Package ‘correlation’

April 9, 2021

Type Package
Title Methods for Correlation Analysis
Version 0.6.1
Maintainer Indrajeet Patil <patilindrajeet.science@gmail.com>
Description Lightweight package for computing different kinds of correlations, such as partial correlations, Bayesian correlations, multilevel correlations, polychoric correlations, biweight correlations, distance correlations and more. Part of the 'easystats' ecosystem.
License GPL-3
URL https://easystats.github.io/correlation/
BugReports https://github.com/easystats/correlation/issues
Depends R (>= 3.4)
Imports bayestestR (>= 0.9.0), datasets, effectsize (>= 0.4.4), insight (>= 0.13.2), parameters (>= 0.12.0), stats
Suggests BayesFactor, dplyr, energy, forcats, ggcorrplot, geplot2, gt, Hmisc, knitr, lme4, polycor, ppcor, psych, rmarkdown, rmcorr, rstanarm, see, spelling, testthat (>= 3.0.1), tidyr, wdm, WRS2
VignetteBuilder knitr
Encoding UTF-8
Language en-US
RoxygenNote 7.1.1.9001
Config/testthat/edition 3
NeedsCompilation no

**Description**

Performs a correlation analysis.

**Usage**

```r
correlation(
  data,
  data2 = NULL,
  select = NULL,
  select2 = NULL,
  method = "pearson",
  p_adjust = "holm",
  ci = 0.95,
  bayesian = FALSE,
  bayesian_prior = "medium",
  bayesian_ci_method = "hdi",
  bayesian_test = c("pd", "rope", "bf"),
  redundant = FALSE,
  include_factors = FALSE,
  partial = FALSE,
  partial_bayesian = FALSE,
  multilevel = FALSE,
  ranktransform = FALSE,
  robust = NULL,
  winsorize = FALSE,
  verbose = TRUE,
)```
correlation

...}

Arguments

data A data frame.
data2 An optional data frame. If specified, all pair-wise correlations between the variables in data and data2 will be computed.
select, select2 (Ignored if data2 is specified.) Optional names of variables that should be selected for correlation. Instead of providing the data frames with those variables that should be correlated, data can be a data frame and select and select2 are (quoted) names of variables (columns) in data. correlation() will then compute the correlation between data[select] and data[select2]. If only select is specified, all pair-wise correlations between the select variables will be computed. This is a "pipe-friendly" alternative way of using correlation() (see 'Examples').

method A character string indicating which correlation coefficient is to be used for the test. One of "pearson" (default), "kendall", "spearman" (but see also the robust argument), "biserial", "polychoric", "tetrachoric", "biweight", "distance", "percentage" (for percentage bend correlation), "blomqvist" (for Blomqvist's coefficient), "hoeffding" (for Hoeffding's D), "gamma", "gaussian" (for Gaussian Rank correlation) or "shepherd" (for Shepherd's Pi correlation). Setting "auto" will attempt at selecting the most relevant method (polychoric when ordinal factors involved, tetrachoric when dichotomous factors involved, point-biserial if one dichotomous and one continuous and pearson otherwise).

p_adjust Correction method for frequentist correlations. Can be one of "holm" (default), "hochberg", "hommel", "bonferroni", "BH", "BY", "fdr", "somers" or "none". See p.adjust() for further details.

ci Confidence/Credible Interval level. If "default", then it is set to 0.95 (95% CI).

bayesian If TRUE, will run the correlations under a Bayesian framework. Note that for partial correlations, you will also need to set partial_bayesian to TRUE to obtain "full" Bayesian partial correlations. Otherwise, you will obtain pseudo-Bayesian partial correlations (i.e., Bayesian correlation based on frequentist partialization).

bayesian_prior For the prior argument, several named values are recognized: "medium.narrow", "medium", "wide", and "ultrawide". These correspond to scale values of 1/sqrt(27), 1/3, 1/sqrt(3) and 1, respectively. See the BayesFactor::correlationBF function.

bayesian_ci_method See arguments in model_parameters for BayesFactor tests.

bayesian_test See arguments in model_parameters for BayesFactor tests.

redundant Should the data include redundant rows (where each given correlation is repeated two times).
include_factors
If TRUE, the factors are kept and eventually converted to numeric or used as random effects (depending of multilevel). If FALSE, factors are removed upfront.

partial
Can be TRUE or "semi" for partial and semi-partial correlations, respectively.

partial_bayesian
