of the functions of the package.
Common parameters for the clinical data reporting function

**Arguments**

- **indexPath**
  String with path to the index file, by default 'index.Rmd' in inputDir.

- **configDir**
  String with directory with config files, by default a 'config' folder in inputDir. It should contain a general 'config.yml' file and dedicated 'config-[X].yml' for each chapter. The order of each chapter is specified in the 'config' slot in the general 'config.yml'.

- **inputDir**
  String with input directory, working directory by default.

- **outputDir**
  String with output directory, ('report' by default).

- **intermediateDir**
  String with intermediate directory ('interim' by default), where markdown files and rds file specifying Js libraries (with knit_meta) for each sub report are stored.

**Value**

No return value, used for the documentation of the clinical data reporting functions of the package.

Common arguments for the plotting functions summary statistics of the clinDataReview package

**Arguments**

- **vars**
  Character vector with variables of data containing plot nodes. If multiple, they should be specified in hierarchical order (from parent to child node).

- **varsLab**
  Named character vector with labels for vars.

- **valueVar, valueLab**
  String with numeric variable of data containing node value, and associated label.
valueType  String with type of values in valueVar (branchvalues of the `plot_ly` function), among others: 'total' (default, only if sum(child) <= to parent) or 'relative'.

pathVar  String with variable of data containing hyperlinks with path to the subject-specific report, formatted as:

    <a href="/path-to-report">label</a>

If multiple, they should be separated by: ','.

The report(s) will be:

- compressed to a zip file and downloaded if the user clicks on the 'p' (a.k.a 'profile') key when hovering on a point of the plot
- included in a collapsible row, and clickable with hyperlinks in the table

pathLab  String with label for pathVar, included in the collapsible row in the table.

table  Logical, if TRUE (FALSE by default) returns also a datatable containing the plot data. (The plot and the table are not linked.)

Value

No return value, used for the documentation of the plotting functions of summary statistics of the package.

---

**clinDataReview-templates**

*Rmarkdown templates for clinical data*

---

**Description**

Template reports with standard visualizations/tables available in the package are described here.

**Details**

For each template, required parameters are indicated in **bold**.

**Value**

No return value, used for the documentation of the Rmarkdown template reports contained in the package.

**Parameter type**

Please note that the type mentioned below corresponds to the type in the config file (in YAML/JSON format). The mapping to R data type is as followed:

- string: character vector of length 1
- integer: integer vector of length 1
- array: vector/list without names
- object: list with names
Clinical data template for a visualization of count data: \texttt{countsVisualizationTemplate}\texttt{\textbackslash Rmd}

This report computes counts of variable(s) of interest (with the \texttt{inTextSummaryTable} package) and visualizes them with a treemap and/or sunburst.

The following parameters are available:

- \texttt{template}: string set to: 'countsVisualizationTemplate.Rmd', name of the template report
- \texttt{templatePackage}: string set to: 'clinDataReview', package from which the template should be extracted
- \texttt{reportTitle}: string, header title
- \texttt{reportTitleLevel}: (optional) integer, header level, 1 by default (1: 'chapter', '2': 'section', '3': subsection, ...)
- \texttt{dataFileName}: string, name of the data file of interest
- \texttt{dataProcessing}: (optional) array, data processing parameters, passed to \texttt{processData}
- \texttt{dataTotalFileName}: (optional) string, filename of the total dataset
- \texttt{dataTotalProcessing}: (optional) array, data processing parameters for 'dataTotalFileName', passed to \texttt{processData}
- \texttt{countVar}: string, variable of data to count on
- \texttt{parentVar}: (optional) string or array, parent variable(s) of the counting variable, used for grouping
- \texttt{colorVar}: (optional) string or object, numeric variable(s) to consider for coloring, named by count/parent variable if different for each variable
- \texttt{colorRange}: (optional) array of number(s) of length: minimum 2, maximum 2, range of the color variable for the visualization
- \texttt{loopingVar}: (optional) array or string, data variable(s) to loop over. Each group of the variable(s) is displayed in a separated section of the report.
- \texttt{loopingNMax}: (optional) integer, maximum number of elements of \texttt{loopingVar} to include in the report
- \texttt{loopingTotal}: (optional) boolean, should the total also be computed by \texttt{loopingVar} (\texttt{TRUE} by default)?
- \texttt{typePlot}: (optional) array or string of string(s)
- \texttt{startup}: (optional) array or string, R commands that should be run at the start of the report

Clinical data template to create a report division: \texttt{divisionTemplate}\texttt{\textbackslash Rmd}

This report includes a division, i.e. extra chapter, section of subsection in the report.

The following parameters are available:

- \texttt{template}: string set to: 'divisionTemplate.Rmd', name of the template report
- \texttt{templatePackage}: string set to: 'clinDataReview', package from which the template should be extracted
- \texttt{reportTitle}: string, header title
- \texttt{reportTitleLevel}: (optional) integer, header level, 1 by default (1: 'chapter', '2': 'section', '3': subsection, ...)
- \texttt{content}: (optional) string, any content that should be included after the title
Clinical data template to create a listing: listingTemplate

This report displays a listing of the variables and data of interest, displayed in an interactive table. This table can contain comparison with a previous batch ('comparisonTable' parameters).

The following parameters are available:

- template: string set to: 'listingTemplate.Rmd', name of the template report
- templatePackage: string set to: 'clinDataReview', package from which the template should be extracted
- reportTitle: string, header title
- reportTitleLevel: (optional) integer, header level, 1 by default (1: 'chapter', '2': 'section', '3': subsection, ...)
- dataFileName: string, name of the data file of interest
- dataProcessing: (optional) array, data processing parameters, passed to processData
- dataTotalFileName: (optional) string, filename of the total dataset
- dataTotalProcessing: (optional) array, data processing parameters for 'dataTotalFileName', passed to processData
- tableParams: (optional) object, parameters to create the table, passed to tableClinData
- comparisonTableType: (optional) string among: 'none', 'newData-diff-interactive', 'table-comparison-interactive', output type of the comparison table
- comparisonTableParams: (optional) object, parameters for the comparison table, passed to compareTables
- loopingVar: (optional) array or string, data variable(s) to loop over. Each group of the variable(s) is displayed in a separated section of the report.
- loopingNMax: (optional) integer, maximum number of elements of loopingVar to include in the report
- listingDocx: (optional) boolean, export listing to Word

Clinical data template for the creation of patient profiles: patientProfilesTemplate

This report creates the specified patient profiles (with the patientProfilesVis package) by subject, and export them to a specified directory.

The following parameters are available:

- template: string set to: 'patientProfilesTemplate.Rmd', name of the template report
- templatePackage: string set to: 'clinDataReview', package from which the template should be extracted
- reportTitle: string, header title
- reportTitleLevel: (optional) integer, header level, 1 by default (1: 'chapter', '2': 'section', '3': subsection, ...)
- createPatientProfiles: (optional) boolean, Should the patient profiles be created or only loaded from a previous execution?
- patientProfilesGeneralParams: (optional) object, set of parameters used for all patient profiles modules. These parameters are passed to all subjectProfile[]Plot functions.
patientProfilesParams: array of object(s)
The following parameters are available:
  - typePlot: string among: ‘text’, ‘line’, ‘interval’, ‘event’, plot type, used to get the appropriate plot module function:
    * ‘text’: subjectProfileTextPlot
    * ‘line’: subjectProfileLinePlot
    * ‘interval’: subjectProfileIntervalPlot
    * ‘event’: subjectProfileEventPlot
  - dataFileName: string, name of the data file of interest
  - dataProcessing: (optional) array, data processing parameters, passed to processData
  - plotParams: object, parameters for the plotting function. Parameters depending on the dataset of interest can be specified as:
    [parameterName]: !r-lazy [dataI]
  - patientProfilesCreateReportParams: (optional) object, parameters for the creation of the patient profile report(s), passed to createSubjectProfileReport
  - tableParams: (optional) object, parameters specifying a table containing data of interest and links to created patient profiles
  - startup: (optional) array or string, R commands that should be run at the start of the report

Clinical data generic template for visualization: plotTemplate

This report visualizes input data with a function of the clinical data review package. The data can be compared to the data of a previous batch, in the table associated to the plot (‘comparisonTable’ parameters). Summary statistics can be computed optionally and included in the plot (see ‘tableParams’ parameter).

The following parameters are available:

- template: string set to: ‘plotTemplate.Rmd’, name of the template report
- templatePackage: string set to: ‘clinDataReview’, package from which the template should be extracted
- reportTitle: string, header title
- reportTitleLevel: (optional) integer, header level, 1 by default (1: ‘chapter’, 2: ‘section’, 3: subsection, ...)
- dataFileName: string, name of the data file of interest
- dataProcessing: (optional) array, data processing parameters, passed to processData
- plotParams: object, parameters for the plotting function. Parameters depending on the dataset of interest can be specified as:
  [parameterName]: !r-lazy [dataI]
- tableParams: (optional) object, parameters for a summary table, passed to computeSummaryStatisticsTable

Summary statistics are computed and merged as extra columns available for the plot data.
Clinical data template for visualization of summarized data: summaryPlotTemplate

This report summarizes the data of interest (with the inTextSummaryTable package) and visualizes it with any clinical data review plot function.

The following parameters are available:

- template: string set to: 'summaryPlotTemplate.Rmd', name of the template report
- templatePackage: string set to: 'clinDataReview', package from which the template should be extracted
- reportTitle: string, header title
- reportTitleLevel: (optional) integer, header level, 1 by default (1: 'chapter', 2: 'section', 3: subsection, ...)
- dataFileName: string, name of the data file of interest
- dataProcessing: (optional) array, data processing parameters, passed to processData
- dataTotalFileName: (optional) string, filename of the total dataset
- dataTotalProcessing: (optional) array, data processing parameters for 'dataTotalFileName', passed to processData
- tableParams: object, parameters to summarize the data in a table, passed to computeSummaryStatisticsTable
- tableProcessing: (optional) array, data processing parameters for the summary table, passed to processData
- plotFunction: string among: 'timeProfileIntervalPlot', 'scatterplotClinData', 'sunburst-ClinData', 'treemapClinData', 'barplotClinData', 'errorbarClinData', plotting function to visualize summary data
- plotParams: object, parameters for the plotting function
- loopingVar: (optional) array or string, data variable(s) to loop over. Each group of the variable(s) is displayed in a separated section of the report.
- loopingNMax: (optional) integer, maximum number of elements of loopingVar to include in the report
- loopingTotal: (optional) boolean, should the total also be computed by loopingVar (TRUE by default)?
- startup: (optional) array or string, R commands that should be run at the start of the report
Clinical data template for a summary table of the data: summaryTableTemplate

This report summarizes the data of interest (with the inTextSummaryTable package). This table is displayed with an interactive table in the report, and exported to a docx file. This table can be compared to a summary table of a previous batch ('comparisonTable' parameters).

The following parameters are available:

- **template**: string set to: 'summaryTableTemplate.Rmd', name of the template report
- **templatePackage**: string set to: 'clinDataReview', package from which the template should be extracted
- **reportTitle**: string, header title
- **reportTitleLevel**: (optional) integer, header level, 1 by default (1: 'chapter', '2': 'section', '3': subsection, ...)
- **dataFileName**: (optional) string, name of the data file of interest
- **dataProcessing**: (optional) array, data processing parameters, passed to processData
- **dataTotalFileName**: (optional) string, filename of the total dataset
- **dataTotalProcessing**: (optional) array, data processing parameters for 'dataTotalFileName', passed to processData
- **tableParams**: object, parameters to summarize the data in a table, passed to computeSummaryStatisticsTable. Parameters depending on the dataset of interest can be specified as: [parameterName]: !r-lazy [dataI].
- **tableParamsDocx**: (optional) object, parameters to format the table to the docx format, passed to exportSummaryStatisticsTable
- **tableParamsDT**: (optional) object, parameters to format the table to the DT interactive table included in the report, passed to exportSummaryStatisticsTable
- **comparisonTableType**: (optional) string among: 'none', 'table-comparison-interactive', 'newData-diff', 'table-combine', output type of the comparison table
- **comparisonTableParams**: (optional) object, parameters for the comparison table, passed to compareTables. By default, statistics variables are compared across row and column elements.
- **loopingVar**: (optional) array or string, data variable(s) to loop over. Each group of the variable(s) is displayed in a separated section of the report.
- **loopingNMax**: (optional) integer, maximum number of elements of loopingVar to include in the report
- **loopingTotal**: (optional) boolean, should the total also be computed by loopingVar (TRUE by default)?

