Package ‘data.table’

May 27, 2018

Version  1.11.4
Title  Extension of `data.frame`
Depends  R (>= 3.1.0)
Imports  methods
Suggests  bit64, curl, knitr, xts, nanotime, zoo, reshape2
Description  Fast aggregation of large data (e.g. 100GB in RAM), fast ordered joins, fast add/modify/delete of columns by group using no copies at all, list columns, friendly and fast character-separated-value read/write. Offers a natural and flexible syntax, for faster development.
License  MPL-2.0 | file LICENSE

data.table-package

Description

data.table inherits from data.frame. It offers fast and memory efficient: file reader and writer, aggregations, updates, equi, non-equi, rolling, range and interval joins, in a short and flexible syntax, for faster development.

It is inspired by A[B] syntax in R where A is a matrix and B is a 2-column matrix. Since a data.table is a data.frame, it is compatible with R functions and packages that accept only data.frames.

Type vignette(package="data.table") to get started. The Introduction to data.table vignette introduces data.table’s x[i, j, by] syntax and is a good place to start. If you have read the vignettes and the help page below, please read the data.table support guide.

Please check the homepage for up to the minute live NEWS.

Tip: one of the quickest ways to learn the features is to type example(data.table) and study the output at the prompt.

Usage

data.table(..., keep.rownames=FALSE, check.names=FALSE, key=NULL, stringsAsFactors=FALSE)

## S3 method for class 'data.table'
x[i, j, by, keyby, with = TRUE,
nomatch = getOption("datatable.nomatch"), # default: NA_integer_
mult = "all",
roll = FALSE,
rollends = if (roll=="nearest") c(TRUE,TRUE)
    else if (roll<=0) c(FALSE,TRUE)
    else c(TRUE,FALSE),
which = FALSE,
.SDcols,
verbose = getOption("datatable.verbose"), # default: FALSE
allow.cartesian = getOption("datatable.allow.cartesian"), # default: FALSE
drop = NULL, on = NULL]
Arguments

Just as ... in `data.frame`. Usual recycling rules are applied to vectors of different lengths to create a list of equal length vectors.

**keep.rownames**
If ... is a matrix or `data.frame`, TRUE will retain the rownames of that object in a column named `rn`.

**check.names**
Just as `check.names` in `data.frame`.

**key**
Character vector of one or more column names which is passed to `setkey`. It may be a single comma separated string such as `key="x,y,z"`, or a vector of names such as `key=c("x", "y", "z")`.

**stringsAsFactors**
Logical (default is FALSE). Convert all character columns to factors?

**x**
A `data.table`.

**i**
Integer, logical or character vector, single column numeric matrix, expression of column names, list, `data.frame` or `data.table`.

1. Integer and logical vectors work the same way they do in `[,data.frame` except logical NAs are treated as FALSE.
2. Expression is evaluated within the frame of the `data.table` (i.e. it sees column names as if they are variables) and can evaluate to any of the other types.
3. Character, list and `data.frame` input to `i` is converted into a `data.table` internally using `as.data.table`.

If `i` is a `data.table`, the columns in `i` to be matched against `x` can be specified using one of these ways:

- **on** argument (see below). It allows for both equi- and the newly implemented non-equijoins.
- If not, `x` must be keyed. Key can be set using `setkey`. If `i` is also keyed, then first `key` column of `i` is matched against first `key` column of `x`, second against second, etc..
  - If `i` is not keyed, then first column of `i` is matched against first `key` column of `x`, second column of `i` against second `key` column of `x`, etc...
  - This is summarised in code as `min(length(key(x)), if (haskey(i)) length(key(i)) else ncol(x))`.

Using `on=` is recommended (even during keyed joins) as it helps understand the code better and also allows for non-equijoins.

When the binary operator `==` alone is used, an equi join is performed. In SQL terms, `x[i]` then performs a right join by default. `i` prefixed with `!` signals a not-join or not-select.

Support for non-equijoin was recently implemented, which allows for other binary operators `>=`, `>`, `<`, and `<`.

See Keys and fast binary search based subset and Secondary indices and auto indexing.

**Advanced:** When `i` is a single variable name, it is not considered an expression of column names and is instead evaluated in calling scope.

**j**
When `with=TRUE` (default), `j` is evaluated within the frame of the `data.table`; i.e., it sees column names as if they are variables. This allows to not just `select` columns in `j`, but also compute on them e.g., `x[, a]` and `x[, sum(a)]` returns
$x \cdot a$ and \( \text{sum}(x \cdot a) \) as a vector respectively. \( x[, .(a, b)] \) and \( x[, .(sa=\text{sum}(a), sb=\text{sum}(b))] \) returns a two column data.table each, the first simply selecting columns \( a, b \) and the second computing their sums.

The expression \'(.)\' is a shorthand alias to \texttt{list()}, they both mean the same. (An exception is made for the use of \(.()\) within a call to \texttt{bquote}, where \( .() \) is left unchanged.) As long as \( j \) returns a list, each element of the list becomes a column in the resulting data.table. This is the default \texttt{enhanced} mode.

When \texttt{with=}FALSE, \( j \) can be a vector of column names or positions to select (as in \texttt{data.frame}), or a logical vector with length \( ncol(x) \) defining columns to select. Note: if a logical vector with length \( k < ncol(x) \) is passed, it will be filled to length \( ncol(x) \) with FALSE, which is different from \texttt{data.frame}, where the vector is recycled.

\texttt{Advanced:} \( j \) also allows the use of special \texttt{read-only} symbols: \texttt{SD, N, I, .GRP, .BY}.

\texttt{Advanced:} When \( i \) is a \texttt{data.table}, the columns of \( i \) can be referred to in \( j \) by using the prefix \texttt{i\[\], e.g., \( X[Y, .(val, i.val)] \). Here \( val \) refers to \( X \)'s column and \( i.val \)'s.

\texttt{Advanced:} Columns of \( x \) can now be referred to using the prefix \( x \). and is particularly useful during joining to refer to \( x \)'s \texttt{join} columns as they are otherwise masked by \( i \)'s. For example, \( X[Y, .(x.a-i.a, b), on="a"] \).

\texttt{See Introduction to data.table vignette and examples.}

\texttt{by}  
Column names are seen as if they are variables (as in \( j \) when \texttt{with=}TRUE). The \texttt{data.table} is then grouped by \( \texttt{by} \) and \( j \) is evaluated within each group. The order of the rows within each group is preserved, as is the order of the groups. \( \texttt{by} \) accepts:

- A single unquoted column name: e.g., \( DT[, .(sa=\text{sum}(a)), by=x] \)
- A \texttt{list()} of expressions of column names: e.g., \( DT[, .(sa=\text{sum}(a)), by=.x=x>0, y] \)
- A single character string containing comma separated column names (where spaces are significant since column names may contain spaces even at the start or end): e.g., \( DT[, \text{sum}(a), by="x,y,z"] \)
- A character vector of column names: e.g., \( DT[, \text{sum}(a), by=c("x", "y") ] \)
- Or of the form \texttt{startcol:endcol}: e.g., \( DT[, \text{sum}(a), by=x:z] \)

\texttt{Advanced:} When \( i \) is a \texttt{list} (or \texttt{data.frame} or \texttt{data.table}), \( DT[i, j, by=.EACHSI] \) evaluates \( j \) for the groups in \texttt{'DT'} that each row in \( i \) joins to. That is, you can join (in \( i \)) and aggregate (in \( j \)) simultaneously. We call this \texttt{grouping by each i}. See \texttt{this StackOverflow answer} for a more detailed explanation until we roll out vignettes.

\texttt{Advanced:} In the \texttt{X[Y, j]} form of grouping, the \( j \) expression sees variables in \( X \) first, then \( Y \). We call this \texttt{join inherited scope}. If the variable is not in \( X \) or \( Y \) then the calling frame is searched, its calling frame, and so on in the usual way up to and including the global environment.

\texttt{keyby}  
Same as \texttt{by}, but with an additional \texttt{setkey()} run on the by columns of the result, for convenience. It is common practice to use \texttt{'keyby='} routinely when you wish the result to be sorted.

\texttt{with}  
By default \texttt{with=}TRUE and \( j \) is evaluated within the frame of \texttt{x}; column names can be used as variables.
When with=FALSE j is a character vector of column names, a numeric/logical vector of column positions to select or of the form startcol:endcol, and the value returned is always a data.table. with=FALSE is often useful in data.table to select columns dynamically. Note that x[, cols, with=FALSE] is equivalent to x[, .SD, .SDcols=cols].

nomatch
Same as nomatch in match. When a row in i has no match to x, nomatch=NA (default) means NA is returned. 0 means no rows will be returned for that row of i. Use options(datatable.nomatch=0) to change the default value (used when nomatch is not supplied).

mult
When i is a list (or data.frame or data.table) and multiple rows in x match to the row in i, mult controls which are returned: "all" (default), "first" or "last".

roll
When i is a data.table and its row matches to all but the last x join column, and its value in the last i join column falls in a gap (including after the last observation in x for that group), then:

- +Inf (or TRUE) rolls the prevailing value in x forward. It is also known as last observation carried forward (LOCF).
- -Inf rolls backwards instead; i.e., next observation carried backward (NOCB).
- finite positive or negative number limits how far values are carried forward or backward.
- "nearest" rolls the nearest value instead.

Rolling joins apply to the last join column, generally a date but can be any variable. It is particularly fast using a modified binary search.

A common idiom is to select a contemporaneous regular time series (dts) across a set of identifiers (ids): DT[CJ(ids,dts),roll=TRUE] where DT has a 2-column key (id,date) and CJ stands for cross join.

rollends
A logical vector length 2 (a single logical is recycled) indicating whether values falling before the first value or after the last value for a group should be rolled as well.

- If rollends[2]=TRUE, it will roll the last value forward. TRUE by default for LOCF and FALSE for NOCB rolls.
- If rollends[1]=TRUE, it will roll the first value backward. TRUE by default for NOCB and FALSE for LOCF rolls.

When roll is a finite number, that limit is also applied when rolling the ends.

which
TRUE returns the row numbers of x that i matches to. If NA, returns the row numbers of i that have no match in x. By default FALSE and the rows in x that match are returned.

.SDcols
Specifies the columns of x to be included in the special symbol .SD which stands for Subset of data.table. May be character column names or numeric positions. This is useful for speed when applying a function through a subset of (possibly very many) columns; e.g., DT[, lapply(.SD, sum), by="x,y", .SDcols=301:350].

For convenient interactive use, the form startcol:endcol is also allowed (as in by), e.g., DT[, lapply(.SD, sum), by=x:y, .SDcols=a:f]
verbose

TRUE turns on status and information messages to the console. Turn this on by default using `options(data.table.verbose=TRUE)`. The quantity and types of verbosity may be expanded in future.

allow.cartesian

FALSE prevents joins that would result in more than `nrow(x)*nrow(i)` rows. This is usually caused by duplicate values in `i`'s join columns, each of which join to the same group in 'x' over and over again: a misspecified join. Usually this was not intended and the join needs to be changed. The word 'cartesian' is used loosely in this context. The traditional cartesian join is (deliberately) difficult to achieve in `data.table`: where every row in `i` joins to every row in `x` (a `nrow(x)*nrow(i)` row result). 'cartesian' is just meant in a 'large multiplicative' sense.

drop

Never used by `data.table`. Do not use. It needs to be here because `data.table` inherits from `data.frame`. See `datatable-faq`.

on

Indicate which columns in `x` should be joined with which columns in `i` along with the type of binary operator to join with (see non-equi joins below on this). When specified, this overrides the keys set on `x` and `i`. There are multiple ways of specifying the `on` argument:

- As an unnamed character vector, e.g., `X[Y, on=c("a", "b")], used when columns `a` and `b` are common to both `X` and `Y`.
- Foreign key joins: As a named character vector when the join columns have different names in `X` and `Y`. For example, `X[Y, on=c(x1="y1", x2="y2")]

ONB joins `X` and `Y` by matching columns `x1` and `x2` in `X` with columns `y1` and `y2` in `Y`, respectively.

From v1.9.8, you can also express foreign key joins using the binary operator `\|`, e.g. `X[Y, on=c("a\|b", y\|b)]`. NB: shorthand like `X[Y, on=c("a", y\|b)]` is also possible if, e.g., column "a" is common between the two tables.

- For convenience during interactive scenarios, it is also possible to use .() syntax as `X[Y, on=.a, b])`.

- From v1.9.8, (non-equi) joins using binary operators `\|`, `\|`, `\|` are also possible, e.g., `X[Y, on=c("x\|y", "y\|b")]. or for interactive use as `X[Y, on=(x\|a, y\|b])`.

See examples as well as Secondary indices and auto indexing.

Details

data.table builds on base `R` functionality to reduce 2 types of time:

1. programming time (easier to write, read, debug and maintain), and
2. compute time (fast and memory efficient).

The general form of data.table syntax is:
The way to read this out loud is: "Take DT, subset rows by i, then compute j grouped by by. Here are some basic usage examples expanding on this definition. See the vignette (and examples) for working examples.

A data.table is a list of vectors, just like a data.frame. However:

1. it never has or uses rownames. Rownames based indexing can be done by setting a key of one or more columns or done ad-hoc using the on argument (now preferred).
2. it has enhanced functionality in [.data.table for fast joins of keyed tables, fast aggregation, fast last observation carried forward (LOCF) and fast add/modify/delete of columns by reference with no copy at all.

See the see also section for the several other methods that are available for operating on data.tables efficiently.

Note

If keep.rownames or check.names are supplied they must be written in full because R does not allow partial argument names after `.‘. For example, data.table(DF, keep=TRUE) will create a column called "keep" containing TRUE and this is correct behaviour; data.table(DF, keep.rownames=TRUE) was intended.

POSIXct is not supported as a column type because it uses 40 bytes to store a single datetime. They are implicitly converted to POSIXct type with warning. You may also be interested in IDateTime instead; it has methods to convert to and from POSIXlt.

# select|compute columns data.table way
DT[, v]                       # v column (as vector)
DT[, list(v)]                  # v column (as data.table)
DT[, .(v)]                     # same as above, .() is a shorthand alias to list()  
DT[, sum(v)]                   # sum of column v, returned as vector
DT[, .(sum(v))]                # same, but return data.table (column autonamed V1)
DT[, .(sv=sum(v))]             # same, but column named "sv"
DT[, .(v, v*2)]                # return two column data.table, v and v*2