If TRUE, will run the correlations under a Bayesian framework. Note that for partial correlations, you will also need to set partial_bayesian to TRUE to obtain "full" Bayesian partial correlations. Otherwise, you will obtain pseudo-Bayesian partial correlations (i.e., Bayesian correlation based on frequentist partialization).

multilevel
If TRUE, the factors are included as random factors. Else, if FALSE (default), they are included as fixed effects in the simple regression model.

ranktransform
If TRUE, will rank-transform the variables prior to estimating the correlation, which is one way of making the analysis more resistant to extreme values (outliers). Note that, for instance, a Pearson’s correlation on rank-transformed data is equivalent to a Spearman’s rank correlation. Thus, using robust=TRUE and method="spearman" is redundant. Nonetheless, it is an easy option to increase the robustness of the correlation as well as flexible way to obtain Bayesian or multilevel Spearman-like rank correlations.

robust
Old name for ranktransform. Will be removed in subsequent versions, so better to use ranktransform which is more explicit about what it does.

winsorize
Another way of making the correlation more "robust" (i.e., limiting the impact of extreme values). Can be either FALSE or a number between 0 and 1 (e.g., 0.2) that corresponds to the desired threshold. See the winsorize() function for more details.

verbose
Toggle warnings.

... Additional arguments (e.g., alternative) to be passed to other methods. See stats::cor.test for further details.

Details

Correlation Types:

• **Pearson’s correlation**: This is the most common correlation method. It corresponds to the covariance of the two variables normalized (i.e., divided) by the product of their standard deviations.

• **Spearman’s rank correlation**: A non-parametric measure of rank correlation (statistical dependence between the rankings of two variables). The Spearman correlation between two variables is equal to the Pearson correlation between the rank values of those two variables; while Pearson’s correlation assesses linear relationships, Spearman’s correlation assesses monotonic relationships (whether linear or not). Confidence Intervals (CI) for Spearman’s correlations are computed using the Fieller et al. (1957) correction (see Bishara and Hittner, 2017).

• **Kendall’s rank correlation**: In the normal case, the Kendall correlation is preferred than the Spearman correlation because of a smaller gross error sensitivity (GES) and a smaller asymptotic variance (AV), making it more robust and more efficient. However, the interpretation of Kendall’s tau is less direct than that of Spearman’s rho, in the sense that it quantifies
the difference between the % of concordant and discordant pairs among all possible pairwise events. Confidence Intervals (CI) for Kendall’s correlations are computed using the Fieller et al. (1957) correction (see Bishara and Hittner, 2017).

• **Biweight midcorrelation:** A measure of similarity that is median-based, instead of the traditional mean-based, thus being less sensitive to outliers. It can be used as a robust alternative to other similarity metrics, such as Pearson correlation (Langfelder & Horvath, 2012).

• **Distance correlation:** Distance correlation measures both linear and non-linear association between two random variables or random vectors. This is in contrast to Pearson’s correlation, which can only detect linear association between two random variables.

• **Percentage bend correlation:** Introduced by Wilcox (1994), it is based on a down-weight of a specified percentage of marginal observations deviating from the median (by default, 20%).

• **Shepherd’s Pi correlation:** Equivalent to a Spearman’s rank correlation after outliers removal (by means of bootstrapped Mahalanobis distance).

• **Blomqvist’s coefficient:** The Blomqvist’s coefficient (also referred to as Blomqvist’s Beta or medial correlation; Blomqvist, 1950) is a median-based non-parametric correlation that has some advantages over measures such as Spearman’s or Kendall’s estimates (see Shmid and Schimdt, 2006).

• **Hoeffding’s D:** The Hoeffding’s D statistics is a non-parametric rank based measure of association that detects more general departures from independence (Hoeffding 1948), including non-linear associations. Hoeffding’s D varies between -0.5 and 1 (if there are no tied ranks, otherwise it can have lower values), with larger values indicating a stronger relationship between the variables.

