Package ‘contact’

April 13, 2020

**Title**  Creating Contact and Social Networks

**Version**  1.2.2

**Description**  Process spatially- and temporally-discrete data into contact and social networks, and facilitate network analysis by randomizing individuals' movement paths and/or related categorical variables. To use this package, users need only have a dataset containing spatial data (i.e., latitude/longitude, or planar x & y coordinates), individual IDs relating spatial data to specific individuals, and date/time information relating spatial locations to temporal locations. The functionality of this package ranges from data “cleaning” via multiple filtration functions, to spatial and temporal data interpolation, and network creation and analysis. Functions within this package are not limited to describing interpersonal contacts. Package functions can also identify and quantify “contacts” between individuals and fixed areas (e.g., home ranges, water bodies, buildings, etc.). As such, this package is an incredibly useful resource for facilitating epidemiological, ecological, ethological and sociological research.

**Depends**  R (>= 3.6.0)

**Imports**  ape (>= 5.3), data.table (>= 1.12.2), doParallel (>= 1.0.15), foreach (>= 1.4.8), geosphere (>= 1.5-10), igraph (>= 1.2.4.1), lubridate (>= 1.7.4), methods (>= 3.6.0), parallel (>= 3.6.0), raster (>= 2.9-5), rgdal (>= 1.4-4), rgeos (>= 0.4-3), sf (>= 0.7-4), sp (>= 1.3-1), stats (>= 3.6.0)

**License**  CC0

**Encoding**  UTF-8

**LazyData**  true

**RoxygenNote**  7.1.0

**BugReports**  https://github.com/lanzaslab/contact/issues

**Suggests**  knitr, rmarkdown

**VignetteBuilder**  knitr

**NeedsCompilation**  no

Real-time location data for 19 baboons

Description

A dataset containing geographic real-time point locations for 19 baboons observed between 03:00:00 and 04:00:00 UTC on August 13th 2012, and are included here primarily to be used for function-testing purposes.

Usage

data(baboons)

Format

A data frame with 65140 rows and 5 variables:

- **timestamp**: The date and time a sensor measurement was taken. Time units are in UTC (Coordinated Universal Time) or GPS time, which is a few leap seconds different from UTC.

- **location.long**: The geographic longitude of a location along an animal track as estimated by the processed sensor data. Positive values are east of the Greenwich Meridian, negative values are west of it. Presented as decimal degrees based on the WGS84 reference system.

- **location.lat**: The geographic latitude of a location along an animal track as estimated by the processed sensor data. Positive values are north of the equator, negative values are west of it. Presented as decimal degrees based on the WGS84 reference system.

- **individual.local.identifier**: A unique individual identifier for the animal, provided by the data owner.

- **dateTime**: The date and time, rounded to the nearest second that a sensor measurement was taken. Derived from timestamps. Note that this variable is not present in the source data set.

Details

This data file a subset of a larger one published by the Movebank Data Repository (www.datarepository.movebank.org). The larger data set on Movebank contains baboon locations between 08/01/2012 and 08/14/2012. As of the time of publication of this package, a version of the published animal tracking data set can be viewed on Movebank (www.movebank.org) in the study "Collective movement in wild baboons (data from Strandburg-Peshkin et al. 2015)". Individual attributes in the data files are defined here and in the Movebank Attribute Dictionary, available at www.movebank.org/node/2381.

The item descriptions described herein appear in the README text provided for the repository entry verbatim.

Note that according to data publishers, "this dataset does not include interpolated locations or locations that failed the speed filter (see Strandburg-Peshkin et al. 2015 for details)."

**calves**  
*Reral-time location data for 10 calves on May 2nd 2016*

Description

A dataset containing planar real-time point locations for 10 calves between 00:00:00 and 02:00:00 UTC on May 2nd, 2016. These data are a subset of the data set published in the supplemental materials of Dawson et al. 2019, and are included here primarily to be used for function-testing purposes.

Usage

data(calves)

Format

A data frame with 11118 rows and 5 variables:

- **calftag** a unique identifier for each calf
- **x** planar x coordinate
- **y** planar y coordinate
- **time** UTC time at which location fix was obtained
- **date** date on which fix location occurred

Details

Calves were approximately 1.5-year-old beef cattle kept in a 30 X 35 m2 pen at the Kansas State University Beef Cattle Research Center in Manhattan, KS.

Data collection was supported by U.S. National Institute of Health (NIH) grant R01GM117618 as part of the joint National Science Foundation-NIH-United States Department of Agriculture Ecology and Evolution of Infectious Disease program.

calves2018

Real-time location data for 20 calves in June 2018

Description
A dataset containing planar real-time point locations for 20 calves between 00:00:00 on June 1st, 2018 and 23:59:59 UTC on June 3, 2018.

Usage
data(calves2018)

Format
A data frame with 193551 rows and 4 variables:

calftag a unique identifier for each calf
x planar x coordinate
y planar y coordinate
dateTime UTC date and time at which location fix was obtained

Details
Calves were approximately 1.5-year-old castrated male cattle (i.e., steer) kept in a 30 X 35 m2 pen at the Kansas State University Beef Cattle Research Center in Manhattan, KS.

Data collection was supported by U.S. National Institute of Health (NIH) grant R01GM117618 as part of the joint National Science Foundation-NIH-United States Department of Agriculture Ecology and Evolution of Infectious Disease program.

head(calves2018)
Identify and Remove Data Points Outside of a Specified Area

Description

Identifies and removes timepoints when tracked individuals were observed outside of a defined polygon (note: the polygon should be described by the vectors confinementCoord.x (x coordinates) and confinementCoord.y (y coordinates). These vectors must be the same length and the coordinates should be listed in the clockwise or counter-clockwise order that they are observed on the confining polygon.

Usage

confine(
  x, 
  point.x = NULL, 
  point.y = NULL, 
  confinementCoord.x, 
  confinementCoord.y, 
  filterOutput = TRUE
)

Arguments

x Data frame or non-data-frame list that will be filtered.

point.x Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what planar-x or longitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "x" exists in x. Defaults to NULL.

point.y Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what planar-y or latitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "y" exists in x. Defaults to NULL.

confinementCoord.x Vector describing x-coordinates of confining-polygon vertices. Each vertex should be described in clockwise or counter-clockwise order, and ordering should be consistent with confinementCoord.y.

confinementCoord.y Vector describing y-coordinates of confining-polygon vertices. Each vertex should be described in clockwise or counter-clockwise order, and ordering should be consistent with confinementCoord.x.

filterOutput Logical. If TRUE, output will be a data frame or list of data frames (depending on whether or not x is a data frame or not) containing only points within confinement polygons. If FALSE, no observations are removed and a "confinement_status" column is appended to x, detailing the relationship of each point to the confinement polygon. Defaults to TRUE.
Details

If users are not actually interested in filtering datasets, but rather, determining what observations should be filtered, they may set filterOutput == FALSE. By doing so, this function will append a "confinement_status" column to the output dataframe, which reports the results of sp::point.in.polygon function that is used to determine if individuals are confined within a given polygon. In this column, values are: 0: point is strictly exterior to pol; 1: point is strictly interior to pol; 2: point lies on the relative interior of an edge of pol; 3: point is a vertex of pol (see ?sp::point.in.polygon).

Value

If filterOutput == TRUE, returns x less observations where points were located outside of the polygon defined by points in confinementCoord.x and confinementCoord.y.

If filterOutput == FALSE, returns x appended with a "confinement_status" column which reports the results of sp::point.in.polygon function, which is used to determine if observed points are confined within the polygon defined by points in confinementCoord.x and confinementCoord.y.

Examples

data("calves")

water_trough.x<- c(61.43315, 61.89377, 62.37518, 61.82622) #water polygon x-coordinates
water_trough.y<- c(62.44815, 62.73341, 61.93864, 61.67411) #water polygon y-coordinates

headWater1<- confine(calves, point.x = calves$x, point.y = calves$y,
                     confinementCoord.x = water_trough.x, confinementCoord.y = water_trough.y,
                     filterOutput = TRUE) #creates a data set comprised ONLY of points within the water polygon.

headWater2<- confine(calves, point.x = calves$x, point.y = calves$y,
                     confinementCoord.x = water_trough.x, confinementCoord.y = water_trough.y,
                     filterOutput = FALSE) #appends the "confinement_status" column to x.

Description

These functions have been removed from our package.

Details

- contactTest: contactTest is defunct and was removed in version 1.2.0. Please consider using another contact-comparison function instead (e.g., contactCompare_chisq, contactCompare_mantel, etc.)
ContactCompare_chisq

Compare Observed Contacts to a Random Distribution

Description

This function is used to determine if tracked individuals in an empirical dataset had more or fewer contacts with other tracked individuals/specified locations than would be expected at random. The function works by comparing an empirical contact distribution (generated using x.summary and x.potential) to a NULL distribution (generated using y.summary and y.potential) using a X-squared goodness-of-fit test. Note that this function SHOULD NOT be used to compare two empirical networks using Chi-squared tests, as the function assumes x.summary and y.summary represent observed and expected values, respectively.

This function was inspired by the methods described by Spiegel et al. 2016. They determined individuals to be expressing social behavior when nodes had greater degree values than would be expected at random, with randomized contact networks derived from movement paths randomized according to their novel methodology (that can be implemented using our randomizePaths function). Here, users can also identify when more or fewer contacts (demonstrated by the sign of values in the "difference" column in the output) with specific individuals than would be expected at random, given a pre-determined p-value threshold. Such relationships suggest social affinities or aversions, respectively, may exist between specific individuals.

Note: The default tested column (i.e., categorical data column from which data is drawn to be compared to randomized sets herein) is "id." This means that contacts involving each individual (defined by a unique "id") will be compared to randomized sets. Users may not use any data column for analysis other than "id." If users want to use another categorical data column in analyses rather than "id," we recommend re-processing data (starting from the dist.all/distToArea functions), while specifying this new data as an "id." For example, users may annotate an illness status column to the empirical input, wherein they describe if the tracked individual displayed gastrointestinal ("gastr"), respiratory ("respr"), both ("both"), illness symptoms, or were consistently healthy ("hel") over the course of the tracking period. Users could set this information as the "id," and carry it forward as such through the data-processing pipeline. Ultimately, they could determine if each of these disease states affected contact rates, relative to what would be expected at random.

Take care to ensure that the same shuffle.type is denoted as was originally used to randomize individuals’ locations (assuming the randomizePaths function was used to do so). This is important for two reasons: 1.) If there was no y.potential input, the function assumes that x.potential is relevant to the random set as well. This is a completely fair assumption when importBlocks == FALSE or when the shuffleUnit == 0. In cases when the shuffle.type is 1 or 2, however, this assumption can lead to erroneous results and/or errors in the function. 2.) In the randomizePaths function, setting shuffle.type == 2 produces only 1 shuffle.unit’s worth of data (e.g., 1 day), rather than a dataset with the same length of x. As such, there may be a different number of blocks in y compared to x. Here we assume that the mean randomized durations per block in y.summary and y.potential, are representative of mean randomized durations per block across each shuffle unit (e.g., day 1 is representative of day 3, etc.).

Finally, if X-squared expected values will be very small, approximations of p may not be correct (and in fact, all estimates will be poor). It may be best to weight these tests differently. To address this, We’ve added the function reported that results may be inaccurate.
Usage

```r
contactCompare_chisq(
  x.summary,  
  y.summary,  
  x.potential,  
  y.potential = NULL, 
  importBlocks = FALSE,  
  shuffle.type = 1,  
  popLevelOutput = FALSE,  
  parallel = FALSE,  
  nCores = (parallel::detectCores()/2)
)
```

Arguments

- `x.summary` List or single-data frame output from the `summarizeContacts` function referring to the empirical data. Note that if `x.summary` is a list of data frames, only the first data frame will be used in the function.