Description

Please note that the button is of class: 'hideshow', defined in the 'input.hideshow.js' js file included in the package.
Usage

collapseHtmlContent(input, title = "Click to show or hide")

Arguments

  input Object to be collapse, e.g. datatable.
  title String with button title.

Value

tag object

Author(s)

Laure Cougnaud

---

convertMdToHtml

Convert clinical data Markdown files to HTML

Description

This consists of:

1. importing the general config file ('config'.yml) to identify each report of interest ('config' tag)
2. for each report of interest: checking if the associated Markdown and rds file (list of Js dependencies) are available in intermediateDir
3. combining all Rmarkdown reports to a single document: main.md
4. converting main.md to an HTML document

Usage

convertMdToHtml(
    outputDir = "./report",
    inputDir = ".",
    configDir = file.path(inputDir, "config"),
    indexPath = file.path(inputDir, "index.Rmd"),
    intermediateDir = "/interim",
    mdFiles = NULL,
    ...
)
countNLines

**Arguments**

- **outputDir**: String with output directory, ('report' by default).
- **inputDir**: String with input directory, working directory by default.
- **configDir**: String with directory with config files, by default a 'config' folder in inputDir. It should contain a general 'config.yml' file and dedicated 'config-[X].yml' for each chapter. The order of each chapter is specified in the 'config' slot in the general general 'config.yml'.
- **indexPath**: String with path to the index file, by default 'index.Rmd' in inputDir.
- **intermediateDir**: String with path to the index file, by default 'interim' by default, where markdown files and rds file specifying Js libraries (with knit_meta) for each sub report are stored.
- **mdFiles**: (optional) Path to the Markdown files that should be converted. If specified, the specified config files in configDir are ignored.
- **...**: Any parameters passed to render, for expert use only.

**Value**

String with path to the front page of the clinical data report.

**Author(s)**

Laure Cougnaud

### countNLines

**Count number of lines in a vector**

**Description**

Count number of lines in a vector

**Usage**

`countNLines(x)`

**Arguments**

- **x**: Character vector.
createClinDataReviewReportSkeleton

Value

Integer vector of length x with number of lines

Author(s)

Laure Cougnaud

Examples

\[
\text{countNLines}(x = \text{c(“A\nB”, “blabla”, “This\nis\na\nsentence.”)})
\]

Description

Creates the skeleton of a report to start running the analyses.

Usage

\[
\text{createClinDataReviewReportSkeleton(dir = ".")}
\]

Arguments

\[
\begin{align*}
\text{dir} & \quad \text{String with the path of the directory where the skeleton should be created. The current working directory is used as default.}
\end{align*}
\]

Details

This function is meant to get familiar with the use of the package and the necessary files to create a report.

It will create a ready-to-use report with example data from the clinUtils package. After getting use to the file structure, the user can substitute the example data with custom data sets and add specific configuration files.

Value

The files to run a report are written in the specified directory. To run the report, the user can call the \texttt{render_clinDataReviewReport}. 

createExampleMetadata  

Create an example metadata file

Description
Create an example of metadata file for the `createClinDataReviewReportSkeleton`.

Usage
```
createExampleMetadata(dir)
```

Arguments
- **dir**
  - String, path to the directory.

Value
Nothing, the example metadata file is created in the specified directory.

createMainConfigSkeleton

Create the config file for the skeleton

Description
This function creates the main config file for the `createClinDataReviewReportSkeleton` with the directory where the data are stored.

Usage
```
createMainConfigSkeleton(dir, dirData)
```

Arguments
- **dir**
  - String, path to the directory.
- **dirData**
  - String, path to the directory of the data.

Value
No return value, a file `_config.yml_` is created in the specified directory.
createPatientProfileVar

Create link to patient profile

Description
Create a link to a patient profile directory (where the patient profile files are saved) by adding an extra column with the link in the data. The path to the patient profile is built as: [patientProfilePath]/subjectProfile-[subjectID].pdf, where '/' are replaced with '-' in the subject identifier (subjectVar).

Usage
createPatientProfileVar(
  data,
  patientProfilePath,
  subjectVar = "USUBJID",
  checkExist = TRUE
)

Arguments
- data: a data.frame
- patientProfilePath: string indicating the directory where the patient profiles are stored.
- subjectVar: string indicating which column in the data represents the unique subject identifier, "USUBJID" by default.
- checkExist: Logical, if TRUE (by default) the patientProfilePath is checked for existence, and an error is returned if this directory doesn’t exist.

Value
A data.frame with two extra columns: patientProfilePath and patientProfileLink with the path to the patient profile and an hyperlink to it, respectively.

Author(s)
Michela Pasetto

Examples
# Typical CDISC dataset contains universal subject ID (USUBJID)
data <- data.frame(USUBJID = c("subj1", "subj2", "subj3"))
dataWithPatientProfileVar <- createPatientProfileVar(
data = data,
  patientProfilePath = "pathProfiles",
  checkExist = FALSE
)
# path and HTML link are included in the output dataset
head(dataWithPatientProfileVar[, c("USUBJID", "patientProfilePath", "patientProfileLink")])
**createRedirectPage**  
Create a redirect page

**Description**
Create an HTML page that redirects to the "1-introduction.html" page of the clinical data report available in a directory. See output from `render_clinDataReviewReport`.

**Usage**
```r
createRedirectPage(redirectPage = "report.html", dir = "report_dependencies")
```

**Arguments**
- `redirectPage` String with the path of the HTML file that redirects to the "1-introduction.html" page of the report.
- `dir` String for the path where the "1-introduction.html" is stored.

**Value**
The HTML file is created.

**createTemplateDoc**  
Create documentation for clinical data template reports available in the 'template' folder of the package.

**Description**
If a JSON schema file available, the information relative to the template is extracted from this file with the function `JSONSchToRd`.

**Usage**
```r
createTemplateDoc(
  templatePath = system.file("template", package = "clinDataReview")
)
```

**Arguments**
- `templatePath` String with path where the template Rmd reports and associated JSON schema files are stored, by default path of the installed version of the package. This parameter is only for expert use of the package.

**Value**
Character vector with Rd code containing description for all template documents.
Author(s)
Laure Cougnaud

errorbarClinData  Interactive plot of confidence interval/error interval of clinical data.

Description
This plot is designed to display summary statistics of a continuous variable with (confidence) intervals.
The intervals are either displayed:
• vertically if yErrorVar is specified
• horizontally if xErrorVar is specified

Error bars can visualized by group, via the color variable parameter.
Different symbols are set for each central point of the error bar via the shape variable parameter.

Usage
errorbarClinData(
data,
xVar,
xLab = getLabelVar(xVar, labelVars = labelVars),
yVar,
yLab = getLabelVar(yVar, labelVars = labelVars),
yErrorVar = NULL,
yErrorLab = getLabelVar(yErrorVar, labelVars = labelVars),
xErrorVar = NULL,
xErrorLab = getLabelVar(xErrorVar, labelVars = labelVars),
xLabVars = NULL,
xAxisLab = paste(c(xLab, xErrorLab), collapse = " and "),
yAxisLab = paste(c(yLab, yErrorLab), collapse = " and "),
colorVar = NULL,
colorLab = getLabelVar(colorVar, labelVars = labelVars),
colorPalette = NULL,
shapeVar = NULL,
shapeLab = getLabelVar(shapeVar, labelVars = labelVars),
shapePalette = NULL,
size = 6,
titleExtra = NULL,
title = paste(c(paste(yAxisLab, "vs", xAxisLab), titleExtra), collapse = "<br>")

subtitle = NULL,
```r
# errorbarClinData

caption = NULL,
labelVars = NULL,
mode = "markers",
legendPosition = "bottom",
width = NULL,
height = NULL,
pathVar = NULL,
pathLab = getLabelVar(pathVar, labelVars = labelVars),
hoverVars,
hoverLab,
table = FALSE,
tableVars,
tableLab,
tableButton = TRUE,
tablePars = list(),
id = paste0("plotClinData", sample.int(n = 1000, size = 1)),
verbose = FALSE
)

Arguments

data
  Data.frame with data.
xVar
  String with column of data containing x-variable.
xLab
  String with label for xVar.
yVar
  String with column of data containing y-variable.
yLab
  String with label for xVar.
xErrorVar, yErrorVar
  String with variable of data containing the width of the interval (from the center of the interval) for horizontal or vertical intervals.
xErrorLab, yErrorLab
  String with labels for xErrorVar/yErrorVar variables.
xLabVars
  (vertical error bars) Character vector with variable(s) to be displayed as the labels of the ticks in the x-axis. By default, xVar is displayed. In case the variable(s) contain different elements by xVar, they are combined and displayed below each other.
xAxisLab, yAxisLab
  Label for the x/y-axis.
colorVar
  (optional) String with color variable.
colorLab
  String with label for colorVar.
colorPalette
  (optional) Named character vector with color palette. If not specified, the viridis color palette is used. See clinColors.
shapeVar
  (optional) String with shape variable.
shapeLab
  String with label for shapeVar.
```

**Arguments**
- **data**: Data.frame with data.
- **xVar**: String with column of data containing x-variable.
- **xLab**: String with label for xVar.
- **yVar**: String with column of data containing y-variable.
- **yLab**: String with label for xVar.
- **xErrorVar, yErrorVar**: String with variable of data containing the width of the interval (from the center of the interval) for horizontal or vertical intervals.
- **xErrorLab, yErrorLab**: String with labels for xErrorVar/yErrorVar variables.
- **xLabVars**: (vertical error bars) Character vector with variable(s) to be displayed as the labels of the ticks in the x-axis. By default, xVar is displayed. In case the variable(s) contain different elements by xVar, they are combined and displayed below each other.
- **xAxisLab, yAxisLab**: Label for the x/y-axis.
- **colorVar**: (optional) String with color variable.
- **colorLab**: String with label for colorVar.
- **colorPalette**: (optional) Named character vector with color palette. If not specified, the viridis color palette is used. See clinColors.
- **shapeVar**: (optional) String with shape variable.
- **shapeLab**: String with label for shapeVar.
shapePalette (optional) Named character vector with shape palette, clinShapes by default.
size Integer with size of markers in pixels, 6 by default.
titleExtra String with extra title for the plot (appended after title).
title String with title for the plot.
subtitle String with subtitle.
The subtitle is included at the top left of the plot, below the title.
caption String with caption.
The caption is included at the bottom right of the plot. Please note that this
might overlap with vertical or rotated x-axis labels.
labelVars Named character vector containing variable labels.
mode String with the mode of the plot, ’markers’ by default, so only data points are
displayed.
This can also be set to ’lines’ to include a line connecting the center of the error
bars instead; or ’lines+markers’ to include both a marker and a line.
See mode attribute for plotly scatter.
legendPosition String with position of the legend, among: ’top’/’left’/’bottom’/’right’, ’bottom’
by default.
width Numeric, width of the plot in pixels, 700 by default.
height Numeric, height of the plot in pixels, 700 by default.
pathVar String with variable of data containing hyperlinks with path to the subject-
specific report, formatted as:

```
<a href="./path-to-report">label</a>
```

If multiple, they should be separated by: ’,’.
The report(s) will be:
• compressed to a zip file and downloaded if the user clicks on the ’p’ (a.k.a
  ’profile’) key when hovering on a point of the plot
• included in a collapsible row, and clickable with hyperlinks in the table
pathLab String with label for pathVar, included in the collapsible row in the table.
hoverVars Character vector with variable(s) to be displayed in the hover, by default any
position and aesthetic variables displayed in the plot.
hoverLab Named character vector with labels for hoverVars.
table Logical, if TRUE (FALSE by default) returns also a datatable containing the
plot data. (The plot and the table are not linked.)
tableVars Character vector with variables to be included in the table.
tableLab Named character vector with labels for each tableVars.
tableButton Logical, if TRUE (by default) the table is included within an HTML button.
tablePars List with parameters passed to the getClinDT function.
id String with general id for the plot:
• ’id’ is used as group for the SharedData
errorbarClinData

- 'button:[id]' is used as button ID if table is TRUE
  If not specified, a random id, as 'plotClinData[X]' is used.

verbose

Logical, if TRUE (FALSE by default) progress messages are printed in the current console. For the visualizations, progress messages during download of subject-specific report are displayed in the browser console.