• **Somers’ D:** The Somers’ D statistics is a non-parametric rank based measure of association between a binary variable and a continuous variable, for instance, in the context of logistic regression the binary outcome and the predicted probabilities for each outcome. Usually, Somers’ D is a measure of ordinal association, however, this implementation it is limited to the case of a binary outcome.

• **Point-Biserial and biserial correlation:** Correlation coefficient used when one variable is continuous and the other is dichotomous (binary). Point-Biserial is equivalent to a Pearson’s correlation, while Biserial should be used when the binary variable is assumed to have an underlying continuity. For example, anxiety level can be measured on a continuous scale, but can be classified dichotomously as high/low.

• **Gamma correlation:** The Goodman-Kruskal gamma statistic is similar to Kendall’s Tau coefficient. It is relatively robust to outliers and deals well with data that have many ties.

• **Winsorized correlation:** Correlation of variables that have been formerly Winsorized, i.e., transformed by limiting extreme values to reduce the effect of possibly spurious outliers.

• **Gaussian rank Correlation:** The Gaussian rank correlation estimator is a simple and well-performing alternative for robust rank correlations (Boudt et al., 2012). It is based on the Gaussian quantiles of the ranks.

• **Polychoric correlation:** Correlation between two theorized normally distributed continuous latent variables, from two observed ordinal variables.

• **Tetrachoric correlation:** Special case of the polychoric correlation applicable when both observed variables are dichotomous.

**Partial Correlation:** Partial correlations are estimated as the correlation between two variables after adjusting for the (linear) effect of one or more other variable. The correlation test is then
run after having partialized the dataset, independently from it. In other words, it considers partialization as an independent step generating a different dataset, rather than belonging to the same model. This is why some discrepancies are to be expected for the t- and p-values, CIs, BFIs etc (but not the correlation coefficient) compared to other implementations (e.g., ppcor). (The size of these discrepancies depends on the number of covariates partialled-out and the strength of the linear association between all variables.) Such partial correlations can be represented as Gaussian Graphical Models (GGM), an increasingly popular tool in psychology. A GGM traditionally include a set of variables depicted as circles ("nodes"), and a set of lines that visualize relationships between them, which thickness represents the strength of association (see Bhushan et al., 2019).

**Multilevel correlations** are a special case of partial correlations where the variable to be adjusted for is a factor and is included as a random effect in a mixed model (note that the remaining continuous variables of the dataset will still be included as fixed effects, similarly to regular partial correlations). That said, there is an important difference between using cor_test() and correlation(): If you set multilevel=TRUE in correlation() but partial is set to FALSE (as per default), then a back-transformation from partial to non-partial correlation will be attempted (through pcor_to_cor). However, this is not possible when using cor_test() so that if you set multilevel=TRUE in it, the resulting correlations are partial one. Note that for Bayesian multilevel correlations, if partial = FALSE, the back transformation will also recompute p-values based on the new r scores, and will drop the Bayes factors (as they are not relevant anymore). To keep Bayesian scores, don’t forget to set partial = TRUE.

**Notes:**
- Kendall and Spearman correlations when bayesian=TRUE: These are technically Pearson Bayesian correlations of rank transformed data, rather than pure Bayesian rank correlations (which have different priors).

**Value**
A correlation object that can be displayed using the print, summary or table methods.

**Multiple tests correction:** The p_adjust argument can be used to adjust p-values for multiple comparisons. All adjustment methods available in p.adjust function stats package are supported.

**References**

**Examples**