- `y.summary` List or single-data frame output from the `summarizeContacts` function referring to the randomized data (i.e., NULL model contact-network edge weights). Note that if `y.summary` is a list of data frames, only the first data frame will be used in the function.

- `x.potential` List or single-data frame output from the `potentialDurations` function referring to the empirical data. Note that if `x.potential` is a list of data frames, potential contact durations used in the function will be determined by averaging those reported in each list entry.

- `y.potential` List or single-data frame output from the `potentialDurations` function referring to the randomized data. Note that if `y.potential` is a list of data frames, potential contact durations used in the function will be determined by averaging those reported in each list entry. If NULL, reverts to `x.potential`. Defaults to NULL.

- `importBlocks` Logical. If true, each block in `x.summary` will be analyzed separately. Defaults to FALSE. Note that the "block" column must exist in `x.summary` AND `x.potential` objects, and values must be identical (i.e., if block 100 exists in `x` inputs, it must also exist in `y` inputs), otherwise an error will be returned.

- `shuffle.type` Integer. Describes which shuffle.type (from the `randomizePaths` function) was used to randomize the `y.summary` data set(s). Takes the values "0," "1," or "2." This is important because there are different assumptions associated with each `shuffle.type`.

- `popLevelOutput` Logical. If TRUE a secondary output describing population-level comparisons will be appended to the standard, individual-level function output.

- `parallel` Logical. If TRUE, sub-functions within the `summarizeContacts` wrapper will be parallelized. Note that the only sub-function parallelized here is called ONLY when `importBlocks == TRUE`.

- `nCores` Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., `(parallel::detectCores()/2)`).
Value

Output format is dependent on popLevelOutput value.

If popLevelOutput == FALSE output will be a single two data frame containing individual-level pairwise analyses of node degree, total edge weight (i.e., the sum of all observed contacts involving each individual), and specific dyad weights (e.g., contacts between individuals 1 and 2). The data frame contains the following columns:

- **id**: the id of the specific individual.
- **metric**: designation of what is being compared (e.g., totalDegree, totalContactDurations, individual 2, etc.). Content will change depending on which data frame is being observed.
- **method**: Statistical test used to determine significance.
- **X.squared**: Test statistic associated with the comparison.
- **p.val**: p.values associated with each comparison.
- **df**: Degrees of freedom associated with the statistical test.
- **contactDurations.x**: Describes the number of observed events in x.summary.
- **contactDurations.y**: Describes the number of observed events in y.summary.
- **noContactDurations.x**: Describes the number of empircal events that were not observed given the total number of potential events in x.potential.
- **noContactDurations.y**: Describes the number of random events that were not observed given the total number of potential events in y.potential.
- **difference**: The absolute value given by subtracting contactDurations.y from contactDurations.x.
- **warning**: Denotes if any specific warning occurred during analysis.
- **block.x** (Only if importBlocks == TRUE): Denotes the specific time block from x.
- **block.start.x** (Only if importBlocks == TRUE): Denotes the specific timepoint at the beginning of each time block.
- **block.end.x** (Only if importBlocks == TRUE): Denotes the specific timepoint at the end of each time block.
- **block.y** (Only if importBlocks == TRUE): Denotes the specific time block from y.
- **block.start.y** (Only if importBlocks == TRUE): Denotes the specific timepoint at the beginning of each time block.
- **block.end.y** (Only if importBlocks == TRUE): Denotes the specific timepoint at the end of each time block.

If popLevelOutput == TRUE, output will be a list of two data frames: The one described above, and second describing the population-level comparisons. Columns in each data frame are identical.

---

**contactCompare_mantel Statistically Compare Two Contact Matrices**

**Description**

Tests for similarity of the x.summary input to y.summary. Please note that this is function of convenience that is essentially a wrapper for the ape::mantel.test function, that allows users to easily compare contact networks created using our pipeline of contact:: functions. Please understand that ape::mantel.test does not allow for missing values in matrices, so all NAs will be treated as zeroes.

**Usage**

```r
contactCompare_mantel(
  x.summary, y.summary,
  numPermutations = 1000,
  alternative.hyp = "two.sided",
  importBlocks = FALSE
)
```

**Arguments**

- **x.summary**
  List or single-data frame output from the summarizeContacts function refering to the empirical data. Note that if x.summary is a list of data frames, only the first data frame will be used in the function.

- **y.summary**
  List or single-data frame output from the summarizeContacts function refering to the randomized data (i.e., NULL model contact-network edge weights). Note that if y.summary is a list of data frames, only the first data frame will be used in the function.

- **numPermutations**
  Integer. Number of times to permute the data. Defaults to 1000.
alternative.hyp
Character string. Describes the nature of the alternative hypothesis being tested when test == "mantel." Takes the values "two.sided," "less," or "greater."Defaults to "two.sided."

importBlocks
Logical. If true, each block in x.summary will be analyzed separately. Defaults to FALSE. Note that the "block" column must exist in .summary objects AND values must be identical (i.e., if block 100 exists in x.summary, it must also exist in y.summary), otherwise an error will be returned.

Value
Output format is a single data frame with the following columns.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>method</td>
<td>Statistical test used to determine significance.</td>
</tr>
<tr>

data(calves) #load data

calves.dateTime<-datetime.append(calves, date = calves$date,
time = calves$time) #add dateTime column

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calfTag,
dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x,
point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE,
extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE,
na.rm = TRUE, smooth.type = 1) #aggregate to 5-min timepoints

calves.dist<-dist2All_df(x = calves.agg, parallel = FALSE,
dataType = "Point", lonlat = FALSE) #calculate inter-calf distances

calves.contact.block<-contactDur.all(x = calves.dist, dist.threshold=1,
sec.threshold=10, blocking = TRUE, blockUnit = "hours", blockLength = 1,
contactDur.all

Description

This function uses the output from dist2All to determine when and for how long tracked individuals are in "contact" with one another. Individuals are said to be in a "contact" event if they are observed within a given distance (<= dist.threshold) at a given timestep. Contacts are broken when individuals are observed outside the specified distance threshold from one another for > sec.threshold seconds. Sec.threshold dictates the maximum amount of time between concurrent observations during which potential "contact" events remain unbroken. For example, if sec.threshold == 10, only "contacts" occurring within 10secs of one another will be regarded as a single "contact" event of duration sum(h). If in this case, a time difference between contacts was 11 seconds, the function will report two separate contact events.

The output of this function is a data frame containing a time-ordered contact edge set detailing inter-animal contacts.
contactDur.all

Usage

contactDur.all(
  x,
  dist.threshold = 1,
  sec.threshold = 10,
  blocking = FALSE,
  blockLength = 1,
  blockUnit = "hours",
  blockingStartTime = NULL,
  equidistant.time = FALSE,
  parallel = FALSE,
  nCores = (parallel::detectCores()/2),
  reportParameters = TRUE
)

Arguments

  x                  Output from the dist2All function. Can be either a data frame or non-data-frame list.
  dist.threshold    Numeric. Radial distance (in meters) within which "contact" can be said to occur. Defaults to 1. Note: If you are defining contacts as occurring when polygons intersect, set dist.threshold to 0.
  sec.threshold     Numeric. Dictates the maximum amount of time between concurrent observations during which potential "contact" events remain unbroken. Defaults to 10.
  blocking          Logical. If TRUE, contacts will be evaluated for temporal blocks spanning blockLength blockUnit (e.g., 6 hours) within the data set. Defaults to FALSE.
  blockLength       Integer. Describes the number blockUnits within each temporal block. Defaults to 1.
  blockUnit         Character string taking the values, "secs," "mins," "hours," "days," or "weeks." Describes the temporal unit associated with each block. Defaults to "hours."
  blockingStartTime Character string or date object describing the date OR dateTime starting point of the first time block. For example, if blockingStartTime = "2016-05-01" OR "2016-05-01 00:00:00", the first timeblock would begin at "2016-05-01 00:00:00." If NULL, the blockingStartTime defaults to the minimum dateTime point in x. Note: any blockingStartTime MUST precede or be equivalent to the minimum timepoint in x. Additional note: If blockingStartTime is a character string, it must be in the format ymd OR ymd hms.
  equidistant.time  Logical. If TRUE, location fixes in individuals’ movement paths are temporally equidistant (e.g., all fix intervals are 30 seconds). Defaults to FALSE. Note: This is a time-saving argument. A sub-function here calculates the time difference (dt) between each location fix. If all fix intervals in an individuals’ path are identical, it saves a lot of time.
  parallel          Logical. If TRUE, sub-functions within the contactDur.all wrapper will be parallelized. Defaults to FALSE.
nCores: Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., (parallel::detectCores()/2)).

reportParameters: Logical. If TRUE, function argument values will be appended to output data frame(s). Defaults to TRUE.

Value

Returns a data frame (or list of data frames if x is a list of data frames) with the following columns:

- dyadMember1: The unique ID of an individual observed in contact with a specified second individual.
- dyadMember2: The unique ID of an individual observed in contact with dyadMember1.
- dyadID: The unique dyad ID used to identify the pair of individuals dyadMember1 and dyadMember2.
- contactDuration: The number of sequential timepoints in x that dyadMember1 and dyadMember2 were observed to be in contact with one another.
- contactstartTime: The timepoint in x at which contact between dyadMember1 and dyadMember2 begins.
- contactEndTime: The timepoint in x at which contact between dyadMember1 and dyadMember2 ends.

If blocking == TRUE, the following columns are appended to the output data frame described above:

- block: Integer ID describing unique blocks of time during which contacts occur.
- block.start: The timepoint in x at which the block begins.
- block.end: The timepoint in x at which the block ends.
- numBlocks: Integer describing the total number of time blocks observed within x at which the block

Finally, if reportParameters == TRUE function arguments distThreshold, secThreshold, equidistant.time, and blockLength (if applicable) will be appended to the output data frame.

Examples

data(calves)

calves.dateTime<-datetime.append(calves, date = calves$date, time =
  calves$time) #create a dataframe with dateTime identifiers for location foxes

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag,
  dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x,
  point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE,
  extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE,
This function uses the output from `dist2Area` to determine when tracked individuals are in "contact" with fixed locations. Individuals are said to be in a "contact" event (h) if they are observed within a given distance (<= dist.threshold) at a given timestep(i). Sec.threshold dictates the maximum amount of time a single, potential "contact" event should exist. For example, if sec.threshold=10, only "contacts" occurring within 10secs of one another will be regarded as a single "contact" event of duration sum(h). If in this case, a time difference between contacts was 11 seconds, the function will report two separate contact events.

The output of this function is a data frame containing a time-ordered contact edge set detailing animal-environment contacts.

**Usage**

```r
contactDur.area(  
  x,  
  dist.threshold = 1,  
  sec.threshold = 10,  
  blocking = FALSE,  
  blockLength = 1,  
  blockUnit = "hours",  
  blockingStartTime = NULL,  
  equidistant.time = FALSE,  
  parallel = FALSE,  
  nCores = (parallel::detectCores())/2,  
  reportParameters = TRUE  
)
```

**Arguments**

- `x` Output from the `dist2Area` function (either df or sf variant). Can be either a data frame or non-data-frame list.
**dist.threshold** Numeric. Radial distance (in meters) within which "contact" can be said to occur. Defaults to 1. Note: If you are defining contacts as occurring when polygons intersect, set dist.threshold to 0.

**sec.threshold** Numeric. Dictates the maximum amount of time between concurrent observations during which potential "contact" events remain unbroken. Defaults to 10.

**blocking** Logical. If TRUE, contacts will be evaluated for temporal blocks spanning blockLength blockUnit (e.g., 6 hours) within the data set. Defaults to FALSE.