Value

Either:

- if a table is requested: a clinDataReview object, a.k.a a list with the 'plot' (plotly object) and 'table' (datatable object)
- otherwise: a plotly object

)

---

**exportSessionInfoToMd** Combine all session informations across all clinical data reports and export them into a dedicated Markdown document

**Description**

Combine all session informations across all clinical data reports and export them into a dedicated Markdown document

**Usage**

```r
exportSessionInfoToMd(sessionInfos, mdFiles, intermediateDir = "interim", ...)
```

**Arguments**

- `sessionInfos` List with `sessionInfo` objects
- `mdFiles` Character vector with Markdown files
- `intermediateDir` String with intermediate directory ("interim" by default), where markdown files and rds file specifying Js libraries (with knit_meta) for each sub report are stored.
  - `...` Any parameters passed to `renderInNewSession`, for expert use only.

**Value**

String with path to Markdown file containing the session information, NULL if no session information(s) are provided.

**Author(s)**

Laure Cougnaud
**filterData**

Filter dataset based on specified filters.

**Description**

A dataset can be filtered:

- based:
  - on a specific value of interest
  - on a function of the variable (valueFct parameter), e.g. maximum of the variable
  - to retain only non missing values of a variable (keepNA set to FALSE)
- by groups (varsBy parameter)

**Note that by default, missing values in the filtering variable are retained (which differs from the default behaviour in R)**. To filter missing records, please set the keepNA parameter to FALSE.

**Usage**

```r
filterData(
  data,  # Data.frame with data.
  filters,  # Unique filter or list of filters. Each filter should be a list containing:
    keepNA = TRUE,  # (optional) Logical, if TRUE (by default), missing values in var are retained.
    returnAll = FALSE,  # (optional) Logical, if TRUE, all records are returned.
    verbose = FALSE,  # (optional) Logical, if TRUE, verbose output is produced.
    labelVars = NULL,  # (optional) Character vector with labels for variables.
    labelData = "data"  # (optional) Character string with label for data.
)
```

**Arguments**

- **data**  
  Data.frame with data.

- **filters**  
  Unique filter or list of filters. Each filter should be a list containing:
  - 'var': String with variable from data to filter on.
  - 'value': (optional) Character vector with values from var to consider/keep.
  - 'valueFct': (optional) Function (or string with this function) to be applied on var to extract value to consider. For example, valueFct = max will extract the records with the maximum variable value.
  - 'op': (optional) String with operator used to retain records from value. If not specified, the inclusion operator: `%in%` is considered, a.k.a records with var in value are retained.
  - 'rev': (optional) Logical, if TRUE (FALSE by default), filtering condition based on value/valueFct is reversed.
  - 'keepNA': (optional) Logical, if TRUE (by default), missing values in var are retained.

If not specified, keepNA general parameter is used.
filterData

- 'varsBy': (optional) Character vector with variables in data containing groups to filter by
- 'varNew': (optional) String with name for the new variable created
- 'labelNew': (optional) String with label for varNew

If a list of filters is specified, the logical operator (see Logic) linking the different conditions can be specified between the two conditions, e.g.: `list(list(var = "SEX", value = "F"),"&",list(var = "COUNTRY", value = "DEU")).`

keepNA Logical, if TRUE (by default) missing values in var are retained. If set to FALSE, missing values are ignored for all filters. The specification within filters prevails on this parameter.

returnAll Logical:
- if FALSE (by default): the data for only the filtered records is returned.
- if TRUE: the full data is returned. Records are flagged based on the filters condition, in a new column: varNew (if specified), or 'keep' otherwise; containing TRUE if the record fulfill all conditions, FALSE otherwise

verbose Logical, if TRUE (FALSE by default) progress messages are printed in the current console. For the visualizations, progress messages during download of subject-specific report are displayed in the browser console.

labelVars Named character vector containing variable labels.

labelData (optional) String with label for input data, that will be included in progress messages.

Value

Filtered data if returnAll is FALSE (by default). Otherwise data with additional column: keep or varNew (if specified), containing TRUE for records which fulfill the specified condition(s) and FALSE otherwise.

Author(s)

Laure Cougnaud

Examples

```r
library(clinUtils)

data(dataADaMCDISCP01)
labelVars <- attr(dataADaMCDISCP01, "labelVars")

dataDM <- dataADaMCDISCP01$ADSL

## single filter

# filter with inclusion criteria:
filterData(
  data = dataDM,
  filters = list(var = "SEX", value = "M"),
  verbose = TRUE
)
```
# filter with non-inclusion criteria
filterData(
data = dataDM,
filters = list(var = "SEX", value = "M", rev = TRUE),
verbose = TRUE
)

# filter based on inequality operator
filterData(
data = dataDM,
filters = list(var = "AGE", value = 75, op = "<="),
verbose = TRUE
)

# missing values are retained by default!
dataDMNA <- dataDM
dataDMNA[1:2, "AGE"] <- NA
filterData(
data = dataDMNA,
filters = list(var = "AGE", value = 75, op = "<="),
verbose = TRUE
)

# filter missing values on variable
filterData(
data = dataDMNA,
filters = list(var = "AGE", value = 75, op = "<="), keepNA = FALSE),
verbose = TRUE
)

# retain only missing values
filterData(
data = dataDMNA,
filters = list(var = "AGE", value = NA, keepNA = TRUE),
verbose = TRUE
)

# filter missing values
filterData(
data = dataDMNA,
filters = list(var = "AGE", keepNA = FALSE),
verbose = TRUE
)

## multiple filters

# by default the records fulfilling all conditions are retained ('AND')
filterData(
data = dataDM,
filters = list(
filterDataSingle

Filter data for a single filter

Description

Filter data for a single filter

Usage

filterDataSingle(
  data,
  filters,
  keepNA = TRUE,
  returnAll = FALSE,
  labelVars = NULL,
forceParams = forceParams

labelData = "data"
}

Arguments

data Data.frame with data.
filters Unique filter or list of filters.
keepNA Logical, if TRUE (by default) missing values in var are retained. If set to FALSE, missing values are ignored for all filters. The specification within filters prevails on this parameter.
returnAll Logical:
  • if FALSE (by default): the data for only the filtered records is returned.
  • if TRUE: the full data is returned. Records are flagged based on the filters condition, in a new column: varNew (if specified), or 'keep' otherwise; containing TRUE if the record fulfill all conditions, FALSE otherwise
labelVars Named character vector containing variable labels.
labelData (optional) String with label for input data, that will be included in progress messages.

Value

Updated data.

Author(s)

Laure Cougnaud

Description

This function is only useful if some parameters should be lazy-evaluated in the report. These parameters should have the class: r-lazy. A typical use case is a parameter that consists of a R expression depending on objects created in a template report (typically data). Parameters are searched in the environment in which this function is called from.

Usage

forceParams(params)

Arguments

params List of parameters as obtained via the getParamsFromConfig function.
formatDataForPlotClinData

Value

Input parameter list, with object(s) of class r-lazy evaluated.

Author(s)

Laure Cougnaud

See Also

getParamsFromConfig

Other clinical data reporting: checkReportTitles(), convertMdToHtml(), getMdHeader(), getParamsFromConfig(),
gitbook_clinDataReview_report(), html_clinDataReview_report(), knitPrintClinDataReview(),
render_clinDataReviewReport()

Examples

data <- mtcars
params <- list(label = "Cars dataset", nrow = structure("nrow(data)", class = "r-lazy"))
str(params)
str(forceParams(params))

Description

Format data for interactive plot for clinical data

Usage

formatDataForPlotClinData(
  data,
  hoverVars = NULL,
  hoverLab = getLabelVar(hoverVars, labelVars = labelVars),
  hoverByVar = NULL,
  keyVar = NULL,
  id = paste0("plotClinData", sample.int(n = 1000, size = 1)),
  labelVars = NULL
)

Arguments

data Data.frame with data.
hoverVars Character vector with variable(s) to be displayed in the hover, by default any position and aesthetic variables displayed in the plot.
hoverLab Named character vector with labels for hoverVars.
formatHoverText

HoverByVar Character vector with variables identifying unique elements in the plot, usually x, y, facet variables. These variables are used to identify records with the same position in the plot, their information are combined in the hover.

keyVar String with unique key variable, identifying unique group for which the link between the table and the plot should be done.

id String with general id for the plot:

• 'id' is used as group for the SharedData
• 'button:[id]' is used as button ID if table is TRUE

If not specified, a random id, as 'plotClinData[X]' is used.

labelVars Named character vector containing variable labels.

Value

Updated SharedData with:

• extra column: ‘hover’ with combined info from hoverVars

Author(s)

Laure Cougnaud

formatHoverText Format hover text for use in plotly interactive plots. The labels are wrapped to multiple lines if exceed the width of the plotly hover box, e.g. in case labels for points with same x/y coordinates overlap, and corresponding labels are truncated.

Description

Format hover text for use in plotly interactive plots. The labels are wrapped to multiple lines if exceed the width of the plotly hover box, e.g. in case labels for points with same x/y coordinates overlap, and corresponding labels are truncated.

Usage

formatHoverText(x, label, width = 50)

Arguments

x Vector with hover text information.
label Label for the variable
width Integer, number of characters at which the hover text should be cut at to multiple lines.

Value

String with formatted hover label.
**formatPathDateInfoMetadata**

*Format the info on paths from metadata*

**Description**

Format the info on paths from metadata

**Usage**

```r
formatPathDateInfoMetadata(summaryInfo, namesInfo)
```

**Arguments**

- `summaryInfo`: matrix, see output from `getMetadata`
- `namesInfo`: Named vector to rename the final output.

**Value**

A kable object, to be printed.

---

**formatPlotlyClinData**

*Format interactive plot, with possibility to download patient profiles on a click event.*

**Description**

Format interactive plot, with possibility to download patient profiles on a click event.

**Usage**

```r
formatPlotlyClinData(
  pl,
  data,
  idVar = "USUBJID",
  pathVar = NULL,
  pathDownload = TRUE,
  idFromDataPlot = FALSE,
  idVarPlot = "key",
  labelVarPlot = NULL,
  highlightOn = "plotly_click",
  highlightOff = "plotly_doubleclick",
  id = paste0("plotClinData", sample.int(n = 1000, size = 1)),
  verbose = FALSE
)
```
Arguments

pl  
    ggplotly object.

data  
    Data.frame with data.

idVar  
    String with variable of data containing plot element.

pathVar  
    String with variable of data containing path to a subject-specific report (e.g. patient profiles).

pathDownload  
    Logical, if TRUE (by default) the subject-specific report(s) are downloaded in a zip compressed file. If FALSE (only available if unique report per idVarPlot), each report is opened in a new window.

idFromDataPlot  
    Logical, if TRUE (by default) idVarPlot is extracted from the data of the plot output object (e.g. if this plot was created from ggplotly), otherwise directly from the plot object (if the plot was created from plot_ly directly).

idVarPlot  
    String with variable in the plotly output containing IDs.

labelVarPlot  
    String with plotly variable used to extract label to build the file name of the zip compressed file containing patient report. If not specified, the label are extracted based on the idVarPlot of the selected plot element.

highlightOn  
    String with event to turn on the selection (on parameter of highlight), 'plotly_click' by default.

highlightOff  
    String with event to turn off the selection (off parameter of highlight), 'plotly_doubleclick' by default.

id  
    String with general id for the plot:
    • 'id' is used as group for the SharedData
    • 'button:id' is used as button ID if table is TRUE

    If not specified, a random id, as 'plotClinData[X]' is used.

verbose  
    Logical, if TRUE report progress messages during execution (included in the browser 'Console').

Value

Updated plotly object.

Author(s)

Laure Cougnaud
formatToHierarchicalData

Format data to a hierarchical data, in the format as required by the plotly sunburst and treemap.

Description

Note that new variables are created for each variable of interest (the variables are not overwritten) to avoid issues with cases where the value in the child and parent variables are the same.

Usage

formatToHierarchicalData(data, vars, valueVar)

Arguments

data Data.frame with data.
vars Character vector with variables of data containing plot nodes. If multiple, they should be specified in hierarchical order (from parent to child node).
valueVar String with numeric variable of data containing node value, and associated label.

Value

Updated data.frame with vars in hierarchical format, with extra attributes (in ’metadat’):

- ’varID’: String with column of output containing ID of specific element. This is a combination from the specified vars, or ’Overall’ for the grand total.
- ’varParent’: String with column of output containing ID of the parent element
- ’varLabel’: String with column of output containing the label to display. This is usually the name of the child element.