```r
library(correlation)
results <- correlation(iris)

results
summary(results)
summary(results, redundant = TRUE)

# pipe-friendly usage
if (require("dplyr")) {
  iris %>%
  correlation(select = "Petal.Width", select2 = "Sepal.Length")
}

# Grouped dataframe
if (require("dplyr")) {
  # grouped correlations
  iris %>%
  group_by(Species) %>%
  correlation()

  # selecting specific variables for correlation
  mtcars %>
  group_by(am) %>
  correlation(
    select = c("cyl", "wt"),
    select2 = c("hp")
  )
}

# automatic selection of correlation method
correlation(mtcars[-2], method = "auto")
```

**cor_test**

**Correlation test**

**Description**

This function performs a correlation test between two variables.
Usage

cor_test(
  data,
  x, y,
  method = "pearson",
  ci = 0.95,
  bayesian = FALSE,
  bayesian_prior = "medium",
  bayesian_ci_method = "hdi",
  bayesian_test = c("pd", "rope", "bf"),
  include_factors = FALSE,
  partial = FALSE,
  partial_bayesian = FALSE,
  multilevel = FALSE,
  ranktransform = FALSE,
  robust = NULL,
  winsorize = FALSE,
  verbose = TRUE,
  ...
)

Arguments

data A data frame.
x, y Names of two variables present in the data.
method A character string indicating which correlation coefficient is to be used for the test. One of "pearson" (default), "kendall", "spearman" (but see also the robust argument), "biserial", "polychoric", "tetrachoric", "biweight", "distance", "percentage" (for percentage bend correlation), "blomqvist" (for Blomqvist's coefficient), "hoeffding" (for Hoeffding's D), "gamma", "gaussian" (for Gaussian Rank correlation) or "shepherd" (for Shepherd's Pi correlation). Setting "auto" will attempt at selecting the most relevant method (polychoric when ordinal factors involved, tetrachoric when dichotomous factors involved, point-biserial if one dichotomous and one continuous and pearson otherwise).

ci Confidence/Credible Interval level. If "default", then it is set to 0.95 (95% CI).

bayesian, partial_bayesian
If TRUE, will run the correlations under a Bayesian framework. Note that for partial correlations, you will also need to set partial_bayesian to TRUE to obtain "full" Bayesian partial correlations. Otherwise, you will obtain pseudo-Bayesian partial correlations (i.e., Bayesian correlation based on frequentist partialization).

bayesian_prior For the prior argument, several named values are recognized: "medium.narrow", "medium", "wide", and "ultrawide". These correspond to scale values of 1/sqrt(27), 1/3, 1/sqrt(3) and 1, respectively. See the BayesFactor::correlationBF function.
Correlation Tests:

- **Pearson’s correlation**: This is the most common correlation method. It corresponds to the covariance of the two variables normalized (i.e., divided) by the product of their standard deviations.

- **Spearman’s rank correlation**: A non-parametric measure of rank correlation (statistical dependence between the rankings of two variables). The Spearman correlation between two variables is equal to the Pearson correlation between the rank values of those two variables; while Pearson’s correlation assesses linear relationships, Spearman’s correlation assesses monotonic relationships (whether linear or not). Confidence Intervals (CI) for Spearman’s correlations are computed using the Fieller et al. (1957) correction (see Bishara and Hittner, 2017).

- **Kendall’s rank correlation**: In the normal case, the Kendall correlation is preferred than the Spearman correlation because of a smaller gross error sensitivity (GES) and a smaller asymptotic variance (AV), making it more robust and more efficient. However, the interpretation of Kendall’s tau is less direct than that of Spearman’s rho, in the sense that it quantifies the difference between the % of concordant and discordant pairs among all possible pairwise events. Confidence Intervals (CI) for Kendall’s correlations are computed using the Fieller et al. (1957) correction (see Bishara and Hittner, 2017).
- **Biweight midcorrelation**: A measure of similarity that is median-based, instead of the traditional mean-based, thus being less sensitive to outliers. It can be used as a robust alternative to other similarity metrics, such as Pearson correlation (Langfelder & Horvath, 2012).

- **Distance correlation**: Distance correlation measures both linear and non-linear association between two random variables or random vectors. This is in contrast to Pearson’s correlation, which can only detect linear association between two random variables.

- **Percentage bend correlation**: Introduced by Wilcox (1994), it is based on a down-weight of a specified percentage of marginal observations deviating from the median (by default, 20%).

- **Shepherd’s Pi correlation**: Equivalent to a Spearman’s rank correlation after outliers removal (by means of bootstrapped Mahalanobis distance).