**blockLength** Integer. Describes the number blockUnits within each temporal block. Defaults to 1.

**blockUnit** Character string taking the values, "secs," "mins," "hours," "days," or "weeks." Describes the temporal unit associated with each block. Defaults to "hours."

**blockingStartTime** Character string or date object describing the date OR dateTime starting point of the first time block. For example, if blockingStartTime = "2016-05-01" OR "2016-05-01 00:00:00", the first timeblock would begin at "2016-05-01 00:00:00." If NULL, the blockingStartTime defaults to the minimum dateTime point in x. Note: any blockingStartTime MUST precede or be equivalent to the minimum timepoint in x. Additional note: If blockingStartTime is a character string, it must be in the format ymd OR ymd hms.

**equidistant.time** Logical. If TRUE, location fixes in individuals' movement paths are temporally equidistant (e.g., all fix intervals are 30 seconds). Defaults to FALSE. Note: This is a time-saving argument. A sub-function here calculates the time difference (dt) between each location fix. If all fix intervals are identical, it saves a lot of time.

**parallel** Logical. If TRUE, sub-functions within the contactDur.all wrapper will be parallelized. Defaults to FALSE.

**nCores** Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., (parallel::detectCores()/2)).

**reportParameters** Logical. If TRUE, function argument values will be appended to output data frame(s). Defaults to TRUE.

**Value**

Returns a data frame (or list of data frames if x is a list of data frames) with the following columns:

- **indiv.id** The unique ID of an individual observed in contact with a specified fixed point/polygon.
- **area.id** The unique ID of a fixed point/polygon observed in contact with indiv.id.
- **contact.id** The unique ID used to identify contacts between the indiv.id and contact.id pair.
- **contactDuration** The number of sequential timepoints in x that indiv.id and area.id were observed to be in contact.
- **contactStartTime** The timepoint in x at which contact between indiv.id and area.id begins.
contactEndTime  The timepoint in x at which contact between indiv.id and area.id ends.

If blocking == TRUE, the following columns are appended to the output data frame described above:

block    Integer ID describing unique blocks of time during which contacts occur.
block.start    The timepoint in x at which the block begins.
block.end    The timepoint in x at which the block ends.
numBlocks    Integer describing the total number of time blocks observed within x at which
the block

Finally, if reportParameters == TRUE function arguments distThreshold, secThreshold, equidistant.time,
and blockLength (if applicable) will be appended to the output data frame.

Examples

data(calves)
calves.dateTime<-datetime.append(calves, date = calves$date,
time = calves$time) #create a dataframe with dateTime identifiers for location fixes.

water<- data.frame(x = c(61.43315, 61.89377, 62.37518, 61.82622),
y = c(62.44815, 62.73341, 61.93864, 61.67411))

water_poly<-data.frame(matrix(ncol = 8, nrow = 1)) #(ncol = number of vertices)*2 #arrange data
colnum = 0
for(h in 1:nrow(water)){
  water_poly[[1,colnum + h]] <- water$x[h] #pull the x location for each vertex
  water_poly[[1, (colnum + 1 + h)]] <- water$y[h] #pull the y location for each vertex
  colnum <- colnum + 1
}

water_dist<-dist2Area_df(x = calves.agg, y = water_poly,
  x.id = calves.agg$id, y.id = "water", dateTime = "dateTime", point.x = calves.agg$x,
  point.y = calves.agg$y, poly.xy = NULL, parallel = FALSE, dataType = "Point",
  lonlat = FALSE, numVertices = NULL) #find distances to the water trough

water_contacts <- contactDurationarea(water_dist, dist.threshold=1,
  sec.threshold=10, blocking = FALSE, blockUnit = "mins", blockLength = 10,
  equidistant.time = FALSE, parallel = FALSE, reportParameters = TRUE)
contactTest

Determine if Observed Contacts are More or Less Frequent than in a Random Distribution (Defunct)

Description

This DEFUNCT function was used to determine if tracked individuals in an empirical dataset had more or fewer contacts with other tracked individuals/specified locations than would be expected at random. The function works by comparing an empirically-based contactDur.all or contactDur.area function output (emp.input) to the contactDur.all or contactDur.area output generated from randomized data (rand.input).

Usage

contactTest(...)  

Arguments

...  

Any input will return the error message: "'contactTest' is now defunct. Please consider using another contact-comparison function instead (e.g., contactCompare_chisq, contactCompare_mantel, etc.)."

Value

Always returns the error message: "'contactTest' is now defunct. Please consider using another contact-comparison function instead (e.g., contactCompare_chisq, contactCompare_mantel, etc.)."

dateFake

Create Fake Date Information

Description

This function assigns fake date information, beginning 01/01/startYear, to each empirical timestamp. Users can control what format the output vector is in by changing the dateFormat argument (format: "mdy" = month-day-year, "ymd" = year-month-day, "dmy" = day-month-year, or "ydm" = year-day-month).

This is a sub-function that can be found within datetime.append.

Usage

dateFake(timestamp, dateFormat = "mdy", startYear = 2000)
Arguments

timestamp  Vector of time information with format "hour:minute:second."
dateFormat  Character string. Defines how date information will be presented in output. Takes values "mdy" (i.e., month/day/year), "ymd" (i.e., year/month/day), "dmy" (i.e., day/month/year), or "ydm" (i.e., year/day/month). Defaults to "mdy."
startYear  Numerical. Denotes what year fake date information will begin if dateFake == TRUE. Defaults to 2000.

Details

Note that the timestamp argument should be a vector of all relevant timepoints. Additionally, time-points should be in hms ("hour, minute, second") format.

Value

Output is a vector of date values (e.g., "01-1-2000") with length length(timestamp).

Examples

data("calves")
dateFake(calves$time, dateFormat = "mdy", startYear = 2000)

Description

This function appends date-time information to a dataset in POSIXct date_time format. It also uses functions from the lubridate package and minor calculations to parse out month, day, hour, minute, second, daySecond (the sequentially ordered second of a day), and totalSecond (sequentially ordered second over the course of the study period) of observations in a given dataset with date (format: "mdy" = month/day/year, "ymd" = year/month/day, "dmy" = day/month/year, or "ydm" = year/day/month (note: no preceding zeroes should be included before numbers <10)) and time (format: hour:minute:second (note: preceding zeroes must be included before numbers < 10, ex. 00:00:01)) information, appends this metadata to the dataset, and can assign each day a unique ID.

Usage

datetime.append(
  x,
  date = NULL,
  time = NULL,
  dateTime = NULL,
  dateFormat = "mdy",
  dateFake = FALSE,
  startYear = 2000,
```
tz.in = "UTC",
tz.out = NULL,
month = FALSE,
day = FALSE,
year = FALSE,
hour = FALSE,
minute = FALSE,
second = FALSE,
daySecond = FALSE,
totalSecond = FALSE
```

Arguments

- **x**: Data frame or list of data frames to which new information will be appended.
- **date**: Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what date information will be used. If argument == NULL, datetime.append assumes a column with the colname "date" exists in x, or that the dateTime argument != NULL. Defaults to NULL.
- **time**: Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what time information will be used. If argument == NULL, datetime.append assumes a column with the colname "time" exists in x, or that the dateTime argument != NULL. Defaults to NULL.
- **dateTime**: Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what dateTime information will be used. If argument == NULL, date and time arguments must be appropriately defined, OR "date and "time" columns must exist in x. Defaults to NULL.
- **dateFormat**: Character string. Defines how date information is presented. Takes values "mdy" (i.e., month/day/year), "ymd" (i.e., year/month/day), "dmy" (i.e., day/month/year), or "ydm" (i.e., year/day/month). Defaults to "mdy."
- **dateFake**: Logical. If TRUE, the function will assign fake date information, beginning 01/01/startYear, to each of the timestamps. Defaults to FALSE.
- **startYear**: Numerical. Denotes what year fake date information will begin if dateFake == TRUE. Defaults to 2000.
- **tz.in**: Character. Identifies the timezone associated with the time/dateTime argument input. Defaults to "UTC." Timezone names often take the form "Country/City." See the listing of timezones at: http://en.wikipedia.org/wiki/List_of_tz_database_time_zones.
- **tz.out**: Character. Identifies the timezone that the output dateTime information will be converted to. If NULL, tz.out will be identical to tz.in. Defaults to NULL. Timezone names often take the form "Country/City." See the listing of timezones at: http://en.wikipedia.org/wiki/List_of_tz_database_time_zones.
- **month**: Logical. If TRUE, output will contain a "month" column with relevant information derived from dateTime information. Defaults to FALSE.
- **day**: Logical. If TRUE, output will contain a "day" column with relevant information derived from dateTime information. Defaults to FALSE.
Logical. If TRUE, output will contain a "year" column with relevant information derived from date\Time information. Defaults to FALSE.

hour
Logical. If TRUE, output will contain a "hour" column with relevant information derived from date\Time information. Defaults to FALSE.

minute
Logical. If TRUE, output will contain a "minute" column with relevant information derived from date\Time information. Defaults to FALSE.

second
Logical. If TRUE, output will contain a "second" column with relevant information derived from date\Time information. Defaults to FALSE.

daySecond
Logical. If TRUE, output will contain a "daySecond" column with information detailing what the second of a given day the associated date\Time value corresponds to. Defaults to FALSE.

totalSecond
Logical. If TRUE, output will contain a "totalSecond" column with information detailing what the second of the entire data set the associated date\Time value corresponds to. Defaults to FALSE.

Value
Output is \( x \) with new columns appended according to corresponding arguments.

Examples

data("calves")
calves.dateTime<-datetime.append(calves, date = calves$date, time = calves$time)
head(calves.dateTime) #see now that a date\Time column exists.

\begin{verbatim}

dist2All_df

\end{verbatim}

\textit{Calculate Distances Between All Individuals}

Description
Calculates the distance between all tracked individuals at a given timestep. Users can choose whether to calculate distances based on a single point, or polygons representative of individuals’ locations. If individuals set \texttt{dataType} == "Polygon", the distance matrix reported describes the shortest distances between polygons’ edges (Note that the \texttt{rgeos::gDistance} function is used to obtain these distances).

Usage

dist2All_df(
  \( x = \) NULL, 
  \( id = \) NULL, 
  \( dateTime = \) NULL, 
  \( point.x = \) NULL, 
  \( point.y = \) NULL, 
  \( poly.xy = \) NULL, 
  \( elev = \) NULL,
)
parallel = FALSE,
nCores = (parallel::detectCores()/2),
dataType = "Point",
lonlat = FALSE,
numVertices = 4
)

Arguments

x Data frame or list of data frames containing real-time-location data.

id Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what unique ids for tracked individuals will be used. If argument == NULL, the function assumes a column with the colname "id" exists in x. Defaults to NULL.

dateTime Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what dateTime information will be used. If argument == NULL, the function assumes a column with the colname "dateTime" exists in x. Defaults to NULL.

point.x Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what planar-x or longitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "x" exists in x. Defaults to NULL.

point.y Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what planar-y or latitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "y" exists in x. Defaults to NULL.

poly.xy Columns within x denoting polygon xy-coordinates. Polygon coordinates must be arranged in the format of those in referencePointToPolygon output. Defaults to NULL.

elev Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes vertical positioning of each individual in 3D space (e.g., elevation). If argument != NULL, relative vertical positioning will be incorporated into distance calculations. Defaults to NULL.

parallel Logical. If TRUE, sub-functions within the dist2All wrapper will be parallelized. Defaults to FALSE.

nCores Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., (parallel::detectCores()/2)).

dataType Character string referring to the type of real-time-location data presented in x, taking values of "Point" or "Polygon." If argument == "Point," individuals’ locations are drawn from point.x and point.y. If argument == "Polygon," individuals’ locations are drawn from poly.xy. Defaults to "Point."

lonlat Logical. If TRUE, point.x and point.y contain geographic coordinates (i.e., longitude and latitude). If FALSE, point.x and point.y contain planar coordinates. Defaults to FALSE.

numVertices Numerical. If dataType == "Polygon," users must specify the number of vertices contained in each polygon. Defaults to 4. Note: all polygons must contain the same number of vertices.
Details

If dataType == "Point," users have the option of setting lonlat == TRUE (by default lonlat == FALSE). lonlat is a logical argument that tells the function to calculate the distance between points on the WGS ellipsoid (if lonlat == TRUE), or on a plane (lonlat == FALSE) (see raster::pointDistance). If lonlat == TRUE, coordinates should be in degrees. Otherwise, coordinates should represent planar ('Euclidean') space (e.g. units of meters). This function is not currently able to calculate distances between polygons on the WGS ellipsoid (i.e., if dataType == "Polygon," lonlat must = FALSE). We aim to address this issue in future versions.