# subset rows and select|compute data.table way
DT[2:3, sum(v)]               # sum(v) over rows 2 and 3, return vector
DT[2:3, .(sum(v))]            # same, but return data.table with column V1
```
DT[2:3,.(sv=sum(v))]  # same, but return data.table with column sv
DT[2:5,cat(v, "\n")]  # just for j's side effect

# select columns the data.frame way
DT[,2,with=FALSE]  # 2nd column, returns a data.table always
colNum = 2
DT[,colNum,with=FALSE]  # same, equivalent to DT[, .SD, .SDcols=colNum]
DT["v"]  # same as DT[, v] but much faster

# grouping operations - j and by
DT[,sum(v),by=x]  # ad hoc by, order of groups preserved in result
DT[,sum(v),keyby=x]  # same, but order the result on by cols
DT[,sum(v),by=x][order(x)]  # same but by chaining expressions together

# fast ad hoc row subsets (subsets as joins)
DT["a",on="x"]  # same as x == "a" but uses binary search (fast)
DT["a",on.(x)]  # same, for convenience, no need to quote every column
DT[.("a"),on="x"]  # same
DT[x=="a"]  # same, single "==" internally optimised to use binary search (fast)
DT[x!="b" | y!=3]  # not yet optimized, currently vector scan subset
DT[.("b",3),on=c("x","y")]["z"]  # join on columns x,y of DT; uses binary search (fast)
DT[.("b",3),on.(x,y)]  # same, but using on=.()
DT[.("b",1:2),on=c("x","y")]["z"]  # no match returns NA
DT[.("b",1:2),on.(x,y),nomatch=0]  # no match row is not returned
DT[.("b",1:2),on=c("x","y"),roll=Inf]  # locf, nomatch row gets rolled by previous row
DT[.("b",1:2),on.(x,y),roll=-Inf]  # nocb, nomatch row gets rolled by next row
DT["b",sum(v*y),on="x"]  # on rows where DT$x=="b", calculate sum(v*y)

# all together now
DT[x=!"a",sum(v),by=x]  # get sum(v) by "x" for each i != "a"
DT[!"a",sum(v),by=EACHI, on="x"]  # same, but using subsets-as-joins
DT[!("b","c"),sum(v),by=EACHI, on="x"]  # same
DT[!("b","c"),sum(v),by=EACHI, on.(x)]  # same, using on=.()

# joins as subsets
X = data.table(x=c("c","b"),v=8:7, foo=c(4,2))
X

DT[X, on="x"]  # right join
XDT, on="x"  # left join
DT[X, on="x",nomatch=0]  # inner join
DT[X, on."x"]  # not join
DT[X, on=c(y="v")]["z"]  # join using column "y" of DT with column "v" of X
DT[X, on="y=v"]  # same as above (v1.9.8+)

DT[X, on.(y<foo)]["z"]  # NEW non-equi join (v1.9.8+)
DT[X, on."y<foo"]  # same as above
DT[X, on=c(\'(\'<foo\')]]["z"]  # same as above
DT[X, on.(y>foo)]["z"]  # NEW non-equi join (v1.9.8+)
DT[X, on.(x,y<foo)]["z"]  # NEW non-equi join (v1.9.8+)
DT[X, on.(x,y>foo)]["z"]  # Select x's join columns as well

DT[X, on="x",mult="first"]  # first row of each group
DT[X, on="x", mult="last"]  # last row of each group
DT[X, sum(v), by=.EACHI, on="x"]  # join and eval j for each row in i
DT[X, sum(v)*foo, by=.EACHI, on="x"]  # join inherited scope
DT[X, sum(v)*i.v, by=.EACHI, on="x"]  # 'i,v' refers to X's v column
DT[X, on.=x, v=v, sum(y)*foo, by=.EACHI]  # NEW non-equi join with by=.EACHI (v1.9.8+)

# setting keys
kDT = copy(DT)  # (deep) copy DT to kDT to work with it.
setkeyv(kDT,x)  # set a 1-column key. No quotes, for convenience.
setkeyv(kDT,"x")  # same (v in setkeyv stands for vector)
v="x"
setkeyv(kDT,v)  # same
# key(kDT)<-"x"  # copies whole table, please use set* functions instead
haskey(kDT)  # TRUE
key(kDT)  # "x"

# fast *keyed* subsets
kDT["a"]  # subset-as-join on *key* column 'x'
kDT["a", on="x"]  # same, being explicit using 'on=' (preferred)

# all together
kDT[!"a", sum(v), by=.EACHI]  # get sum(v) for each i != "a"

# multi-column key
setkeyv(kDT,T,y)  # 2-column key
setkeyv(kDT,c("x","y"))  # same

# fast *keyed* subsets on multi-column key

Assignment by reference

Description

Fast add, remove and update subsets of columns, by reference. := operator can be used in two ways: LHS := RHS form, and Functional form. See Usage.

set is a low-overhead loop-able version of :=. It is particularly useful for repetitively updating rows of certain columns by reference (using a for-loop). See Examples. It can not perform grouping operations.

Usage

# 1. LHS := RHS form
# DT[i, LHS := RHS, by = ...]
# DT[i, c("LHS1", "LHS2") := list(RHS1, RHS2), by = ...]

# 2. Functional form
# DT[i, `:=`(LHS1 = RHS1,
#     LHS2 = RHS2,
#     ...), by = ...]

set(x, i = NULL, j, value)

Arguments

LHS A character vector of column names (or numeric positions) or a variable that evaluates as such. If the column doesn’t exist, it is added, by reference.

RHS A list of replacement values. It is recycled in the usual way to fill the number of rows satisfying i, if any. To remove a column use NULL.

x A data.table. Or, set() accepts data.frame, too.

i Optional. Indicates the rows on which the values must be updated with. If not provided, implies all rows. The := form is more powerful as it allows subsets and joins based add/update columns by reference. See Details.

In set, only integer type is allowed in i indicating which rows value should be assigned to. NULL represents all rows more efficiently than creating a vector such as 1:nrow(x).
Column name(s) (character) or number(s) (integer) to be assigned value when column(s) already exist, and only column name(s) if they are to be created.

A list of replacement values to assign by reference to $x[i, j]$.

Details

$:= $ is defined for use in $j$ only. It adds or updates or removes column(s) by reference. It makes no copies of any part of memory at all. Read the Reference Semantics HTML vignette to follow with examples. Some typical usages are:

- $\text{DT}[i, \text{col} := \text{val}]$ # update (or add at the end if doesn’t exist) a column called $\text{col}$
- $\text{DT}[i, \text{col} := \text{val}]$ # same as above, but only for those rows specified in $i$ and
- $\text{DT}[i, \text{"col a" := val}]$ # same. column is called "col a"
- $\text{DT}[i, (3:6) := \text{val}]$ # update existing columns 3:6 with value. Aside: parens are
- $\text{DT}[i, \text{colvector} := \text{val}, \text{with} = \text{FALSE}]$ # OLD syntax. The contents of "colvector" in calling scope
- $\text{DT}[i, (\text{colvector}) := \text{val}]$ # same (NOW PREFERRED) shorthand syntax. The parens are e
- $\text{DT}[i, \text{colC} := \text{mean(colB), by = colA}]$ # update (or add) column called "colC" by reference by $j$
- $\text{DT}[\ldots := \langle \text{new1} = \text{sum(colB), new2 = sum(colC)\rangle}]$ # Functional form

All of the following result in a friendly error (by design):

- $x := 1 \text{L}$
- $\text{DT}[i, \text{col}] := \text{val}$
- $\text{DT}[i] \text{\$col} := \text{val}$
- $\text{DT}[\ldots := \langle \text{col1 := 1\text{L; col2 := 2\text{L}}}]$ # Use the functional form, ‘$:=\langle\rangle\textrm{, instead (see above).}$

For additional resources, check the FAQs vignette. Also have a look at StackOverflow’s data.table tag.

$:= $ in $j$ can be combined with all types of $i$ (such as binary search), and all types of by. This a one reason why $:= $ has been implemented in $j$. See the Reference Semantics HTML vignette and also FAQ 2.16 for analogies to SQL.

When LHS is a factor column and RHS is a character vector with items missing from the factor levels, the new level(s) are automatically added (by reference, efficiently), unlike base methods.

Unlike $<$- for data.frame, the (potentially large) LHS is not coerced to match the type of the (often small) RHS. Instead the RHS is coerced to match the type of the LHS, if necessary. Where this involves double precision values being coerced to an integer column, a warning is given (whether or not fractional data is truncated). The motivation for this is efficiency. It is best to get the column types correct up front and stick to them. Changing a column type is possible but deliberately harder: provide a whole column as the RHS. This RHS is then plonked into that column slot and we call this plonk syntax, or replace column syntax if you prefer. By needing to construct a full length vector of a new type, you as the user are more aware of what is happening, and it’s clearer to readers of your code that you really do intend to change the column type.

data.tables are not copied-on-change by $:= $, setkey or any of the other set* functions. See copy.

Value

$\text{DT}$ is modified by reference and returned invisibly. If you require a copy, take a copy first (using $\text{DT2} = \text{copy(DT)}$).
Advanced (internals):

It is easy to see how sub-assigning to existing columns is done internally. Removing columns by reference is also straightforward by modifying the vector of column pointers only (using memmove in C). However adding (new) columns is more tricky as to how the data.table can be grown by reference: the list vector of column pointers is over-allocated, see truelength. By defining := in j we believe update syntax is natural, and scales, but it also bypasses [<- dispatch and allows := to update by reference with no copies of any part of memory at all.

Since [.data.table incurs overhead to check the existence and type of arguments (for example), set() provides direct (but less flexible) assignment by reference with low overhead, appropriate for use inside a for loop. See examples. := is more powerful and flexible than set() because := is intended to be combined with 1 and by in single queries on large datasets.

Note:

DT[a > 4, b := c] is different from DT[a > 4][, b := c]. The first expression updates (or adds) column b with the value c on those rows where a > 4 evaluates to TRUE. X is updated by reference, therefore no assignment needed.

The second expression on the other hand updates a new data.table that’s returned by the subset operation. Since the subsetted data.table is ephemeral (it is not assigned to a symbol), the result would be lost; unless the result is assigned, for example, as follows: ans <- DT[a > 4][, b := c].

See Also
data.table, copy, alloc.col, truelength, set

Examples

DT = data.table(a = LETTERS[c(3L,1:3)], b = 4:7)
DT[, c := 8]  # add a numeric column, 8 for all rows
DT[, d := 9L]  # add an integer column, 9L for all rows
DT[, c := NULL]  # remove column c
DT[2, d := -8L]  # subassign by reference to d; 2nd row is -8L now
DT  # DT changed by reference
DT[2, d := 10L][]  # shorthand for update and print

DT[b > 4, b := d * 2L]  # subassign to b with d*2L on those rows where b > 4 is TRUE
DT[b > 4][, b := d * 2L]  # different from above. [, := ] is performed on the subset
# which is an new (ephemeral) data.table. Result needs to be
# assigned to a variable (using `<-`).

DT[, e := mean(d), by = a]  # add new column by group by reference
DT["A", b := 0L, on = "a"]  # ad-hoc update of column b for group "A" using
  # joins-as-subsets with binary search and 'on'=
# same as above but using keys
setkey(DT, a)
DT["A", b := 0L]  # binary search for group "A" and set column b using keys
DT["B", f := mean(d)]  # subassign to new column, NA initialized

# Adding multiple columns
## by name
\[
\text{DT[ , c('sin_d', 'log_e', 'cos_d') := }
\text{ (sin(d), log(e), cos(d))]}
\]

\# by patterned name
\[
\text{DT[ , paste(c('sin', 'cos'), 'b', sep = '_') :=}
\text{ (sin(b), cos(b))]}
\]

\# using lapply & .SD
\[
\text{DT[ , paste0('tan_', c('b', 'd', 'e'))) :=}
\text{ lapply(.SD, tan), .SDcols = c('b', 'd', 'e'))}
\]

\# using forced evaluation to disambiguate a vector of names
\# and overwrite existing columns with their squares
\[
\text{sq_cols = c('b', 'd', 'e')}
\text{DT[ , (sq_cols) := lapply(.SD, `^`, 2L), .SDcols = sq_cols]}
\]

\# by integer (NB: for robustness, it is not recommended
\# to use explicit integers to update/define columns)
\[
\text{DT[ , c(2L, 3L, 4L) := (sqrt(b), sqrt(d), sqrt(e))]}
\]

\# by implicit integer
\[
\text{DT[ , grep('a$', names(DT)) := tolower(a)]}
\]

\# by implicit integer, using forced evaluation
\[
\text{sq_col_idx = grep('d$', names(DT))}
\text{DT[ , (sq_col_idx) := lapply(.SD, dnorm),}
\text{ .SDcols = sq_col_idx]}
\]

\# Not run:
\# Speed example ...

\[
\text{m = matrix(1, nrow = 2e6L, ncol = 100L)}
\text{DF = as.data.frame(m)}
\text{DT = as.data.table(m)}
\]

\text{system.time(for (i in 1:1000) DF[i, 1] = i)}
\# 15.856 seconds
\text{system.time(for (i in 1:1000) DT[i, V1 := i])}
\# 0.279 seconds (57 times faster)
\text{system.time(for (i in 1:1000) set(DT, i, 1L, i))}
\# 0.002 seconds (7930 times faster, overhead of [.data.table is avoided)
\]

\# However, normally, we call [.data.table *once* on *large* data, not many times on small data.
\# The above is to demonstrate overhead, not to recommend looping in this way. But the option
\# of set() is there if you need it.

\# End(Not run)

---

**address**

**Address in RAM of a variable**

---

**Description**

Returns the pointer address of its argument.
all.equal

Usage

address(x)

Arguments

x Anything.

Details

Sometimes useful in determining whether a value has been copied or not, programmatically.

Value

A character vector length 1.

References

http://stackoverflow.com/a/10913296/403310 (but implemented in C without using .Internal(inspect()))

all.equal

Equality Test Between Two Data Tables

Description

Convenient test of data equality between data.table objects. Performs some factor level stripping.

Usage

## S3 method for class 'data.table'
all.equal(target, current, trim.levels=TRUE, check.attributes=TRUE,
ignore.col.order=FALSE, ignore.row.order=FALSE, tolerance=sqrt(.Machine$double.eps),
...)

Arguments

target, current data.tables to compare
trim.levels A logical indicating whether or not to remove all unused levels in columns that are factors before running equality check. It effect only when check.attributes is TRUE and ignore.row.order is FALSE.
check.attributes A logical indicating whether or not to check attributes, will apply not only to data.table but also attributes of the columns. It will skip c("row.names",".internal.selfref") data.table attributes.
ignore.col.order A logical indicating whether or not to ignore columns order in data.table.
ignore.row.order

A logical indicating whether or not to ignore rows order in data.table. This option requires datasets to use data types on which join can be made, so no support for list, complex, raw, but still supports integer64.

tolerance

A numeric value used when comparing numeric columns, by default sqrt(.Machine$double.eps). Unless non-default value provided it will be forced to 0 if used together with ignore.row.order and duplicate rows detected or factor columns present.

... Passed down to internal call of all.equal.

Details

For efficiency data.table method will exit on detected non-equality issues, unlike most all.equal methods which process equality checks further. Besides that fact it also handles the most time consuming case of ignore.row.order = TRUE very efficiently.

Value

Either TRUE or a vector of mode "character" describing the differences between target and current.

See Also

all.equal

Examples

dt1 <- data.table(A = letters[1:10], X = 1:10, key = "A")
dt2 <- data.table(A = letters[5:14], Y = 1:10, key = "A")
isTRUE(all.equal(dt1, dt1))
is.character(all.equal(dt1, dt2))

# ignore.col.order
x <- copy(dt1)
y <- dt1[, .(X, A)]
all.equal(x, y)
all.equal(x, y, ignore.col.order = TRUE)

# ignore.row.order
x <- setkeyv(copy(dt1), NULL)
y <- dt1[sample(nrow(dt1))]
all.equal(x, y)
all.equal(x, y, ignore.row.order = TRUE)

# check.attributes
x = copy(dt1)
y = setkeyv(copy(dt1), NULL)
all.equal(x, y)
all.equal(x, y, check.attributes = FALSE)

# trim.levels
x <- data.table(A = factor(letters[1:10])[1:4]) # 10 levels
as.data.table

Coerce to data.table

Description

Functions to check if an object is data.table, or coerce it if possible.

Usage

as.data.table(x, keep.rownames=FALSE, ...)

## S3 method for class 'data.table'
as.data.table(x, ...)

## S3 method for class 'array'
as.data.table(x, keep.rownames=FALSE, sorted=TRUE, value.name="value", na.rm=TRUE, ...)

is.data.table(x)

Arguments

x  
An R object.

keep.rownames  
Default is FALSE. If TRUE, adds the input object's names as a separate column named "rn". keep.rownames = "id" names the column "id" instead.

sorted  
logical used in array method, default TRUE.

value.name  
character scalar used in array method, default "value".

na.rm  
logical used in array method, default TRUE will remove rows with NA values.

...  
Additional arguments to be passed to or from other methods.

Details

as.data.table is a generic function with many methods, and other packages can supply further methods.

If a list is supplied, each element is converted to a column in the data.table with shorter elements recycled automatically. Similarly, each column of a matrix is converted separately. character objects are not converted to factor types unlike as.data.frame.

If a data.frame is supplied, all classes preceding "data.frame" are stripped. Similarly, for data.table as input, all classes preceding "data.table" are stripped. as.data.table methods returns a copy of original data. To modify by reference see setDT and setDF.

keep.rownames argument can be used to preserve the (row)names attribute in the resulting data.table.

Examples

```r
nn = c(a=0.1, b=0.2, c=0.3, d=0.4)
as.data.table(nn)
as.data.table(nn, keep.rownames=TRUE)
as.data.table(nn, keep.rownames="rownames")

# char object not converted to factor
cc = c(X="a", Y="b", Z="c")
as.data.table(cc)
as.data.table(cc, keep.rownames=TRUE)
as.data.table(cc, keep.rownames="rownames")

mm = matrix(1:4, ncol=2, dimnames=list(c("r1", "r2"), c("c1", "c2")))
as.data.table(mm)
as.data.table(mm, keep.rownames=TRUE)
as.data.table(mm, keep.rownames="rownames")

ll = list(a=1:2, b=3:4)
as.data.table(ll)
as.data.table(ll, keep.rownames=TRUE)
as.data.table(ll, keep.rownames="rownames")

DF = data.frame(x=rep(c("x","y","z"),each=2), y=c(1,3,6), row.names=LETTERS[1:6])
as.data.table(DF)
as.data.table(DF, keep.rownames=TRUE)
as.data.table(DF, keep.rownames="rownames")

DT = data.table(x=rep(c("x","y","z"),each=2), y=c(1:6))
as.data.table(DT)

ar = rnorm(27)
ar[sample(27, 15)] = NA
dim(ar) = c(3L,3L,3L)
as.data.table(ar)
```

Description

Efficient conversion xts to data.table.

Usage

```r
## S3 method for class 'xts'
as.data.table(x, keep.rownames = TRUE, ...)
```
as.matrix

Convert a data.table to a matrix

Description

Converts a data.table into a matrix, optionally using one of the columns in the data.table as the matrix rownames.

Usage

## S3 method for class 'data.table'
as.matrix(x, rownames, ...)

Arguments

x a data.table

rownames optional, a single column name or column index to use as the rownames in the returned matrix. If TRUE the key of the data.table will be used if it is a single column, otherwise the first column in the data.table will be used. Alternative a vector of length nrow(x) to assign as the row names of the returned matrix.

... additional arguments to be passed to or from methods.

Examples

if (requireNamespace("xts", quietly = TRUE)) {
data(sample_matrix, package = "xts")
sample.xts <- xts::as.xts(sample_matrix)  # xts might not be attached on search path
# print head of xts
print(head(sample.xts))
# print data.table
print(as.data.table(sample.xts))
}
Details

`as.matrix` is a generic function in base R. It dispatches to `as.matrix.data.table` if its `x` argument is a `data.table`.

The method for `data.tables` will return a character matrix if there are only atomic columns and any non-(numeric/logical/complex) column, applying `as.vector` to factors and `format` to other non-character columns. Otherwise, the usual coercion hierarchy (logical < integer < double < complex) will be used, e.g., all-logical data frames will be coerced to a logical matrix, mixed logical-integer will give an integer matrix, etc.

An additional argument `rownames` is provided for `as.matrix.data.table` to facilitate conversions to matrices where the `rownames` are stored in a single column of `x`, e.g. the first column after using `dcast.data.table`.

Value

A new matrix containing the contents of `x`.

See Also

data.table, as.matrix, data.matrix array

Examples

```r
(dt1 <- data.table(A = letters[1:10], X = 1:10, Y = 11:20))
as.matrix(dt1) # character matrix
as.matrix(dt1, rownames = "A")
as.matrix(dt1, rownames = 1)
as.matrix(dt1, rownames = TRUE)

(dt1 <- data.table(A = letters[1:10], X = 1:10, Y = 11:20))
setkey(dt1, A)
as.matrix(dt1, rownames = TRUE)
```

---

**as.xts.data.table**  
Efficient data.table to xts conversion

Description

Efficient conversion of data.table to xts, data.table must have `POSIXct` or `Date` type in first column.

Usage

`as.xts.data.table(x, ...)`

Arguments

- `x` data.table to convert to xts, must have `POSIXct` or `Date` in the first column. All others non-numeric columns will be omitted with warning.
- `...` ignored, just for consistency with generic method.
between

See Also

as.data.table.xts

Examples

```r
if (requireNamespace("xts", quietly = TRUE)) {
  sample.dt <- data.table(date = as.Date((Sys.Date()-999):Sys.Date(), origin="1970-01-01"),
                          quantity = sample(10:50,1000,TRUE),
                          value = sample(100:1000,1000,TRUE))

  # print data.table
  print(sample.dt)
  # print head of xts
  print(head(as.xts.data.table(sample.dt))) # xts might not be attached on search path
}
```

between | Convenience functions for range subsets.

Description

Intended for use in i in [.data.table.

between is equivalent to \( x \geq lower \land x \leq upper \) when incbounds=TRUE, or \( x > lower \land y < upper \) when FALSE.

inrange checks whether each value in \( x \) is in between any of the intervals provided in lower, upper.

Usage

between(x, lower, upper, incbounds=TRUE)
  x %between% y

inrange(x, lower, upper, incbounds=TRUE)
  x %inrange% y

Arguments

x | Any orderable vector, i.e., those with relevant methods for `<=`, such as numeric, character, Date, etc. in case of between and a numeric vector in case of inrange.

lower | Lower range bound.

upper | Upper range bound.

y | A length-2 vector or list, with y[[1]] interpreted as lower and y[[2]] as upper.

incbounds | TRUE means inclusive bounds, i.e., [lower,upper]. FALSE means exclusive bounds, i.e., (lower,upper).

It is set to TRUE by default for infix notations.
Details

From v1.9.8+, between is vectorised. lower and upper are recycled to length(x) if necessary.

non-equi joins were recently implemented in v1.9.8. It extends binary search based joins in data.table to other binary operators including >=, <=, >, <. inrange makes use of this new functionality and performs a range join.

Value

Logical vector as the same length as x with value TRUE for those that lie within the specified range.

Note

Current implementation does not make use of ordered keys for %between%.

See Also

data.table, like, %chin%

Examples

```r
X = data.table(a=1:5, b=6:10, c=c(5:1))
X[b %between% c(7,9)]
X[between(b, 7, 9)] # same as above
# NEW feature in v1.9.8, vectorised between
X[c %between% list(a,b)]
X[between(c, a, b)] # same as above
X[between(c, a, b, incbounds=FALSE)] # open interval

# inrange()
Y = data.table(a=c(8,3,10,7,-10), val=runif(5))
range = data.table(start = 1:5, end = 6:10)
Y[a %inrange% range]
Y[inrange(a, range$start, range$end)] # same as above
Y[inrange(a, range$start, range$end, incbounds=FALSE)] # open interval
```

Usage

chmatch(x, table, nomatch=NA_integer_)
  x %chin% table
chorder(x)
chgroup(x)

Arguments

x            character vector: the values to be matched, or the values to be ordered or grouped
table        character vector: the values to be matched against.
nomatch      the value to be returned in the case when no match is found. Note that it is coerced to integer.

Details

Fast versions of match, %in% and order, optimised for character vectors. chgroup groups together duplicated values but retains the group order (according the first appearance order of each group), efficiently. They have been primarily developed for internal use by data.table, but have been exposed since that seemed appropriate.

Strings are already cached internally by R (CHARSXP) and that is utilised by these functions. No hash table is built or cached, so the first call is the same speed as subsequent calls. Essentially, a counting sort (similar to base::sort.list(x, method="radix"), see setkey) is implemented using the (almost) unused truelength of CHARXP as the counter. Where R has used truelength of CHARXP (where a character value is shared by a variable name), the non zero truelengths are stored first and reinstated afterwards. Each of the ch* functions implements a variation on this theme. Remember that internally in R, length of a CHARXP is the nchar of the string and DATAPTR is the string itself.

Methods that do build and cache a hash table (such as the fastmatch package) are much faster on subsequent calls (almost instant) but a little slower on the first. Therefore chmatch may be particularly suitable for ephemeral vectors (such as local variables in functions) or tasks that are only done once. Much depends on the length of x and table, how many unique strings each contains, and whether the position of the first match is all that is required.

It may be possible to speed up fastmatch’s hash table build time by using the technique in data.table, and we have suggested this to its author. If successful, fastmatch would then be fastest in all cases.

Value

As match and %in%. chorder and chgroup return an integer index vector.

Note

The name charmatch was taken by charmatch, hence chmatch.

See Also

match, %in%
Examples

# Please type 'example(chmatch)' to run this and see timings on your machine

N = 1e5
# N is small here (1e5) to reduce runtime because every day CRAN runs all example sections in all
# manual pages (as well as the package's test suite) using latest R-devel to catch problems early.
# The comments here apply when N has been changed to 1e8. Timings were run on 2018-05-13 with
# R 3.5.0 and data.table 1.11.2.

u = as.character(as.hexmode(1:10000))
y = sample(u,N,replace=TRUE)
x = sample(u)

system.time(a <- match(x,y))       # With N=1e8 ...
system.time(b <- chmatch(x,y))     # 4.6s
identical(a,b)

system.time(a <- x %in% y)         # 4.5s
system.time(b <- x %chin% y)       # 1.7s
identical(a,b)

# Different example with more unique strings ...

u = as.character(as.hexmode(1:(N/10)))
y = sample(u,N,replace=TRUE)
x = sample(u,N,replace=TRUE)

system.time(a <- match(x,y))       # 46s
system.time(b <- chmatch(x,y))     # 16s
identical(a,b)

Description

In data.table parlance, all set* functions change their input by reference. That is, no copy is
made at all, other than temporary working memory, which is as large as one column. The only
other data.table operator that modifies input by reference is :=. Check out the See Also section
below for other set* function data.table provides.

copy() copies an entire object.

Usage

copy(x)

Arguments

x A data.table.
Details

data.table provides functions that operate on objects by reference and minimise full object copies as much as possible. Still, it might be necessary in some situations to work on an object’s copy which can be done using DT.copy <- copy(DT). It may also be sometimes useful before := (or set) is used to subassign to a column by reference.

A copy() may be required when doing dt_names = names(DT). Due to R’s copy-on-modify, dt_names still points to the same location in memory as names(DT). Therefore modifying DT by reference now, say by adding a new column, dt_names will also get updated. To avoid this, one has to explicitly copy: dt_names <- copy(names(DT)).

Value

Returns a copy of the object.

See Also

data.table, setkey, setDT, setDF, set :=, setorder, setattr, setnames

Examples

# Type 'example(copy)' to run these at prompt and browse output

DT = data.table(A=5:1, B=letters[5:1])
DT2 = copy(DT)  # explicit copy() needed to copy a data.table
setkey(DT2,B)   # now just changes DT2
identical(DT,DT2) # FALSE. DT and DT2 are now different tables

DT = data.table(A=5:1, B=letters[5:1])
nm1 = names(DT)
nm2 = copy(names(DT))
DT[, C := 1L]
identical(nm1, names(DT)) # TRUE, nm1 is also changed by reference
identical(nm2, names(DT)) # FALSE, nm2 is a copy, different from names(DT)

data.table-class  S4 Definition for data.table

Description

A data.table can be used in S4 class definitions as either a parent class (inside a contains argument of setClass), or as an element of an S4 slot.

Author(s)

Steve Lianoglou

See Also

data.table
Examples