Author(s)

Laure Cougnaud
getAxisLabs  

*Set different variables for the x-axis labels*

**Description**
Set different variables for the x-axis labels

**Usage**
getAddressLabs(data, var, labVars)

**Arguments**
- `data`: Data.frame with data.
- `var`: String with variable displayed in the axis.
- `labVars`: Character vector with variable(s) to be displayed as the labels of the ticks in the axis.

**Value**
Named character vector. The names are the position in the x-axis, the values are the new labels.

**Author(s)**
Laure Cougnaud

getAxisLimPlot  

*Get axis limits for a ggplot plot from the input dataset.*

**Description**
Get axis limits for a ggplot plot from the input dataset.

**Usage**
getAddressLimPlot(
  data,
  xVar,
  yVar,
  xLim = NULL,
  yLim = NULL,
  facetPars = NULL,
  refLineData = NULL
)

getDatReferenceLines

Arguments

data Data.frame with data.
xVar String with column of data containing x-variable.
yVar String with column of data containing y-variable.
xLim Numeric vector of length 2 with limits for the x/y axes.
yLim Numeric vector of length 2 with limits for the x/y axes.
facetPars List with facetting parameters, passed to the facetting function. Variables should be specified as character or formula. For 'wrap' facetting (facetType is 'wrap'), if the layout is not specified via nrow/ncol, 2 columns are used by default.
refLineData Data used for the reference lines, as output of the getDatReferenceLines function.

Value

Data.frame with limits of the:

• x-axis: 'xmin'/xmax'
• y-axis: 'ymin'/ymax'

for each element of the facetting variable (if any).

dataDatReferenceLines  Extract data for the reference lines

Description

This function especially extracts the data if an aesthetic variable is specified in the reference line parameters.

Usage

getDatReferenceLines(refLinePars, data, facetPars = NULL)

Arguments

refLinePars (optional) Nested list, with parameters for each reference line(s). Each sublist (a.k.a reference line) contains:

• aesthetic value(s) or variable(s) for the lines (in this case column names of data) for reference lines. The line position is controlled by the aesthetics supported in geom_vline, geom_hline and geom_abline.
• 'label': (optional) Logical specifying if the line should be annotated (FALSE to not annotate the line) or string with annotation label. By default, the value of the position of the horizontal/vertical line or the equation of the diagonal line is displayed.

data Data.frame with data.
**facetPars**  List with facetting parameters, passed to the facetting function. Variables should be specified as character or formula. For ‘wrap’ facetting (facetType is ‘wrap’), if the layout is not specified via `nrow/ncol`, 2 columns are used by default.

**Value**

List of data for the lines

**Author(s)**

Laure Cougnaud
getFacetVars

Get facetting variables from facet parameters.

Description
Get facetting variables from facet parameters.

Usage
getFacetVars(facetPars = list())

Arguments
- facetPars: List with facetting parameters, passed to the facetting function. Variables should be specified as character or formula. For 'wrap' facetting (facetType is 'wrap'), if the layout is not specified via nrow/ncol, 2 columns are used by default.

Value
Character vector with facetting variable

Author(s)
Laure Cougnaud

getFctTypeReferenceLines

Get the names of the ggplot function to use for the reference lines

Description
Get the names of the ggplot function to use for the reference lines

Usage
getFctTypeReferenceLines(refLinePars)

Arguments
- refLinePars: (optional) Nested list, with parameters for each reference line(s). Each sublist (a.k.a reference line) contains:
  - aesthetic value(s) or variable(s) for the lines (in this case column names of data) for reference lines. The line position is controlled by the aesthetics supported in geom_vline, geom_hline and geom_abline.
  - 'label': (optional) Logical specifying if the line should be annotated (FALSE to not annotate the line) or string with annotation label. By default, the value of the position of the horizontal/vertical line or the equation of the diagonal line is displayed.
Value
List of type of each reference lines, among: 'vline', 'hline' and 'abline'.

Author(s)
Laure Cougnaud

---

getHeightLab  Get height of labels: title, subtitle or caption

Description
Get height of labels: title, subtitle or caption

Usage
getHeightLab(lab)

Arguments
lab  String with label.

Value
Integer with height in pixels for this element.

Author(s)
Laure Cougnaud

---

getJitterVar  Add jitter to the variable of the plot, based on the different groups of a grouping variable

Description
Add jitter to the variable of the plot, based on the different groups of a grouping variable

Usage
getJitterVar(data, var, byVar)

Arguments
data  Data.frame with data.
var  String with variable to add a jitter to.
byVar  String with variable containing the groups to jitter by.
Value

Numeric vector of length nrow(data) containing the jittered variable.

Author(s)

Laure Cougnaud

description

Get Javascript custom scripts required for specific clinical data functionalities.

Usage

getJsDepClinDataReview(
  type = c("collapsibleButton", "patientProfiles"),
  dep = NULL
)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>(optional) Character vector with type of dependencies, either: 'collapsibleButton' or 'patientProfiles'.</td>
</tr>
<tr>
<td>dep</td>
<td>(optional) Character vector with names of Javascript dependencies. By default, all dependencies are included.</td>
</tr>
</tbody>
</table>

Value

List of htmlDependency. To include this dependency in a report e.g. generated with rmarkdown, these can be passed to the: extra_dependencies parameter of the output_format specific function, e.g.: rmarkdown::render(...,output_format = rmarkdown::html_document(extra_dependencies = dep))

Author(s)

Laure Cougnaud
getMdFromConfig

Get path of the Markdown file corresponding to a specific config file.

Description

The name of the Markdown file is based on:

- for the general config.yml file: the basename of the specified indexPath
- for other config file (each sub-report): the name of the config file, after removal of the 'config-' part.

Usage

getMdFromConfig(
  configFiles,
  indexPath = "index.Rmd",
  intermediateDir = ".\interim"
)

Arguments

configFiles Character vector with name or path of the config file(s).
indexPath String with path to the index file, by default 'index.Rmd' in inputDir.
intermediateDir String with intermediate directory ('interim' by default), where markdown files and rds file specifying Js libraries (with knit_meta) for each sub report are stored.

Value

String with path to the

Author(s)

Laure Cougnaud

getMdHeader

Get Markdown header, for creation in Rmarkdown.

Description

The depth is extracted:

1. from the settings if a specified depth is provided in the 'rmd_file_depth' for the current knitted file
2. level parameter otherwise
**getMetadata**

Usage

getMdHeader(title, level = 1)

Arguments

title String with header title.
level Integer of length 1 with header depth/level, 1 by default

Value

String with Markdown header, to be included in R within cat.

See Also

Other clinical data reporting: checkReportTitles(), convertMdToHtml(), forceParams(), getParamsFromConfig(), gitbook_clinDataReview_report(), html_clinDataReview_report(), knitPrintClinDataReview(), render_clinDataReviewReport()

---

**getMetadata**

Read metadata file

Description

Read the metadata file from a yaml format. This function checks for existence of the metadata file and its content. In particular, within the yaml file matches the following strings:

- path Path to the data. More than one path is allowed.
- dateTime Date and time, usually of the SDTM data creation. When printing the metadata in Rmd document, there is the possibility to add the date and time of the report generation. See knit_print.clinDataReviewMetadata.
- dataSetInfo General information about the data sets.

Usage

getMetadata(filePath, namesInfo)

Arguments

filePath String of path to file. Currently only one file path is supported. If more than one paths are provided, a warning will be printed and the first path will be used.

namesInfo Named vector to rename the final output when printed in Rmd. The renaming happens only if the metadata info are printed in Rmd and not in the console.

Details

Note that the input names do not necessarily have to match the exact names. For instance, the user can also write "dateTimeMySDTMData", and the function will parse for existence of the string "dateTime".
getParamsFromConfig

Value

A list of:

- `summaryInfo` Information extracted from the inputs `path`, and `dateTime`.
- `datasetInfo` Information extracted from `datasetInfo`.

Examples

```r
# Create temporary yaml file
tmpdir <- tempdir()
library(yaml)

tmpYamlFile <- tempfile(  
  pattern = "file", tmpdir = tempdir(), fileext = ".yml"
)
listArgs <- list(  
  pathSDTs = "path/To/SDTM",
  pathSDTMReformat = "path/To/SDTMReformat",
  dateTime = "20200101",
  datasetInfo = list(  
    list(  
      column1 = "ex.xpt",
      column2 = "20200101"
    ),
    list(  
      column1 = "sl.xpt",
      column2 = "20200101",
      column3 = "OK"
    )  
  )
)
write_yaml(  
  listArgs,  
  file = tmpYamlFile
)

# Run metadata  
# Note: the 'datasetInfo' can also contain empty elements
getMetadata(filePath = tmpYamlFile)
```

getParamsFromConfig  

Get parameters from a config file

Description

Please note that the information from this config file and the general config file: `config.yml` are considered.
In case parameters are defined both in the general and specific config files, the parameter from the general config file is ignored.
getParamsFromConfig

Usage

getParamsFromConfig(
  configFile,
  configDir = file.path(inputDir, "config"),
  inputDir = "."
)

Arguments

  configFile     String with filename of the config file of interest in YAML format.
  configDir      String with directory with config files, by default a 'config' folder in inputDir. It should contain a general 'config.yml' file and dedicated 'config-[X].yml' for each chapter. The order of each chapter is specified in the 'config' slot in the general general 'config.yml'.
  inputDir       String with input directory, working directory by default.

Value

List with parameters from the specified configFile and the general config file: config.yml. There are two specific handlers:

  • parameters tagged with '[param] !r [value]' are evaluated in R, and their evaluated value is returned
  • parameters tagged with '[param] !r-lazy [value]' are imported as character, and need to be further process with forceParams inside the report.

Parameters with YAML type 'r-lazy' are imported as character, with this additional class.

forceParams

Other clinical data reporting: checkReportTitles(), convertMdToHtml(), forceParams(), getMdHeader(), gitbook_clinDataReview_report(), html_clinDataReview_report(), knitPrintClinDataReview(), render_clinDataReviewReport()
getParFctReferenceLines

*Get parameter of function used for reference lines*

**Description**
Get parameter of function used for reference lines

**Usage**
getParFctReferenceLines(type)

**Arguments**
- **type**: string with line type, either: ‘hline’, ‘abline’ or ‘vline’.

**Value**
Character vector with parameter names of the functions

**Author(s)**
Laure Cougnaud

getPathHyperlink

*Get path (’href’) property from hyperlink(s).*

**Description**
Get path (’href’) property from hyperlink(s).

**Usage**
getPathHyperlink(x)

**Arguments**
- **x**: Character vector with hyperlink(s). If multiple, the hyperlinks should be separated by: ‘,’.

**Value**
Character vector of length x containing only the hyperlinks.

**Author(s)**
Laure Cougnaud
getPathTemplate

Get path of template clinical data report

Description
Get path of template clinical data report

Usage
getPathTemplate(file, package = "clinDataReview")

Arguments
- file: String with name of the template Rmd document
- package: String, which package the template should be extracted from, by default the clinDataReview package.

Value
String with path to the template in the installed clinDataReview package

Author(s)
Laure Cougnaud

Examples
```r
## Not run:
pathDivisionTemplate <- getPathTemplate("divisionTemplate.Rmd") # get path template in the package
directory <- getPlotTableVars()
# copy to current directory
rmarkdown::render(pathDivisionTemplate) # run file
## End(Not run)
```

getPlotTableVars

Extract variables displayed in the attached table, for each available plotting function of the clinDataReview package.

Description
This function is used in each plotting function of the package to extract the variable(s) displayed in the table associated to the plot and their associated labels. This can also be used in the template reports, e.g. to extract reference variable(s) for the comparison table functionality in the plot template report. The following framework is used:
• if variables to be displayed in the table (tableVars) are not specified:
  all variables displayed in the plot are selected, based on the plot arguments.
  For example: the variables displayed in the x and y axis and for coloring are extracted for the
  `scatterplotClinData` plotting function.
  Label for these variable(s) are extracted from the associated parameter (e.g. `xLab` for `xVar`
  and so on) or the general parameter for the variable labels (labelVars) if not specified.
• if variables to be displayed in the table (tableVars) are specified:
  these variable(s) are returned.
  The associated label(s) are extracted from the associated parameter (tableLab) or the general
  parameter for the variable labels (labelVars) if not specified.

For the functions: `plotCountClinData`, `treemapClinData`, `sunburstClinData`: value to repre-
sent are included in the table and colored with a bar.