Note that if inputting a separate matrix/dataframe with polygon xy coordinates (poly.xy), coordinates must be arranged in the format of those in referencePointToPolygon outputs (i.e., col1 = point1.x, col2 = point1.y, col3 =point2.x, col4 = point2.y, etc., with points listed in a clockwise (or counter-clockwise) order).

Value

Returns a data frame (or list of data frames if x is a list of data frames) with the following columns:

dateTime The unique date-time information corresponding to when tracked individuals were observed in x.

totalIndividuals The total number of individuals observed at least one time within x.

individualsAtTimestep The number of individuals in x observed at the timepoint described in the dateTime column.

id The unique ID of a tracked individual for which we will evaluate distances to all other individuals observed in x.

dist.to.indiv... The observed distance between the individual described in the id column to every other individual observed at specific timepoints.

Examples

data(calves)

calves.dateTime<-datetime.append(calves, date = calves$date, time = calves$time)

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag, dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x, point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE, extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE, na.rm = TRUE, smooth.type = 1) #smooth locations to 5-min fix intervals.

calves.dist2<-dist2All_df(x = calves.agg, parallel = FALSE, dataType = "Point", lonlat = FALSE) #calculate distance between all individuals at each timepoint.
dist2Area_df  

Calculate Distances Between Individuals and Fixed Points/Polygons

Description

Calculate distances (either planar or great circle - see dist2All_df) between each individual, reported in x, and a fixed point(s)/polygon(s), reported in y, at each timestep.

Usage

dist2Area_df(
  x = NULL,
  y = NULL,
  x.id = NULL,
  y.id = NULL,
  dateTime = NULL,
  point.x = NULL,
  point.y = NULL,
  poly.xy = NULL,
  parallel = FALSE,
  nCores = (parallel::detectCores()/2),
  dataType = "Point",
  lonlat = FALSE,
  numVertices = 4
)

Arguments

x  
Data frame or list of data frames containing real-time-location data for individuals.

y  
Data frame or list of data frames describing fixed-area polygons/points for which we will calculate distances relative to tracked individuals at all time steps. Polygons contained within the same data frame must have the same number of vertices.

x.id  
Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what unique ids for tracked individuals will be used. If argument == NULL, the function assumes a column with the colname "id" exists in x. Defaults to NULL.

y.id  
Vector of length sum(nrow(data.frame(y[1:length(y)]))) or singular character data, detailing the relevant colname in y, that denotes what unique ids for fixed-area polygons/points will be used. If argument == NULL, the function assumes a column with the colname "id" may exist in y. If such a column does exist, fixed-area polygons will be assigned unique ids based on values in this column. If no such column exists, fixed-area polygons/points will be assigned sequential numbers as unique identifiers. Defaults to NULL.
dist2Area_df

dateTime Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what dateTime information will be used. If argument == NULL, the function assumes a column with the colname "dateTime" exists in x. Defaults to NULL.

point.x Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what planar-x or longitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "x" exists in x. Defaults to NULL.

point.y Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what planar-y or latitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "y" exists in x. Defaults to NULL.

poly.xy Columns within x denoting polygon xy-coordinates. Polygon coordinates must be arranged in the format of those in referencePointToPolygon output. Defaults to NULL.

parallel Logical. If TRUE, sub-functions within the dist2Area_df wrapper will be parallelized. Note that this can significantly speed up processing of relatively small data sets, but may cause R to crash due to lack of available memory when attempting to process large datasets. Defaults to FALSE.

nCores Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., (parallel::detectCores()/2)).

dataType Character string referring to the type of real-time-location data presented in x, taking values of "Point" or "Polygon." If argument == "Point," individuals' locations are drawn from point.x and point.y. If argument == "Polygon," individuals' locations are drawn from poly.xy. Defaults to "Point."

lonlat Logical. If TRUE, point.x and point.y contain geographic coordinates (i.e., longitude and latitude). If FALSE, point.x and point.y contain planar coordinates. Defaults to FALSE.

numVertices Numerical. If dataType == "Polygon," users must specify the number of vertices contained in each polygon described in x. Defaults to 4. Note: all polygons must contain the same number of vertices.

Details

Polygon coordinates (in both x and y inputs) must be arranged in the format of those in referencePointToPolygon outputs (i.e., col1 = point1.x, col2 = point1.y, col3 =point2.x, col4 = point2.y, etc., with points listed in a clockwise (or counter-clockwise) order).

This variant of dist2Area requires x and y inputs to be non-shapefile data.

Value

Returns a data frame (or list of data frames if x is a list of data frames) with the following columns:

dateTime The unique date-time information corresponding to when tracked individuals were observed in x.

totalIndividuals The total number of individuals observed at least one time within x.
individualsAtTimestep

The number of individuals in x observed at the timepoint described in the dateTime column.

id

The unique ID of a tracked individual for which we will evaluate distances to all other individuals observed in x.

dist.to...

The observed distance between the individual described in the id column to every each polygon/fixed location

Examples

data(calves)

calves.dateTime<-datetime.append(calves, date = calves$date,
 time = calves$time) #create a dataframe with dateTime identifiers for location fixes.

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag,
 dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x,
 point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE,
extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE,
 na.rm = TRUE, smooth.type = 1) #smooth to 5-min fix intervals.

water<- data.frame(x = c(61.43315, 61.89377, 62.37518, 61.82622),
 y = c(62.44815, 62.73341, 61.93864, 61.67411)) #delineate water polygon

water_poly<-data.frame(matrix(ncol = 8, nrow = 1)) #make coordinates to dist2Area specifications

for(h in 1:nrow(water)){
 water_poly[1, colnum + h] <- water$x[h] #pull the x location for each vertex
 water_poly[1, (colnum + 1 + h)] <- water$y[h] #pull the y location for each vertex
 colnum <- colnum + 1
}

water_dist<-dist2Area_df(x = calves.agg, y = water_poly,
 x.id = calves.agg$id, y.id = "water", dateTime = "dateTime", point.x = calves.agg$x,
 point.y = calves.agg$y, poly.xy = NULL, parallel = FALSE, dataType = "Point",
 lonlat = FALSE, numVertices = NULL)

__dt.calc__

**Calculate Time Difference Between Relocations**

**Description**

This function calculates the time difference between relocation events, accounting for individuals’ ids. This function has the capability to calculate the differences between sequential timepoints related to two different features (e.g., contactStartTime and contactEndTime) if both dateTime1 and dateTime2 are defined, or just sequential timepoints from a single vector (e.g., contactStartTime) if only dateTime1 is defined.

This is a sub-function contained within contactDur variants and contactTest functions.
Usage

dt.calc(
  x = NULL,
  id = NULL,
  dateTime1 = NULL,
  dateTime2 = NULL,
  timeUnits = "secs",
  parallel = FALSE,
  nCores = (parallel::detectCores()/2),
  timeStepRelation = 1
)

Arguments

x data frame containing time data. If NULL at least dateTime must be defined._defaults to NULL.
id Vector of length nrow(data.frame(x)) that denotes what unique ids for tracked individuals will be used. If argument == NULL, the function assumes a column with the colname "id" exists in x. Defaults to NULL.
dateTime1 Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what dateTime information will be used. If argument == NULL, the function assumes a column with the colname "dateTime" exists in x. Defaults to NULL.
dateTime2 Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what dateTime information will be used. If argument == NULL, the function will calculate differences between sequential timepoints in dateTime1. If != NULL, the function will calculate differences between dateTime1 and dateTime2 values. Defaults to NULL.
timeUnits Character string describing the time unit of calculated differences. It takes the values "secs," "mins," "hours," "days," or "weeks." Defaults to "secs."
parallel Logical. If TRUE, sub-functions within the dt.calc wrapper will be parallelized. Defaults to FALSE.
nCores Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., (parallel::detectCores()/2)).
timeStepRelation Numerical. Takes the value "1" or "2." If argument == "1," dt values in output represent the difference between time t and time t-1. If argument == "2," dt values in output represent the difference between time t and time t+1. Defaults to 1.

Value

Output is a data frame with the following columns

id The unique ID of a tracked individual.
dt Time difference between relocation events.
units Temporal unit defined by timeUnits argument.
Examples

data(calves) #load calves data set
calves.datetime<-datetime.append(calves)
dt<-dt.calc(x = calves.datetime, id = calves.datetime$calftag,
  dateTime1 = calves.datetime$dateTime, dateTime2 = NULL,
  timeUnits = "secs", parallel = FALSE, timeStepRelation = 1)

head(dt)

dup  Identify and Remove Duplicated Data Points

Description

dup (a.k.a. Multiple instance filter) identifies and removes timepoints when tracked individuals were observed in >1 place concurrently. If avg == TRUE, duplicates are replaced by a single row describing an individuals’ average location (e.g., planar xy coordinates) during the duplicated time point. If avg == FALSE, all duplicated timepoints will be removed, as there is no way for the function to determine which instance among the duplicates should stay. If users are not actually interested in filtering datasets, but rather, determining what observations should be filtered, they may set filterOutput == FALSE. By doing so, this function will append a "duplicated" column to the dataset, which reports values that describe if any timepoints in a given individual’s path are duplicated. Values are: 0: timepoint is not duplicated, 1: timepoint is duplicated.

Usage

dup(
x,
id = NULL,
point.x = NULL,
point.y = NULL,
dateTime = NULL,
avg = TRUE,
parallel = FALSE,
nCores = (parallel::detectCores()/2),
filterOutput = TRUE
)

Arguments

x Data frame containing real-time-location data that will be filtered.
id Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what unique ids for tracked individuals will be used. If argument == NULL, the function assumes a column with the colname "id" exists in x. Defaults to NULL.
point.x Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what planar-x or longitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "x" exists in x. Defaults to NULL.

point.y Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what planar-y or latitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "y" exists in x. Defaults to NULL.

dateTime Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what dateTime information will be used. If argument == NULL, the function assumes a column with the colname "dateTime" exists in x. Defaults to NULL.

avg Logical. If TRUE, point.x and point.y values for duplicated time steps will be averaged, producing a singular point for all time steps in individuals' movement paths. If FALSE, all duplicated time steps wherein individuals were observed in different locations concurrently are removed from the data set.

parallel Logical. If TRUE, sub-functions within the dup wrapper will be parallelized. This is only relevant if avg == TRUE. Defaults to FALSE.

nCores Integer. Describes the number of cores to be dedicated to parallel processes.Defaults to the maximum number of cores available (i.e., (parallel::detectCores()/2)).

filterOutput Logical. If TRUE, output will be a data frame containing only movement paths with non-duplicated timesteps. If FALSE, no observations are removed and a "duplicated" column is appended to x, detailing if time steps are duplicated (column value == 1), or not (column value == 0). Defaults to TRUE.