```r
## Used in inheritance.
setClass('SuperDataTable', contains='data.table')

## Used in a slot
setClass('Something', representation(x='character', dt='data.table'))
x <- new("Something", x='check', dt=data.table(a=1:10, b=11:20))
```

Description
data.table internally optimises certain expressions in order to improve performance. This section briefly summarises those optimisations.

Note that there’s no additional input needed from the user to take advantage of these optimisations. They happen automatically.

Run the code under the example section to get a feel for the performance benefits from these optimisations.

Details
data.table reads the global option `datatable.optimize` to figure out what level of optimisation is required. The default value `Inf` activates all available optimisations.

At optimisation level $\geq 1$, i.e., `getOption("datatable.optimize") $\geq 1`, these are the optimisations:

- The base function `order` is internally replaced with `data.table`’s fast ordering. That is, `DT[order(...)]] gets internally optimised to `DT[forder(...)].`
- The expression `DT[, lapply(.SD, fun), by=.]` gets optimised to `DT[, list(fun(a), fun(b), ...), by=.]` where `a,b, ...` are columns in `.SD`. This improves performance tremendously.
- Similarly, the expression `DT[, c(.N, lapply(.SD, fun)), by=.]` gets optimised to `DT[, list(.N, fun(a), fun(b), ...)]`. `.N` is just for example here.
- `base::mean` function is internally optimised to use `data.table`’s fast `mean` function. `mean()` from `base` is an S3 generic and gets slow with many groups.

At optimisation level $\geq 2$, i.e., `getOption("datatable.optimize") >= 2, additional optimisations are implemented on top of the optimisations already shown above.

- Expressions in `j` which contain only the functions `min`, `max`, `mean`, `median`, `var`, `sd`, `sum`, `prod`, `first`, `last`, `head`, `tail` (for example, `DT[, list(mean(x), median(x), min(y), max(y)), by=z])`, they are very effectively optimised using what we call `GForce`. These functions are automatically replaced with a corresponding `GForce` version with pattern `g*`, e.g., `prod` becomes `gprod`.

Normally, once the rows belonging to each group are identified, the values corresponding to the group are gathered and the `j`-expression is evaluated. This can be improved by computing
the result directly without having to gather the values or evaluating the expression for each
group (which can get costly with large number of groups) by implementing it specifically for
a particular function. As a result, it is extremely fast.

- In addition to all the functions above, ‘N’ is also optimised to use GForce, when used sep-
  arately or when combined with the functions mentioned above. Note further that GForce-
  optimized functions must be used separately, i.e., code DT[ , max(x) - min(x), by=z] will not
  currently be optimized to use gmax, gmin.
- Expressions of the form DT[i, j, by] are also optimised when i is a subset operation and j
  is any/all of the functions discussed above.

At optimisation level >= 3, i.e., getOption("datatable.optimize") >= 3, additional optimisations
for subsets in i are implemented on top of the optimisations already shown above. Subsetting
operations are - if possible - translated into joins to make use of blazing fast binary search using
indices and keys. The following queries are optimized:

- Supported operators: ==, %in%. Non-equi operators(>, <, etc.) are not supported yet because
  non-equi joins are slower than vector based subsets.
- Queries on multiple columns are supported, if the connector is &, e.g. DT[x == 2 & y == 3]
  is supported, but DT[x == 2 | y == 3] is not.
- Optimization will currently be turned off when doing subset when cross product of elements
  provided to filter on exceeds > 1e4. This most likely happens if multiple %in%, or %chin%
  queries are combined, e.g. DT[x %in% 1:100 & y %in% 1:200] will not be optimized since
  100 * 200 = 2e4 > 1e4.
- Queries with multiple criteria on one column are not supported, e.g. DT[x == 2 & x %in% c(2,5)]
  is not supported.
- Queries with non-missing j are supported, e.g. DT[x == 3 & y == 5, .(new = x-y)]
  or DT[x == 3 & y == 5, new := x-y] are supported. Also extends to queries using
  with = FALSE.
- "notjoin" queries, i.e. queries that start with !, are only supported if there are no & connections,
  e.g. DT[!x==3] is supported, but DT[!x==3 & y == 4] is not.

If in doubt, whether your query benefits from optimization, call it with the verbose = TRUE
argument. You should see "Optimized subsetting...".

Auto indexing: In case a query is optimized, but no appropriate key or index is found, data.table
automatically creates an index on the first run. Any successive subsets on the same column then
reuse this index to binary search (instead of vector scan) and is therefore fast. Auto indexing can
be switched off with the global option options(data.table.auto.index = FALSE). To switch off
using existing indices set global option options(data.table.use.index = FALSE).

system.time(DT[id in 100:500]) # vector scan

options(datatable.optimize = 3L)
system.time(ans1 <- DT[id==100L]) # index + binary search subset
system.time(ans2 <- DT[id==100L]) # only binary search subset
system.time(DT[id in 100:500]) # only binary search subset again

## End(Not run)
dcast.data.table

**Fast dcast for data.table**

**Description**

dcast.data.table is a much faster version of reshape2::dcast, but for data.tables. More importantly, it’s capable of handling very large data quite efficiently in terms of memory usage in comparison to reshape2::dcast.

From 1.9.6, dcast is implemented as an S3 generic in data.table. To melt or cast data.tables, it is not necessary to load reshape2 any more. If you have load reshape2, do so before loading data.table to prevent unwanted masking.

**NEW**: dcast.data.table can now cast multiple value.var columns and also accepts multiple functions to fun.aggregate. See Examples for more.

**Usage**

```r
# S3 method for class 'data.table'
dcast(data, formula, fun.aggregate = NULL, sep = " ",
   ..., margins = NULL, subset = NULL, fill = NULL,
   drop = TRUE, value.var = guess(data),
   verbose =getOption("datatable.verbose")
```

**Arguments**

- `data` A data.table.
- `formula` A formula of the form LHS ~ RHS to cast, see Details.
- `fun.aggregate` Should the data be aggregated before casting? If the formula doesn’t identify a single observation for each cell, then aggregation defaults to length with a message.
  
  **NEW**: it is possible to provide a list of functions to fun.aggregate. See Examples.

- `sep` Character vector of length 1, indicating the separating character in variable names generated during casting. Default is _ for backwards compatibility.

- `...` Any other arguments that may be passed to the aggregating function.

- `margins` Not implemented yet. Should take variable names to compute margins on. A value of TRUE would compute all margins.

- `subset` Specified if casting should be done on a subset of the data. Ex: subset = .(col1 <= 5) or subset = .(variable != "January").

- `fill` Value with which to fill missing cells. If fun.aggregate is present, takes the value by applying the function on a 0-length vector.

- `drop` FALSE will cast by including all missing combinations.

  **NEW**: Following #1512, c(FALSE, TRUE) will only include all missing combinations of formula LHS. And c(TRUE, FALSE) will only include all missing combinations of formula RHS. See Examples.
**value.var**  
Name of the column whose values will be filled to cast. Function `guess()` tries to, well, guess this column automatically, if none is provided.  
**NEW:** it is now possible to cast multiple `value.var` columns simultaneously. See Examples.

**verbose**  
Not used yet. May be dropped in the future or used to provide informative messages through the console.

### Details
The cast formula takes the form LHS ~ RHS, ex: `var1 + var2 ~ var3`. The order of entries in the formula is essential. There are two special variables: . and .... represents no variable; ... represents all variables not otherwise mentioned in formula; see Examples.

dcast also allows `value.var` columns of type list.

When variable combinations in formula doesn’t identify a unique value in a cell, `fun.aggregate` will have to be specified, which defaults to `length` if unspecified. The aggregating function should take a vector as input and return a single value (or a list of length one) as output. In cases where `value.var` is a list, the function should be able to handle a list input and provide a single value or list of length one as output.

If the formula’s LHS contains the same column more than once, ex: `dcast(DT, x+x~ y)`, then the answer will have duplicate names. In those cases, the duplicate names are renamed using `make.unique` so that key can be set without issues.

Names for columns that are being cast are generated in the same order (separated by an underscore, `_`) from the (unique) values in each column mentioned in the formula RHS.

From v1.9.4, dcast tries to preserve attributes wherever possible.

**NEW:** From v1.9.6, it is possible to cast multiple `value.var` columns and also cast by providing multiple `fun.aggregate` functions. Multiple `fun.aggregate` functions should be provided as a list, for e.g., `list(mean, sum, function(x) paste(x, collapse=""))`. `value.var` can be either a character vector or list of length=1, or a list of length equal to `length(fun.aggregate)`. When `value.var` is a character vector or a list of length 1, each function mentioned under `fun.aggregate` is applied to every column specified under `value.var` column. When `value.var` is a list of length equal to `length(fun.aggregate)` each element of `fun.aggregate` is applied to each element of `value.var` column.

### Value
A keyed data.table that has been cast. The key columns are equal to the variables in the formula LHS in the same order.

### See Also
melt.data.table, rowid, https://cran.r-project.org/package=reshape

### Examples
```r
require(data.table)
names(ChickWeight) <- tolower(names(ChickWeight))
DT <- melt(as.data.table(ChickWeight), id=2:4) # calls melt.data.table
```
# dcast is an S3 method in data.table from v1.9.6

dcast(DT, time ~ variable, fun=mean)
dcast(DT, diet ~ variable, fun=mean)
dcast(DT, diet+chick ~ time, drop=FALSE)
dcast(DT, diet+chick ~ time, drop=FALSE, fill=0)

# using subset
dcast(DT, chick ~ time, fun=mean, subset=(time < 10 & chick < 20))

# drop argument, #1512
DT <- data.table(v1 = c(1.1, 1.1, 1.1, 2.2, 2.2, 2.2),
v2 = factor(c('1L', '1L', '1L', '3L', '3L', '3L'), levels=1:3),
v3 = factor(c('2L', '2L', '2L', '6L', '6L', '6L'), levels=1:6),
v4 = c(3L, 2L, 2L, 5L, 4L, 3L))
# drop=TRUE
dcast(DT, v1 + v2 ~ v3)                      # default is drop=TRUE
dcast(DT, v1 + v2 ~ v3, drop=FALSE)         # all missing combinations of both LHS and RHS
dcast(DT, v1 + v2 ~ v3, drop=(FALSE, TRUE)) # all missing combinations of only LHS

dcast(DT, v1 + v2 ~ v3, drop=(TRUE, FALSE)) # all missing combinations of only RHS

# using . and ...
DT <- data.table(v1 = rep(1:2, each = 6),
                 v2 = rep(rep(1:3, 2), each = 2),
                 v3 = rep(1:2, 6),
                 v4 = rnorm(6))
dcast(DT, ... ~ v3, value.var = "v4")  # same as v1 + v2 ~ v3, value.var = "v4"
dcast(DT, v1 + v2 + v3 ~ ., value.var = "v4")

## for each combination of (v1, v2), add up all values of v4
dcast(DT, v1 + v2 ~ ., value.var = "v4", fun.aggregate = sum)

## Not run:
# benchmark against reshape2's dcast, minimum of 3 runs
set.seed(45)
DT <- data.table(aa=sample(1e4, 1e6, TRUE),
                 bb=sample(1e3, 1e6, TRUE),
                 cc = sample(letters[1:6], 1e6, TRUE),
                 dd=runif(1e6))
system.time(dcast(DT, aa ~ cc, fun=sum))  # 0.12 seconds
system.time(dcast(DT, bb ~ cc, fun=mean))  # 0.04 seconds
# reshape2::dcast takes 31 seconds
system.time(dcast(DT, aa + bb ~ cc, fun=sum))  # 1.2 seconds

## End(Not run)

# NEW FEATURE - multiple value.var and multiple fun.aggregate
DT = data.table(x=sample(5,20,TRUE),
y=sample(2,20,TRUE),
z=sample(letters[1:2], 20,TRUE),
d1 = runif(20),
d2=1L)
# multiple value.var

dcast(DT, x + y ~ z, fun=sum, value.var=c("d1","d2"))
# multiple fun.aggregate

dcast(DT, x + y ~ z, fun=list(sum, mean), value.var="d1")
# multiple fun.agg and value.var (all combinations)
dcast(DT, x + y - z, fun=list(sum, mean), value.var=c("d1", "d2"))
# multiple fun.agg and value.var (one-to-one)
dcast(DT, x + y - z, fun=list(sum, mean), value.var=list("d1", "d2"))

---

duplicated 

**Determine Duplicate Rows**

**Description**

duplicated returns a logical vector indicating which rows of a data.table are duplicates of a row with smaller subscripts.

unique returns a data.table with duplicated rows removed, by columns specified in by argument. When no by then duplicated rows by all columns are removed.

anyDuplicated returns the index i of the first duplicated entry if there is one, and 0 otherwise.

uniqueN is equivalent to length(unique(x)) when x is an atomic vector, and nrow(unique(x)) when x is a data.frame or data.table. The number of unique rows are computed directly without materialising the intermediate unique data.table and is therefore faster and memory efficient.

**Usage**

```r
## S3 method for class 'data.table'
duplicated(x, incomparables=FALSE, fromLast=FALSE, by=seq_along(x), ...)

## S3 method for class 'data.table'
unique(x, incomparables=FALSE, fromLast=FALSE, by=seq_along(x), ...)

## S3 method for class 'data.table'
anyDuplicated(x, incomparables=FALSE, fromLast=FALSE, by=seq_along(x), ...)

uniqueN(x, by=if (is.list(x)) seq_along(x) else NULL, na.rm=FALSE)
```

**Arguments**

- `x` A data.table. uniqueN accepts atomic vectors and data.frames as well.
- `...` Not used at this time.
- `incomparables` Not used. Here for S3 method consistency.
- `fromLast` logical indicating if duplication should be considered from the reverse side, i.e., the last (or rightmost) of identical elements would correspond to duplicated = FALSE.
- `by` character or integer vector indicating which combinations of columns from x to use for uniqueness checks. By default all columns are being used. That was changed recently for consistency to data.frame methods. In version < 1.9.8 default was key(x).
- `na.rm` Logical (default is FALSE). Should missing values (including NaN) be removed?
Details

Because data.tables are usually sorted by key, tests for duplication are especially quick when only
the keyed columns are considered. Unlike `unique.data.frame`, `paste` is not used to ensure equal-
ity of floating point data. It is instead accomplished directly and is therefore quite fast. `data.table`
provides `setNumericRounding` to handle cases where limitations in floating point representation is
undesirable.

v1.9.4 introduces `anyDuplicated` method for data.tables and is similar to base in functionality. It
also implements the logical argument `fromLast` for all three functions, with default value `FALSE`.

Value

duplicated returns a logical vector of length `nrow(x)` indicating which rows are duplicates.
unique returns a data table with duplicated rows removed.
anyDuplicated returns a integer value with the index of first duplicate. If none exists, 0L is re-
turned.
uniqueN returns the number of unique elements in the vector, `data.frame` or `data.table`.

Examples

```r
DT <- data.table(A = rep(1:3, each=4), B = rep(1:4, each=3),
C = rep(1:2, 6), key = "A,B")
duplicated(DT)
unique(DT)

Duplicated(DT, by="B")
unique(DT, by="B")

duplicated(DT, by=c("A", "C"))
unique(DT, by=c("A", "C"))

DT = data.table(a=c(2L,1L,2L), b=c(1L,2L,1L))  # no key
unique(DT)                                   # rows 1 and 2 (row 3 is a duplicate of row 1)

DT = data.table(a=c(3.142, 4.2, 4.2, 3.142, 1.223, 1.223), b=rep(1,6))
unique(DT)                                   # rows 1,2 and 5

DT = data.table(a=tan(pi*(1/4 + 1:10)), b=rep(1,10))  # example from ?all.equal
length(unique(DT$a))                           # 10 strictly unique floating point values
all.equal(DT$a,rep(1,10))                      # TRUE, all within tolerance of 1.0
DT[which.min(a)]                              # row 10, the strictly smallest floating point value
identical(unique(DT),DT[1])                    # TRUE, stable within tolerance
identical(unique(DT),DT[10])                   # FALSE

# fromLast=TRUE
```
DT <- data.table(A = rep(1:3, each=4), B = rep(1:4, each=3),
                  C = rep(1:2, 6), key = "A,B")
duplicated(DT, by="B", fromLast=TRUE)
unique(DT, by="B", fromLast=TRUE)

# anyDuplicated
anyDuplicated(DT, by=c("A", "B"))  # 3L
any(duplicated(DT, by=c("A", "B")))  # TRUE

# uniqueN, unique rows on key columns
uniqueN(DT, by = key(DT))
# uniqueN, unique rows on all columns
uniqueN(DT)
# uniqueN while grouped by "A"
DT[, .(uN=uniqueN(.SD)), by=A]

# uniqueN's na.rm=TRUE
x = sample(c(NA, NaN, runif(3)), 10, TRUE)
uniqueN(x, na.rm = FALSE)  # 5, default
uniqueN(x, na.rm=TRUE)  # 3

first

First item of an object

Description

Returns the first item of a vector or list, or the first row of a data.frame or data.table.

Usage

first(x, ...)

Arguments

x

A vector, list, data.frame or data.table. Otherwise the S3 method of xts::first is deployed.

...

Not applicable for data.table::first. Any arguments here are passed through to xts::first.

Value

If no other arguments are supplied it depends on the type of x. The first item of a vector or list. The first row of a data.frame or data.table. Otherwise, whatever xts::first returns (if package xts has been loaded, otherwise a helpful error).

If any argument is supplied in addition to x (such as n or keep in xts::first), regardless of x's type, then xts::first is called if xts has been loaded, otherwise a helpful error.
See Also

NROW, head, tail, last

Examples

```r
first(1:5) # [1] 1
x = data.table(x=1:5, y=6:10)
first(x) # same as x[1]
```

Description

A fast binary-search based overlap join of two `data.table` objects. This is very much inspired by `findOverlaps` function from the Bioconductor package IRanges (see link below under See Also).

Usually, `x` is a very large `data.table` with small interval ranges, and `y` is much smaller keyed `data.table` with relatively larger interval spans. For a usage in genomics, see the examples section.

NOTE: This is still under development, meaning it’s stable, but some features are yet to be implemented. Also, some arguments and/or the function name itself could be changed.

Usage