Usage
getPlotTableVars(plotFunction, plotArgs)

Arguments
plotFunction  String with name of the plotting function, be available in the clinDataReview
  package.
plotArgs  List with parameters passed to the plotting function.

Value
Character vector with variable to include in the table, with extra attributes (passed to `tableClinData`):
  • 'tableLab': Named character vector with labels for the table variables
  • 'tablePars' :extra table parameters, only included if specified as input or specified internally.

---

**getPositionAndMargins**

*Get margins and positions of specific elements for a clinical data plot*

Description
The elements are positioned as following:

• on top of the plot
  1. title
  2. subtitle
getPositionAndMargins

3. legend, if positioned on top of the plot
4. facet title
- at the bottom of the plot
  1. label for the x-axis
  2. legend, if positioned on the bottom of the plot
  3. caption

Margins are computed based on the presence of these elements. Only one line is counted for the legend, as plotly will extend the margin if necessary for the legend (for bottom legend).

Usage

getPositionAndMargins(
  title = NULL,
  subtitle = NULL,
  xLab = NULL,
  caption = NULL,
  facet = FALSE,
  includeLegend = TRUE,
  legendPosition = "right"
)

Arguments

title String with title for the plot.
subtitle String with subtitle.
The subtitle is included at the top left of the plot, below the title.
xLab String with label for xVar.
caption String with caption.
The caption is included at the bottom right of the plot. Please note that this might overlap with vertical or rotated x-axis labels.
facet Logical, if TRUE the plot contains facets.
includeLegend Logical, if TRUE (by default) a legend is available in the plot.
legendPosition String with position of the legend, among: 'top'/left/bottom/right', 'right' by default.

Value

List with:

- 'margin': List with bottom ('t') and top ('t') margins in pixels
- 'position': List with position of the following plot elements:
  - on top of the plot: subtitle and legend (if positioned at the top).
    The position is defined as the distance in pixels from the top of the plotting area to the bottom of the element (yanchor = 'bottom')
getSizePlot

Get dimensions for a clinical data plot

Description

This function set sensitive defaults dimensions for a plot in the package. This includes:

- setting a default width for a figure to fit in a standard clinical data review report
- increasing the figure height:
  - for faceted plot, ensuring that each facet is relatively squared
  - if a caption, subtitle, title, title for the x-axis are specified
  - if a legend is set at the bottom or the top of the plot
- increasing the figure width if a legend is set at the left or the right of the plot

Usage

getSizePlot(
  width = NULL,
  height = NULL,
  gg = NULL,
  nrow = 1L,
  ncol = 1L,
  title = NULL,
  subtitle = NULL,
  caption = NULL,
  xLab = NULL,
  facet = FALSE,
  includeLegend = TRUE,
  legendPosition = "right",
  y = NULL
)

Author(s)

Laure Cougnaud
Arguments

width  
Numeric, width of the plot in pixels, 700 by default.

height  
Numeric, height of the plot in pixels, 700 by default.

gg  
ggplot

nrow  
single-length integer specifying the number of facet rows in the plot. (default = 1) Overwritten if gg is specified.

ncol  
single-length integer specifying the number of facet columns in the plot. (default = 1) Overwritten if gg is specified.

title  
String with title for the plot.

subtitle  
String with subtitle.  
The subtitle is included at the top left of the plot, below the title.

caption  
String with caption.  
The caption is included at the bottom right of the plot. Please note that this might overlap with vertical or rotated x-axis labels.

xLab  
String with label for xVar.

facet  
Logical, if TRUE the plot contains facets.

includeLegend  
Logical, if TRUE (by default) a legend is available in the plot.

legendPosition  
String with position of the legend, among: ‘top’/’left’/’bottom’/’right’, ‘right’ by default.

y  
Character vector or factor with elements in the y-axis.

Value

Numeric vector with width (‘width’) and height (‘height’) of the plot in pixels.

Author(s)

Laure Cougnaud

---

gitbook_clinDataReview_report

*Clinical data format for bookdown report.*

Description

This function is only meant to set sensitive defaults for gitbook.  
`gitbook` can be used instead.
Usage

```r
gitbook_clinDataReview_report(
  logo = NULL,
  logoHeight = "60px",
  split_by = "section+number",
  config = list(sharing = NULL, toc = list(collapse = "section")),
  extra_dependencies = NULL,
  css = NULL,
  ...
)
```

Arguments

- `logo` String, path to the logo. No logo is printed by default.
- `logoHeight` String, indicating the logo height; 60px height by default.
- `split_by` String, how the reports should be split, (see help of the `gitbook` function)
- `config` List with config parameters, by default: no sharing and collapsed by section. (see help of the `gitbook` function)
- `extra_dependencies` NULL by default
- `css` String, path to the css.
- `...` Extra parameters passed to the `gitbook` function.

Value

R Markdown output format to pass to `render_book`.

Author(s)

Laure Cougnaud

See Also

Other clinical data reporting: `checkReportTitles()`, `convertMdToHtml()`, `forceParams()`, `getMdHeader()`, `getParamsFromConfig()`, `html_clinDataReview_report()`, `knitPrintClinDataReview()`, `render_clinDataReviewReport()`

---

**html_clinDataReview_report**

Clinical data format for rmarkdown report.

Description

This function only kept for back-compatibility, `html_document` can be used instead.
Usage

html_clinDataReview_report(extra_dependencies = NULL, ...)

Arguments

extra_dependencies
    NULL by default.
...
    Extra parameters passed to the html_document function.

Value

R Markdown output format to pass to render.

Author(s)

Laure Cougnaud

See Also

Other clinical data reporting: checkReportTitles(), convertMdToHtml(), forceParams(), getMdHeader(),
getParamsFromConfig(), gitbook_clinDataReview_report(), knitPrintClinDataReview(),
render_clinDataReviewReport()

JSONSchToRd

Get R Documentation from a JSON schema.

Description

Note: this function doesn’t support the full JSON schema specification, currently only the function-
alities required by the templates of the package are implemented.

Usage

JSONSchToRd(JSONSch, title = NULL)

Arguments

JSONSch  List with JSON schema, as returned by fromJSON.
title    (optional) String with title. This will combined with the JSON schema ‘title’ tag
          if this is specified. is not available.

Value

Character vector with R documentation for the specified JSON schema.
Supported JSON schema tags

- 'title' is used as Rd section header
- 'description' is included in the text
- parameters are extracted from the following 'properties' tag:
  - 'type': object type
  - 'doc': documentation for the parameter (custom JSON schema tag). This can contain any Roxygen tags, e.g.: \[package\][\function].
  - 'pattern' (optional): required value for the parameter
  - 'items' (optional): JSON schema for the different elements of an 'object'
  - 'minItems'/maxItems' (optional): minimum/maximum number of elements in an 'array'
  - 'enum' (optional): set of possible values
  - 'const' (optional): fixed value for the parameter (a.k.a 'constant')

If a parameter is required, it should be listed in the 'required' tag of the schema (outside of the 'properties' tag).

Laure Cougnaud

knitPrintClinDataReview

\textit{Include output from clinical data, or list of such outputs in a Rmarkdown report, with an appropriate title.}

Description

Include output from clinical data, or list of such outputs in a Rmarkdown report, with an appropriate title.

Usage

knitPrintClinDataReview(list, sep = ".", level = 1)

Arguments

\begin{itemize}
\item list: Named list of clinical data plots, the names are used for the section header. If several section header should be created, either:
  - a list of level 1 named by the different group elements, separated by sep, e.g. list('group1.param1' = ..., 'group1.param2' = ...). Such list is e.g. created with \texttt{dlply}.
  - a nested list, named with the different groups, e.g. created with \texttt{lapply}
\item sep: String with separator used to distinguish different levels in the labels of the list. e.g. '.' by default.
\item level: Integer with base level for section, 1 by default.
\end{itemize}
Value

No returned value, the plots are included in the report. If a element in the list are empty (NULL), these elements (and the associated sections) are not included in the report.

Author(s)

Laure Cougnaud

Other clinical data reporting: checkReportTitles(), convertMdToHtml(), forceParams(), getMdHeader(), getParamsFromConfig(), gitbook_clinDataReview_report(), html_clinDataReview_report(), render_clinDataReviewReport()

**knit_print.clinDataReview**

Print `clinDataReviewTable` object in a knitted document (e.g. Rmarkdown document).

**Description**

Print `clinDataReviewTable` object in a knitted document (e.g. Rmarkdown document).

**Usage**

```r
## S3 method for class 'clinDataReview'
knit_print(x, ...)  
```

**Arguments**

- `x` Object of class `clinDataReview`
- `...` Extra parameters for compatibility with `knit_print`, not used currently.

**Author(s)**

Laure Cougnaud
knit_print.clinDataReviewMetadata

Print metadata file in the clinical data report

Description

This function receives the metadata information from `getMetadata` and prints them in a format for an Rmd report. In general, any list could be called as long as it is composed by two elements:

- `summaryInfo` an R object.
- `datasetInfo` a data.frame or a matrix.

The first (`summaryInfo`) is printed as `kable` object and the second (`datasetInfo`) is printed as hide/show html button with the function `collapseHtmlContent`.

Usage

```r
## S3 method for class 'clinDataReviewMetadata'
knit_print(x, options = list(), ...)
```

Arguments

- `x` List of two elements named `summaryInfo` and `datasetInfo`.
- `options` List of extra options to be passed as chunk options. The option `dateReportRun` sets to true prints the date and time of the report creation.
- `...` Extra arguments to be passed.

Value

Nothing. The tables are ready to be printed in Rmd.

html code to include metadata in a report

layoutClinData

Set layout for a clinical data plot.

Description

Set layout for a clinical data plot.
Usage

`layoutClinData(
  xLab = NULL,
  yLab = NULL,
  title = NULL,
  caption = NULL,
  subtitle = NULL,
  includeLegend = FALSE,
  legendPosition = "right",
  facet = FALSE,
  nrow = 1L,
  ncol = 1L,
  width,
  height,
  ...
)
``

Arguments

- `xLab` String with label for xVar.
- `yLab` String with label for yVar.
- `title` String with title for the plot.
- `caption` String with caption. The caption is included at the bottom right of the plot. Please note that this might overlap with vertical or rotated x-axis labels.
- `subtitle` String with subtitle. The subtitle is included at the top left of the plot, below the title.
- `includeLegend` Logical, if TRUE (by default) a legend is available in the plot.
- `legendPosition` String with position of the legend, among: 'top'/'left'/bottom'/right', 'right' by default.
- `facet` Logical (FALSE by default), does the plot contains facets?
- `nrow` single-length integer specifying the number of facet rows in the plot. (default = 1) Overwritten if gg is specified.
- `ncol` single-length integer specifying the number of facet columns in the plot. (default = 1) Overwritten if gg is specified.
- `width` Numeric, width of the plot in pixels, 700 by default.
- `height` Numeric, height of the plot in pixels, 700 by default.
- `...` Any parameters for the `layout` function. This should contain at least the plot object.

Value

The updated plotly object
moveSkeletonFiles

Description
Move skeleton files from the package to a directory

Usage
moveSkeletonFiles(dir)

Arguments

dir String, path to the directory.

Value
Nothing, the files are available in the specified directory.

Author(s)
Laure Cougnaud

merge.sessionInfo
Merge multiple session information

Description
Merge multiple session information

Usage
## S3 method for class 'sessionInfo'
merge(...)

Arguments
...

objects of type sessionInfo

Value

sessionInfo with combined information

Author(s)
Laure Cougnaud
moveXpt  

Move data sets from clinUtils

Description
Move SDTM data sets available in clinUtils into a specified local directory.

Usage
moveXpt(dir)

Arguments

| dir | String, path to the directory. |

Value
Nothing, the data are saved in the dedicated location.

plotCountClinData  

Interactive plot of 'count' data

Description
Note: the table and plot are not (yet) linked.