- **Blomqvist’s coefficient**: The Blomqvist’s coefficient (also referred to as Blomqvist’s Beta or medial correlation; Blomqvist, 1950) is a median-based non-parametric correlation that has some advantages over measures such as Spearman’s or Kendall’s estimates (see Shmid and Schimdt, 2006).

- **Hoeffding’s D**: The Hoeffding’s D statistics is a non-parametric rank based measure of association that detects more general departures from independence (Hoeffding 1948), including non-linear associations. Hoeffding’s D varies between -0.5 and 1 (if there are no tied ranks, otherwise it can have lower values), with larger values indicating a stronger relationship between the variables.

- **Somers’ D**: The Somers’ D statistics is a non-parametric rank based measure of association between a binary variable and a continuous variable, for instance, in the context of logistic regression the binary outcome and the predicted probabilities for each outcome. Usually, Somers’ D is a measure of ordinal association, however, this implementation it is limited to the case of a binary outcome.

- **Point-Biserial and biserial correlation**: Correlation coefficient used when one variable is continuous and the other is dichotomous (binary). Point-Biserial is equivalent to a Pearson’s correlation, while Biserial should be used when the binary variable is assumed to have an underlying continuity. For example, anxiety level can be measured on a continuous scale, but can be classified dichotomously as high/low.

- **Gamma correlation**: The Goodman-Kruskal gamma statistic is similar to Kendall’s Tau coefficient. It is relatively robust to outliers and deals well with data that have many ties.

- **Winsorized correlation**: Correlation of variables that have been formerly Winsorized, i.e., transformed by limiting extreme values to reduce the effect of possibly spurious outliers.

- **Gaussian rank Correlation**: The Gaussian rank correlation estimator is a simple and well-performing alternative for robust rank correlations (Boudt et al., 2012). It is based on the Gaussian quantiles of the ranks.

- **Polychoric correlation**: Correlation between two theorized normally distributed continuous latent variables, from two observed ordinal variables.

- **Tetrachoric correlation**: Special case of the polychoric correlation applicable when both observed variables are dichotomous.

**Partial Correlation**: Partial correlations are estimated as the correlation between two variables after adjusting for the (linear) effect of one or more other variable. The correlation test is then run after having partialized the dataset, independently from it. In other words, it considers partialization as an independent step generating a different dataset, rather than belonging to the same model. This is why some discrepancies are to be expected for the t- and p-values, CIs, BF etc (but not the correlation coefficient) compared to other implementations (e.g., ppcor). (The size
of these discrepancies depends on the number of covariates partialled-out and the strength of the linear association between all variables.) Such partial correlations can be represented as Gaussian Graphical Models (GGM), an increasingly popular tool in psychology. A GGM traditionally include a set of variables depicted as circles ("nodes"), and a set of lines that visualize relationships between them, which thickness represents the strength of association (see Bhushan et al., 2019).

**Multilevel correlations** are a special case of partial correlations where the variable to be adjusted for is a factor and is included as a random effect in a mixed model (note that the remaining continuous variables of the dataset will still be included as fixed effects, similarly to regular partial correlations). That said, there is an important difference between using \texttt{cor_test()} and \texttt{correlation()}: If you set multilevel=\texttt{TRUE} in \texttt{correlation()} but partial is set to \texttt{FALSE} (as per default), then a back-transformation from partial to non-partial correlation will be attempted (through \texttt{pcor_to_cor}). However, this is not possible when using \texttt{cor_test()} so that if you set multilevel=\texttt{TRUE} in it, the resulting correlations are partial one. Note that for Bayesian multilevel correlations, if partial = \texttt{FALSE}, the back transformation will also recompute p-values based on the new r scores, and will drop the Bayes factors (as they are not relevant anymore). To keep Bayesian scores, don’t forget to set partial = \texttt{TRUE}.

**Notes:**

- Kendall and Spearman correlations when bayesian=\texttt{TRUE}: These are technically Pearson Bayesian correlations of rank transformed data, rather than pure Bayesian rank correlations (which have different priors).

**Examples**