```r
foverlaps(x, y, by.x = if (!is.null(key(x))) key(x) else key(y),
            by.y = key(y), maxgap = 0L, minoverlap = 1L,
            type = c("any", "within", "start", "end", "equal"),
            mult = c("all", "first", "last"),
            nomatch = getOption("datatable.nomatch"),
            which = FALSE, verbose = getOption("datatable.verbose"))
```

Arguments

- `x, y` `data.tables`. `y` needs to be keyed, but not necessarily `x`. See examples.
- `by.x, by.y` A vector of column names (or numbers) to compute the overlap joins. The last two columns in both `by.x` and `by.y` should each correspond to the start and end interval columns in `x` and `y` respectively. And the start column should always be `<=` end column. If `x` is keyed, `by.x` is equal to `key(x)`, else `key(y)`. `by.y` defaults to `key(y)`.
- `maxgap` It should be a non-negative integer value, >= 0. Default is 0 (no gap). For intervals `[a,b]` and `[c,d]`, where `a<=b` and `c<=d`, when `c > b` or `d < a`, the two intervals don’t overlap. If the gap between these two intervals is <= `maxgap`, these two intervals are considered as overlapping. Note: This is not yet implemented.
f overlaps

minoverlap  It should be a positive integer value, > 0. Default is 1. For intervals \([a, b]\) and \([c, d]\), where \(a < b\) and \(c < d\), when \(c < b\) and \(d > a\), the two intervals overlap. If the length of overlap between these two intervals is \(\geq \text{minoverlap}\), then these two intervals are considered to be overlapping. Note: This is not yet implemented.

type  Default value is any. Allowed values are any, within, start, end and equal. Note: equal is not yet implemented. But this is just a normal join of the type \(y[x, \ldots]\), unless you require also using maxgap and minoverlap arguments. The types shown here are identical in functionality to the function \(\text{findoverlaps}\) in the bioconductor package IRanges. Let \([a, b]\) and \([c, d]\) be intervals in \(x\) and \(y\) with \(a < b\) and \(c < d\). For type="start", the intervals overlap iff \(a = c\). For type="end", the intervals overlap iff \(b = d\). For type="within", the intervals overlap iff \(a < c\) and \(b < d\). For type="equal", as long as \(c < b\) and \(d > a\), they overlap. In addition to these requirements, they also have to satisfy the minoverlap argument as explained above.

NB: maxgap argument, when > 0, is to be interpreted according to the type of the overlap. This will be updated once maxgap is implemented.

mult  When multiple rows in \(y\) match to the row in \(x\), mult= controls which values are returned - "all" (default), "first" or "last".

nomatch  Same as nomatch in match. When a row (with interval say, \([a, b]\)) in \(x\) has no match in \(y\), nomatch=NA (default) means NA is returned for \(y\)'s non-by\(y\) columns for that row of \(x\). nomatch=0 means no rows will be returned for that row of \(x\). The default value (used when nomatch is not supplied) can be changed from NA to 0 using options(datatable.nomatch=0).

which  When TRUE, if mult="all" returns a two column data.table with the first column corresponding to \(x\)'s row number and the second corresponding to \(y\)'s. when nomatch=NA, no matches return NA for \(y\), and if nomatch=0, those rows where no match is found will be skipped; if mult="first" or "last", a vector of length equal to the number of rows in \(x\) is returned, with no-match entries filled with NA or 0 corresponding to the nomatch argument. Default is FALSE, which returns a join with the rows in \(y\).

verbose  TRUE turns on status and information messages to the console. Turn this on by default using options(datatable.verbose=TRUE). The quantity and types of verbosity may be expanded in future.

Details

Very briefly, f overlaps() collapses the two-column interval in \(y\) to one-column of unique values to generate a lookup table, and then performs the join depending on the type of overlap, using the already available binary search feature of data.table. The time (and space) required to generate the lookup is therefore proportional to the number of unique values present in the interval columns of \(y\) when combined together.

Overlap joins takes advantage of the fact that \(y\) is sorted to speed-up finding overlaps. Therefore \(y\) has to be keyed (see ?setkey) prior to running f overlaps(). A key on \(x\) is not necessary, although it might speed things further. The columns in by\(x\) argument should correspond to the columns specified in by\(y\). The last two columns should be the interval columns in both by\(x\) and by\(y\).
The first interval column in \(by.x\) should always be \(<=\) the second interval column in \(by.x\), and likewise for \(by.y\). The storage.mode of the interval columns must be either double or integer. It therefore works with bit64::integer64 type as well.

The lookup generation step could be quite time consuming if the number of unique values in \(y\) are too large (ex: in the order of tens of millions). There might be improvements possible by constructing lookup using RLE, which is a pending feature request. However most scenarios will not have too many unique values for \(y\).

**Value**

A new data.table by joining over the interval columns (along with other additional identifier columns) specified in \(by.x\) and \(by.y\).

**NB:** When which = TRUE: a) mult = “first” or ”last” returns a vector of matching row numbers in \(y\), and b) when mult = “all” returns a data.table with two columns with the first containing row numbers of \(x\) and the second column with corresponding row numbers of \(y\).

nomatch = NA or \(0\) also influences whether non-matching rows are returned or not, as explained above.

**See Also**

**Examples**

```
require(data.table)
## simple example:
x = data.table(start=c(5,31,22,16), end=c(8,50,25,18), val2 = 7:10)
y = data.table(start=c(10, 20, 30), end=c(15, 35, 45), val1 = 1:3)
setkey(y, start, end)
foverlaps(x, y, type="any", which=TRUE) ## return overlap indices
foverlaps(x, y, type="any") ## return overlap join
foverlaps(x, y, type="any", mult="first") ## returns only first match
foverlaps(x, y, type="within") ## matches iff 'x' is within 'y'

## with extra identifiers (ex: in genomics)
x = data.table(chr=c("Chr1", "Chr1", "Chr2", "Chr2", "Chr2"),
              start=c(5,10, 1, 25, 50), end=c(11,20,4,52,60))
y = data.table(chr=c("Chr1", "Chr1", "Chr2"), start=c(1, 15,1),
              end=c(4, 18, 55), geneid=letters[1:3])
setkey(y, chr, start, end)
foverlaps(x, y, type="any", which=TRUE)
foverlaps(x, y, type="any")
foverlaps(x, y, type="any", nomatch=0L)
foverlaps(x, y, type="within", which=TRUE)
foverlaps(x, y, type="within")
foverlaps(x, y, type="start")

## x and y have different column names - specify by.x
x = data.table(seq=c("Chr1", "Chr1", "Chr2", "Chr2"),
              start=c(5,10, 1, 25, 50), end=c(11,20,4,52,60))
```
frank

Description

Similar to base::rank but much faster. And it accepts vectors, lists, data.frames or data.tables as input. In addition to the ties.method possibilities provided by base::rank, it also provides ties.method="dense". bit64::integer64 type is also supported.

Usage

frank(x, ..., na.last=TRUE, ties.method=c("average", "first", "random", "max", "min", "dense"))

frankv(x, cols=seq_along(x), order=1L, na.last=TRUE, ties.method=c("average", "first", "random", "max", "min", "dense"))

Arguments

x A vector, or list with all it’s elements identical in length or data.frame or data.table.

... Only for lists, data.frames and data.tables. The columns to calculate ranks based on. Do not quote column names. If ... is missing, all columns are considered by default. To sort by a column in descending order prefix a "-", e.g., frank(x, a, -b, c). The -b works when b is of type character as well.

cols A character vector of column names (or numbers) of x, to which obtain ranks for.

order An integer vector with only possible values of 1 and -1, corresponding to ascending and descending order. The length of order must be either 1 or equal to that of cols. If length(order) == 1, it’s recycled to length(cols).

na.last Control treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed; if "keep" they are kept with rank NA.

ties.method A character string specifying how ties are treated, see Details.
Details

To be consistent with other `data.table` operations, NAs are considered identical to other NAs (and NaNs to other NaNs), unlike base::rank. Therefore, for `na.last=TRUE` and `na.last=FALSE`, NAs (and NaNs) are given identical ranks, unlike `rank`.

`frank` is not limited to vectors. It accepts `data.tables` (and `lists` and `data.frames`) as well. It accepts unquoted column names (with names preceded with a `-` sign for descending order, even on character vectors), for e.g., `frank(DT, a, -b, c, ties.method="first")` where `a,b,c` are columns in `DT`. The equivalent in `frankv` is the `order` argument.

In addition to the `ties.method` values possible using base’s `rank`, it also provides another additional argument "dense" which returns the ranks without any gaps in the ranking. See examples.

Value

A numeric vector of length equal to `NROW(x)` (unless `na.last = NA`, when missing values are removed). The vector is of integer type unless `ties.method = "average"` when it is of double type (irrespective of ties).

See Also

data.table, setkey, setorder

Examples

# on vectors
x = c(4, 1, 4, NA, 1, NA, 4)
# NAs are considered identical (unlike base R)
# default is average
frankv(x) # na.last=TRUE
frankv(x, na.last=FALSE)

# ties.method = min
frankv(x, ties.method="min")
# ties.method = dense
frankv(x, ties.method="dense")

# on data.table
DT = data.table(x, y=c(1, 1, 1, 0, NA, 0, 2))
frankv(DT, cols="x") # same as frankv(x) from before
frankv(DT, cols="x", na.last="keep")
frankv(DT, cols="x", ties.method="dense", na.last=NA)
frank(DT, x, ties.method="dense", na.last=NA) # equivalent of above using frank
# on both columns
frankv(DT, ties.method="first", na.last="keep")
frankv(DT, ties.method="first", na.last="keep") # equivalent of above using frank

# order argument
frankv(DT, -y, ties.method="first")
# equivalent of above using frankv
frankv(DT, order=c(1L, -1L), ties.method="first")
**Description**

Similar to `read.table` but faster and more convenient. All controls such as `sep`, `colClasses` and `nrows` are automatically detected. `bit64::integer64` types are also detected and read directly without needing to read as character before converting.

Dates are read as character currently. They can be converted afterwards using the excellent `fasttime` package or standard base functions.

‘fread’ is for regular delimited files; i.e., where every row has the same number of columns. In future, secondary separator (`sep2`) may be specified within each column. Such columns will be read as type `list` where each cell is itself a vector.

**Usage**

```r
fread(input, file = "auto", sep = "auto", dec = ".", quote = "\"",
nrows = Inf, header = "auto",
na.strings =getOption("datatable.na.strings", "NA"),
# due to change to ""; see NEWS
stringsAsFactors = FALSE, verbose = getOption("datatable.verbose", FALSE),
skip = "__auto__", select = NULL, drop = NULL, colClasses = NULL,
imong64 = getOption("datatable.integer64", "integer64"),
col.names,
check.names = FALSE, encoding = "unknown",
strip.white = TRUE, fill = FALSE, blank.lines.skip = FALSE,
key = NULL, index = NULL,
showProgress = getOption("datatable.showProgress", interactive()),
data.table = getOption("datatable.freaddatatable", TRUE),
nThread = getDTthreads(),
logical01 = getOption("datatable.logical01", FALSE),
# due to change to TRUE; see NEWS
autostart = NA )
```

**Arguments**

- **input**
  Either the file name to read (containing no \n character), a shell command that pre-processes the file (e.g. `fread("grep blah filename")`) or the input itself as a string (containing at least one \n), see examples. In both cases, a length 1 character string. A filename input is passed through `path.expand` for convenience. input can also be a URL starting with `http://` or `file://`; see Details.

- **sep**
  The separator between columns. Defaults to the character in the set [,\t \;:] that separates the sample of rows into the most number of lines with the same number of fields. Use `NULL` or "" to specify no separator; i.e. each line a single character column like `base::readLines` does.
sep2

The separator within columns. A list column will be returned where each cell is a vector of values. This is much faster using less working memory than `strsplit` afterwards or similar techniques. For each column `sep2` can be different and is the first character in the same set above [, \t \;], other than `sep`, that exists inside each field outside quoted regions in the sample. NB: `sep2` is not yet implemented.

nrows

The maximum number of rows to read. Unlike `read.table`, you do not need to set this to an estimate of the number of rows in the file for better speed because that is already automatically determined by `fread` almost instantly using the large sample of lines. `nrows=0` returns the column names and typed empty columns determined by the large sample; useful for a dry run of a large file or to quickly check format consistency of a set of files before starting to read any of them.

header

Does the first data line contain column names? Defaults according to whether every non-empty field on the first data line is type character. If so, or `TRUE` is supplied, any empty column names are given a default name.

na.strings

A character vector of strings which are to be interpreted as `NA` values. By default, `"\,"` for columns of all types, including type `character` is read as `NA` for consistency. `"\"\"`, is unambiguous and read as an empty string. To read `,NA`, as `NA`, set `na.strings="NA"`. To read , as blank string `""`, set `na.strings=NULL`. When they occur in the file, the strings in `na.strings` should not appear quoted since that is how the string literal `,"NA"`, is distinguished from `,NA`, for example, when `na.strings="NA"`.

file

File path, useful when we want to ensure that no shell commands will be executed. File path can also be provided to `input` argument.

stringsAsFactors

Convert all character columns to factors?

verbose

Be chatty and report timings?

skip

If 0 (default) start on the first line and from there finds the first row with a consistent number of columns. This automatically avoids irregular header information before the column names row. `skip>0` means ignore the first `skip` rows manually. `skip="string"` searches for "string" in the file (e.g. a substring of the column names row) and starts on that line (inspired by `read.xls` in package `gdata`).

select

Vector of column names or numbers to keep, drop the rest.

drop

Vector of column names or numbers to drop, keep the rest.

colClasses

A character vector of classes (named or unnamed), as `read.csv`. Or a named list of vectors of column names or numbers, see examples. `colClasses` in `fread` is intended for rare overrides, not for routine use. `fread` will only promote a column to a higher type if `colClasses` requests it. It won’t downgrade a column to a lower type since NAs would result. You have to coerce such columns afterwards yourself, if you really require data loss.

integer64

"integer64" (default) reads columns detected as containing integers larger than $2^{31}$ as type `bit64::integer64`. Alternatively, "double" | "numeric" reads as `base::read.csv` does; i.e., possibly with loss of precision and if so silently. Or, "character".
dec
The decimal separator as in base::read.csv. If not "." (default) then usually ",". See details.

col.names
A vector of optional names for the variables (columns). The default is to use the header column if present or detected, or if not "V" followed by the column number. This is applied after check.names and before key and index.

check.names
default is FALSE. If TRUE then the names of the variables in the data.table are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by make.names) so that they are, and also to ensure that there are no duplicates.

encoding
default is "unknown". Other possible options are "UTF-8" and "Latin-1". Note: it is not used to re-encode the input, rather enables handling of encoded strings in their native encoding.

quote
By default ("\""), if a field starts with a double quote, fread handles embedded quotes robustly as explained under Details. If it fails, then another attempt is made to read the field as is, i.e., as if quotes are disabled. By setting quote="\", the field is always read as if quotes are disabled. It is not expected to ever need to pass anything other than \"\" to quote; i.e., to turn it off.

strip.white
default is TRUE. Strips leading and trailing whitespaces of unquoted fields. If FALSE, only header trailing spaces are removed.

fill
logical (default is FALSE). If TRUE then in case the rows have unequal length, blank fields are implicitly filled.

blank.lines.skip
logical, default is FALSE. If TRUE blank lines in the input are ignored.

key
Character vector of one or more column names which is passed to setkey. It may be a single comma separated string such as key="x,y,z", or a vector of names such as key=c("x","y","z"). Only valid when argument data.table=TRUE. Where applicable, this should refer to column names given in col.names.

index
Character vector or list of character vectors of one or more column names which is passed to setindexv. As with key, comma-separated notation like index="x,y,z" is accepted for convenience. Only valid when argument data.table=TRUE. Where applicable, this should refer to column names given in col.names.

showProgress
TRUE displays progress on the console if the ETA is greater than 3 seconds. It is produced in fread's C code where the very nice (but R level) txtProgressBar and tkProgressbar are not easily available.

data.table
TRUE returns a data.table. FALSE returns a data.frame.

nThread
The number of threads to use. Experiment to see what works best for your data on your hardware.

logical01
If TRUE a column containing only 0s and 1s will be read as logical, otherwise as integer.

autostart
Deprecated and ignored with warning. Please use skip instead.

Details
A sample of 10,000 rows is used for a very good estimate of column types. 100 contiguous rows are read from 100 equally spaced points throughout the file including the beginning, middle and the
fread

very end. This results in a better guess when a column changes type later in the file (e.g. blank at the beginning/only populated near the end, or 001 at the start but 0A0 later on). This very good type guess enables a single allocation of the correct type up front once for speed, memory efficiency and convenience of avoiding the need to set colClasses after an error. Even though the sample is large and jumping over the file, it is almost instant regardless of the size of the file because a lazy on-demand memory map is used. If a jump lands inside a quoted field containing newlines, each newline is tested until 5 lines are found following it with the expected number of fields. The lowest type for each column is chosen from the ordered list: logical, integer, integerVT, double, character. Rarely, the file may contain data of a higher type in rows outside the sample (referred to as an out-of-sample type exception). In this event fread will automatically reread just those columns from the beginning so that you don’t have the inconvenience of having to set colClasses yourself; particularly helpful if you have a lot of columns. Such columns must be read from the beginning to correctly distinguish “00” from “000” when those have both been interpreted as integer 0 due to the sample but 00A occurs out of sample. Set verbose=TRUE to see a detailed report of the logic deployed to read your file.

There is no line length limit, not even a very large one. Since we are encouraging list columns (i.e. sep2) this has the potential to encourage longer line lengths. So the approach of scanning each line into a buffer first and then rescanning that buffer is not used. There are no buffers used in fread’s C code at all. The field width limit is limited by R itself: the maximum width of a character string (currently 2^31-1 bytes, 2GB).

The filename extension (such as .csv) is irrelevant for “auto” sep and sep2. Separator detection is entirely driven by the file contents. This can be useful when loading a set of different files which may not be named consistently, or may not have the extension .csv despite being csv. Some datasets have been collected over many years, one file per day for example. Sometimes the file name format has changed at some point in the past or even the format of the file itself. So the idea is that you can loop fread through a set of files and as long as each file is regular and delimited, fread can read them all. Whether they all stack is another matter but at least each one is read quickly without you needing to vary colClasses in read.table or read.csv.

If an empty line is encountered then reading stops there with warning if any text exists after the empty line such as a footer. The first line of any text discarded is included in the warning message. Unless, it is single-column input. In that case blank lines are significant (even at the very end) and represent NA in the single column. So that fread fwrite DT == DT. This default behaviour can be controlled using blank.lines.skip=TRUE|FALSE.

Line endings: All known line endings are detected automatically: \n (*NIX including Mac), \r\n (Windows CRLF), \r (old Mac) and \n\r (just in case). There is no need to convert input files first. fread running on any architecture will read a file from any architecture. Both \r and \n may be embedded in character strings (including column names) provided the field is quoted.

Decimal separator and locale: fread(., dec="",") should just work. fread uses C function strtod to read numeric data; e.g., 1.23 or 1,23. strtod retrieves the decimal separator (. or , usually) from the locale of the R session rather than as an argument passed to the strtod function. So for fread(., dec="",") to work, fread changes this (and only this) R session’s locale temporarily to a locale which provides the desired decimal separator.

On Windows, ”French_France.1252” is tried which should be available as standard (any locale with comma decimal separator would suffice) and on unix ”fr.FR.utf8” (you may need to install this locale on unix). fread() is very careful to set the locale back again afterwards, even if the function fails with an error. The choice of locale is determined by options()$datatable.fread.dec.locale.
This may be a `vector` of locale names and if so they will be tried in turn until the desired `dec` is obtained; thus allowing more than two different decimal separators to be selected. This is a new feature in v1.9.6 and is experimental. In case of problems, turn it off with `options(datatable.fread.dec.experiment=FALSE)`.

**Quotes:**

When `quote` is a single character,

- Spaces and other whitespace (other than `sep` and `\n`) may appear in unquoted character fields, e.g., `...2`, `Joe Bloggs`, `3.14`, ...
- When character columns are quoted, they must start and end with that quoting character immediately followed by `sep` or `\n`, e.g., `...2", "Joe Bloggs", 3.14", ...`

In essence quoting character fields are required only if `sep` or `\n` appears in the string value. Quoting may be used to signify that numeric data should be read as text. Unescaped quotes may be present in a quoted field, e.g., `...2"Joe", "Bloggs", 3.14", ...`, as well as escaped quotes, e.g., `...2"", "Bloggs""", 3.14", ...`

If an embedded quote is followed by the separator inside a quoted field, the embedded quotes up to that point in that field must be balanced; e.g., `...2"www.blah?x="one", y="two"", 3.14", ...`

On those fields that do not satisfy these conditions, e.g., fields with unbalanced quotes, fread re-attempts that field as if it isn’t quoted. This is quite useful in reading files that contains fields with unbalanced quotes as well, automatically.

To read fields as is instead, use `quote = ""`.

**File Download:**

When input begins with http://, https://, ftp://, ftps://, or file://, fread detects this and downloads the target to a temporary file (at `tempfile()`) before proceeding to read the file as usual. Secure URLs (ftps:// and https://) are downloaded with `curl::curl_download`; ftp:// and http:// paths are downloaded with `download.file` and method set to `getOption("download.file.method")`, defaulting to "auto"; and file:// is downloaded with `download.file` with method="internal".

NB: this implies that for file://, even files found on the current machine will be "downloaded" (i.e., hard-copied) to a temporary file. See `download.file` for more details.

**Value**

A `data.table` by default. A `data.frame` when argument `data.table=FALSE`; e.g. `options(datatable.fread.datatable=FALSE)`.

# check.names usage
fread("a b, a b\n1,2\n")
fread("a b, a b\n1,2\n", check.names=TRUE)  # no duplicates + syntactically valid names

## fsort

### Fast parallel sort

**Description**
Similar to base::sort but parallel. Experimental.

**Usage**

```
fsort(x, decreasing = FALSE, na.last = FALSE, internal=FALSE, verbose=FALSE, ...)
```

**Arguments**

- `x` A vector. Type double, currently.
- `decreasing` Decreasing order?
- `na.last` Control treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed; if "keep" they are kept with rank NA.
- `internal` Internal use only. Temporary variable. Will be removed.
- `verbose` Print tracing information.
- `...` Not sure yet. Should be consistent with base R.
fwrite

Details

Returns the input in sorted order. Fast using parallelism.

Value

The input in sorted order.

Examples