Details

If users want to remove specific duplicated observations, we suggest setting filterOutput == FALSE, reviewing what duplicated timepoints exist in individuals' paths, and manually removing observations of interest.

Value

If filterOutput == TRUE, returns x less observations at duplicated timepoints.

If filterOutput == FALSE, returns x appended with a "duplicated" column which reports timepoints are duplicated (column value == 1), or not (column value == 0).

Examples

data(calves2018) #load the data set
calves_dup<- dup(calves2018, id = calves2018$calftag, point.x = calves2018$x, point.y = calves2018$y, dateTime = calves2018$dateTime, avg = FALSE, parallel = FALSE, filterOutput = TRUE) #there were no duplicates to remove in the first place.
findDistThresh

Identify Point-Based Distance Threshold for Contact

Description

Sample from a multivariate normal distribution to create "in-contact" n point pairs based on real-time-location systems accuracy, and generate a distribution describing observed distances between point pairs.

Usage

```r
findDistThresh(
  n = 1000,
  acc.Dist1 = 0.5,
  acc.Dist2 = NULL,
  pWithin1 = 90,
  pWithin2 = NULL,
  spTh = 0.666
)
```

Arguments

- `n` Integer. Number of "in-contact" point-pairs used in the expected-distance distribution(s). Defaults to 1000.
- `acc.Dist2` Numerical. Accuracy distance for point 2. If == NULL, defaults to acc.Dist1 value.
- `pWithin1` Numerical. Percentage of data points within acc.Dist of true locations for point 1.
- `pWithin2` Numerical. Percentage of data points within acc.Dist of true locations for point 2. If == NULL, defaults to pWithin1 value.
- `spTh` Numerical. Pre-determined distance representing biological threshold for contact.

Details

This function is for adjusting contact-distance thresholds (spTh) to account for positional accuracy of real-time-location systems, assuming random (non-biased) error in location-fix positions relative to true locations. Essentially this function can be used to determine an adjusted spTh value that likely includes >= 99-percent of true contacts defined using the initial spTh.

Value

Output is a named vector with 22 observations describing the mean, max, and upper 5, 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95, 99-percent CI values, and the true-positive rate (i.e., TPR) calculated from the contact-distance distribution.
References

Examples

findDistThresh(n = 10, acc.Dist1 = 0.5, acc.Dist2 = NULL, pWithin1 = 90, pWithin2 = NULL, spTh = 0.5)

makePlanar

Project Geographic Coordinates onto a Plane

Description

This function converts lon/lat data (decimal degrees) from a geographic coordinate system to planar coordinates using a custom azimuthal equidistant projection, and appends these new coordinates to an input data frame (x). By default, the function assumes longitude and latitude coordinates were produced using the WGS84 datum, but users may change this datum if they wish.

Usage

makePlanar(
  x = NULL,
  x.lon = NULL,
  x.lat = NULL,
  origin.lon = NULL,
  origin.lat = NULL,
  datum = "WGS84"
)

Arguments

x

Data frame or matrix containing geographic data. Defaults to NULL.

x.lon

Vector of length(nrow(x)) or singular character data, detailing the relevant col-name in x, that denotes what longitude information will be used. If argument == NULL, makePlanar assumes a column with the colname "lon" exists in x. Defaults to NULL.

x.lat

Vector of length(nrow(x)) or singular character data, detailing the relevant col-name in x, that denotes what latitude information will be used. If argument == NULL, makePlanar assumes a column with the colname "lat" exists in x. Defaults to NULL.

origin.lon

Numerical. Describes the longitude will be used as the origin-point longitude for the azimuthal-equidistant projection. If NULL, defaults to the longitude of the data set’s centroid. Defaults to NULL.
origin.lat  Numerical. Describes the latitude will be used as the origin-point latitude for the azimuthal-equidistant projection. If NULL, defaults to the latitude of the data set’s centroid. Defaults to NULL.

datum  Character string describing the datum used to generate x.lon and x.lat. Defaults to "WGS84."

Details

Users may specify longitude and latitude coordinates to become the origin of the projection (i.e., the (0,0) coordinate). If they do not specify these values, however, the function calculates the centroid of the data and will use this as the origin point.

Note: this function does not allow any NA coordinate values in longitude/latitude vectors. If NAs exist you will get the following error: "Error in .local(obj, ...) : NA values in coordinates." If NAs exist in your data, we suggest 1.) removing them, or 2.) smoothing data using contact::tempAggregate prior to running this function.

Value

Output is x appended with the following columns:

- planar.x  Planar x-coordinate values derived from longitude observations.
- planar.y  Planar y-coordinate values derived from latitude observations.
- origin.lon  Longitude of the origin point, either user specified or the longitude of the data’s centroid.
- origin.lat  Latitude of the origin point, either user specified or the latitude of the data’s centroid.
- origin.distance  Linear distance (m) between every point and the origin point.

Examples

data(baboons)

head(baboons)  #see that locations are in geographic coordinates

lon.na <- which(is.na(baboons$location.long) == TRUE)  #pull row ids of lon NAs
lat.na <- which(is.na(baboons$location.lat) == TRUE)  #pull row ids of lat NAs

baboons.naRM <- droplevels(baboons[-unique(c(lon.na, lat.na)),])  #remove NAs

baboons.naRM_planar <- makePlanar(x = baboons.naRM,
                                   x.lon = baboons.naRM$location.long, x.lat = baboons.naRM$location.lat,
                                   origin.lon = NULL, origin.lat = NULL, datum = "WGS84")  #note no specified origin coords

head(baboons.naRM_planar)  #see that planar coordinates are reported
mps

Identify and Remove Data Points Based on Observed Movement Speed

Description

mps (a.k.a. Meters-per-Second Filter) identifies and removes timepoints when tracked individuals were observed moving faster than a set distance threshold (representing either the great-circle distance between two points a planar distance metric, depending on whether or not lonlat == TRUE or FALSE, respectively) per second. (i.e., if it is impossible/highly unlikely that individuals moved faster than a given speed (mps), we can assume that any instances when they were observed doing so were the result of erroneous reporting, and should be removed). When running the mps filter, users have the option of setting lonlat == TRUE (by default lonlat == FALSE), lonlat is a logical argument that tells the function to calculate the distance between points on the WGS ellipsoid (if lonlat == TRUE), or on a plane (lonlat == FALSE) (see raster::pointDistance). If lonlat == TRUE, coordinates should be in degrees. Otherwise, coordinates should represent planar ('Euclidean') space (e.g. units of meters).

Usage

```r
mps(
  x,
  id = NULL,
  point.x = NULL,
  point.y = NULL,
  dateTime = NULL,
  mpsThreshold = 10,
  lonlat = FALSE,
  parallel = FALSE,
  nCores = (parallel::detectCores()/2),
  filterOutput = TRUE
)
```

Arguments

- `x` List or data frame containing real-time location data that will be filtered.
- `id` Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what unique ids for tracked individuals will be used. If argument == NULL, the function assumes a column with the colname "id" exists in x. Defaults to NULL.
- `point.x` Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what planar-x or longitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "x" exists in x. Defaults to NULL.
- `point.y` Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what planar-y or latitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "y" exists in x. Defaults to NULL.
dateTime

Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what dateTime information will be used. If argument == NULL, the function assumes a column with the colname "dateTime" exists in x. Defaults to NULL.

mpsThreshold

Numerical. Distance (in meters) representing the maximum distance individuals can realistically travel over a single second.

lonlat

Logical. If TRUE, point.x and point.y contain geographic coordinates (i.e., longitude and latitude). If FALSE, point.x and point.y contain planar coordinates. Defaults to FALSE.

parallel

Logical. If TRUE, sub-functions within the mps wrapper will be parallelized. Defaults to FALSE.

nCores

Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., (parallel::detectCores() / 2)).

filterOutput

Logical. If TRUE, output will be a data frame or list of data frames (depending on whether or not x is a data frame or not) containing only points that adhere to the mpsThreshold rule. If FALSE, no observations are removed and an "mps" column is appended to x, which reports the avg distance per second individuals moved to get from observation i-1 to observation i. Defaults to TRUE.

Details

If users are not actually interested in filtering datasets, but rather determining what observations should be filtered, they may set filterOutput == FALSE. By doing so, this function will append an "mps" column to the dataset, which reports the avg distance per second individuals moved to get from observation i-1 to observation i.

Value

If filterOutput == TRUE, returns x less observations representing impossible/unlikely movements.
If filterOutput == FALSE, returns x appended with an "mps" column which reports the avg distance per second individuals moved to get from observation i-1 to observation i.

Examples

data(calves) #load calves data
calves.dateTime <- datetime.append(calves, date = calves$date, time = calves$time) #create a dataframe with dateTime identifiers for location fixes.
calves_filter1 <- mps(x = calves.dateTime, id = calves.dateTime$calftag, point.x = calves.dateTime$x, point.y = calves.dateTime$y, dateTime = calves.dateTime$dateTime, mpsThreshold = 10, lonlat = FALSE, parallel = FALSE, filterOutput = TRUE)
ntwrkEdges

Compile List of Network Edges from a Contact Table

Description

This function takes the output from contactDur.all or contactDur.area and generates a data frame showing the list of edges in the contact network.

Usage

ntwrkEdges(
  x,
  importBlocks = FALSE,
  removeDuplicates = TRUE,
  parallel = FALSE,
  nCores = (parallel::detectCores()/2)
)

Arguments

x Output from the contactDur.all or contactDur.area functions. Can be either a data frame or list.
importBlocks Logical. If true blocks will be carried over from x input, allowing for time-ordered and time-aggregated network creation. Defaults to FALSE.
removeDuplicates Logical. If x is from contactDur.all, to-from node pairs in output will be reported twice (i.e., nodes will be listed as both a to- and a from-node). If removeDuplicates == true, duplicated edges are removed. Defaults to TRUE.
parallel Logical. If TRUE, sub-functions within the ntwrkEdges wrapper will be parallelized. Note that the only sub-function parallelized here is called ONLY when importBlocks == TRUE.
nCores Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., (parallel::detectCores()/2)).

Value

Output is a data frame with the following columns, and can easily be used as input for igraph functions.

from The "from" nodes in a contact network. Can also be considered "tail" nodes.
to The "to" nodes in a contact network. Can also be considered "head" nodes.
durations The duration of each contact reported in x.
block (if applicable) time block during which reported contacts occurred.
potentialDurations

Identify Potential Contact Durations

Description

This function uses the output from dist2All to determine the potential maximum number of direct-contact durations between individuals in a data set. The max number of durations potentially observed is the number of TSWs both individuals (or an individual and fixed area) were observed at the same time over the study period/temporal block. The output of this function is required for using the "chisq" test argument in the contactTest function.

Usage

potentialDurations(
potentialDurations

x,
blocking = FALSE,
blockLength = 1,
blockUnit = "hours",
blockingStartTime = NULL,
distFunction = "dist2All_df"
)

Arguments

x
Output from the dist2All or distArea function. Can be either a data frame or non-data-frame list.

blocking
Logical. If TRUE, contacts will be evaluated for temporal blocks spanning blockLength blockUnit (e.g., 6 hours) within the data set. Defaults to FALSE.

blockLength
Integer. Describes the number blockUnits within each temporal block. Defaults to 1.

blockUnit
Character string taking the values: "secs," "mins," "hours," "days," or "weeks." Describes the temporal unit associated with each block. Defaults to "hours."

blockingStartTime
Character string or date object describing the date OR dateTime starting point of the first time block. For example, if blockingStartTime = "2016-05-01" OR "2016-05-01 00:00:00", the first timeblock would begin at "2016-05-01 00:00:00." If NULL, the blockingStartTime defaults to the minimum dateTime point in x. Note: any blockingStartTime MUST precede or be equivalent to the minimum timepoint in x. Additional note: If blockingStartTime is a character string, it must be in the format ymd OR ymd hms.

distFunction
Character string taking the values: "dist2All_df", or "dist2Area_df." Describes the contact-package function used to generate x.