Usage
plotCountClinData(
data,
  vars,
  varsLab = getLabelVar(vars, labelVars = labelVars),
  valueVar,
  valueLab = getLabelVar(valueVar, labelVars = labelVars),
  colorVar = NULL,
  colorLab = getLabelVar(valueVar, labelVars = labelVars),
  colorPalette = getOption("clinDataReview.colors"),
  colorRange = NULL,
  valueType = "total",
  titleExtra = NULL,
  title = paste(paste(valueLab, "by", paste(varsLab, collapse = " and "), titleExtra),
                collapse = "<br>")
  subtitle = NULL,
  caption = NULL,
  labelVars = NULL,
  width = NULL,
Arguments

data

Character vector with variables of data containing plot nodes. If multiple, they should be specified in hierarchical order (from parent to child node).

varsLab

Named character vector with labels for vars.

valueVar

String with numeric variable of data containing node value, and associated label.

valueLab

String with numeric variable of data containing node value, and associated label.

colorVar

(optional) String with coloring variable (NULL by default). By default, the treemap is colored based by section.

colorLab

String with label for colorVar.

colorPalette

(optional) Named character vector with color palette. If not specified, the viridis color palette is used. See clinColors.

colorRange

(optional) Numeric vector of length 2 with range for the color variable, in case it is a numeric variable.

valueType

String with type of values in valueVar (branchvalues of the plot_ly function), among others: ‘total’ (default, only if sum(child) <= to parent) or ‘relative’.

titleExtra

String with extra title for the plot (appended after title).

title

String with title for the plot.

subtitle

String with subtitle. The subtitle is included at the top left of the plot, below the title.

caption

String with caption. The caption is included at the bottom right of the plot. Please note that this might overlap with vertical or rotated x-axis labels.

labelVars

Named character vector containing variable labels.
width Numeric, width of the plot in pixels, 700 by default.
height Numeric, height of the plot in pixels, 700 by default.
pathVar String with variable of data containing hyperlinks with path to the subject-specific report, formatted as:

<a href="./path-to-report">label</a>

If multiple, they should be separated by: , ".
The report(s) will be:
• compressed to a zip file and downloaded if the user clicks on the 'p' (a.k.a 'profile') key when hovering on a point of the plot
• included in a collapsible row, and clickable with hyperlinks in the table
pathLab String with label for pathVar, included in the collapsible row in the table.
hoverVars Character vector with variable(s) to be displayed in the hover, by default any position and aesthetic variables displayed in the plot.
hoverLab Named character vector with labels for hoverVars.
table Logical, if TRUE (FALSE by default) returns also a datatable containing the plot data. (The plot and the table are not linked.)
tableVars Character vector with variables to be included in the table.
tableLab Named character vector with labels for tableVars.
tableButton Logical, if TRUE (by default) the table is included within an HTML button.
tablePars List with parameters passed to the getClinDT function.
id String with general id for the plot:
• 'id' is used as group for the SharedData
• 'button:[id]' is used as button ID if table is TRUE
If not specified, a random id, as 'plotClinData[X]' is used.
verbose Logical, if TRUE (FALSE by default) progress messages are printed in the current console. For the visualizations, progress messages during download of subject-specific report are displayed in the browser console.
iplotType Plot string with plot type, 'treemap' or 'sunburst'.

Value

Either:
• if a table is requested: a clinDataReview object, a.k.a a list with the 'plot' (plotly object) and 'table' (datatable object)
• otherwise: a plotly object

Author(s)

Laure Cougnaud
See Also

Other visualizations of summary statistics for clinical data: `barplotClinData()`, `boxplotClinData()`, `errorbarClinData()`, `sunburstClinData()`, `treemapClinData()`

processData

Run specified data processing steps.

Description

This function is intended to automate all data processing steps for use in the 'clinDataReview' reports using config files.

Usage

```
processData(data, processing, labelVars = NULL, ...)
```

Arguments

- **data**: Data.frame with data.
- **processing**: List with details of the steps to process the data. Each element in the list should be a named list containing the parameters for the specific processing function. The name specifies which processing step, among:
  - 'annotate' for `annotateData` (annotations parameter)
  - 'filter' for `filterData` (filters parameter)
  - 'transform' for `transformData` (transformations parameter)
- **labelVars**: Named character vector containing variable labels.
- **...**: Any parameters passed to all processing functions (if this parameter is available). If specified, these parameters shouldn't be specified also in `processing`.

Value

Data.frame with processed data, with extra attribute: `labelVars`.

Author(s)

Laure Cougnaud
renamePathDateInfoMetadata

*Rename variable names of metadata info*

**Description**

Rename variable names referring to the paths and the date.

**Usage**

```
renamePathDateInfoMetadata(summaryInfo, namesInfo)
```

**Arguments**

- `summaryInfo` A matrix, see output from `getMetadata`.
- `namesInfo` Named vector to rename the final output.

**Value**

A matrix, same as input `summaryInfo` with renamed variable names.

---

renderInNewSession

*Render a rmarkdown doc in a new session, with the possibility to save output in a log file, and saving also session information.*

**Description**

Note: this function is inspired from `xfun::Rscript_call`

**Usage**

```
renderInNewSession(
    input,
    run_pandoc = FALSE,
    output_options = list(keep_md = TRUE),
    encoding = "UTF-8",
    params = NULL,
    ...
)
```
**render_clinDataReviewReport**

**Render a clinical data report.**

**Arguments**

- **input**: Input file to be rendered.
- **run_pandoc**: Logical, if TRUE (FALSE by default) convert Md to specified output with pandoc.
- **output_options**: List of output options, by default `keep_md = TRUE` (keep Markdown file)
- **encoding**: String with encoding, `UTF-8` by default.
- **params**: List with input parameters for this document.
  These parameters should be accessed in the Rmd document via `params$...`.
  These parameters will be saved to a RDS file and imported during the report rendering.
- **...**: Any extra parameters passed to `render`, for expert use only.

**Value**

Output of the function executed in the new R session with additional attribute: `sessionInfo` containing the details of the session information in the separated R session. If the report fails, an error message is returned.

**Author(s)**

Laure Cougnaud

```r
render_clinDataReviewReport(configFiles = NULL, 
configDir = file.path(inputDir, "config"), 
logFile = NULL, 
indexPath = file.path(inputDir, "index.Rmd"), 
inputDir = ".", 
outputDir = ".\report", 
intermediateDir = ".\interim", 
extraDirs = file.path(inputDir, c("figures", "tables")), 
quiet = FALSE)
```
**render_clinDataReviewReport**

**Arguments**

- **configFiles** *(optional)* Character vector with specific config files to be converted from Rmarkdown to Markdown. If
  - not specified (by default): all config files specified in the general 'config.yml' will be run (Rmd -> md)
  - specified *(expert use only)*: only the specified files will be run (Rmd -> md). Other config files mentioned in the general 'config.yml' file won’t be rerun, so the associated 'md' file should be already available in the intermediateDir folder.

- **configDir** String with directory with config files, by default a 'config' folder in inputDir. It should contain a general 'config.yml' file and dedicated 'config-[X].yml' for each chapter. The order of each chapter is specified in the 'config' slot in the general general 'config.yml'.

- **logFile** *(optional)* String with path to a log file, where output (also error/messages/warnings) should be stored. If specified, the entire output is re-directed to this file.

- **indexPath** String with path to the index file, by default 'index.Rmd' in inputDir.

- **inputDir** String with input directory, working directory by default.

- **outputDir** String with output directory, ('report' by default).

- **intermediateDir** String with intermediate directory ('interim' by default), where markdown files and rds file specifying Js libraries (with knit_meta) for each sub report are stored.

- **extraDirs** Character vector with extra directories required by the report, directory with external images. By default, the directories: 'figures', 'tables' and mentioned in the 'patientProfilePath' parameter of the general config file are included. All these folders should be available in inputDir.

- **quiet** Logical, if TRUE (FALSE by default) messages during the execution of each report are not displayed in the console (see render).

**Value**

String with path to the front page of the clinical data report.

**Framework**

This function is based on the render_book function, enabling specification of chapter-specific input parameters, specified in YAML configuration files. This consists of:

1. importing the general config file ('config'.yml) to identify each report of interest ('config' tag)

2. for each report of interest:
   - loading the report specific parameters from the associated 'config' file (see the getParamsFromConfig function)
   - if the template should be extracted from a specified package (templatePackage tag), this template is copied to the current directory. Please note that if a file with same name is available in the working directory, this file will be overwritten.
scatterplotClinData

- executing the report (‘template’ tag) with the associated parameters in a **new R session for reproducibility**, to obtain the associated Markdown file

3. combining all Markdown files to a html document (see the convertMdToHtml function)

If the execution of a specific report fails with error, a warning message is triggered. A report containing only the specified title is created, to ensure output consistency (especially html file numbering) in case the report succeeds.

**Available template report**

see ?'clinDataReview-templates' for list of clinical data template report available in the package.

**Author(s)**

Laure Cougnaud

**See Also**

Other clinical data reporting: checkReportTitles(), convertMdToHtml(), forceParams(), getMdHeader(), getParamsFromConfig(), gitbook_clinDataReview_report(), html_clinDataReview_report(), knitPrintClinDataReview()

---

**scatterplotClinData**  
*Scatterplot of variables of interest for clinical data visualization.*

**Description**

The parameters for this visualization are based on ggplot2 (aesthetic, scale, ...), parameter specification, unlike the other visualizations of the package.

**Usage**

```r
scatterplotClinData(
  data,
  xVar,
  yVar,
  xLab = getLabelVar(xVar, labelVars = labelVars),
  yLab = getLabelVar(yVar, labelVars = labelVars),
  aesPointVar = list(),
  aesLineVar = list(),
  lineInclude = length(aesLineVar) > 0,
  aesLab,
  xTrans = "identity",
  yTrans = "identity",
  xPars = list(),
  yPars = list(),
  xLabVars = NULL,
```
Arguments

data

Data.frame with input data.

xVar

String with column of data containing x-variable.

yVar

String with column of data containing y-variable.

xLab

String with label for xVar.

yLab

String with label for xVar.

aesPointVar

List with specification of aesthetic variable(s), for the point, passed to the mapping parameter of geom_point, e.g. list(color = "TRTP"). Please note by default symbols with fill and color are used. Color is used for the outside of the points, fill for the inside and the hover. Usually, you might want to specify both filling and coloring.

aesLineVar

List with specification of aesthetic variable(s), for the line, passed to the mapping parameter of geom_point, e.g. list(group = "USUBJID").

lineInclude

Logical, if TRUE (by default if aesLineVar is specified) include a scatterplot.
aesLab Named character vector with labels for each aesthetic variable.
xTrans Transformation for the x/y- variables, passed to the trans parameter of scale_x_continuous/scale_y_continuous.
yTrans Transformation for the x/y- variables, passed to the trans parameter of scale_x_continuous/scale_y_continuous.
xPars List with extra parameters for x/y axis, passed to the scale_x_continuous/scale_y_continuous functions, besides trans and limits.
yPars List with extra parameters for x/y axis, passed to the scale_x_continuous/scale_y_continuous functions, besides trans and limits.
xLabVars Character vector with variable(s) to be displayed as the labels of the ticks in the x-axis. By default, xVar is displayed. If specified, this overwrites any labels specified via xPars. In case the variable(s) contain different elements by xVar or between facets, they are combined and displayed below each other.
yLim Numeric vector of length 2 with limits for the x/y axes.
xLim Numeric vector of length 2 with limits for the x/y axes.
yLimExpandData Logical (TRUE by default), should the limits specified via xLim/yLim be expanded to include any data points outside of these limits? Please note that the same limits are set for all facets.
xLimExpandData Logical (TRUE by default), should the limits specified via xLim/yLim be expanded to include any data points outside of these limits? Please note that the same limits are set for all facets.
titleExtra String with extra title for the plot (appended after title).
title String with title for the plot.
caption String with caption. The caption is included at the bottom right of the plot. Please note that this might overlap with vertical or rotated x-axis labels.
subtitle String with subtitle. The subtitle is included at the top left of the plot, below the title.
facetPars List with facetting parameters, passed to the facetting function.
facetAddress String with facetting type, either:
  • 'wrap': facet_wrap
  • 'grid': facet_grid
scalePars List with parameters to customize scales. Each sublist should contains a set of parameters passed to the scale_continuous_manual function.
  If palette(s) are not specified, default palettes are used (see getColorPalette, getShapePalette, getLinetypePalette)
themePars List with general theme parameters (see theme).
refLinePars (optional) Nested list, with parameters for each reference line(s). Each sublist (a.k.a reference line) contains:
• aesthetic value(s) or variable(s) for the lines (in this case column names of data) for reference lines. The line position is controlled by the aesthetics supported in geom_vline, geom_hline and geom_abline.