```r
x = runif(1e6)
system.time(ans1 <- sort(x, method="quick"))
system.time(ans2 <- fsort(x))
identical(ans1, ans2)
```

fwrite  Fast CSV writer

Description

As write.csv but much faster (e.g. 2 seconds versus 1 minute) and just as flexible. Modern machines almost surely have more than one CPU so fwrite uses them; on all operating systems including Linux, Mac and Windows.

This is new functionality as of Nov 2016. We may need to refine argument names and defaults.

Usage

```r
fwrite(x, file = "", append = FALSE, quote = "auto",
sep = ",", sep2 = c("", ",", "|", ""),
eol = if (.Platform$OS.type=="windows") "\r\n" else "\n",
na = "", dec = ".", row.names = FALSE, col.names = TRUE,
qmethod = c("double","escape"),
logical01 = getOption("datatable.logical01", FALSE), # due to change to TRUE; see NEWS
logicalAsInt = logical01, # deprecated
dateTimeAs = c("ISO","squash","epoch","write.csv"),
bufMB = 8L, nThread = getDTthreads(),
showProgress =getOption("datatable.showProgress", interactive()),
verbose = getOption("datatable.verbose", FALSE))
```

Arguments

- `x`  Any list of same length vectors; e.g. data.frame and data.table.
- `file`  Output file name. ":" indicates output to the console.
- `append`  If TRUE, the file is opened in append mode and column names (header row) are not written.
quote  When "auto", character fields, factor fields and column names will only be surrounded by double quotes when they need to be; i.e., when the field contains the separator sep, a line ending \n, the double quote itself or (when list columns are present) sep2[2] (see sep2 below). If FALSE the fields are not wrapped with quotes even if this would break the CSV due to the contents of the field. If TRUE double quotes are always included other than around numeric fields, as write.csv.

sep  The separator between columns. Default is ",".

sep2  For columns of type list where each item is an atomic vector, sep2 controls how to separate items within the column. sep2[1] is written at the start of the output field, sep2[2] is placed between each item and sep2[3] is written at the end. sep2[1] and sep2[3] may be any length strings including empty "" (default). sep2[2] must be a single character and (when list columns are present and therefore sep2 is used) different from both sep and dec. The default () is chosen to visually distinguish from the default sep. In speaking, writing and in code comments we may refer to sep2[2] as simply "sep2".

eol  Line separator. Default is \r\n for Windows and \n otherwise.

na  The string to use for missing values in the data. Default is a blank string "".

dec  The decimal separator, by default ".". See link in references. Cannot be the same as sep.

row.names  Should row names be written? For compatibility with data.frame and write.csv since data.table never has row names. Hence default FALSE unlike write.csv.

col.names  Should the column names (header row) be written? The default is TRUE. However, if missing, append=TRUE and the file already exists, the default is set to FALSE for convenience to prevent column names appearing again mid file.

qmethod  A character string specifying how to deal with embedded double quote characters when quoting strings.

• "escape" - the quote character (as well as the backslash character) is escaped in C style by a backslash, or

• "double" (default, same as write.csv), in which case the double quote is doubled with another one.

logical01  Should logical values be written as 1 and 0 rather than "TRUE" and "FALSE"?

logicalAsInt  Deprecated. Old name for ‘logical01’. Name change for consistency with ‘fread’ for which ‘logicalAsInt’ would not make sense.

datetimeAs  How Date/IDate, ITime and POSIXct items are written.

• "ISO" (default) - 2016-09-12, 18:12:16 and 2016-09-12T18:12:16.999999Z. 0, 3 or 6 digits of fractional seconds are printed if and when present for convenience, regardless of any R options such as digits.secs. The idea being that if milli and microseconds are present then you most likely want to retain them. R’s internal UTC representation is written faithfully to encourage ISO standards, stymie timezone ambiguity and for speed. An option to consider is to start R in the UTC timezone simply with "$ TZ=’UTC’ R" at the shell (NB: it must be one or more spaces between TZ=’UTC’ and R, anything else will be silently ignored; this TZ setting applies just to that R process) or Sys.setenv(TZ=’UTC’) at the R prompt and then continue as if UTC were local time.
• "squash" - 20160912, 181216 and 20160912181216999. This option allows fast and simple extraction of yyyy, mm, dd and (most commonly to group by) yyyyymm parts using integer div and mod operations. In R for example, one line helper functions could use %/%1000, %/%100%%100, %%%100 and %%%100 respectively. POSIXct UTC is squashed to 17 digits (including 3 digits of milliseconds always, even if 000) which may be read comfortably as integer64 (automatically by fread()).

• "epoch" - 17856, 65536 and 1473703936, 999999. The underlying number of days or seconds since the relevant epoch (1970-01-01, 00:00:00 and 1970-01-01T00:00:00Z respectively), negative before that (see ?Date). 0, 3 or 6 digits of fractional seconds are printed if and when present.

• "write.csv" - this currently affects POSIXct only. It is written as write.csv does by using the as.character method which heeds digitssecs and converts from R's internal UTC representation back to local time (or the "tzone" attribute) as of that historical date. Accordingly this can be slow. All other column types (including Date, IDate and ITime which are independent of timezone) are written as the "ISO" option using fast C code which is already consistent with write.csv.

The first three options are fast due to new specialized C code. The epoch to date-part conversion uses a fast approach by Howard Hinnant (see references) using a day-of-year starting on 1 March. You should not be able to notice any difference in write speed between those three options. The date range supported for Date and IDate is [0000-03-01, 9999-12-31]. Every one of these 3,652,365 dates have been tested and compared to base R including all 2,790 leap days in this range.

This option applies to vectors of date/time in list column cells, too.

A fully flexible format string (such as "%m/%d/%Y") is not supported. This is to encourage use of ISO standards and because that flexibility is not known how to make fast at C level. We may be able to support one or two more specific options if required.

buffMB The buffer size (MB) per thread in the range 1 to 1024, default 8MB. Experiment to see what works best for your data on your hardware.
nThread The number of threads to use. Experiment to see what works best for your data on your hardware.
showProgress Display a progress meter on the console? Ignored when file="".
verbose Be chatty and report timings?

Details

fwrite began as a community contribution with pull request #1613 by Otto Seiskari. This gave Matt Dowle the impetus to specialize the numeric formatting and to parallelize: http://blog.h2o.ai/2016/04/fast-csv-writing-for-r/. Final items were tracked in issue #1664 such as automatic quoting, bit64::integer64 support, decimal/scientific formatting exactly matching write.csv between 2.225074e-308 and 1.797693e+308 to 15 significant figures, row.names, dates (between 0000-03-01 and 9999-12-31), times and sep2 for list columns where each cell can itself be a vector.

Examples

```r
DF = data.frame(A=1:3, B=c("foo", "A,Name","baz"))
fwrite(DF)
write.csv(DF, row.names=FALSE, quote=FALSE)  # same
fwrite(DF, row.names=TRUE, quote=TRUE)
write.csv(DF)  # same

DF = data.frame(A=c(2.1,-1.234e-307,pi), B=c("foo","A,Name","bar"))
fwrite(DF, quote='auto')  # Just DF[2,2] is auto quoted
write.csv(DF, row.names=FALSE)  # same numeric formatting

DT = data.table(A=c(2.5,6,-3),B=list(1:3,c("foo","A,Name","bar"),round(pi=1:3,2)))
fwrite(DT)
fwrite(DT, sep="|", sep2=c("","",""))

# Not run:
set.seed(1)
DT = as.data.table( lapply(1:10, sample,
    x=as.numeric(1:5e7), size=5e6))  # 382MB
system.time(fwrite(DT, "/dev/shm/tmp1.csv"))  # 0.8s
system.time(write.csv(DT, "/dev/shm/tmp2.csv",
    quote=FALSE, row.names=FALSE))
system("diff /dev/shm/tmp1.csv /dev/shm/tmp2.csv")  # identical

set.seed(1)
N = 1e7
DT = data.table(
    str1=sample(sprintf("%010d",sample(N,1e5,replace=TRUE)), N, replace=TRUE),
    str2=sample(sprintf("%9d",sample(N,1e5,replace=TRUE)), N, replace=TRUE),
    str3=sample(sapply(sample(2:30, 100, TRUE), function(n)
        paste0(sample(LETTERS, n, TRUE), collapse="")), N, TRUE),
    str4=sample(sprintf("%05d",sample(sample(1e5,50),N,TRUE)),
        num1=sample(round(rnorm(1e6,mean=6.5,sd=15)),2), N, replace=TRUE),
        num2=sample(round(rnorm(1e6,mean=6.5,sd=15),10), N, replace=TRUE),
        str5=sample(c("Y","N",TRUE),
        str6=sample(c("M","F"),N,TRUE),
        int=sample(ceiling(rexp(1e6)), N, replace=TRUE),
        int2=sample(N,N,replace=TRUE)-N/2
    ) )  # 774MB
system.time(fwrite(DT,"/dev/shm/tmp1.csv"))  # 1.1s
```
### Description

Calculate aggregates at various levels of groupings producing multiple (sub-)totals. Reflects SQLs `GROUPING SETS` operations.

### Usage

```r
rollup(x, ...)  # S3 method for class 'data.table'
rollup(x, j, by, .SDcols, id = FALSE, ...)
cube(x, ...)  # S3 method for class 'data.table'
cube(x, j, by, .SDcols, id = FALSE, ...)
groupingsets(x, ...)  # S3 method for class 'data.table'
groupingsets(x, j, by, sets, .SDcols, id = FALSE, jj, ...)
```

### Arguments

- `x`: `data.table`
- `...`: argument passed to custom user methods. Ignored for `data.table` methods.
- `j`: expression passed to `data.table j`.
- `by`: character column names by which we are grouping.
- `sets`: list of character vector reflecting grouping sets, used in `groupingsets` for flexibility.
- `.SDcols`: columns to be used in `j` expression in `.SD object`.
- `id`: logical default FALSE. If TRUE it will add leading column with bit mask of grouping sets.
- `jj`: quoted version of `j argument`, for convenience. When provided function will ignore `j argument`.
groupingsets

Details

All three functions rollup, cube, groupingsets are generic methods, data.table methods are provided.

Value

A data.table with various aggregates.

**DateTime**

Integer based date class

**Description**

Date and time classes with integer storage for fast sorting and grouping. Still experimental!

**Usage**

```r
as.IDate(x, ...)
## Default S3 method:
as.IDate(x, ..., tz = attr(x, "tzone"))
## S3 method for class 'Date'
as.IDate(x, ...)
## S3 method for class 'IDate'
as.Date(x, ...)
## S3 method for class 'IDate'
as.POSIXct(x, tz = "UTC", time = 0, ...)
## S3 method for class 'IDate'
round(x, digits = c("weeks", "months", "quarters","years"), ...)

as.ITime(x, ...)
## Default S3 method:
as.ITime(x, ...)
## S3 method for class 'ITime'
as.POSIXct(x, tz = "UTC", date = as.Date(Sys.time()), ...)
## S3 method for class 'ITime'
as.character(x, ...)
## S3 method for class 'ITime'
format(x, ...)

IDateTime(x, ...)
## Default S3 method:
IDateTime(x, ...)

second(x)
minute(x)
hour(x)
yday(x)
wday(x)
mday(x)
week(x)
isoweek(x)
month(x)
quarter(x)
year(x)
```
Arguments

x      an object
...    arguments to be passed to or from other methods. For \texttt{as.IDate.default}, arguments are passed to \texttt{as.Date}. For \texttt{as.ITA}\texttt{me.default}, arguments are passed to \texttt{as.POSIXlt}.

tz     time zone (see \texttt{strptime}).
date   date object convertable with \texttt{as.IDate}.
time   time-of-day object convertable with \texttt{as.ITA}\texttt{me}.
digits really units; one of the units listed for rounding. May be abbreviated.

Details

\texttt{IDate} is a date class derived from \texttt{Date}. It has the same internal representation as the \texttt{Date} class, except the storage mode is integer. \texttt{IDate} is a relatively simple wrapper, and it should work in almost all situations as a replacement for \texttt{Date}.

Functions that use \texttt{Date} objects generally work for \texttt{IDate} objects. This package provides specific methods for \texttt{IDate} objects for \texttt{mean}, \texttt{cut}, \texttt{seq}, \texttt{c}, \texttt{rep}, and \texttt{split} to return an \texttt{IDate} object.

\texttt{ITA}\texttt{me} is a time-of-day class stored as the integer number of seconds in the day. \texttt{as.ITA}\texttt{me} does not allow days longer than 24 hours. Because \texttt{ITA}\texttt{me} is stored in seconds, you can add it to a \texttt{POSIXct} object, but you should not add it to a \texttt{Date} object.

Conversions to and from \texttt{Date} and \texttt{POSIXct} formats are provided.

\texttt{ITA}\texttt{me} does not account for time zones. When converting \texttt{ITA}\texttt{me} and \texttt{IDate} to \texttt{POSIXct} with \texttt{as.POSIXct}, a time zone may be specified.

In \texttt{as.POSIXct} methods for \texttt{ITA}\texttt{me} and \texttt{IDate}, the second argument is required to be \texttt{tz} based on the generic template, but to make converting easier, the second argument is interpreted as a date instead of a time zone if it is of type \texttt{IDate} or \texttt{ITA}\texttt{me}. Therefore, you can use either of the following: \texttt{as.POSIXct(time, date)} or \texttt{as.POSIXct(date, time)}.

\texttt{IDateTime} takes a date-time input and returns a data table with columns \texttt{date} and \texttt{time}.

Using integer storage allows dates and/or times to be used as data table keys. With positive integers with a range less than 100,000, grouping and sorting is fast because radix sorting can be used (see \texttt{sort.list}).

Several convenience functions like \texttt{hour} and \texttt{quarter} are provided to group or extract by hour, month, and other date-time intervals. \texttt{as.POSIXlt} is also useful. For example, \texttt{as.POSIXlt(x)$mon} is the integer month. The \texttt{R} base convenience functions \texttt{weekdays}, \texttt{months}, and \texttt{quarters} can also be used, but these return character values, so they must be converted to factors for use with \texttt{data.table}. \texttt{ioweek} is ISO 8601-consistent.

The \texttt{round} method for \texttt{IDate}'s is useful for grouping and plotting. It can round to weeks, months, quarters, and years.

Value

For \texttt{as.IDate}, a class of \texttt{IDate} and \texttt{Date} with the date stored as the number of days since some origin.

For \texttt{as.ITA}\texttt{me}, a class of \texttt{ITA}\texttt{me} stored as the number of seconds in the day.
For IDateTime, a data table with columns idate and itime in IDate and ITime format.

second, minute, hour, yday, wday, mday, week, month, quarter, and year return integer values for second, minute, hour, day of year, day of week, day of month, week, month, quarter, and year, respectively.

These values are all taken directly from the POSIXlt representation of x, with the notable difference that while yday, wday, and mon are all 0-based, here they are 1-based.

round(seqdates, "months")

---

**J**

*Creates a Join data table*

**Description**

Creates a data.table to be passed in as the i to a [.data.table join.

**Usage**

```r
# DT[J(...)]  # J() only for use inside DT[...].
SJ(...)  # DT[SJ(...)]
CJ(..., sorted = TRUE, unique = FALSE)  # DT[CJ(...)]
```

**Arguments**

- `...`: Each argument is a vector. Generally each vector is the same length but if they are not then the usual silent repetition is applied.
- `sorted`: logical. Should the input order be retained?
- `unique`: logical. When TRUE, only unique values of each vectors are used (automatically).

**Details**

`SJ` and `CJ` are convenience functions for creating a data.table in the context of a data.table 'query' on x.

`x[data.table(id)]` is the same as `x[J(id)]` but the latter is more readable. Identical alternatives are `x[list(id)]` and `x[.(id)]`.

x must have a key when passing in a join table as the i. See [.data.table

**Value**

- **J**: the same result as calling list. J is a direct alias for list but results in clearer more readable code.
- **SJ**: (S)orted (J)oin. The same value as J() but additionally setkey() is called on all the columns in the order they were passed in to SJ. For efficiency, to invoke a binary merge rather than a repeated binary full search for each row of i.
CJ: (C)ross (J)oin. A data.table is formed from the cross product of the vectors. For example, 10 ids, and 100 dates, CJ returns a 1000 row table containing all the dates for all the ids. It gains sorted, which by default is TRUE for backwards compatibility. FALSE retains input order.

Examples

DT = data.table(A=5:1, B=letters[5:1])
setkey(DT, B)  # re-orders table and marks it sorted.
DT[J("b")]]  # returns the 2nd row
DT[.("b")]]  # same. Style of package plyr.
DT[list("b")]]  # same

# CJ usage examples
CJ(c(5,NA,1), c(1,3,2))  # sorted and keyed data.table
do.call(CJ, list(c(5,NA,1), c(1,3,2)))  # same as above
CJ(c(5,NA,1), c(1,3,2), sorted=FALSE)  # same order as input, unkeyed
# use for 'unique=' argument
x = c(1,1,2)
y = c(4,6,4)
CJ(x, y, unique=TRUE)  # unique(x) and unique(y) are computed automatically

last  

Last item of an object

Description

Returns the last item of a vector or list, or the last row of a data.frame or data.table.

Usage

last(x, ...)

Arguments

x  

A vector, list, data.frame or data.table. Otherwise the S3 method of xts::last is deployed.

...  

Not applicable for data.table::last. Any arguments here are passed through to xts::last.
Value

If no other arguments are supplied it depends on the type of x. The last item of a vector or list. The last row of a data.frame or data.table. Otherwise, whatever xts::last returns (if package xts has been loaded, otherwise a helpful error).

If any argument is supplied in addition to x (such as n or keep in xts::last), regardless of x’s type, then xts::last is called if xts has been loaded, otherwise a helpful error.

See Also

NROW, head, tail, first

Examples

```
last(1:5) # [1] 5
x = data.table(x=1:5, y=6:10)
last(x) # same as x[5]
```

like

Convenience function for calling regexpr.

Description

Intended for use in i in [.data.table.

Usage

```
like(vector, pattern)
vector %like% pattern
```

Arguments

- **vector**: Either a character vector or a factor. A factor is faster.
- **pattern**: Passed on to grepl.

Value

Logical vector, TRUE for items that match pattern.

Note

Current implementation does not make use of sorted keys.

data.table, grepl
Examples

DT = data.table(Name=c("Mary","George","Martha"), Salary=c(2,3,4))
DT[Name %like% "Mar"]

melt.data.table  Fast melt for data.table

Description

An S3 method for melting data.tables written in C for speed and memory efficiency. Since v1.9.6, melt.data.table allows melting into multiple columns simultaneously.

It is not necessary to load reshape2 any more. But if you have to, then load reshape2 package before loading data.table.

Usage

## fast melt a data.table
## S3 method for class 'data.table'
melt(data, id.vars, measure.vars,
     variable.name = "variable", value.name = "value",
     ..., na.rm = FALSE, variable.factor = TRUE,
     value.factor = FALSE,
     verbose = getOption("datatable.verbose"))

Arguments

data  A data.table object to melt.
id.vars  vector of id variables. Can be integer (corresponding id column numbers) or character (id column names) vector. If missing, all non-measure columns will be assigned to it. If integer, must be positive; see Details.
measure.vars  Measure variables for melting. Can be missing, vector, list, or pattern-based.

- When missing, measure.vars will become all columns outside id.vars.
- Vector can be integer (implying column numbers) or character (column names).
- list is a generalization of the vector version – each element of the list (which should be integer or character as above) will become a melted column.
- Pattern-based column matching can be achieved with the regular expression-based patterns syntax; multiple patterns will produce multiple columns.

For convenience/clarity in the case of multiple melted columns, resulting column names can be supplied as names to the elements measure.vars (in the list and patterns usages). See also Examples.

variable.name  name for the measured variable names column. The default name is 'variable'.
value.name
name for the molten data values column(s). The default name is 'value'. Multiple names can be provided here for the case when measure.vars is a list, though note well that the names provided in measure.vars take precedence.

na.rm
If TRUE, NA values will be removed from the molten data.

variable.factor
If TRUE, the variable column will be converted to factor, else it will be a character column.

value.factor
If TRUE, the value column will be converted to factor, else the molten value type is left unchanged.

verbose
TRUE turns on status and information messages to the console. Turn this on by default using options(datatable.verbose=TRUE). The quantity and types of verbosity may be expanded in future.

any other arguments to be passed to/from other methods.

Details
If id.vars and measure.vars are both missing, all non-numeric/integer/logical columns are assigned as id variables and the rest as measure variables. If only one of id.vars or measure.vars is supplied, the rest of the columns will be assigned to the other. Both id.vars and measure.vars can have the same column more than once and the same column can be both as id and measure variables.

melt.data.table also accepts list columns for both id and measure variables.

When all measure.vars are not of the same type, they'll be coerced according to the hierarchy list > character > numeric > integer > logical. For example, if any of the measure variables is a list, then entire value column will be coerced to a list. Note that, if the type of value column is a list, na.rm = TRUE will have no effect.

From version 1.9.6, melt gains a feature with measure.vars accepting a list of character or integer vectors as well to melt into multiple columns in a single function call efficiently. The function patterns can be used to provide regular expression patterns. When used along with melt, if cols argument is not provided, the patterns will be matched against names(data), for convenience.

Attributes are preserved if all value columns are of the same type. By default, if any of the columns to be melted are of type factor, it'll be coerced to character type. This is to be compatible with reshape2’s melt.data.frame. To get a factor column, set value.factor = TRUE.

melt.data.table also preserves ordered factors.

Note that, as opposed to the (undocumented) behaviour of reshape2::melt, id.vars, when specified as numbers, must be between 1 and ncol(data).

Value
An unkeyed data.table containing the molten data.

Examples