Value

Returns a data frame (or list of data frames if x is a list of data frames) with the following columns:

id
The unique ID of an individual observed in the data set.

potenDegree
The maximum degree possible for individual id based on the number of other individuals observed during the time period.

potenTotalContactDurations
The maximum number of contact durations individual id may experience during the time period.

potenContactDurations_...
The maximum number of contact durations individual id may experience with each specific individual/fixed area during the time period.

If blocking == TRUE, the following columns are appended to the output data frame described above:

block
Integer ID describing unique blocks of time during which contacts may occur.

block.start
The timepoint in x at which the block begins.

block.end
The timepoint in x at which the block ends.
randomizeFeature

**Examples**

```r
data(calves)
calves.dateTime <- datetime.append(calves, date = calves$date, time = calves$time)  # create a dataframe with dateTime identifiers for location foxes
calves.agg <- tempAggregate(calves.dateTime, id = calves.dateTime$calftag, dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x, point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE, extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE, na.rm = TRUE, smooth.type = 1)  # smooth locations to 5-min fix intervals.
calves.dist <- dist2All_df(x = calves.agg, parallel = FALSE, dataType = "Point", lonlat = FALSE)  # calculate distance between all individuals at each timepoint
calves.potentialContacts <- potentialDurations(x = calves.dist, blocking = FALSE)
```

**randomizeFeature**    Randomize or Pseudorandomize Categorical Variables

**Description**

This function randomizes the values in a given column (or set of columns (i.e., c(colname(x)[1], colname(x)[2]))) identified by the "feature" argument in a dataset (x).

**Usage**

```r
randomizeFeature(
  x,
  feature = NULL,
  shuffle = FALSE,
  maintainDistr = TRUE,
  numRandomizations = 1
)
```

**Arguments**

- `x`    Data frame containing real-time-location data.
- `feature`    Vector of 1 or more column names describing variables in x to be randomized.
- `shuffle`    Logical. If TRUE, unique values will be replaced with another, random unique value from the same distribution with 100 certainty. For example if the values in a "dose" column c(0mg,100mg,300mg) were shuffled, one possible outcome would be: x$dose.shuff[which(x$dose == "0mg")]<- 300mg, x$dose.shuff[which(x$dose == "100mg")]<- 0mg, and x$dose.shuff[which(x$dose == "300mg")]<- 100mg. Defaults to FALSE.
**randomizePaths**

Randomize or Pseudorandomize Individuals’ Relocation Events

**Description**

Randomizes or pseudorandomizes individuals’ spatial locations. Randomized datasets can later be compared to empirical ones to determine if individuals’ space use differ from what would be expected at random (using the contactTest function).

**Argument**

- **maintainDistr**: Logical. If TRUE, the number of each unique value in the column will be maintained in the function output. Otherwise, the function will draw on the initial distribution to assign randomized values, but the specific number of each unique value may not be maintained. Defaults to TRUE.

- **numRandomizations**: Integer. The number of replicate data frames produced in output. Defaults to 1.

**Details**

Note: the shuffle argument supercedes the maintainDistr argument. Therefore, if shuffle == TRUE, the maintainDistr argument is irrelevant.

**Value**

Output is `x` appended with columns described below.

- `...shuff`: Randomized value of specified variables.
- `randomRep`: Randomization replicate.

**References**

**Examples**

```r
data(calves)

system.time(randomizedValues<-contact::randomizeFeature(x = calves, 
feature = c("calftag", "date"), shuffle = TRUE, maintainDistr = TRUE, 
numRandomizations = 3))

randomizedFrame<-data.frame(randomizedValues[[1]], stringsAsFactors = TRUE)

head(randomizedFrame) #see that randomized-value columns have been appended.
```
Usage

randomizePaths(
  x = NULL,
  id = NULL,
  dateTime = NULL,
  point.x = NULL,
  point.y = NULL,
  poly.xy = NULL,
  parallel = FALSE,
  nCores = parallel::detectCores()/2,
  dataType = "Point",
  numVertices = 4,
  blocking = TRUE,
  blockUnit = "hours",
  blockLength = 1,
  shuffle.type = 0,
  shuffleUnit = "days",
  indivPaths = TRUE,
  numRandomizations = 1,
  reduceOutput = FALSE
)

Arguments

x Data frame containing real-time-location data.
id Vector of length nrow(x) or singular character data, detailing the relevant col-
   name in x, that denotes what unique ids for tracked individuals will be used.
   If argument == NULL, the function assumes a column with the colname "id"
   exists in x. Defaults to NULL.
dateTime Vector of length nrow(x) or singular character data, detailing the relevant col-
   name in x, that denotes what dateTime information will be used. If argument ==
   NULL, the function assumes a column with the colname "dateTime" exists in x.
   Defaults to NULL.
point.x Vector of length nrow(x) or singular character data, detailing the relevant col-
   name in x, that denotes what planar-x or longitude coordinate information will
   be used. If argument == NULL, the function assumes a column with the colname
   "x" exists in x. Defaults to NULL.
point.y Vector of length nrow(x) or singular character data, detailing the relevant col-
   name in x, that denotes what planar-y or latitude coordinate information will
   be used. If argument == NULL, the function assumes a column with the colname
   "y" exists in x. Defaults to NULL.
poly.xy Columns within x denoting polygon xy-coordinates. Polygon coordinates must
   be arranged in the format of those in referencePointToPolygon output. Defaults
   to NULL.
parallel Logical. If TRUE, sub-functions within the randomizePaths wrapper will be
   parallelized. Defaults to FALSE.
randomizePaths

nCores  Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., \(\text{parallel::detectCores()}/2\)).

dataType  Character string referring to the type of real-time-location data presented in x, taking values of "Point" or "Polygon." If dataType == "Point," individuals' locations are drawn from point.x and point.y. If argument == "Polygon," individuals' locations are drawn from poly.xy. Defaults to "Point."

numVertices  Integer. If dataType == "Polygon," users must specify the number of vertices contained in each polygon. Defaults to 4. Note: all polygons must contain the same number of vertices.

blocking  Logical. If TRUE, prior to randomization, timepoints will be categorized into a series of temporal blocks of blockLength-blockUnit length (e.g., 10 mins). After generating blocks, the spatial-location randomization methodology will follow shuffle.type. If FALSE, paths will be randomized by sampling from observed timepoints. No timepoints will be represented more than once in the randomized set. Defaults to TRUE.

blockUnit  Integer. Describes the number blockUnits within each temporal block. Defaults to 1.

blockLength  Character string taking the values, "secs," "mins," "hours," "days," or "weeks." Describes the temporal unit associated with each block. Defaults to "hours."

shuffle.type  Integer. Describes which shuffle.type is used to randomize the rand.input data set(s), given that blocking == TRUE (Note: this value is irrelevant if blocking == FALSE). Takes the values "0," "1," or "2," and defaults to 0. Descriptions of each shuffle.type value can be found under Details.

shuffleUnit  Character string taking the values, "secs," "mins," "hours," "days," or "weeks." Defaults to "days." Describes what temporal unit blocks will be shuffled across given shuffle.type == 2. Blocklength-units may never exceed 1 shuffleUnit (e.g., 25-hour blocks cannot be shuffled using shuffleUnit == "Days," but 1:24-hour blocks work just fine).

indivPaths  Logical. If TRUE, paths will be randomized with no location switching between ids (e.g., randomized xy locations for individual 1 will be generated by sampling only from individual 1’s location distribution). If FALSE, paths will be randomized with potential location switching between ids (e.g., randomized xy locations for individual 1 will be generated by sampling from the entire dataset's location distribution). Defaults to TRUE.

numRandomizations  Integer. The number of replicate data frames produced in output. Defaults to 1.

reduceOutput  Logical. If TRUE, to reduce output size, only "id," "x.rand," "y.rand," "date-Time," and "rand.rep" columns will be included in function output. Defaults to FALSE.

Details

Paths can be randomized, or pseudorandomized differently according to what logical arguments are set to TRUE.

Detailed shuffle.type description: If shuffle.type == 0, within-block timepoints will be randomized by sampling from observed timepoints only within the relevant block (e.g., points in block 1 may...

Examples

data(calves)

calves.dateTime<-datetime.append(calves, date = calves$date, 
    time = calves$time) #create a dataframe with dateTime identifiers for location fixes.

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag, 
    dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x, 
    point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE, 
    extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE, 
    na.rm = TRUE, smooth.type = 1) #smooth to 5-min fix intervals.

calves.agg.rand<-randomizePaths(x = calves.agg, id = "id", 
    dateTime = "dateTime", point.x = "x", point.y = "y", poly.xy = NULL, 
    parallel = FALSE, dataType = "Point", numVertices = 1, blocking = TRUE, 
    blockUnit = "mins", blockLength = 10, shuffle.type = 0, shuffleUnit = NA, 
    indivPaths = TRUE, numRandomizations = 1)

referencePoint2Polygon

Create a Rectangular Polygon Using Planar XY Coordinates

Description

This function creates a square/rectangular polygon from a single reference point by translating its location multiple times using the same method used in repositionReferencePoint. For example, even though calves in our study (see data(calves2018)) were only equipped with RFID tags on their left ear. With this function, we can create polygons that account for the total space used by each individual at each time step. This function is different from similar point-to-polygon functions for two reasons: 1.) It does not assume points lie within the center of the polygon. Rather, the reference point must be a corner of the polygon (Note: "UL" denotes that the reference point lies on the upper-left corner of the polygon, "UR" denotes that reference point lies on the upper-right corner of the polygon, "DL" denotes that reference point lies on the down-left corner of the polygon, "DR" denotes that reference point lies on the down-left corner of the polygon). Note that if you want the reference point to be at the center of the polygon, you can first translate the reference point to a central location on tracked individuals using repositionReferencePoint. 2.) Polygon angles/directionality are based on observed movements of tracked individuals or gyroscope data.

Usage

referencePoint2Polygon( 
    x = NULL, 
    id = NULL, 
    dateTime = NULL, 
    point.x = NULL, 
    point.y = NULL, 
    direction = NULL, 
)
StartLocation = "UL",
UpDownRepositionLen = 1,
LeftRightRepositionLen = 1,
CenterPoint = FALSE,
MidPoints = FALSE,
immobThreshold = 0,
parallel = FALSE,
nCores = (parallel::detectCores()/2),
modelOrientation = 90
}

Arguments

x
Data frame or list of data frames containing real-time-location point data.

id
Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what unique ids for tracked individuals will be used. If argument == NULL, the function assumes a column with the colname "id" exists in x. Defaults to NULL.

dateTime
Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what dateTime information will be used. If argument == NULL, the function assumes a column with the colname "dateTime" exists in x. Defaults to NULL.

point.x
Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what planar-x or longitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "x" exists in x. Defaults to NULL.

point.y
Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what planar-y or latitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "y" exists in x. Defaults to NULL.

direction
Numerical vector of length nrow(data.frame(x)) or singular character data detailing the relevant colname in x, that denotes what movement-direction information will be used. Observations in this vector represent the direction (in degrees) that tracked individuals moved to reach their position at each time point, NOT the direction that they will move to reach their subsequent position (i.e., values represent known orientations at each time point). Note that for the purposes of this function, observations of 0, 90, 180, and 270 degrees indicates that an individual moved straight Eastward, Northward, Westward, and Southward, respectively. If NULL, direction will be calculated using observed point-locations. Defaults to NULL.