```r
library(correlation)

cor_test(iris, "Sepal.Length", "Sepal.Width")
cor_test(iris, "Sepal.Length", "Sepal.Width", method = "spearman")
cor_test(iris, "Sepal.Length", "Sepal.Width", method = "percentage")
if (require("wdm", quietly = TRUE)) {
  cor_test(iris, "Sepal.Length", "Sepal.Width", method = "blomqvist")
}
if (require("Hmisc", quietly = TRUE)) {
}
cor_test(iris, "Sepal.Length", "Sepal.Width", method = "gamma")
cor_test(iris, "Sepal.Length", "Sepal.Width", method = "shepherd")
if (require("BayesFactor", quietly = TRUE)) {
}

# Tetrachoric
if (require("psych", quietly = TRUE)) {
  data <- iris
  data$Sepal.Width_binary <- ifelse(data$Sepal.Width > 3, 1, 0)
  data$Petal.Width_binary <- ifelse(data$Petal.Width > 1.2, 1, 0)
```
cor_test(data, "Sepal.Width_binary", "Petal.Width_binary", method = "tetrachoric")

# Biserial
cor_test(data, "Sepal.Width", "Petal.Width_binary", method = "biserial")

# Polychoric
data$Petal.Width_ordinal <- as.factor(round(data$Petal.Width))
data$Sepal.Length_ordinal <- as.factor(round(data$Sepal.Length))
cor_test(data, "Petal.Width_ordinal", "Sepal.Length_ordinal", method = "polychoric")

# When one variable is continuous, will run 'polyserial' correlation
#
# Robust (these two are equivalent)
cor_test(iris, "Sepal.Length", "Sepal.Width", method = "spearman")

# Winsorized
cor_test(iris, "Sepal.Length", "Sepal.Width", winsorize = 0.2)

## Not run:
# Partial

## End(Not run)

---

cor_to_ci

Convert correlation to p-values and CIs

**Description**

Get statistics, p-values and confidence intervals (CI) from correlation coefficients.

**Usage**

```r
cor_to_ci(cor, n, ci = 0.95, method = "pearson", correction = "fieller", ...)
cor_to_p(cor, n, method = "pearson")
```

**Arguments**

- **cor**: A correlation matrix or coefficient.
- **n**: The sample size (number of observations).
- **ci**: Confidence/Credible Interval level. If "default", then it is set to 0.95 (95% CI).
method A character string indicating which correlation coefficient is to be used for the test. One of "pearson" (default), "kendall", "spearman" (but see also the robust argument), "biserial", "polychoric", "tetrachoric", "biweight", "distance", "percentage" (for percentage bend correlation), "blomqvist" (for Blomqvist's coefficient), "hoeffding" (for Hoeffding's D), "gamma", "gaussian" (for Gaussian Rank correlation) or "shepherd" (for Shepherd's Pi correlation). Setting "auto" will attempt at selecting the most relevant method (polychoric when ordinal factors involved, tetrachoric when dichotomous factors involved, point-biserial if one dichotomous and one continuous and pearson otherwise).

correction Only used if method is 'spearman' or 'kendall'. Can be 'fieller' (default; Fieller et al., 1957), 'bw' (only for Spearman) or 'none'. Bonett and Wright (2000) claim their correction ('bw') performs better, though the Bishara and Hittner (2017) paper favours the Fieller correction. Both are generally very similar.

... Additional arguments (e.g., alternative) to be passed to other methods. See stats::cor.test for further details.

Value A list containing a p-value and the statistic or the CI bounds.

References

Examples

cor.test(iris$Sepal.Length, iris$Sepal.Width)
cor_to_p(-0.1175698, n = 150)
cor_to_p(cor(iris[1:4]), n = 150)
cor_to_ci(-0.1175698, n = 150)
cor_to_ci(cor(iris[1:4]), n = 150)

cor.test(iris$Sepal.Length, iris$Sepal.Width, method = "spearman")
cor_to_p(-0.1667777, n = 150, method = "spearman")
cor_to_ci(-0.1667777, ci = 0.95, n = 150)

cor.test(iris$Sepal.Length, iris$Sepal.Width, method = "kendall")
cor_to_p(-0.07699679, n = 150, method = "kendall")

---

**cor_to_cov** Convert a correlation to covariance

**Description** Convert a correlation to covariance
cor_to_pcor

Usage

\[
\text{cor_to_cov}(\text{cor}, \text{sd} = \text{NULL}, \text{variance} = \text{NULL}, \text{tol} = .\text{Machine}\$\text{double}\$.\text{eps}^{(2/3)})
\]

Arguments

- **cor**: A correlation matrix, or a partial or a semipartial correlation matrix.
- **sd, variance**: A vector that contains the standard deviations, or the variance, of the variables in the correlation matrix.
- **tol**: Relative tolerance to detect zero singular values.

Value

A covariance matrix.

Examples