```r
set.seed(45)
require(data.table)
DT <- data.table(
  i_1 = c(1:5, NA),
  i_2 = c(NA, 6, 7, 8, 9, 10),
  f_1 = factor(sample(c(letters[1:3], NA), 6, TRUE)),
  f_2 = factor(c("z", "a", "x", "c", "x", "x"), ordered=TRUE),
  c_1 = sample(c(letters[1:3], NA), 6, TRUE),
  d_1 = as.Date(c(1:3,NA,4:5), origin="2013-09-01"),
  d_2 = as.Date(6:1, origin="2012-01-01"))
# add a couple of list cols
DT[, L1 := DT[, list(c=list(rep(i_1, sample(5,1))))], by = i_1]$c]
DT[, L2 := DT[, list(c=list(rep(c_1, sample(5,1))))], by = i_1]$c]

# id, measure as character/integer/numeric vectors
melt(DT, id=1:2, measure="f_1")
melt(DT, id=c("i_1", "i_2"), measure=3) # same as above
melt(DT, id=1:2, measure=3L, value.factor=TRUE) # same, but 'value' is factor
melt(DT, id=1:2, measure=3:4, value.factor=TRUE) # 'value' is *ordered* factor

# preserves attribute when types are identical, ex: Date
melt(DT, id=3:4, measure=c("d_1", "d_2"))
melt(DT, id=3:4, measure=c("i_1", "d_1")) # attribute not preserved

# on list
melt(DT, id=1, measure=c("l_1", "l_2")) # value is a list
melt(DT, id=1, measure=c("c_1", "l_1")) # c1 coerced to list

# on character
melt(DT, id=1, measure=c("c_1", "f_1")) # value is char
melt(DT, id=1, measure=c("c_1", "i_2")) # i2 coerced to char

# on na.rm=TRUE. NAs are removed efficiently, from within C
melt(DT, id=1, measure=c("c_1", "i_2"), na.rm=TRUE) # remove NA

# measure.vars can be also a list
# melt "f_1,f_2" and "d_1,d_2" simultaneously, retain 'factor' attribute
# convenient way using internal function patterns()
melt(DT, id=1:2, measure=patterns("f_", "d_"), value.factor=TRUE)
# same as above, but provide list of columns directly by column names or indices
melt(DT, id=1:2, measure=list(3:4, c("d_1", "d_2")), value.factor=TRUE)
# same as above, but provide names directly:
melt(DT, id=1:2, measure=patterns(f="^f_", d="^d_"), value.factor=TRUE)

# na.rm=TRUE removes rows with NAs in any 'value' columns
melt(DT, id=1:2, measure=patterns("f_", "d_"), value.factor=TRUE, na.rm=TRUE)

# return 'NA' for missing columns, 'na.rm=TRUE' ignored due to list column
melt(DT, id=1:2, measure=patterns("l_", "c_"), na.rm=TRUE)
```
merge

Merge two data.tables

Description

Fast merge of two data.tables. The data.table method behaves very similarly to that of data.frame except that, by default, it attempts to merge

- at first based on the shared key columns, and if there are none,
- then based on key columns of the first argument x, and if there are none,
- then based on the common columns between the two data.tables.

Set the by, or by.x and by.y arguments explicitly to override this default.

Usage

```r
## S3 method for class 'data.table'
merge(x, y, by = NULL, by.x = NULL, by.y = NULL, all = FALSE,
      all.x = all, all.y = all, sort = TRUE, suffixes = c(".x", ".y"), no.dups = TRUE,
      allow.cartesian=getOption("datatable.allow.cartesian"), # default FALSE ...
```

Arguments

- **x, y** data tables. y is coerced to a data.table if it isn’t one already.
- **by** A vector of shared column names in x and y to merge on. This defaults to the shared key columns between the two tables. If y has no key columns, this defaults to the key of x.
- **by.x, by.y** Vectors of column names in x and y to merge on.
- **all** logical; all = TRUE is shorthand to save setting both all.x = TRUE and all.y = TRUE.
- **all.x** logical; if TRUE, then extra rows will be added to the output, one for each row in x that has no matching row in y. These rows will have 'NA's in those columns that are usually filled with values from y. The default is FALSE, so that only rows with data from both x and y are included in the output.
- **all.y** logical; analogous to all.x above.
- **sort** logical. If TRUE (default), the merged data.table is sorted by setting the key to the by / by.x columns. If FALSE, the result is not sorted.
- **suffixes** A character(2) specifying the suffixes to be used for making non-by-column names unique. The suffix behaviour works in a similar fashion as the merge.data.frame method does.
- **no.dups** logical indicating that suffixes are also appended to non-by.y column names in y when they have the same column name as any by.x.
- **allow.cartesian** See allow.cartesian in [.data.table.
- **...** Not used at this time.
merge is a generic function in base R. It dispatches to either the merge.data.frame method or merge.data.table method depending on the class of its first argument. Note that, unlike SQL, NA is matched against NA (and NaN against NaN) while merging.

In versions <= v1.9.4, if the specified columns in by were not the key (or head of the key) of x or y, then a copy is first re-keyed prior to performing the merge. This was less performant as well as memory inefficient. The concept of secondary keys (implemented in v1.9.4) was used to overcome this limitation from v1.9.6+. No deep copies are made any more, thereby improving performance and memory efficiency. Also, there is better control for providing the columns to merge on with the help of the newly implemented by.x and by.y arguments.

For a more data.table-centric way of merging two data.tables, see [.data.table; e.g., x[y, ...]. See FAQ 1.12 for a detailed comparison of merge and x[y, ...].

If any column names provided to by.x also occur in names(y) but not in by.y, then this data.table method will add the suffixes to those column names. As of R v3.4.3, the data.frame method will not (leading to duplicate column names in the result) but a patch has been proposed (see r-devel thread here) which is looking likely to be accepted for a future version of R.

Value

A new data.table based on the merged data tables, and sorted by the columns set (or inferred for) the by argument if argument sort is set to TRUE.

data.table, as.data.table, [.data.table, merge.data.frame

Examples

(dt1 <- data.table(A = letters[1:10], X = 1:10, key = "A"))
(dt2 <- data.table(A = letters[5:14], Y = 1:10, key = "A"))
merge(dt1, dt2)
merge(dt1, dt2, all = TRUE)

(dt1 <- data.table(A = letters[rep(1:3, 2)], X = 1:6, key = "A"))
(dt2 <- data.table(A = letters[rep(2:4, 2)], Y = 6:1, key = "A"))
merge(dt1, dt2, allow.cartesian=TRUE)

(dt1 <- data.table(A = c(rep(1L, 5), 2L), B = letters[rep(1:3, 2)], X = 1:6, key = "A,B"))
(dt2 <- data.table(A = c(rep(1L, 5), 2L), B = letters[rep(2:4, 2)], Y = 6:1, key = "A,B"))
merge(dt1, dt2)
merge(dt1, dt2, by="B", allow.cartesian=TRUE)

# test it more:
d1 <- data.table(a=rep(1:2,each=3), b=1:6, key="a,b")
d2 <- data.table(a=0:1, bb=10:11, key="a")
d3 <- data.table(a=0:1, key="a")
d4 <- data.table(a=0:1, b=0:1, key="a,b")
merge(d1, d2)
merge(d2, d1)
merge(d1, d2, all=TRUE)
merge(d2, d1, all=TRUE)

merge(d3, d1)
merge(d1, d3)
merge(d1, d3, all=TRUE)
merge(d3, d1, all=TRUE)

merge(d1, d4)
merge(d1, d4, by="a", suffixes=c(".d1", ".d4"))
merge(d4, d1)
merge(d1, d4, all=TRUE)
merge(d4, d1, all=TRUE)

# new feature, no need to set keys anymore
set.seed(1L)
d1 <- data.table(a=sample(rep(1:3,each=2)), z=1:6)
d2 <- data.table(a=2:0, z=10:12)
merge(d1, d2, by="a")
merge(d1, d2, by="a", all=TRUE)

# new feature, using by.x and by.y arguments
setnames(d2, "a", "b")
merge(d1, d2, by.x="a", by.y="b")
merge(d1, d2, by.x="a", by.y="b", all=TRUE)
merge(d2, d1, by.x="b", by.y="a")

---

**na.omit.data.table**  
*Remove rows with missing values on columns specified*

**Description**

This is a `data.table` method for the S3 generic `stats::na.omit`. The internals are written in C for speed. See examples for benchmark timings.

`bit64::integer64` type is also supported.

**Usage**

```r
## S3 method for class 'data.table'
na.omit(object, cols=seq_along(object), invert=FALSE, ...)
```

**Arguments**

- `object`  
  A `data.table`.

- `cols`  
  A vector of column names (or numbers) on which to check for missing values. Default is all the columns.

- `invert`  
  Logical. If `FALSE` omits all rows with any missing values (default). `TRUE` returns just those rows with missing values instead.

- `...`  
  Further arguments special methods could require.
patterns

Obtain matching indices corresponding to patterns

Description

patterns returns the matching indices in the argument cols corresponding to the regular expression patterns provided. The patterns must be supported by grep.

From v1.9.6, melt.data.table has an enhanced functionality in which measure.vars argument can accept a list of column names and melt them into separate columns. See the Efficient reshaping using data.tables vignette linked below to learn more.
Usage

    patterns(..., cols=character(0))

Arguments

...  A set of regular expression patterns.
cols  A character vector of names to which each pattern is matched.

See Also

    melt, https://github.com/Rdatatable/data.table/wiki/Getting-started

Examples

    DT = data.table(x1 = 1:5, x2 = 6:10, y1 = letters[1:5], y2 = letters[6:10])
    # melt all columns that begin with 'x' & 'y', respectively, into separate columns
    melt(DT, measure.vars = patterns("^x", "^y", cols=names(DT)))
    # when used with melt, 'cols' is implicitly assumed to be names of input
    # data.table, if not provided.
    melt(DT, measure.vars = patterns("^x", "^y"))
Arguments

- **x**: A data.table.
- **topn**: The number of rows to be printed from the beginning and end of tables with more than **nrows** rows.
- **nrows**: The number of rows which will be printed before truncation is enforced.
- **class**: If **TRUE**, the resulting output will include above each column its storage class (or a self-evident abbreviation thereof).
- **row.names**: If **TRUE**, row indices will be printed alongside **x**.
- **col.names**: One of three flavours for controlling the display of column names in output. "auto" includes column names above the data, as well as below the table if nrow(x) > 20. "top" excludes this lower register when applicable, and "none" suppresses column names altogether (as well as column classes if **class** = **TRUE**).
- **print.keys**: If **TRUE**, any **key** and/or **index** currently assigned to **x** will be printed prior to the preview of the data.
- **quote**: If **TRUE**, all output will appear in quotes, as in `print.default`.
- **...**: Other arguments ultimately passed to `format`.

Details

By default, with an eye to the typically large number of observations in a coded data.table, only the beginning and end of the object are displayed (specifically, `head(x, topn)` and `tail(x, topn)` are displayed unless nrow(x) < nrows, in which case all rows will print).

See Also

- `print.default`

Examples

```r
# output compression
DT <- data.table(a = 1:1000)
print(DT, nrows = 100, topn = 4)

#'quote' can be used to identify whitespace
DT <- data.table(blanks = c("12", "34"), noblanks = c("12", "34"))
print(DT, quote = TRUE)

#'class' provides handy column type summaries at a glance
DT <- data.table(a = vector("integer", 3), b = vector("complex", 3),
                 c = as.IDate(paste0("2016-02-0", 1:3)))
print(DT, class = TRUE)

#'row.names' can be eliminated to save space
DT <- data.table(a = 1:3)
print(DT, row.names = FALSE)
```
#'print.keys' can alert which columns are currently keys
DT <- data.table(a=1:3, b=4:6, c=7:9, key="b", a")
setindexv(DT, c("a", "b"))
setindexv(DT, "a")
print(DT, print.keys=TRUE)

---

**rbindlist**

Makes one data.table from a list of many

**Description**

Same as do.call("rbind", 1) on data.frames, but much faster. See DETAILS for more.

**Usage**

```r
rbindlist(l, use.names=fill, fill=FALSE, idcol=NULL)
# rbind(..., use.names=TRUE, fill=FALSE, idcol=NULL)
```

**Arguments**

- **l**
  - A list containing data.table, data.frame or list objects. At least one of the inputs should have column names set. ... is the same but you pass the objects by name separately.
- **use.names**
  - If TRUE items will be bound by matching column names. By default FALSE for rbindlist (for backwards compatibility) and TRUE for rbind (consistency with base). Columns with duplicate names are bound in the order of occurrence, similar to base. When TRUE, at least one item of the input list has to have non-null column names.
- **fill**
  - If TRUE fills missing columns with NAs. By default FALSE. When TRUE, use.names has to be TRUE, and all items of the input list has to have non-null column names.
- **idcol**
  - Generates an index column. Default (NULL) is not to. If idcol=TRUE then the column is auto named .id. Alternatively the column name can be directly provided, e.g., idcol = "id".
    - If input is a named list, ids are generated using them, else using integer vector from 1 to length of input list. See examples.

**Details**

Each item of l can be a data.table, data.frame or list, including NULL (skipped) or an empty object (0 rows). rbindlist is most useful when there are a variable number of (potentially many) objects to stack, such as returned by lapply(fileNames, fread). rbind however is most useful to stack two or three objects which you know in advance. ... should contain at least one data.table for rbind(...) to call the fast method and return a data.table, whereas rbindlist(l) always returns a data.table even when stacking a plain list with a data.frame, for example.

In versions <= v1.9.2, each item for rbindlist should have the same number of columns as the first non empty item. rbind.data.table gained a fill argument to fill missing columns with NA in v1.9.2, which allowed for rbind(...) binding unequal number of columns.
In version > v1.9.2, these functionalities were extended to `rbindlist` (and written entirely in C for speed). `rbindlist` has `use.names` argument, which is set to FALSE by default for backwards compatibility. It also contains `fill` argument as well and can bind unequal columns when set to TRUE.

With these changes, the only difference between `rbind(...)` and `rbindlist()` is their default argument `use.names`.

If column i of input items do not all have the same type; e.g. a `data.table` may be bound with a list or a column is factor while others are character types, they are coerced to the highest type (SEXPTYPE).

Note that any additional attributes that might exist on individual items of the input list would not be preserved in the result.

**Value**

An unkeyed `data.table` containing a concatenation of all the items passed in.

**See Also**

`data.table`, `split.data.table`

**Examples**

```r
# default case
DT1 = data.table(A=1:3, B=letters[1:3])
DT2 = data.table(A=4:5, B=letters[4:5])
l = list(DT1, DT2)
rbindlist(l)

# bind correctly by names
DT1 = data.table(A=1:3, B=letters[1:3])
DT2 = data.table(B=letters[4:5], A=4:5)
l = list(DT1, DT2)
rbindlist(l, use.names=TRUE)

# fill missing columns, and match by col names
DT1 = data.table(A=1:3, B=letters[1:3])
DT2 = data.table(B=letters[4:5], C=factor(1:2))
l = list(DT1, DT2)
rbindlist(l, use.names=TRUE, fill=TRUE)

# generate index column, auto generates indices
rbindlist(l, use.names=TRUE, fill=TRUE, idcol=TRUE)
# let's name the list
setattr(l, 'names', c("a", "b"))
rbindlist(l, use.names=TRUE, fill=TRUE, idcol="ID")
```
rleid

Generate run-length type group id

Description

A convenience function for generating a run-length type id column to be used in grouping operations. It accepts atomic vectors, lists, data.frames or data.tables as input.

Usage

rleid(..., prefix=NULL)
rleidv(x, cols=seq_along(x), prefix=NULL)

Arguments

x A vector, list, data.frame or data.table.
...

A sequence of numeric, integer64, character or logical vectors, all of same length. For interactive use.
cols Only meaningful for lists, data.frames or data.tables. A character vector of column names (or numbers) of x.
prefix Either NULL (default) or a character vector of length=1 which is prefixed to the row ids, returning a character vector (instead of an integer vector).

Details

At times aggregation (or grouping) operations need to be performed where consecutive runs of identical values should belong to the same group (See rle). The use for such a function has come up repeatedly on StackOverflow, see the See Also section. This function allows to generate "run-length" groups directly.

rleid is designed for interactive use and accepts a sequence of vectors as arguments. For programming, rleidv might be more useful.

Value

When prefix = NULL, an integer vector with same length as NROW(x), else a character vector with the value in prefix prefixed to the ids obtained.

See Also

data.table, rowid, http://stackoverflow.com/q/21421047/559784
Examples

DT = data.table(grp=rep(c("A", "B", "C", "A", "B"), c(2,2,3,1,2)), value=1:10)
rleid(DT[,grp]) # get run-length ids
rleidv(DT, "grp") # same as above

rleid(DT[,grp, prefix="grp"])) # prefix with 'grp'

# get sum of value over run-length groups
DT[, sum(value), by=.((grp, rleid(grp))]
DT[, sum(value), by=.((grp, rleid(grp, prefix="grp")]]

rowid

Generate unique row ids within each group

Description

Convenience functions for generating a unique row ids within each group. It accepts atomic vectors, lists, data.frames or data.tables as input.

rowid is intended for interactive use, particularly along with the function dcast to generate unique ids directly in the formula.

rowidv(DT, cols=c("x", "y")) is equivalent to column N in the code DT[, N := seq_len(N), by=c("x", "y")]. See examples for more.

Usage

rowid(..., prefix=NULL)
rowidv(x, cols=seq_along(x), prefix=NULL)

Arguments

x
A vector, list, data.frame or data.table.

... A sequence of numeric, integer64, character or logical vectors, all of same length. For interactive use.

cols Only meaningful for lists, data.frames or data.tables. A character vector of column names (or numbers) of x.

prefix Either NULL (default) or a character vector of length=1 which is prefixed to the row ids, returning a character vector (instead of an integer vector).

Value

When prefix = NULL, an integer vector with same length as NROW(x), else a character vector with the value in prefix prefixed to the ids obtained.

See Also

dcast.data.table, rleid
setattr

Set attributes of objects by reference

Description

In data.table, all set* functions change their input by reference. That is, no copy is made at all, other than temporary working memory which is as large as one column. The only other data.table operator that modifies input by reference is :=. Check out the See Also section below for other set* function that data.table provides.

Usage

setattr(x,name,value)
setnames(x,old,new)

Arguments

x
name
value
old
new

setnames accepts data.frame and data.table. setattr accepts any input; e.g, list, columns of a data.frame or data.table.
The character attribute name.
The value to assign to the attribute or NULL removes the attribute, if present.
When new is provided, character names or numeric positions of column names to change. When new is not provided, the new column names, which must be the same length as the number of columns. See examples.
Optional. New column names, must be the same length as columns provided to old argument.
**setattr**

Details

setnames operates on data.table and data.frame not other types like list and vector. It can be used to change names by name with built-in checks and warnings (e.g., if any old names are missing or appear more than once).

setattr is a more general function that allows setting of any attribute to an object by reference.

A very welcome change in R 3.1+ was that `names<-` and `colnames<-` no longer copy the entire object as they used to (up to 4 times), see examples below. They now take a shallow copy. The `set*` functions in data.table are still useful because they don’t even take a shallow copy. This allows changing names and attributes of a (usually very large) data.table in the global environment from within functions. Like a database.

Value

The input is modified by reference, and returned (invisibly) so it can be used in compound statements: e.g., `setnames(DT,"V1", "Y")[, .N, by=Y]`. If you require a copy, take a copy first (using `DT2=copy(DT)`). See `?copy`.

Note that setattr is also in package bit. Both packages merely expose R’s internal setAttrib function at C level but differ in return value. bit::setattr returns NULL (invisibly) to remind you the function is used for its side effect. data.table::setattr returns the changed object (invisibly) for use in compound statements.

data.table, setkey, setorder, setcolorder, set, :=, setDT, setDF, copy

Examples

```r
DF = data.frame(a=1:2,b=3:4) # base data.frame to demo copies and syntax
if (capabilities()["profmem"])
  tracemem(DF)
  colnames(DF)[1] <- "A" # 4 shallow copies (R >= 3.1, was 4 deep copies before)
  names(DF)[1] <- "A" # 3 shallow copies
  names(DF) <- c("A", "b") # 1 shallow copy
  `names<-`(DF,c("A","b")) # 1 shallow copy