• 'label': (optional) Logical specifying if the line should be annotated (FALSE to not annotate the line) or string with annotation label. By default, the value of the position of the horizontal/vertical line or the equation of the diagonal line is displayed.

labelVars Named character vector containing variable labels.
width Numeric, width of the plot in pixels, 700 by default.
height Numeric, height of the plot in pixels, 700 by default.
hoverVars Character vector with variables to be displayed in the hover, by default xVar, yVar and any aesthetic variables.
hoverLab Named character vector with labels for hoverVars.
idVar String with variable containing subject ID.
idLab String with label for idVar.
pathVar String with variable of data containing path to a subject-specific report. The report info should be unique for each element of idVar. The report will be:

• opened in a different window in the browser if the user clicks on the 'p' (a.k.a 'profile') key when hovering on a point of the plot
• opened in the browser via hyperlink in the table

pathExpand Logical, if FALSE (by default) the path to subject-report is included in an hyperlink in the table, otherwise a collapsed row is created. This should be set to TRUE only if multiple paths are included for each row in pathVar (e.g. in case of summary table).

table Logical, if TRUE (FALSE by default) returns also a datatable containing the plot data. The plot and table are linked when included in a Rmarkdown document: when clicking on an plot element, only the corresponding records are retained in the associated table; when some records are selected in the table, they are highlighted in the associated table.

tableVars Character vector with variables to be included in the table.
tableLab Named character vector with labels for each tableVars.
tableButton Logical, if TRUE (by default) the table is included within an HTML button.
tablePars List with parameters passed to the getClinDT function.
id String with general id for the plot:

• 'id' is used as group for the SharedData
• 'button:[id]' is used as button ID if table is `TRUE`

If not specified, a random id, as 'plotClinData[X]' is used.

verbose Logical, if TRUE (FALSE by default) progress messages are printed in the current console. For the visualizations, progress messages during download of subject-specific report are displayed in the browser console.
Value

Either:

- if a table is requested: a `clinDataReview` object, a.k.a a list with the 'plot' (plotly object) and 'table' (datatable object)
- otherwise: a plotly object

setFacetLayoutWrap

*Set facetting layout for 'wrap' facetting.*

**Description**

By default, the number of columns is 2.

**Usage**

```
setFacetLayoutWrap(data, facetPars = list())
```

**Arguments**

- `data` Data.frame with data.
- `facetPars` List with facetting parameters, passed to the facetting function. Variables should be specified as character or formula. For 'wrap' facetting (`facetType` is 'wrap'), if the layout is not specified via `nrow/ncol`, 2 columns are used by default.

**Value**

Updated `facetPars`.

**Author(s)**

Laure Cougnaud

setPaletteStaticScatterplotClinData

*Get standard palette for the staticScatterplotClinData function.*

**Description**

Get standard palette for the `staticScatterplotClinData` function.

**Usage**

```
setPaletteStaticScatterplotClinData(data, var, aes, scalePars, geomAes, ...)
```
Arguments

- **data**: Data.frame with data for the plot.
- **var**: Character vector with variable(s) to consider. If multiple, currently only the first one is considered.
- **aes**: String with aesthetic, either: 'color', 'shape' or 'linetype'.
- **scalePars**: List with parameters to customize scales. Each sublist should contain a set of parameters passed to the `scale_discrete_manual` function. If palette(s) are not specified, default palettes are used (see `getColorPalette`, `getShapePalette`, `getLinetypePalette`)
- **geomAes**: List with aesthetic for each geom.
- **...**: Any extra parameters than x and n for the default palette fcts.

Value

List with: `scalePars` and `geomAes`, each of those potentially updated with default palette(s).

**staticScatterplotClinData**

*Scatterplot of variables of interest for clinical data visualization*

Description

Scatterplot of variables of interest for clinical data visualization

Usage

```r
staticScatterplotClinData(
  data,
  xVar,
  yVar,
  xLab = getLabelVar(xVar, labelVars = labelVars),
  yLab = getLabelVar(yVar, labelVars = labelVars),
  aesPointVar = list(),
  aesLineVar = list(),
  lineInclude = length(aesLineVar) > 0,
  aesLab,
  xTrans = "identity",
  yTrans = "identity",
  xPars = list(),
  yPars = list(),
  xLabVars = NULL,
```
yLim = NULL,
xLim = NULL,
yLimExpandData = TRUE,
xLimExpandData = TRUE,
titleExtra = NULL,
title = paste(paste(yLab, "vs", xLab, titleExtra), collapse = "<br>"),
facetPars = list(),
facettType = c("wrap", "grid"),
scalePars = list(),
themePars = list(legend.position = "bottom"),
refLinePars = NULL,
labelVars = NULL,
hoverVars = NULL,
geomType = c("point", "col")
)

Arguments

data Data.frame with input data.
xVar String with column of data containing x-variable.
yVar String with column of data containing y-variable.
xLab String with label for xVar.
yLab String with label for xVar.
aesPointVar List with specification of aesthetic variable(s), for the point, passed to the mapping parameter of geom_point, e.g. list(color = "TRTP"). Please note by default symbols with fill and color are used. Color is used for the outside of the points, fill for the inside and the hover. Usually, you might want to specify both filling and coloring.
aesLineVar List with specification of aesthetic variable(s), for the line, passed to the mapping parameter of geom_point, e.g. list(group = "USUBJID").
lineInclude Logical, if TRUE (by default if aesLineVar is specified) include a scatterplot.
aesLab Named character vector with labels for each aesthetic variable.
xTrans, yTrans Transformation for the x/y- variables, passed to the trans parameter of scale_x_continuous/ scale_y_continuous.
xPars, yPars List with extra parameters for x/y axis, passed to the scale_x_continuous/ scale_y_continuous functions, besides trans and limits.
xLabVars Character vector with variable(s) to be displayed as the labels of the ticks in the x-axis.
   By default, xVar is displayed.
   If specified, this overwrites any labels specified via xPars.
   In case the variable(s) contain different elements by xVar or between facets, they are combined and displayed below each other.
yLim Numeric vector of length 2 with limits for the x/y axes.
xLim Numeric vector of length 2 with limits for the x/y axes.
**xLimExpandData, yLimExpandData**

Logical (TRUE by default), should the limits specified via `xlim/ylim` be expanded to include any data points outside of these limits? Please note that the same limits are set for all facets.

**titleExtra**

String with extra title for the plot (appended after `title`).

**title**

String with title for the plot.

**facetPars**

List with facetting parameters, passed to the facetting function.

**facetType**

String with facetting type, either:

- 'wrap': `facet_wrap`
- 'grid': `facet_grid`

**scalePars**

List with parameters to customize scales. Each sublist should contain a set of parameters passed to the `scale_discrete_manual` function. If palette(s) are not specified, default palettes are used (see `getColorPalette`, `getShapePalette`, `getLinetypePalette`).

**themePars**

List with general theme parameters (see `theme`).

**refLinePars**

(Optional) Nested list, with parameters for each reference line(s). Each sublist (a.k.a reference line) contains:

- aesthetic value(s) or variable(s) for the lines (in this case column names of data) for reference lines. The line position is controlled by the aesthetics supported in `geom_vline`, `geom_hline` and `geom_abline`.
- 'label': (optional) Logical specifying if the line should be annotated (FALSE to not annotate the line) or string with annotation label. By default, the value of the position of the horizontal/vertical line or the equation of the diagonal line is displayed.

**labelVars**

Named character vector containing variable labels.

**hoverVars**

Character vector with variables to be displayed in the hover, by default `xVar`, `yVar` and any aesthetic variables.

**geomType**

String with type of the geom used, either:

- 'point': scatterplot with `geom_point` is created
- 'col': barplot with `geom_col` is created

### Value

`ggplot` object

sunburstClinData  

Sunburst interactive plot.

Description

Note: the table and plot are not (yet) linked.

Usage

sunburstClinData(...)

Arguments

...  
Arguments passed on to plotCountClinData

colorVar (optional) String with coloring variable (NULL by default). By default, the treemap is colored based by section.

colorRange (optional) Numeric vector of length 2 with range for the color variable, in case it is a numeric variable.

vars Character vector with variables of data containing plot nodes. If multiple, they should be specified in hierarchical order (from parent to child node).

varsLab Named character vector with labels for vars.

valueVar String with numeric variable of data containing node value, and associated label.

valueLab String with numeric variable of data containing node value, and associated label.

valueType String with type of values in valueVar (branchvalues of the plot_ly function), among others: 'total' (default, only if sum(child) <= to parent) or 'relative'.

pathVar String with variable of data containing hyperlinks with path to the subject-specific report, formatted as:

  <a href="./path-to-report">label</a>

  If multiple, they should be separated by: ','.

  The report(s) will be:

  • compressed to a zip file and downloaded if the user clicks on the 'p' (a.k.a 'profile') key when hovering on a point of the plot

  • included in a collapsible row, and clickable with hyperlinks in the table

pathLab String with label for pathVar, included in the collapsible row in the table.

table Logical, if TRUE (FALSE by default) returns also a datatable containing the plot data. (The plot and the table are not linked.)

data Data.frame with data.

colorLab String with label for colorVar.
colorPalette (optional) Named character vector with color palette. If not
specified, the viridis color palette is used.
See clinColors.
titleExtra String with extra title for the plot (appended after title).
title String with title for the plot.
subtitle String with subtitle.
   The subtitle is included at the top left of the plot, below the title.
caption String with caption.
   The caption is included at the bottom right of the plot. Please note that this
   might overlap with vertical or rotated x-axis labels.
labelVars Named character vector containing variable labels.
width Numeric, width of the plot in pixels, 700 by default.
height Numeric, height of the plot in pixels, 700 by default.
hoverVars Character vector with variable(s) to be displayed in the hover, by
default any position and aesthetic variables displayed in the plot.
hoverLab Named character vector with labels for hoverVars.
id String with general id for the plot:
   • 'id' is used as group for the SharedData
   • 'button:[id]' is used as button ID if table is TRUE
   If not specified, a random id, as 'plotClinData[X]' is used.
verbose Logical, if TRUE (FALSE by default) progress messages are printed
in the current console. For the visualizations, progress messages during
download of subject-specific report are displayed in the browser console.
tableVars Character vector with variables to be included in the table.
tableLab Named character vector with labels for each tableVars.
tableButton Logical, if TRUE (by default) the table is included within an
   HTML button.
tablePars List with parameters passed to the getClinDT function.

Value

   Either:
   • if a table is requested: a clinDataReview object, a.k.a a list with the 'plot' (plotly object)
     and 'table' (datatable object)
   • otherwise: a plotly object

library(clinUtils)

data(dataADaMCDISCP01)
labelVars <- attr(dataADaMCDISCP01, "labelVars")

dataAE <- dataADaMCDISCP01$ADAE
dataDM <- dataADaMCDISCP01$ADSL

## example of basic sunburst:

# sunburst takes as input table with counts
library(inTextSummaryTable)

# total counts: Safety Analysis Set (patients with start date for the first treatment)
dataTotal <- subset(dataDM, RFSTDTC != "")

# compute adverse event table
tableAE <- getSummaryStatisticsTable(
  data = dataAE,
  rowVar = c("AESOC", "AEDECOD"),
  dataTotal = dataTotal,
  rowOrder = "total",
  labelVars = labelVars,
  stats = getStats("count"),
  rowVarTotalInclude = "AEDECOD",
  outputType = "data.frame-base"
)

dataSunburst <- tableAE
dataSunburst$n <- as.numeric(dataSunburst$n)

# create plot
sunburstClinData(
  data = dataSunburst,
  vars = c("AESOC", "AEDECOD"),
  valueVar = "n",
  valueLab = "Number of patients with adverse events"
)

## example where sum(counts) of child = counts of parent

# counts of patients per arm/site
tableDM <- getSummaryStatisticsTable(
  data = dataDM,
  rowVar = c("ARM", "SITEID"),
  labelVars = labelVars,
)
tableClinData

Create a 'clinical data table', associated to a plot.

Description

Interactive table is created, with the possibility to have clickable link to patient-specific report, and included within a button.