```r
cor <- cor(iris[,1:4])
cov(iris[,1:4])

\text{cor_to_cov}(\text{cor}, \text{sd} = \text{sapply(iris[,1:4], sd)})
\text{cor_to_cov}(\text{cor}, \text{variance} = \text{sapply(iris[,1:4], var)})
```

---

cor_to_pcor

Correlation Matrix to (Semi) Partial Correlations

Description

Convert a correlation matrix to a (semi)partial correlation matrix. Partial correlations are a measure of the correlation between two variables that remains after controlling for (i.e., "partiallying" out) all the other relationships. They can be used for graphical Gaussian models, as they represent the direct interactions between two variables, conditioned on all remaining variables. This means that the squared partial correlation between a predictor X1 and a response variable Y can be interpreted as the proportion of (unique) variance accounted for by X1 relative to the residual or unexplained variance of Y that cannot be accounted for by the other variables.

Usage

```r
\text{cor_to_pcor}(\text{cor}, \text{tol} = .\text{Machine}\$\text{double}\$.\text{eps}^{(2/3)})
\text{pcor_to_cor}(\text{pcor}, \text{tol} = .\text{Machine}\$\text{double}\$.\text{eps}^{(2/3)})
\text{cor_to_spcor}(\text{cor} = \text{NULL}, \text{cov} = \text{NULL}, \text{tol} = .\text{Machine}\$\text{double}\$.\text{eps}^{(2/3)})
```
Arguments

- `cor`, `pcor`: A correlation matrix, or a partial or a semipartial correlation matrix.
- `tol`: Relative tolerance to detect zero singular values.
- `cov`: A covariance matrix (or a vector of the SD of the variables). Required for semipartial correlations.

Details

The semi-partial correlation is similar to the partial correlation statistic. However, it represents (when squared) the proportion of (unique) variance accounted for by the predictor X1, relative to the total variance of Y. Thus, it might be seen as a better indicator of the "practical relevance" of a predictor, because it is scaled to (i.e., relative to) the total variability in the response variable.

Value

The (semi) partial correlation matrix.

Examples

```r
cor <- cor(iris[1:4])

# Partialize
cor_to_pcor(cor)
cor_to_spcor(cor, cov = sapply(iris[1:4], sd))

# Inverse
round(pcor_to_cor(cor_to_pcor(cor)) - cor, 2) # Should be 0
```

Description

Export tables (i.e. data frame) into different output formats. `print_md()` is a alias for `display(format = "markdown").

Usage

```r
## S3 method for class 'easycormatrix'
display(
  object,
  format = "markdown",
  digits = 2,
  p_digits = 3,
  stars = TRUE,
  include_significance = NULL,
  ...)
```
## S3 method for class 'easycorrelation'
print_md(x, digits = NULL, p_digits = NULL, stars = NULL, ...)

## S3 method for class 'easycorrelation'
print_html(x, digits = NULL, p_digits = NULL, stars = NULL, ...)

## S3 method for class 'easycormatrix'
print_md(
  x,
  digits = NULL,
  p_digits = NULL,
  stars = NULL,
  include_significance = NULL,
  ...
)

## S3 method for class 'easycormatrix'
print_html(
  x,
  digits = NULL,
  p_digits = NULL,
  stars = NULL,
  include_significance = NULL,
  ...
)

### Arguments

- **object, x**
  An object returned by `correlation()` or its summary.
- **format**
  String, indicating the output format. Currently, only "markdown" is supported.
- **digits, p_digits**
  To do...
- **stars**
  To do...
- **include_significance**
  To do...
- **...**
  Currently not used.

### Details

display() is useful when the table-output from functions, which is usually printed as formatted text-table to console, should be formatted for pretty table-rendering in markdown documents, or if knitted from rmarkdown to PDF or Word files.

### Value

A character vector. If `format = "markdown"`, the return value will be a character vector in markdown-table format.
**distance_mahalanobis**  

*Mahalanobis distance and confidence interval (CI)*

---

**Description**

The Mahalanobis distance (in squared units) measures the distance in multivariate space taking into account the covariance structure of the data. Because a few extreme outliers can skew the covariance estimate, the bootstrapped version is considered as more robust.

**Usage**