DT = data.table(a=1:2,b=3:4,c=5:6) # compare to data.table
if (capabilities()["profmem"])
  tracemem(DT)
  setnames(DT,"b","B") # by name, no match() needed (warning if "b" is missing)
  setnames(DT,3,"C") # by position with warning if 3 > ncol(DT)
  setnames(DT,2:3,c("D","E")) # multiple
  setnames(DT,c("a","E"),c("A","F")) # multiple by name (warning if either "a" or "E" is missing)
  setnames(DT,c("X","Y","Z")) # replace all (length of names must be == ncol(DT))

DT <- data.table(x = 1:3, y = 4:6, z = 7:9)
setnames(DT, -2, c("a", "b")) # NEW FR #1443, allows -ve indices in 'old' argument

DT = data.table(a=1:3, b=4:6)
f = function(...) {
```
```r
# ... 
setattr(DT,"myFlag",TRUE)  # by reference  
# ... 
localDT = copy(DT) 
setattr(localDT,"myFlag2",TRUE)  
# ... 
invisible()
}
f() 
attr(DT,"myFlag")  # TRUE  
attr(DT,"myFlag2")  # NULL
```

**setcolorder**

*Fast column reordering of a data.table by reference*

**Description**

In data.table parlance, all set* functions change their input *by reference*. That is, no copy is made at all, other than temporary working memory, which is as large as one column. The only other data.table operator that modifies input by reference is :=. Check out the See Also section below for other set* function data.table provides.

`setcolorder` reorders the columns of data.table, *by reference*, to the new order provided.

**Usage**

`setcolorder(x, neworder)`

**Arguments**

- `x` A data.table.
- `neworder` Character vector of the new column name ordering. May also be column numbers. If `length(neworder) < length(x)`, the specified columns are moved in order to the "front" of `x`.

**Details**

To reorder data.table columns, the idiomatic way is to use `setcolorder(x, neworder)`, instead of doing `x <- x[, neworder, with=FALSE]`. This is because the latter makes an entire copy of the data.table, which maybe unnecessary in most situations. `setcolorder` also allows column numbers instead of names for `neworder` argument, although we recommend using names as a good programming practice.

**Value**

The input is modified by reference, and returned (invisibly) so it can be used in compound statements. If you require a copy, take a copy first (using `DT2 = copy(DT)`). See ?copy.

setkey, setorder, setattr, setnames, set., setDF, setDF, copy, getNumericRounding, setNumericRounding

Examples

```r
set.seed(45L)
DT = data.table(A=sample(3, 10, TRUE),
                B=sample(letters[1:3], 10, TRUE), C=sample(10))
setcolorder(DT, c("C", "A", "B"))
#incomplete specification
setcolorder(DT, "A")
```

---

**setDF**

Coerce a data.table to data.frame by reference

Description

In data.table parlance, all set* functions change their input by reference. That is, no copy is made at all, other than temporary working memory, which is as large as one column. The only other data.table operator that modifies input by reference is :=. Check out the See Also section below for other set* function data.table provides.

A helper function to convert a data.table or list of equal length to data.frame by reference.

Usage

```r
setDF(x, rownames=NULL)
```

Arguments

- `x` A data.table, data.frame or list of equal length.
- `rownames` A character vector to assign as the row names of `x`.

Details

All data.table attributes including any keys of the input data.table are stripped off.

When using `rownames`, recall that the row names of a data.frame must be unique. By default, the assigned set of row names is simply the sequence 1, ..., nrow(x) (or length(x) for lists).

Value

The input data.table is modified by reference to a data.frame and returned (invisibly). If you require a copy, take a copy first (using `DT2 = copy(DT)`). See ?copy.
setDT

Coerce lists and data.frames to data.table by reference

Description

In **data.table** parlance, all set* functions change their input by reference. That is, no copy is made at all, other than temporary working memory, which is as large as one column. The only other **data.table** operator that modifies input by reference is :=. Check out the See Also section below for other set* function **data.table** provides.

**setDT** converts lists (both named and unnamed) and data.frames to data.tables by reference. This feature was requested on Stackoverflow.

Usage

```
setDT(x, keep.rownames=FALSE, key=NULL, check.names=FALSE)
```

Arguments

- `x` A named or unnamed list, data.frame or data.table.
- `keep.rownames` For data.frames, TRUE retains the data.frame’s row names under a new column `rn`.
- `key` Character vector of one or more column names which is passed to **setkeyv**. It may be a single comma separated string such as `key="x,y,z"`, or a vector of names such as `key=c("x","y","z")`.
- `check.names` Just as check.names in **data.frame**.
Details

When working on large lists or data.frames, it might be both time and memory consuming to convert them to a data.table using as.data.table(.), as this will make a complete copy of the input object before to convert it to a data.table. The setDT function takes care of this issue by allowing to convert lists - both named and unnamed lists and data.frames by reference instead. That is, the input object is modified in place, no copy is being made.

Value

The input is modified by reference, and returned (invisibly) so it can be used in compound statements: e.g., setDT(X)[, sum(B), by=A]. If you require a copy, take a copy first (using DT2 = copy(DT)). See ?copy.

See Also

data.table, as.data.table, setDF, copy, setkey, setcolororder, setattr, setnames, set, :=, setorder

Examples

```
set.seed(45L)
X = data.frame(A=sample(3, 10, TRUE),
    B=sample(letters[1:3], 10, TRUE),
    C=sample(10), stringsAsFactors=FALSE)

# Convert X to data.table by reference and
# get the frequency of each "A,B" combination
setDT(X)[, .N, by=.A,B]

# convert list to data.table
# autofill names
X = list(a=1:4, letters[1:4])
setDT(X)

# don't provide names
X = list(a=1:4, letters[1:4])
setDT(X, FALSE)

# setkey directly
X = list(a = 4:1, b=runif(4))
setDT(X, key="a")[]

# check.names argument
X = list(a=1:5, a=6:10)
setDT(X, check.names=TRUE)[]
```
setDTthreads

Set or get number of threads that data.table should use

Description

Set and get number of threads to be used in data.table functions that are parallelized with OpenMP. Default value 0 means to utilize all CPU available with an appropriate number of threads calculated by OpenMP. getDTthreads() returns the number of threads that will be used. This affects data.table only and does not change R itself or other packages using OpenMP. The most common usage expected is setDTthreads(1) to limit data.table to one thread for pre-existing explicitly parallel user code; e.g. via packages parallel and foreach. Otherwise, nested parallelism may bite. As data.table becomes more parallel automatically internally, we expect explicit user parallelism to be needed less often.

Attempting to setDTthreads() to more than the number of logical CPUs is intended to be ineffective; i.e., getDTthreads() will still return the number of logical CPUs in that case. Further, there is a hard coded limit of 1024 threads (with warning when imposed) to prevent accidentally picking up the value of INT_MAX (2 billion; i.e. unlimited) fromomp_get_thread_limit(). We have followed the advice of section 1.2.1.1 in the R-exts manual: "... or, better, for the regions in your code as part of their specification... num_threads(nthreads).... That way you only control your own code and not that of other OpenMP users." All the parallel region in data.table contain this directive. This is mandated by a grep in the package’s quality control release procedure script.

Usage

setDTthreads(threads)
getDTthreads(verbose =getOption("datatable.verbose","FALSE"))

Arguments

threads An integer >= 0. Default 0 means use all CPU available and leave the operating system to multi task.
verbose Display the value returned by some OpenMP function calls.

Value

A length 1 integer. The old value is returned by setDTthreads so you can store that value and pass it to setDTthreads again after the section of your code where you, probably, limited to one thread.
**setkey**  
*Create key on a data table*

**Description**

In data.table parlance, all set* functions change their input *by reference*. That is, no copy is made at all, other than temporary working memory, which is as large as one column. The only other data.table operator that modifies input by reference is :=. Check out the See Also section below for other set* function data.table provides.

`setkey()` sorts a data.table and marks it as sorted (with an attribute `sorted`). The sorted columns are the key. The key can be any columns in any order. The columns are sorted in ascending order always. The table is changed *by reference* and is therefore very memory efficient.

`setindex()` creates an index (or indices) on provided columns. This index is simply an order of the dataset's according to the provided columns. This order is stored as a data.table attribute, and the dataset retains the original order in memory. See the Secondary indices and auto indexing vignette for more details.

`key()` returns the data.table’s key if it exists, and NULL if none exist.

`haskey()` returns a logical TRUE/FALSE depending on whether the data.table has a key (or not).

**Usage**

```
setkey(x, ..., verbose=getOption("datatable.verbose"), physical = TRUE)
setkeyv(x, cols, verbose=getOption("datatable.verbose"), physical = TRUE)
setindex(...)
setindexv(x, cols, verbose=getOption("datatable.verbose"))
key(x)
indices(x, vectors = FALSE)
haskey(x)
key(x) <- value  # DEPRECATED, please use setkey or setkeyv instead.
```

**Arguments**

- `x`  
  A data.table.

- `...`  
  The columns to sort by. Do not quote the column names. If `...` is missing (i.e. `setkey(DT)`), all the columns are used. NULL removes the key.

- `cols`  
  A character vector of column names. For `setindexv`, this can be a list of character vectors, in which case each element will be applied as an index.

- `value`  
  In (deprecated) `key<-`, a character vector (only) of column names.

- `verbose`  
  Output status and information.

- `physical`  
  TRUE changes the order of the data in RAM. FALSE adds a secondary key a.k.a. index.

- `vectors`  
  logical scalar default FALSE, when set to TRUE then list of character vectors is returned, each vector refers to one index.
setkey reorders (or sorts) the rows of a data.table by the columns provided. In versions 1.9+, for integer columns, a modified version of base’s counting sort is implemented, which allows negative values as well. It is extremely fast, but is limited by the range of integer values being <= 1e5. If that fails, it falls back to a (fast) 4-pass radix sort for integers, implemented based on Pierre Terdiman’s and Michael Herf’s code (see links below). Similarly, a very fast 6-pass radix order for columns of type double is also implemented. This gives a speed-up of about 5-8x compared to QNYK on setkey and all internal order/sort operations. Fast radix sorting is also implemented for character and bit64::integer64 types.

The sort is stable; i.e., the order of ties (if any) is preserved, in both versions - <= 1.8.10 and >= 1.9.0.

In data.table versions <= 1.8.10, for columns of type integer, the sort is attempted with the very fast "radix" method in sort.list. If that fails, the sort reverts to the default method in order. For character vectors, data.table takes advantage of R’s internal global string cache and implements a very efficient order, also exported as chorder.

In v1.7.8, the key<- syntax was deprecated. The <- method copies the whole table and we know of no way to avoid that copy without a change in R itself. Please use the set* functions instead, which make no copy at all. setkey accepts unquoted column names for convenience, whilst setkeyv accepts one vector of column names.

The problem (for data.table) with the copy by key<- (other than being slower) is that R doesn’t maintain the over allocated truelength, but it looks as though it has. Adding a column by reference using := after a key<- was therefore a memory overwrite and eventually a segfault; the over allocated memory wasn’t really there after key<-’s copy. data.tables now have an attribute .internal.selfref to catch and warn about such copies. This attribute has been implemented in a way that is friendly with identical() and object.size().

For the same reason, please use the other set* functions which modify objects by reference, rather than using the <- operator which results in copying the entire object.

It isn’t good programming practice, in general, to use column numbers rather than names. This is why setkey and setkeyv only accept column names. If you use column numbers then bugs (possibly silent) can more easily creep into your code as time progresses if changes are made elsewhere in your code; e.g., if you add, remove or reorder columns in a few months time, a setkey by column number will then refer to a different column, possibly returning incorrect results with no warning. (A similar concept exists in SQL, where "select * from ..." is considered poor programming style when a robust, maintainable system is required.) If you really wish to use column numbers, it’s possible but deliberately a little harder; e.g., setkeyv(DT, colnames(DT)[1:2]).

Value

The input is modified by reference, and returned (invisibly) so it can be used in compound statements: e.g., setkey(DT, a)[J("foo")]. If you require a copy, take a copy first (using DT2 = copy(DT)). copy() may also sometimes be useful before := is used to subassign to a column by reference. See ?copy.

Note

Despite its name, base::sort.list(x, method="radix") actually invokes a counting sort in R, not a radix sort. See do_radixsort in src/main/sort.c. A counting sort, however, is particularly
suitable for sorting integers and factors, and we like it. In fact we like it so much that `data.table` contains a counting sort algorithm for character vectors using R’s internal global string cache. This is particularly fast for character vectors containing many duplicates, such as grouped data in a key column. This means that character is often preferred to factor. Factors are still fully supported, in particular ordered factors (where the levels are not in alphabetic order).

Examples

# Type 'example(setkey)' to run these at prompt and browse output

DT = data.table(A=5:1,B=letters[5:1])
DT # before
setkey(DT,B) # re-orders table and marks it sorted.
DT # after
tables() # KEY column reports the key'd columns
key(DT)
keycols = c("A","B")
setkeyv(DT,keycols) # rather than key(DT)<-keycols (which copies entire table)

DT = data.table(A=5:1,B=letters[5:1])
DT2 = DT # does not copy
setkey(DT2,B) # does not copy-on-write to DT2
identical(DT,DT2) # TRUE. DT and DT2 are two names for the same keyed table

DT = data.table(A=5:1,B=letters[5:1])
DT2 = copy(DT) # explicit copy() needed to copy a data.table
setkey(DT2,B) # now just changes DT2
identical(DT,DT2) # FALSE. DT and DT2 are now different tables

DT = data.table(A=5:1,B=letters[5:1])
setindex(DT) # set indices
setindex(DT, A)
setindex(DT, B)
indices(DT) # get indices single vector
indices(DT, vectors = TRUE) # get indices list
setNumericRounding  
*Change or turn off numeric rounding*

**Description**

Change rounding to 0, 1 or 2 bytes when joining, grouping or ordering numeric (i.e. double, POSIXct) columns.

**Usage**

```r
setNumericRounding(x)
getNumericRounding()
```

**Arguments**

- `x` integer or numeric vector: 0 (default), 1 or 2 byte rounding

**Details**

Computers cannot represent some floating point numbers (such as 0.6) precisely, using base 2. This leads to unexpected behaviour when joining or grouping columns of type 'numeric'; i.e. 'double', see example below. In cases where this is undesirable, data.table allows rounding such data up to approximately 11 s.f. which is plenty of digits for many cases. This is achieved by rounding the last 2 bytes off the significand. Other possible values are 1 byte rounding, or no rounding (full precision, default).

It’s bytes rather than bits because it’s tied in with the radix sort algorithm for sorting numerics which sorts byte by byte. With the default rounding of 0 bytes, at most 8 passes are needed. With rounding of 2 bytes, at most 6 passes are needed (and therefore might be a tad faster).

For large numbers (integers > $2^{31}$), we recommend using `bit64::integer64`, even though the default is to round off 0 bytes (full precision).

**Value**

`setNumericRounding` returns no value; the new value is applied. `getNumericRounding` returns the current value: 0, 1 or 2.

**See Also**

- [Floating point](http://en.wikipedia.org/wiki/Floating_point)
- [ncg_goldberg.html](http://docs.oracle.com/cd/E19957-01/806-3568/ncg_goldberg.html)
Examples

```
DT = data.table(a=seq(0,1,by=0.2),b=1:2, key="a")
DT
setNumericRounding(0) # By default, rounding is turned off
DT[,.(0.4)]    # works
DT[,.(0.6)]    # no match, can be confusing since 0.6 is clearly there in DT
                # happens due to floating point representation limitations

setNumericRounding(2) # round off last 2 bytes
DT[,.(0.6)]    # works

# using type 'numeric' for integers > 2^31 (typically ids)
DT = data.table(id = c(1234567890123, 1234567890124, 1234567890125), val=1:3)
print(DT, digits=15)
DT[,N,by=id]    # 1 row, (last 2 bytes rounded)
setNumericRounding(0)
DT[,N,by=id]    # 3 rows, (no rounding, default)
                # better to use bit64::integer64 for such ids
```

Description

Similar to base's set functions, union, intersect, setdiff and setequal but for data.tables. Additional all argument controls if/how duplicate rows are returned. bit64::integer64 is also supported.

Unlike SQL, data.table functions will retain order of rows in result.

Usage

```
fintersect(x, y, all = FALSE)
fssetdiff(x, y, all = FALSE)
funion(x, y, all = FALSE)
fssetequal(x, y)
```

Arguments

```
x,y        data.tables.
all        Logical. Default is FALSE and removes duplicate rows on the result. When TRUE, if there are xn copies of a particular row in x and yn copies of the same row in y, then:
          • fintersect will return min(xn, yn) copies of that row.
          • fssetdiff will return max(0, xn-yn) copies of that row.
          • funion will return xn+yn copies of that row.
```
Details

Columns of type complex and list are not supported except for function.

Value

A data.table in case of fintersect, funion and fsetdiff. Logical TRUE or FALSE for fsetequal.

References

Examples

```r
x = data.table(c(1,2,2,3,4,4))
y = data.table(c(2,3,4,4,5,5))
fintersect(x, y)  # intersect
fintersect(x, y, all=TRUE)  # intersect all
fsetdiff(x, y)  # except
fsetdiff(x, y, all=TRUE)  # except all
funion(x, y)  # union
funion(x, y, all=TRUE)  # union all
fsetequal(x, y)  # setequal
```

Description

In data.table parlance, all set* functions change their input by reference. That is, no copy is made at all, other than temporary working memory, which is as large as one column. The only other data.table operator that modifies input by reference is :=. Check out the See Also section below for other set* function data.table provides.

setorder (and setorderv) reorders the rows of a data.table based on the columns (and column order) provided. It reorders the table by reference and is therefore very memory efficient.

Also x[order(.)] is now optimised internally to use data.table’s fast order. data.table always reorders in “C-locale” (see Details). To sort by session locale, use x[base::order(.)].

bit64::integer64 type is also supported for reordering rows of a data.table.

Usage