StartLocation
Character string taking the values "UL," "UR," "DL," or "DR" describing where the reference point (i.e., point corresponding to xy-coordinates in the data set) lies on the rectangle that this function will delineate. Defaults to "UL."

UpDownRepositionLen
Numerical. Describes the height, in planar units (e.g., meters) of the output polygon. Planar units are inherent to the real-time-location input. Defaults to 1.
LeftRightRepositionLen
Numerical. Describes the width, in planar units (e.g., meters) of the output polygon. Planar units are inherent to the real-time-location input. Defaults to 1.

CenterPoint
Logical. If TRUE, in addition to the xy-coordinates for each polygon vertex, xy-coordinates for centroid of each polygon will be reported in the output. Defaults to FALSE.

MidPoints
Logical. If TRUE, in addition to the xy-coordinates for each polygon vertex, xy-coordinates for mid-point of each polygon edge will be reported in the output. Defaults to FALSE.

immobThreshold
Numerical. Describes what we call, the immobility threshold, which is a movement distance (in planar units) within which we assume individuals’ physical locations and orientations remain unchanged. This immobility threshold allows us to discount observed movements so miniscule that the majority of animals’ physical-space usage is likely unaffected (e.g., head shaking). Defaults to 0.

parallel
Logical. If TRUE, sub-functions within the referencePoint2Polygon wrapper will be parallelized. Defaults to FALSE.

nCores
Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., (parallel::detectCores()/2)).

modelOrientation
Numerical. Describes the relative orientation (in degrees) of a planar model (see vignette or Farthing et al. in Press (note: when this manuscript is officially published, we will update this citation/reference information)) describing vertex locations relative to tracking-device point-locations. Defaults to 90.

Details
Currently, this function only supports input data with coordinates representing planar ('Euclidean') space (e.g. units of meters).

In the output, point1.x and point1.y represent the xy coordinates from the input file. Point2-n coordinates move in a clockwise direction from point1. For example: if point1 is located on the upper left ("UL") corner of the polygon, point2 would be on the upper right corner, point3 on the bottom right, and point 4 on the bottom left.

If distance == NULL, then function will require information (dist, dx, dy) from 2 points on an individual’s path to work properly. Because of this, when no gyroscopic data are provided, at least the first point in each individual’s path will be removed (the function will report NAs for adjusted locations). Also note that if the distance between an individual’s first point in their path and the second one is 0, the function will also report NAs for the second point’s adjusted coordinates. The first non-NA values will only be reported for the instance where dist > 0.

Note that populating the direction argument with gyroscopic accelerometer data (or data collected using similar devices) collected concurrently with point-locations allows us to overcome a couple of assumptions associated with using point-locations alone.

First, unless the direction argument is specifically given (i.e., direction != NULL), vertex locations in output are subject to the assumption that dt values are sufficiently small to capture individuals’ orientations (i.e., individuals do not face unknown directions inbetween observed relocations). If input was previously processed using tempAggregate with resolutionLevel == "reduced," dt > secondAgg indicates that tracked individuals were missing in the original dataset for a period of time.
In this case, the assumption that individuals are facing a given direction because they moved from the previous timepoint may not be accurate. Consider removing these rows (rows following one with \( dt > \text{secondAgg} \); remember that \( dt \) indicates the time between reported xy coordinates in row \( i \) to row \( i + 1 \)) from your data set.

Second, unless the direction argument is specifically given (i.e., direction \(!= \text{NULL}\)), this function assumes tracked individuals are always forward-facing. This is because by observing only a single point on each individual, we cannot ascertain the true positioning of individuals' bodies. For example, even if we know a point-location moved \( x \) distance in a 90-degree direction, from this information alone we cannot determine what direction said individual was facing at the time (e.g., this could be an example of forward, backwards, or sideward movement). However, gyroscopic data (or data collected using similar devices) can tell us absolute movement directions, as opposed to relative ones.

**Value**

Output is a data frame with the following columns:

- **id**: Unique ID of tracked individuals.
- **cornerPoint\_x**: Planar x coordinates of polygon-corner vertices.
- **cornerPoint\_y**: Planar y coordinates of polygon-corner vertices.
- **startLocation**: Describes the location of input point-locations in the vertex outputs. see `StartLocation` argument.
- **upDownRepositionLength**: Describes the vertical movement of point-locations on planar models. see `UpDownRepositionLen` argument.
- **leftRightRepositionLength**: Describes the horizontal movement of point-locations on planar models. see `leftRightRepositionLen` argument.
- **immob**: If "0", distance between observed movements is \(< \text{immobThreshold}\).
- **immobThreshold**: Returns the value from the `immobThreshold` argument.
- **dateTime**: Timepoint at which polygons were observed.
- **dt**: The time between reported xy coordinates in row \( i \) to row \( i + 1 \) in each individuals’ movement path.

If MidPoints or CenterPoints \(==\) TRUE, additional columns will be appended to output data frame.

**References**

repositionReferencePoint

Examples

```r
data("calves")
calves.dateTime<-datetime.append(calves, date = calves$date,
    time = calves$time) #add dateTime identifiers for location fixes.

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag,
    dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x,
    point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE,
    extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE,
    na.rm = TRUE, smooth.type = 1) #smooth to 5-min fix intervals.

calf_heads <- referencePoint2Polygon(x = calves.agg,
    id = calves.agg$id, dateTime = calves.agg$dateTime,
    point.x = calves.agg$x, point.y = calves.agg$y, direction = NULL,
    StartLocation = "DL",UpDownRepositionLen = 0.333, LeftRightRepositionLen = 0.333,
    CenterPoint = FALSE, MidPoints = FALSE, immobThreshold = 0.1, parallel = FALSE,
    modelOrientation = 90)
```

---

**repositionReferencePoint**

*Move Data Point a Specified Distance*

**Description**

Translates locations of a single rfid tag/gps transmitter to a different location a fixed distance away, given a known angular offset (in degrees), while maintaining orientations associated with observed movements (see vignette or Farthing et al. in Review (note: when this manuscript is officially published, we will update this citation/reference information)) For example, calves in our study (see calves2018) were equipped with RFID tags on their left ear. With this function, we can move this reference point somewhere else on the body of each individual. This might be done for a number of reasons, but is very useful for use in the referencePoint2Polygon function later on (for delineating polygons representing entire individuals). Currently, this function only supports input data with coordinates representing planar (‘Euclidean’) space (e.g. units of meters).

**Usage**

```r
repositionReferencePoint(
    x = NULL,
    id = NULL,
    dateTime = NULL,
    point.x = NULL,
    point.y = NULL,
    direction = NULL,
    repositionAngle = 0,
    repositionDist = 1,
    immobThreshold = 0,
```
parallel = FALSE,
nCores = (parallel::detectCores()/2),
modelOrientation = 90
)

Arguments

x Data frame or list of data frames containing real-time-location point data.

id Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what unique ids for tracked individuals will be used. If argument == NULL, the function assumes a column with the colname "id" exists in x. Defaults to NULL.

dateTime Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what dateTime information will be used. If argument == NULL, the function assumes a column with the colname "dateTime" exists in x. Defaults to NULL.

point.x Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what planar-x or longitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "x" exists in x. Defaults to NULL.

point.y Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what planar-y or latitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "y" exists in x. Defaults to NULL.

direction Numerical vector of length nrow(data.frame(x)) or singular character data detailing the relevant colname in x, that denotes what movement-direction information will be used. Observations in this vector represent the direction (in degrees) that tracked individuals moved to reach their position at each time point, NOT the direction that they will move to reach their subsequent position (i.e., values represent known orientations at each time point). Note that for the purposes of this function, observations of 0, 90, 180, and 270 degrees indicates that an individual moved straight Eastward, Northward, Westward, and Southward, respectively. If NULL, direction will be calculated using observed point-locations. Defaults to NULL.

repositionAngle Numerical. Describes the angle (in degrees) between empirical point-locations and the desired vertex location as represented in a planar model (see vignette or Farthing et al. in Review (note: when this manuscript is officially published, we will update this citation/reference information)). Essentially, this is the direction you want new points to be from orginal points. Note that for the purposes of this function, observations of 0, 90, 180, and 270 degrees indicates that an individual moved straight Eastward, Northward, Westward, and Southward, respectively. Defaults to 0.

repositionDist Numerical. Describes the distance from the empirical point-locations to desired vertex locations in planar units (e.g., meters) inherent to the real-time-location input. Defaults to 1.
repositionReferencePoint

immobThreshold Numerical. Describes what we call, the immobility threshold, which is a movement distance (in planar units) within which we assume individuals’ physical locations and orientations remain unchanged. This immobility threshold allows us to discount observed movements so miniscule that the majority of animals’ physical-space usage is likely unaffected (e.g., head shaking). Defaults to 0.

parallel Logical. If TRUE, sub-functions within the repositionReferencePoint wrapper will be parallelized. Note that this can significantly speed up processing of relatively small data sets, but may cause R to crash due to lack of available memory when attempting to process large datasets. Defaults to FALSE.

nCores Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., (parallel::detectCores()/2)).

modelOrientation Numerical. Describes the relative orientation (in degrees) of a planar model (see vignette or Farthing et al. in Press (note: when this manuscript is officially published, we will update this citation/reference information)) describing vertex locations relative to tracking-device point-locations. Defaults to 90.

Details

In this function, if the distance individuals moved was less than/equal to the noted immobThreshold, individuals are said to be immobile ("immob"), and their position will not change relative to their previous one. (i.e., you assume that any observed movement less than immobThreshold was due to errors or miniscule bodily movements (e.g., head shaking) that are not indicative of actual movement.)

If distance == NULL, then function will require information (dist, dx, dy) from 2 points on an individual’s path to work properly. Because of this, when no gyroscopic data are provided, at least the first point in each individual’s path will be removed (the function will report NAs for adjusted locations). Also note that if the distance between an individual’s first point in their path and the second one is 0, the function will also report NAs for the second point’s adjusted coordinates. The first non-NA values will only be reported for the instance where dist > 0.

Note that populating the direction argument with gyroscopic accelerometer data (or data collected using similar devices) collected concurrently with point-locations allows us to overcome a couple of assumptions associated with using point-locations alone.

First, unless the direction argument is specifically given (i.e., direction != NULL), new point-locations in output are subject to the assumption that dt values are sufficiently small to capture individuals’ orientations (i.e., individuals do not face unknown directions inbetween observed relocations). If input was previously processed using tempAggregate with resolutionLevel == "reduced," dt > secondAgg indicates that tracked individuals were missing in the original dataset for a period of time. In this case, the assumption that individuals are facing a given direction because they moved from the previous timepoint may not be accurate. Consider removing these rows (rows following one with dt > secondAgg; remember that dt indicates the time between recording xy coordinates in row i to row i + 1) from your data set.

Second, unless the direction argument is specifically given (i.e., direction != NULL), this function assumes tracked individuals are always forward-facing. This is because by observing only a single point on each individual, we cannot ascertain the true positioning of individuals’ bodies. For example, even if we know a point-location moved x distance in a 90-degree direction, from this information alone we cannot determine what direction said individual was facing at the time (e.g.,
this could be an example of forward, backward, or sideward movement). However, gyroscopic data (or data collected using similar devices) can tell us absolute movement directions, as opposed to relative ones.