```r
distance_mahalanobis(data, ci = 0.95, iterations = 1000, robust = TRUE, ...)
```

**Arguments**

- `data` A data frame.
- `ci` Confidence/Credible Interval level. If "default", then it is set to 0.95 (95% CI).
- `iterations` The number of draws to simulate/bootstrap (when `robust` is `TRUE`).
- `robust` If `TRUE`, will run a bootstrapped version of the function with i iterations.
- `...` Additional arguments (e.g., `alternative`) to be passed to other methods. See `stats::cor.test` for further details.

**Value**

Description of the Mahalanobis distance.

**References**

**Examples**

```r
library(correlation)

distance_mahalanobis(iris[, 1:4])
distance_mahalanobis(iris[, 1:4], robust = FALSE)
```
is.cor

Check if matrix ressembles a correlation matrix

Description
Check if matrix ressembles a correlation matrix

Usage
is.cor(x)

Arguments
x A matrix.

Value
TRUE of the matrix is a correlation matrix or FALSE otherwise.

isSquare

Check if Square Matrix

Description
Check if Square Matrix

Usage
isSquare(m)

Arguments
m A matrix.

Value
TRUE of the matrix is square or FALSE otherwise.
matrix_inverse

Matrix Inversion

Description

Performs a Moore-Penrose generalized inverse (also called the Pseudoinverse).

Usage

```r
matrix_inverse(m, tol = .Machine$double.eps^(2/3))
```

Arguments

- `m`: Matrix for which the inverse is required.
- `tol`: Relative tolerance to detect zero singular values.

Value

An inversed matrix.

See Also

- `pinv` from the pracma package

Examples

```r
m <- cor(iris[1:4])
matrix_inverse(m)
```

simulate_simpson

Simpson’s paradox dataset simulation

Description

Simpson’s paradox, or the Yule-Simpson effect, is a phenomenon in probability and statistics, in which a trend appears in several different groups of data but disappears or reverses when these groups are combined.

Usage

```r
simulate_simpson(n = 100, r = 0.5, groups = 3, difference = 1)
```
Arguments

- `n`: The number of observations for each group to be generated.
- `r`: A value or vector corresponding to the desired correlation coefficients.
- `groups`: Number of groups.
- `difference`: Difference between groups.

Value

A dataset.

Examples

```r
data <- simulate_simpson(n = 100, groups = 5, r = 0.5)

library(ggplot2)
ggplot(data, aes(x = V1, y = V2)) +
  geom_point(aes(color = Group)) +
  geom_smooth(aes(color = Group), method = "lm") +
  geom_smooth(method = "lm")
```

Description

Winsorizing or winsorization is the transformation of statistics by limiting extreme values in the statistical data to reduce the effect of possibly spurious outliers. The distribution of many statistics can be heavily influenced by outliers. A typical strategy is to set all outliers (values beyond a certain threshold) to a specified percentile of the data; for example, a 90% winsorization would see all data below the 5th percentile set to the 5th percentile, and data above the 95th percentile set to the 95th percentile. Winsorized estimators are usually more robust to outliers than their more standard forms.

Usage

```r
winsorize(data, ...)
```

# S3 method for class 'numeric'
```r
winsorize(data, threshold = 0.2, verbose = TRUE, ...)
```

Arguments

- `data`: Dataframe or vector.
- `...`: Currently not used.
- `threshold`: The amount of winsorization.
- `verbose`: Toggle warnings.
Examples

```r
library(correlation)

winsorize(iris$Sepal.Length, threshold = 0.2)
winsorize(iris, threshold = 0.2)
```

---

### z_fisher

**Fisher z-transformation**

**Description**

The Fisher z-transformation converts the standard Pearson’s r to a normally distributed variable $z'$. It is used to compute confidence intervals to correlations. The $z'$ variable is different from the z-statistic.

**Usage**

```r
z_fisher(r = NULL, z = NULL)
```

**Arguments**

- `r, z`
  - The r or the $z'$ value to be converted.

**Value**

The transformed value.

**References**

**Examples**

```r
z_fisher(r = 0.7)
z_fisher(z = 0.867)
```