Usage

```r
tableClinData(
  data,
  idVar = "USUBJID",
  idLab = getLabelVar(idVar, labelVars = labelVars),
  keyVar = NULL,
  keyLab = getLabelVar(keyVar, labelVars = labelVars),
  pathVar = NULL,
  pathLab = getLabelVar(pathVar, labelVars = labelVars),
  pathExpand = FALSE,
  tableVars = colnames(data),
  tableLab = getLabelVar(tableVars, labelVars = labelVars),
  tableButton = TRUE,
  tablePars = list(),
  id = paste0("plotClinData", sample.int(n = 1000, size = 1)),
  labelVars = NULL,
  verbose = FALSE
)
```

Arguments

data: Data.frame with data.
### tableClinData

- **idVar**: String with variable containing subject ID.
- **idLab**: String with label for `idVar`.
- **keyVar**: String with unique key variable, identifying unique group for which the link between the table and the plot should be done.
- **keyLab**: String with label for `keyVar`.
- **pathVar**: String with variable of data containing hyperlinks with path to the subject-specific report, formatted as:
  ```html
  <a href="./path-to-report">label</a>
  ```
  If multiple, they should be separated by ‘,’. The report(s) will be:
  - compressed to a zip file and downloaded if the user clicks on the ‘p’ (a.k.a ‘profile’) key when hovering on a point of the plot
  - included in a collapsible row, and clickable with hyperlinks in the table
- **pathLab**: String with label for `pathVar`, included in the collapsible row in the table.
- **pathExpand**: Logical, should the variable in `pathExpand` be included in a collapsible row or as hyperlink in the table? Should be TRUE for if multiple paths are included for each `idVar`, FALSE otherwise (by default).
- **tableVars**: Character vector with variables to be included in the table.
- **tableLab**: Named character vector with labels for each `tableVars`.
- **tableButton**: Logical, if TRUE (by default) the table is included within an HTML button.
- **tablePars**: List with parameters passed to the `getClinDT` function.
- **id**: String with general id for the plot:
  - ‘id’ is used as group for the `SharedData`
  - ‘button:[id]’ is used as button ID if `table` is TRUE
  If not specified, a random id, as ‘plotClinData[X]’ is used.
- **labelVars**: Named character vector containing variable labels.
- **verbose**: Logical, if TRUE (FALSE by default) progress messages are printed in the current console.

### Value

- **datatable**

timeProfileIntervalPlot

Visualize time intervals across subjects/parameters.

Description

Visualize time intervals across subjects/parameters.

Usage

timeProfileIntervalPlot(
data,
  paramVar,
  paramLab = getLabelVar(paramVar, labelVars = labelVars),
  paramVarSep = " - ",
  paramGroupVar = NULL,
  timeStartVar,
  timeStartLab = getLabelVar(timeStartVar, labelVars = labelVars),
  timeEndVar,
  timeEndLab = getLabelVar(timeEndVar, labelVars = labelVars),
  timeStartShapeVar = NULL,
  timeStartShapeLab = getLabelVar(timeStartShapeVar, labelVars = labelVars),
  timeEndShapeVar = NULL,
  timeEndShapeLab = getLabelVar(timeEndShapeVar, labelVars = labelVars),
  shapePalette = NULL,
  colorVar = NULL,
  colorLab = getLabelVar(colorVar, labelVars = labelVars),
  colorPalette = NULL,
  alpha = 1,
  yLab = NULL,
  xLab = paste(c(timeStartLab, timeEndLab), collapse = " and "),
  title = NULL,
  subtitle = NULL,
  caption = NULL,
  labelVars = NULL,
  width = 800,
  height = NULL,
  hoverVars,
  hoverLab,
  idVar = "USUBJID",
  idLab = getLabelVar(idVar, labelVars = labelVars),
  pathVar = NULL,
  pathLab = getLabelVar(pathVar, labelVars = labelVars),
  table = FALSE,
  tableVars,
  tableLab,
  tableButton = TRUE,
tablePars = list(),
id = paste0("plotClinData", sample.int(n = 1000, size = 1)),
verbose = FALSE
)

Arguments

data    Data.frame with data.
paramVar Character vector with variable of data to represent in the y-axis.
paramLab (optional) String with label for paramVar.
paramVarSep (optional) String with separator used to combined paramVar if multiple.
paramGroupVar (optional) Character vector with variable(s) to group/order the paramVar elements in the y-axis.
timeStartVar String with variable with the start of the time interval.
timeStartLab (optional) String with label for timeStartVar.
timeEndVar String with variable with the end of the time interval.
timeEndLab (optional) String with label for timeEndVar.
timeStartShapeVar (optional) String with variable used for the shape of the start of the time interval.
timeStartShapeLab (optional) String with label for timeStartShapeVar.
timeEndShapeVar (optional) String with variable used for the shape of the end of the time interval.
timeEndShapeLab (optional) String with label for timeEndShapeVar.
shapePalette (optional) Character vector with shape palette for timeStartShapeVar and timeEndShapeVar.
colorVar (optional) String with color variable.
colorLab String with label for colorVar.
colorPalette (optional) Named character vector with color palette. If not specified, the viridis color palette is used. See clinColors.
alpha (optional) Numeric with transparency, 1 by default.
xLab, yLab (optional) String with labels for the x/y-axis.
title String with title for the plot.
subtitle String with subtitle. The subtitle is included at the top left of the plot, below the title.
caption String with caption. The caption is included at the bottom right of the plot. Please note that this might overlap with vertical or rotated x-axis labels.
labelVars Named character vector containing variable labels.
width Numeric, width of the plot in pixels, 700 by default.
height Numeric, height of the plot in pixels, 700 by default.
hoverVars: Character vector with variable(s) to be displayed in the hover, by default any position and aesthetic variables displayed in the plot.

hoverLab: Named character vector with labels for hoverVars.

idVar: String with variable containing subject ID.

idLab: String with label for idVar.

pathVar: String with variable of data containing hyperlinks with path to the subject-specific report, formatted as:

```html
<a href="./path-to-report">label</a>
```

If multiple, they should be separated by ': , '.
The report(s) will be:

- compressed to a zip file and downloaded if the user clicks on the 'p' (a.k.a 'profile') key when hovering on a point of the plot
- included in a collapsible row, and clickable with hyperlinks in the table

pathLab: String with label for pathVar, included in the collapsible row in the table.

table: Logical, if TRUE (FALSE by default) returns also a datatable containing the plot data. The plot and table are linked when included in a Rmarkdown document: when clicking on an plot element, only the corresponding records are retained in the associated table; when some records are selected in the table, they are highlighted in the associated table.

tableVars: Character vector with variables to be included in the table.

tableLab: Named character vector with labels for each tableVars.

tableButton: Logical, if TRUE (by default) the table is included within an HTML button.

tablePars: List with parameters passed to the getClinDT function.

id: String with general id for the plot:

- 'id' is used as group for the SharedData
- 'button:[id]' is used as button ID if table is TRUE

If not specified, a random id, as 'plotClinData[X]' is used.

verbose: Logical, if TRUE (FALSE by default) progress messages are printed in the current console. For the visualizations, progress messages during download of subject-specific report are displayed in the browser console.

Value:

Either:

- if a table is requested: a clinDataReview object, a.k.a a list with the 'plot' (plotly object) and 'table' (datatable object)
- otherwise: a plotly object

Author(s):

Laure Cougnaud
transformData

Transform data.

Description
Transform data from long to wide format. This function converts formats with the `stats::reshape` function.

Usage
```
transformData(data, transformations, verbose = FALSE, labelVars = NULL)
```

Arguments
data
Data.frame with input data to transform.

transformations
Transformations (or list of those) as a list with:
  - 'type': String with type of transformation. Currently, only: 'pivot_wider' is available
  - extra parameters for the transformation, for:
    - 'pivot_wider':
      - 'varsID': Character vector with variable(s) of data defining unique records in the wide format. Corresponds to the `idvar` parameter of the `reshape` function.
      - 'varPivot': String with unique variable of data containing elements to pivot in different columns in the wide format (used for column names). Corresponds to the `timevar` parameter of the `reshape` function.
      - 'varsValue': Character vector with variable(s) of data used to fill the columns in the wide format. Corresponds to the `v.names` parameter of the `reshape` function.

verbose
Logical, if TRUE (FALSE by default) progress messages are printed in the current console. For the visualizations, progress messages during download of subject-specific report are displayed in the browser console.

labelVars
Named character vector containing variable labels.

Value
A data.frame in wide format.

Author(s)
Laure Cougnaud
Description

Note: the table and plot are not (yet) linked.

Usage

treemapClinData(...)

Arguments

Arguments passed on to \texttt{plotCountClinData}

\begin{itemize}
  \item \texttt{colorVar} (optional) String with coloring variable (NULL by default). By default, the treemap is colored based by section.
  \item \texttt{colorRange} (optional) Numeric vector of length 2 with range for the color variable, in case it is a numeric variable.
  \item \texttt{vars} Character vector with variables of \texttt{data} containing plot nodes. If multiple, they should be specified in hierarchical order (from parent to child node).
  \item \texttt{varsLab} Named character vector with labels for \texttt{vars}.
  \item \texttt{valueVar} String with numeric variable of \texttt{data} containing node value, and associated label.
  \item \texttt{valueLab} String with numeric variable of \texttt{data} containing node value, and associated label.
  \item \texttt{valueType} String with type of values in \texttt{valueVar} (branchvalues of the \texttt{plot_ly} function), among others: 'total' (default, only if sum(child) <= to parent) or 'relative'.
  \item \texttt{pathVar} String with variable of \texttt{data} containing hyperlinks with path to the subject-specific report, formatted as:
  \begin{verbatim}
  \texttt{<a href="./path-to-report">label</a>}
  \end{verbatim}
    If multiple, they should be separated by: ',', '.
    The report(s) will be:
    \begin{itemize}
      \item compressed to a zip file and downloaded if the user clicks on the 'p' (a.k.a 'profile') key when hovering on a point of the plot
      \item included in a collapsible row, and clickable with hyperlinks in the table pathLab String with label for \texttt{pathVar}, included in the collapsible row in the table.
  \end{itemize}
  \item \texttt{table} Logical, if TRUE (FALSE by default) returns also a \texttt{datatable} containing the plot data. (The plot and the table are not linked.)
  \item \texttt{data} Data.frame with data.
  \item \texttt{colorLab} String with label for \texttt{colorVar}.
\end{itemize}
colorPalette (optional) Named character vector with color palette. If not specified, the viridis color palette is used. See clinColors.

titleExtra String with extra title for the plot (appended after title).
title String with title for the plot.
subtitle String with subtitle.
    The subtitle is included at the top left of the plot, below the title.
caption String with caption.
    The caption is included at the bottom right of the plot. Please note that this might overlap with vertical or rotated x-axis labels.
labelVars Named character vector containing variable labels.
width Numeric, width of the plot in pixels, 700 by default.
height Numeric, height of the plot in pixels, 700 by default.
hoverVars Character vector with variable(s) to be displayed in the hover, by default any position and aesthetic variables displayed in the plot.
hoverLab Named character vector with labels for hoverVars.
id String with general id for the plot:
    • 'id' is used as group for the SharedData
    • 'button:[id]' is used as button ID if table is TRUE
    If not specified, a random id, as 'plotClinData[X]' is used.
verbose Logical, if TRUE (FALSE by default) progress messages are printed in the current console. For the visualizations, progress messages during download of subject-specific report are displayed in the browser console.
tableVars Character vector with variables to be included in the table.
tableLab Named character vector with labels for each tableVars.
tableButton Logical, if TRUE (by default) the table is included within an HTML button.
tablePars List with parameters passed to the getClinDT function.

Value

Either:

• if a table is requested: a clinDataReview object, a.k.a a list with the 'plot' (plotly object) and 'table' (datatable object)
• otherwise: a plotly object

**varToFm**

Get formula for a specific variable, to be used in aesthetic specification in `plot_ly`.

**Description**

Get formula for a specific variable, to be used in aesthetic specification in `plot_ly`. 

Usage

```r
varToFm(var)
```

Arguments

- `var` Character vector with variable to combine. Otherwise with the `+` operator.

Value

- `as.formula`

### zipClinDataReview

#### zipClinDataReview

#### Zip the clinical data report

Description

Create a zip folder of clinical data reports with a redirect page. The clinical data report out of the `render_clinDataReviewReport` is copied into a new folder. A redirect html page is created to enable the user to navigate the report without needing to look into the new directory.

Usage

```r
zipClinDataReview(
  reportDir = "report",
  newDir = "report_dependencies",
  redirectPage = "report.html",
  zipFolder = "report.zip"
)
```

Arguments

- `reportDir` String for the path to the directory where the clinical data reports are stored
- `newDir` String for the path where the files from `reportDir` should be copied to.
- `redirectPage` String with the path of the html file that redirects to the "1-introduction.html" page of the report.
- `zipFolder` String with the path to the zipped folder.

Value

The zip folder is created in the specified location.