**Value**

Output is a data frame with the following columns:

- **id**: Unique ID of tracked individuals.
- **x.original**: Original x coordinates from input.
- **y.original**: Original y coordinates from input.
- **distance.original**: Original planar distance (m) between point-location \( i \) to point-location \( i + 1 \).
- **dx.original**: Original difference between point-location x-coordinate \( i \) to x-coordinate \( i + 1 \).
- **dy.original**: Original difference between point-location y-coordinate \( i \) to y-coordinate \( i + 1 \).
- **x.adjusted**: Translated x coordinates.
- **y.adjusted**: Translated y coordinates.
- **dist.adjusted**: Planar distance (m) between translated point-location \( i \) to translated point-location \( i + 1 \).
- **dx.adjusted**: Difference between translated point-location x-coordinate \( i \) to translated x-coordinate \( i + 1 \).
- **dy.adjusted**: Difference between translated point-location y-coordinate \( i \) to translated y-coordinate \( i + 1 \).
- **movementDirection**: Describes the angle of movement (in degrees) required to translate point-locations to be congruent with planar-model adjustments.
- **repositionAngle**: Describes the value \( \text{repositionAngle} \) of the argument.
- **repositionDist**: Describes the value \( \text{repositionDist} \) of the argument.
- **immob**: If "0", distance between observed movements is < \( \text{immobThreshold} \).
- **immobThreshold**: Returns the value from the \( \text{immobThreshold} \) argument.
- **dateTime**: Timepoint at which polygons were observed.
- **dt**: The time between reported xy coordinates in row \( i \) to row \( i + 1 \) in each individuals’ movement path.

**References**

summarizeContacts

Examples

data("calves")
calves.dateTime<-datetime.append(calves, date = calves$date,
        time = calves$time) #create a dataframe with dateTime identifiers for location fixes.
calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag,
        dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x,
        point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE,
        extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE,
        na.rm = TRUE, smooth.type = 1) #smooth to 5-min fix intervals.

leftShoulder.point<-repositionReferencePoint(x = calves.agg,
        id = calves.agg$id, dateTime = calves.agg$dateTime,
        point.x = calves.agg$x, point.y = calves.agg$y, direction = NULL,
        repositionAngle = 180, repositionDist = 0.0835, immobThreshold = 0, parallel = FALSE,
        modelOrientation = 90)

summarizeContacts  Summarize Contact Events

Description

This function takes the output from contactDur.all or contactDur.area and reports the number of durations when tracked individuals are in "contact" with one another (contactDur.all) or with specified fixed points/polygons (contactDur.area).

Usage

summarizeContacts(
        x, 
        importBlocks = FALSE, 
        avg = FALSE, 
        parallel = FALSE, 
        nCores = (parallel::detectCores()/2)
)

Arguments

x  Output from the contactDur.all or contactDur.area functions. Can be either a data frame or list of data frames.
importBlocks Logical. If true, each block in x will be analyzed separately. Defaults to FALSE. Note that the "block" column must exist in x.
avg Logical. If TRUE, summary output from all data frames contained in x will be averaged together. Output will produce an extra data frame containing the mean column values for each id (per block if importBlocks == TRUE). Defaults to FALSE.
parallel Logical. If TRUE, sub-functions within the `summarizeContacts` wrapper will be parallelized. Note that the only sub-function parallelized here is called ONLY when `importBlocks == TRUE`.

nCores Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., `(parallel::detectCores() / 2)`).

Details

If `x` is a list, and `avg == TRUE`, this function will produce an extra data frame containing the mean column values for each id (per block if `importBlocks == TRUE`).

This is a sub-function found within the `contactTest` and `ntwrkEdges` function.

Value

Returns a data frame (or list of data frames if `x` is a list of data frames) with the following columns:

- **id** The unique ID of a tracked individual for which we will summarize to all other individuals/fixed locations observed in `x`.
- **id** Sum number of individuals/fixed locations observed in contact specific individuals.
- **id** Sum number of contacts associated with specific individuals.
- **contactDuration_...** Number of contacts between specific dyads.

If `importBlocks == TRUE`, the following columns are appended to the output data frame described above:

- **block** Integer ID describing unique blocks of time during which contacts occur.
- **block.start** The timepoint in `x` at which the block begins.
- **block.end** The timepoint in `x` at which the block ends.
- **numBlocks** Integer describing the total number of time blocks observed within `x` at which the block

Examples

```r
data(calves)

calves.dateTime<-datetime.append(calves, date = calves$date, 
    time = calves$time) # create a dataframe with dateTime identifiers for location fixes

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag, 
    dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x, 
    point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE, 
    extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE, 
    na.rm = TRUE, smooth.type = 1) # smooth to 5-min fix intervals.

calves.dist<-dist2All_df(x = calves.agg, parallel = FALSE, 
    dataType = "Point", lonlat = FALSE)
```
calves.contact.block <- contactDur.all(x = calves.dist, dist.threshold=1, 
  sec.threshold=10, blocking = TRUE, blockUnit = "hours", blockLength = 1, 
  equidistant.time = FALSE, parallel = FALSE, reportParameters = TRUE)

head(calves.contactSumm.NOblock)

calves.contactSumm.block <- summarizeContacts(calves.contact.block, 
  importBlocks = TRUE)

head(calves.contactSumm.block)

---

**tempAggregate**

**Smooth Point-Locations Over Time**

**Description**

Aggregate location data by secondAgg seconds over the course of each day represented in the dataset. The function smooths xy data forwards (smooth.type == 1) or backwards (smooth.type == 2) according to a data-point-averaging smoothing methodology. As part of the smoothing process, tempAggregate fills in any missing values (either due to a lack of data transmission or faulty prior interpolation). We recognize that this procedure is not sensitive to individual presence at given timesteps (e.g., some individuals may be missing on certain days, hours, etc., and therefore may produce inaccurate location aggregates if days/hours exist where individuals are not present in the dataset (e.g., they were purposefully removed, or moved outside of the monitoring area)). To increase accuracy, package users may specify a resolutionLevel ("full" or "reduced") to process individuals’ locations at different resolutions. If resolution == "reduced", if no locations of individuals exist over any secondAgg time block, NAs will be produced for the time points of interest.

This function is based on real-time-location-data-smoothing methods presented by Dawson et al. 2019.

**Usage**

tempAggregate(
  x = NULL,
  id = NULL,
  point.x = NULL,
  point.y = NULL,
  dateTime = NULL,
  secondAgg = 10,
  extrapolate.left = FALSE,
  extrapolate.right = FALSE,
  resolutionLevel = "full",
  parallel = FALSE,
  nCores = (parallel::detectCores()/2),
  na.rm = TRUE,
  smooth.type = 1
)
Arguments

x
Data frame or list of data frames containing real-time-location data.

id
Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what unique ids for tracked individuals will be used. If argument == NULL, the function assumes a column with the colname "id" exists in x. Defaults to NULL.

point.x
Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what planar-x or longitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "x" exists in x. Defaults to NULL.

point.y
Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what planar-y or latitude coordinate information will be used. If argument == NULL, the function assumes a column with the colname "y" exists in x. Defaults to NULL.

dateTime
Vector of length nrow(data.frame(x)) or singular character data, detailing the relevant colname in x, that denotes what dateTime information will be used. If argument == NULL, the function assumes a column with the colname "dateTime" exists in x. Defaults to NULL.

secondAgg
Integer. The number of seconds over which tracked-individuals’ location will be averaged. Defaults to 10.

extrapolate.left
Logical. If TRUE, individuals position at time points prior to their first location fix will revert to their first recorded location. If FALSE, NAs will be placed at these time points in individuals’ movement paths. Defaults to FALSE.

extrapolate.right
Logical. If TRUE, individuals position at time points following their last location fix will revert to their final recorded location. If FALSE, NAs will be placed at these time points in individuals’ movement paths. Defaults to FALSE.

resolutionLevel
Character string taking the value of "full" or "reduced." If "full," if no known locations of individuals exist over any secondAgg time block, xy-coordinates revert to the last-known values for that individual. If "reduced," if no known locations of individuals exist over any secondAgg time block, NAs will be produced for the time blocks of interest. Defaults to "full."

parallel
Logical. If TRUE, sub-functions within the tempAggregate wrapper will be parallelized. Defaults to FALSE.

nCores
Integer. Describes the number of cores to be dedicated to parallel processes. Defaults to half of the maximum number of cores available (i.e., (parallel::detectCores()/2)).

na.rm
Logical. If TRUE, all unknown locations (i.e., xy-coordinate pairs reported as NAs) will be removed from the output. Defaults to TRUE. Note that if na.rm == FALSE, all aggregated location fixes will be temporally equidistant.

smooth.type
Numerical, taking the values 1 or 2. Indicates the type of smoothing used to average individuals’ xy-coordinates. If smooth.type == 1, data are smoothed forwards. If smooth.type == 2, data are smoothed backwards. Defaults to 1.
### Value

Returns a data frame (or list of data frames if `x` is a list of data frames) with the following columns:

- **id**: The unique ID of tracked individuals.
- **x**: Smoothed x coordinates.
- **y**: Smoothed y coordinates.
- **dateTime**: Timepoint at which smoothed points were observed.

### References

### Examples

```r
data("calves")
head(calves) # observe that fix intervals occur every 4-5 seconds.

calves.dateTime<-dateTime.append(calves, date = calves$date,
                   time = calves$time) # add dateTime identifiers for location fixes.

calves.agg<-tempAggregate(calves.dateTime, id = calves.dateTime$calftag,
                   dateTime = calves.dateTime$dateTime, point.x = calves.dateTime$x,
                   point.y = calves.dateTime$y, secondAgg = 300, extrapolate.left = FALSE,
                   extrapolate.right = FALSE, resolutionLevel = "reduced", parallel = FALSE,
                   na.rm = TRUE, smooth.type = 1) # smooth to 5-min fix intervals.
```

---

### timeBlock.append

#### Append TimeBlock Information to a Data Frame

**Description**

Appends "block," "block.start," "block.end," and "numBlocks" columns to an input data frame (`x`) with a `dateTime` (see `dateTime.append`) column. This allows users to "block" data into blockLength-blockUnit-long (e.g., 10-min-long) temporal blocks. If `x == NULL`, the function output will be a data frame with "dateTime" and block-related columns.

**Usage**

```r
timeBlock.append(
    x = NULL,
    dateTime = NULL,
    blockLength = 1,
    blockUnit = "hours",
    blockingstartTime = NULL
)
```
Arguments

x  Data frame containing dateTime information, and to which block information will be appended. If NULL, dateTime input relies solely on the dateTime argument.

dateTime  Vector of length nrow(x) or singular character data, detailing the relevant col-name in x, that denotes what dateTime information will be used. If argument == NULL, the function assumes a column with the colname "dateTime" exists in x. Defaults to NULL.

blockLength  Integer. Describes the number blockUnits within each temporal block. Defaults to 1.

blockUnit  Character string taking the values, "secs," "mins," "hours," "days," or "weeks." Defaults to "hours."

blockingStartTime  Character string or date object describing the date OR dateTime starting point of the first time block. For example, if blockingStartTime = "2016-05-01" OR "2016-05-01 00:00:00", the first timeblock would begin at "2016-05-01 00:00:00." If NULL, the blockingStartTime defaults to the minimum dateTime point in x. Note: any blockingStartTime MUST precede or be equivalent to the minimum timepoint in x. Additional note: If blockingStartTime is a character string, it must be in the format ymd OR ymd hms.

Details

This is a sub-function that can be found in the contactDur functions.

Value

Appends the following columns to x.

block  Integer ID describing unique blocks of time of pre-specified length.

block.start  The timepoint in x at which the block begins.

block.end  The timepoint in x at which the block ends.

numBlocks  Integer describing the total number of time blocks observed within x at which the block

Examples

data("calves")
calves.dateTime<-datetime.append(calves, date = calves$date, 
   time = calves$time) #add dateTime identifiers for location fixes.
calves.block<-timeBlock.append(x = calves.dateTime, 
   dateTime = calves.dateTime$dateTime, blockLength = 10, 
   blockUnit = "mins")
head(calves.block) #see that block information has been appended.