```r
setorder(x, ..., na.last=FALSE)
setorderv(x, cols, order=1L, na.last=FALSE)
# optimised to use data.table's internal fast order
# x[order(. , na.last=TRUE)]
```
Arguments

- **x**: A `data.table`. The columns to sort by. Do not quote column names. If ... is missing ([ex: `setorder(x)`], `x` is rearranged based on all columns in ascending order by default. To sort by a column in descending order use `-1`, i.e., `setorder(x, a, -b, c)`. The `-b` works when `b` is of type character as well.

- **cols**: A character vector of column names of `x`, to which to order by. Do not add `-1` here. Use `order` argument instead.

- **order**: An integer vector with only possible values of `1` and `-1`, corresponding to ascending and descending order. The length of `order` must be either `1` or equal to that of `cols`. If `length(order) == 1`, it's recycled to `length(cols)`.

- **na.last**: logical. If TRUE, missing values in the data are placed last; if FALSE, they are placed first; if `NA` they are removed. `na.last=NA` is valid only for `x[order(., na.last)]` and it's default is TRUE. `setorder` and `setorderv` only accept TRUE/FALSE with default FALSE.

Details

data.table implements fast radix based ordering. In versions <= 1.9.2, it was only capable of increasing order (ascending). From 1.9.4 on, the functionality has been extended to decreasing order (descending) as well.

`setorder` accepts unquoted column names (with names preceded with a `-` sign for descending order) and reorders data.table rows by reference, for e.g., `setorder(x, a, -b, c)`. Note that `-b` also works with columns of type character unlike base::order, which requires `xtfrm(y)` instead (which is slow). `setorderv` in turn accepts a character vector of column names and an integer vector of column order separately.

Note that `setkey` still requires and will always sort only in ascending order, and is different from `setorder` in that it additionally sets the sorted attribute.

`na.last` argument, by default, is FALSE for `setorder` and `setorderv` to be consistent with data.table’s `setkey` and is TRUE for `x[order(., na.last)]` to be consistent with base::order. Only `x[order(.,)]` can have `na.last=NA` as it's a subset operation as opposed to `setorder` or `setorderv` which reorders the data.table by reference.

data.table always reorders in "C-locale". As a consequence, the ordering may be different to that obtained by base::order. In English locales, for example, sorting is case-sensitive in C-locale. Thus, sorting c("c", "a", "B") returns c("B", "a", "c") in data.table but c("a", "B", "c") in base::order. Note this makes no difference in most cases of data; both return identical results on ids where only upper-case or lower-case letters are present ("AB123" < "AC234" is true in both), or on country names and other proper nouns which are consistently capitalized. For example, neither "America" < "Brazil" nor "america" < "brazil" are affected since the first letter is consistently capitalized.

Using C-locale makes the behaviour of sorting in data.table more consistent across sessions and locales. The behaviour of base::order depends on assumptions about the locale of the R session. In English locales, "america" < "BRAZIL" is true by default but false if you either type `Sys.setlocale(locale="C")` or the R session has been started in a C locale for you – which can happen on servers/services since the locale comes from the environment the R session was started...
in. By contrast, "america" < "BRAZIL" is always false in data.table regardless of the way your R session was started.

If setorder results in reordering of the rows of a keyed data.table, then its key will be set to NULL.

Value

The input is modified by reference, and returned (invisibly) so it can be used in compound statements: e.g., setorder(DT[, , -b][, , csum(c), by=list(a, b)]. If you require a copy, take a copy first (using DT2 = copy(DT)). See ?copy.

setkey, setcolorder, setattr, setnames, set, :=, setDT, setDF, copy, setNumericRounding

Examples

set.seed(45L)
DT = data.table(A=sample(3, 10, TRUE),
          B=sample(letters[1:3], 10, TRUE), C=sample(10))

# setorder
setorder(DT, A, -B)

# same as above, but using setorderv
setorderv(DT, c("A", "B"), c(1, -1))

shift

Fast lead/lag for vectors and lists

Description

lead or lag vectors, lists, data.frames or data.tables implemented in C for speed. bit64::integer64 is also supported.

Usage

shift(x, n=1L, fill=NA, type=c("lag", "lead"), give.names=FALSE)

Arguments

x A vector, list, data.frame or data.table.
n Non-negative integer vector denoting the offset to lead or lag the input by. To create multiple lead/lag vectors, provide multiple values to n.
fill Value to pad by.
type default is "lag". The other possible value is "lead".
give.names default is FALSE which returns an unnamed list. When TRUE, names are automatically generated corresponding to type and n.
Details

shift accepts vectors, lists, data.frames or data.tables. It always returns a list except when the input is a vector and length(n) == 1 in which case a vector is returned, for convenience. This is so that it can be used conveniently within data.table’s syntax. For example, DT[, (cols) := shift(.SD, 1L), by=id] would lag every column of .SD by 1 for each group and DT[, newcol := colA + shift(colB)] would assign the sum of two vectors to newcol.

Argument n allows multiple values. For example, DT[, (cols) := shift(.SD, 1:2), by=id] would lag every column of .SD by 1 and 2 for each group. If .SD contained four columns, the first two elements of the list would correspond to lag=1 and lag=2 for the first column of .SD, the next two for second column of .SD and so on. Please see examples for more.

shift is designed mainly for use in data.tables along with := or set. Therefore, it returns an unnamed list by default as assigning names for each group over and over can be quite time consuming with many groups. It may be useful to set names automatically in other cases, which can be done by setting give.names to TRUE.

Value

A list containing the lead/lag of input x.

See Also

data.table

Examples

# on vectors, returns a vector as long as length(n) == 1, #1127
x = 1:5
# lag with n=1 and pad with NA (returns vector)
shift(x, n=1, fill=NA, type="lag")
# lag with n=1 and 2, and pad with 0 (returns list)
shift(x, n=1:2, fill=0, type="lag")

# on data.tables
DT = data.table(year=2010:2014, v1=runif(5), v2=1:5, v3=letters[1:5])
# lag columns ’v1,v2,v3’ DT by 1 and fill with 0
cols = c("v1","v2","v3")
anstyles = paste("lead", cols, sep="_")
DT[, (anscols) := shift(.SD, 1, 0, "lead"), .SDcols=cols]

# return a new data.table instead of updating
# with names automatically set
DT = data.table(year=2010:2014, v1=runif(5), v2=1:5, v3=letters[1:5])
DT[, shift(.SD, 1:2, NA, "lead", TRUE), .SDcols=2:4]

# lag/lead in the right order
DT = data.table(year=2010:2014, v1=runif(5), v2=1:5, v3=letters[1:5])
DT = DT[sample(nrow(DT))]
# add lag=1 for columns ’v1,v2,v3’ in increasing order of ’year’
cols = c("v1","v2","v3")
anstyles = paste("lag", cols, sep="_")
shouldPrint

For use by packages that mimic/divert auto printing e.g. IRkernel and knitr

shouldPrint(x)

Arguments

x A data.table.

Details

Should IRkernel/Jupyter print a data.table returned invisibly by DT[, :=] ? This is a read-once function since it resets an internal flag. If you need the value more than once in your logic, store the value from the first call.

Value

TRUE or FALSE.

References

https://github.com/IRkernel/IRkernel/issues/127
https://github.com/Rdatatable/data.table/issues/933
special-symbols

Description

Nsd, Nby, Nn, .I and .GRP are read only symbols for use in j. N can be used in i as well. See the vignettes and examples here and in data.table.

Details

The bindings of these variables are locked and attempting to assign to them will generate an error. If you wish to manipulate .SD before returning it, take a copy(.SD) first (see FAQ 4.5). Using := in the j of .SD is reserved for future use as a (tortuously) flexible way to update DT by reference by group (even when groups are not contiguous in an ad hoc by).

These symbols are used in j and defined as follows.

- .SD is a data.table containing the Subset of x’s Data for each group, excluding any columns used in by (or keyby).
- .BY is a list containing a length 1 vector for each item in by. This can be useful when by is not known in advance. The by variables are also available to j directly by name; useful for example for titles of graphs if j is a plot command, or to branch with if() depending on the value of a group variable.
- .N is an integer, length 1, containing the number of rows in the group. This may be useful when the column names are not known in advance and for convenience generally. When grouping by i, .N is the number of rows in x matched to, for each row of i, regardless of whether nomatch is NA or 0. It is renamed to N (no dot) in the result (otherwise a column called ".N" could conflict with the .N variable, see FAQ 4.6 for more details and example), unless it is explicitly named; e.g., DT[,list(total=.N),by=a].
- .I is an integer vector equal to seq_len(nrow(x)). While grouping, it holds for each item in the group, it’s row location in x. This is useful to subset in j; e.g. DT[, .I[which.max(somecol)], by=grp].
- .GRP is an integer, length 1, containing a simple group counter. 1 for the 1st group, 2 for the 2nd, etc.

data.table, :=, set, datatable-optimize

Examples

```r
## Not run:
DT = data.table(x=rep(c("b","a","c"),each=3), v=c(1,1,1,2,2,1,1,2,2), y=c(1,3,6), a=1:9, b=9:1)
DT
X = data.table(x=c("c","b"), v=8:7, foo=c(4,2))
X
DT[.N]  # last row, only special symbol allowed in 'i'
```
DT[, .N] # total number of rows in DT
DT[, .N, by=x] # number of rows in each group
DT[, .SD, .SDcols=x:y] # select columns 'x' and 'y'
DT[, .SD[1]] # first row of all columns
DT[, .SD[1], by=x] # first row of 'y' and 'v' for each group in 'x'
DT[, c(.N, lapply(.SD, sum)), by=x] # get rows *and* sum columns 'v' and 'y' by group
DT[, .I[1], by=x] # row number in DT corresponding to each group
DT[, .N, by=rlid(v)] # get count of consecutive runs of 'v'
DT[, c(.y=max(y)), lapply(.SD, min)), by=rlid(v), .SDcols=v:b] # compute 'j' for each consecutive runs of 'v'
DT[, grp := .GRP, by=x] # add a group counter
X[, DT[,BY, y, on="x"], by=x] # join within each group

## End(Not run)

### split

**Split data.table into chunks in a list**

**Description**

Split method for data.table. Faster and more flexible. Be aware that processing list of data.tables will be generally much slower than manipulation in single data.table by group using by argument. read more on data.table.

**Usage**

```r
## S3 method for class 'data.table'
split(x, f, drop = FALSE,
   by, sorted = FALSE, keep.by = TRUE, flatten = TRUE,
   ..., verbose = getOption("datatable.verbose"))
```

**Arguments**

- **x** data.table
- **f** factor or list of factors. Same as split.data.frame. Use by argument instead, this is just for consistency with data.frame method.
- **drop** logical. Default FALSE will not drop empty list elements caused by factor levels not referred by that factors. Works also with new arguments of split data.table method.
- **by** character vector. Column names on which split should be made. For length(by) > 1L and flatten FALSE it will result nested lists with data.tables on leafs.
- **sorted** When default FALSE it will retain the order of groups we are splitting on. When TRUE then sorted list(s) are returned. Does not have effect for f argument.
- **keep.by** logical default TRUE. Keep column provided to by argument.
- **flatten** logical default TRUE will unlist nested lists of data.tables. When using f results are always flattened to list of data.tables.
... passed to data.frame way of processing when using f argument.

verbose logical default FALSE. When TRUE it will print to console data.table split query used to split data.

Details

Argument f is just for consistency in usage to data.frame method. Recommended is to use by argument instead, it will be faster, more flexible, and by default will preserve order according to order in data.

Value

List of data.tables. If using flatten FALSE and length(by) > 1L then recursively nested lists having data.tables as leaves of grouping according to by argument.

See Also

data.table, rbindlist

Examples

```r
set.seed(123)
DT = data.table(x1 = rep(letters[1:2], 6),
                x2 = rep(letters[3:5], 4),
                x3 = rep(letters[5:8], 3),
                y = rnorm(12))
DT = DT[sample(.N)]
DF = as.data.frame(DT)

# split consistency with data.frame: 'x, f, drop'
all.equal(
  split(DT, list(DT$x1, DT$x2)),
  lapply(split(DF, list(DF$x1, DF$x2)), setDT))
)

# nested list using 'flatten' arguments
split(DT, by=c("x1", "x2"))

split(DT, by=c("x1", "x2"), flatten=FALSE)

# dealing with factors
fdt = DT[, c(lapply(.SD, as.factor), list(y=y)), .SDcols=x1:x3]
fdf = as.data.frame(fdt)
sdf = split(fdf, list(fdf$x1, fdf$x2))
all.equal(
  split(fdt, by=c("x1", "x2"), sorted=TRUE),
  lapply(sdf[sort(names(sdf))], setDT))
)

# factors having unused levels, drop FALSE, TRUE
fdt = DT[, .(x1 = as.factor(c(as.character(x1), "c"))[1:13L],
                x2 = as.factor(c("a", as.character(x2)))[1:1L],
                x3 = as.factor(c("a", as.character(x3), "z"))[c(-1L,-14L)],

```
y = y)}

```r
y = y}
```

```r
df = as.data.frame(fdt)
sdf = split(df, list(df$x1, df$x2))
all.equal(
  split(fdt, by=c("x1", "x2"), sorted=TRUE),
  lapply(sdf[sort(names(sdf))], setDT)
)
sdf = split(df, list(df$x1, df$x2), drop=TRUE)
all.equal(
  split(fdt, by=c("x1", "x2"), sorted=TRUE, drop=TRUE),
  lapply(sdf[sort(names(sdf))], setDT)
)
```

---

**subset.data.table**

**Subsetting data.tables**

---

**Description**

Returns subsets of a data.table.

**Usage**

```r
## S3 method for class 'data.table'
subset(x, subset, select, ...)
```

**Arguments**

- `x` data.table to subset.
- `subset` logical expression indicating elements or rows to keep
- `select` expression indicating columns to select from data.table
- `...` further arguments to be passed to or from other methods

**Details**

The `subset` argument works on the rows and will be evaluated in the data.table so columns can be referred to (by name) as variables in the expression.

The data.table that is returned will maintain the original keys as long as they are not select-ed out.

**Value**

A data.table containing the subset of rows and columns that are selected.

**See Also**

`subset`
**Tables**

**Examples**

```r
dT <- data.table(a=sample(c('a', 'b', 'c'), 20, replace=TRUE),
                 b=sample(c('a', 'b', 'c'), 20, replace=TRUE),
                 c=sample(20), key=c('a', 'b'))

sub <- subset(DT, a == 'a')
all.equal(key(sub), key(DT))
```

---

**Tables**

Display `data.table` metadata

**Description**

Convenience function for concisely summarizing some metadata of all `data.tables` in memory (or an optionally specified environment).

**Usage**

```r
tables(mb=TRUE, order.col="NAME", width=80,
       env=parent.frame(), silent=FALSE, index=FALSE)
```

**Arguments**

- `mb` logical; TRUE adds the rough size of each `data.table` in megabytes to the output under column MB.
- `order.col` Column name (character) by which to sort the output.
- `width` integer; number of characters beyond which the output for each of the columns COLS, KEY, and INDICES are truncated.
- `env` An environment, typically the `.GlobalEnv` by default, see Details.
- `silent` logical; should the output be printed?
- `index` logical; if TRUE, the column INDICES is added to indicate the indices assorted with each object, see `indices`.

**Details**

Usually `tables()` is executed at the prompt, where `parent.frame()` returns `.GlobalEnv`. `tables()` may also be useful inside functions where `parent.frame()` is the local scope of the function; in such a scenario, simply set it to `.GlobalEnv` to get the same behaviour as at prompt.

Note that on older versions of R, `object.size` may be slow, so setting `mb=FALSE` may speed up execution of `tables` significantly.

Setting `silent=TRUE` prints nothing; the metadata are returned as a `data.table`, invisibly, whether `silent` is `TRUE` or `FALSE`. 
Value

A data.table containing the information printed.

See Also

data.table, setkey, ls, objects, object.size

Examples

   DT = data.table(A=1:10, B=letters[1:10])
   DT2 = data.table(A=1:10000, ColB=10000:1)
   setkey(DT,B)
   tables()

---

test.data.table      Runs a set of tests.

Description

Runs a set of tests to check data.table is working correctly.

Usage

   test.data.table(verb=FALSE, pkg="pkg", silent=FALSE,
                   with.other.packages=FALSE, benchmark=FALSE)

Arguments

   verbose      If TRUE sets datatable.verbose to TRUE for the duration of the tests.
   pkg          Root directory name under which all package content (ex: DESCRIPTION, src/,
                R/, inst/ etc..) resides.
   silent       Logical, default FALSE, when TRUE it will not raise error on in case of test fails.
   with.other.packages  Run compatibility tests with other packages.
   benchmark     Run the benchmark script.

Details

Runs a series of tests. These can be used to see features and examples of usage, too. Running test.data.table will tell you the full location of the test file(s) to open.

Value

   When silent equals to TRUE it will return TRUE if all tests were successful. FALSE otherwise. If silent equals to FALSE it will return TRUE if all tests were successful. Error otherwise.
timetaken

See Also
data.table

Examples

## Not run:
library(data.table)
test.data.table()

## End(Not run)

timetaken  Pretty print of time taken

Description

Pretty print of time taken since last started.at.

Usage

timetaken(started.at)

Arguments

started.at  The result of proc.time() taken some time earlier.

Value

A character vector of the form HH:MM:SS, or SS.MMMsec if under 60 seconds.

Examples

started.at=proc.time()
Sys.sleep(1)
cat("Finished in",timetaken(started.at),"\n")
transform.data.table  Data table utilities

Description

Utilities for data.table transformation.

Transform by group is particularly slow. Please use := by group instead.

within, transform and other similar functions in data.table are not just provided for users who expect them to work, but for non-data.table-aware packages to retain keys, for example. Hopefully the (much) faster and more convenient data.table syntax will be used in time. See examples.

Usage

```r
## S3 method for class 'data.table'
transform(`_data`, ...)
## S3 method for class 'data.table'
within(data, expr, ...)
```

Arguments

- `data, _data`  data.table to be transformed.
- `...`     for transform, Further arguments of the form `tag=value`. Ignored for within.
- `expr`  expression to be evaluated within the data.table.

Details

within is like with, but modifications (columns changed, added, or removed) are updated in the returned data.table.

Note that transform will keep the key of the data.table provided the targets of the transform (i.e. the columns that appear in `...`) are not in the key of the data.table. within also retains the key provided the key columns are not touched.

Value

The modified value of a copy of `data`.

See Also

transform, within and :=
transpose

Examples

```r
DT <- data.table(a=rep(1:3, each=2), b=1:6)

DT2 <- transform(DT, c = a^2)
DT[, c:=a^2]
identical(DT,DT2)

DT2 <- within(DT, {
  b <- rev(b)
  c <- a^2
  rm(a)
})
DT[, `:=`(b = rev(b),
  c = a^2,
  a = NULL)]
identical(DT,DT2)

DT$d = ave(DT$b, DT$c, FUN=max) # copies entire DT, even if it is 10GB in RAM
DT = DT[, transform(.SD, d=max(b)), by="c"] # same, but even worse as .SD is copied for each group
DT[, d=max(b), by="c"] # same result, but much faster, shorter and scales

# Multiple update by group. Convenient, fast, scales and easy to read.
DT[, `:=`(minb = min(b),
  meanb = mean(b),
  bplusd = sum(b+d)), by=c/%5]
DT
```

transpose

**Efficient transpose of list**

Description

transpose is an efficient way to transpose lists, data frames or data tables.

Usage

`transpose(l, fill=NA, ignore.empty=FALSE)`

Arguments

- `l` A list, data.frame or data.table.
- `fill` Default is NA. It is used to fill shorter list elements so as to return each element of the transposed result of equal lengths.
- `ignore.empty` Default is FALSE. TRUE will ignore length-0 list elements.
Details

The list elements (or columns of data.frame/data.table) should be all atomic. If list elements are of unequal lengths, the value provided in fill will be used so that the resulting list always has all elements of identical lengths. The class of input object is also preserved in the transposed result.

The ignore.empty argument can be used to skip or include length-0 elements.

This is particularly useful in tasks that require splitting a character column and assigning each part to a separate column. This operation is quite common enough that a function tstrsplit is exported.

factor columns are converted to character type. Attributes are not preserved at the moment. This may change in the future.

Value

A transposed list, data.frame or data.table.

See Also

data.table, tstrsplit

Examples

ll = list(1:5, 6:8)
transpose(ll)
setDT(transpose(ll, fill=0))[]

DT = data.table(x=1:5, y=6:10)
transpose(DT)

<table>
<thead>
<tr>
<th>truelength</th>
<th>Over-allocation access</th>
</tr>
</thead>
</table>

Description

These functions are experimental and somewhat advanced. By experimental we mean their names might change and perhaps the syntax, argument names and types. So if you write a lot of code using them, you have been warned! They should work and be stable, though, so please report problems with them.

Usage

truelength(x)
alloc.col(DT,
   n = getOption("datatable.alloccol"),       # default: 1024L
   verbose = getOption("datatable.verbose")   # default: FALSE
Arguments

- `x`: Any type of vector, including `data.table` which is a list vector of column pointers.
- `DT`: A `data.table`.
- `n`: The number of spare column pointer slots to ensure are available. If `DT` is a 1,000 column `data.table` with 24 spare slots remaining, `n=1024L` means grow the 24 spare slots to be 1024. `truelength(DT)` will then be 2024 in this example.
- `verbose`: Output status and information.

Details

When adding columns by reference using `:=`, we could simply create a new column list vector (one longer) and `memcpy` over the old vector, with no copy of the column vectors themselves. That requires negligible use of space and time, and is what v1.7.2 did. However, that copy of the list vector of column pointers only (but not the columns themselves), a shallow copy, resulted in inconsistent behaviour in some circumstances. So, as from v1.7.3 `data.table` over allocates the list vector of column pointers so that columns can be added fully by reference, consistently.

When the allocated column pointer slots are used up, to add a new column `data.table` must re-allocate that vector. If two or more variables are bound to the same `data.table` this shallow copy may or may not be desirable, but we don’t think this will be a problem very often (more discussion may be required on `data.table` issue tracker). Setting `options(data.table.verbose=TRUE)` includes messages if and when a shallow copy is taken. To avoid shallow copies there are several options: use `copy` to make a deep copy first, use `alloc.col` to reallocate in advance, or, change the default allocation rule (perhaps in your `.Rprofile`); e.g., `options(data.table.alloccol=10000L)`.

Please note: over allocation of the column pointer vector is not for efficiency per se. It’s so that `:=` can add columns by reference without a shallow copy.

Value

`truelength(x)` returns the length of the vector allocated in memory. `length(x)` of those items are in use. Currently, it’s just the list vector of column pointers that is over-allocated (i.e. `truelength(DT)`), not the column vectors themselves, which would in future allow fast row `insert()`. For tables loaded from disk however, `truelength` is 0 in R 2.14.0+ (and random in R <= 2.13.2), which is perhaps unexpected. `data.table` detects this state and over-allocates the loaded `data.table` when the next column addition occurs. All other operations on `data.table` (such as fast grouping and joins) do not need `truelength`.

`alloc.col` reallocates `DT` by reference. This may be useful for efficiency if you know you are about to going to add a lot of columns in a loop. It also returns the new `DT`, for convenience in compound queries.

See Also

- `copy`
tstrsplit

strsplit and transpose the resulting list efficiently

Description

This is equivalent to `transpose(strsplit(...))`. This is a convenient wrapper function to split a column using `strsplit` and assign the transposed result to individual columns. See examples.

Usage

tstrsplit(x, ..., fill=NA, type.convert=FALSE, keep, names=FALSE)

Arguments

- **x** The vector to split (and transpose).
- **...** All the arguments to be passed to `strsplit`.
- **fill** Default is `NA`. It is used to fill shorter list elements so as to return each element of the transposed result of equal lengths.
- **type.convert** `TRUE` calls `type.convert` with `as.is=TRUE` on the columns.
- **keep** Specify indices corresponding to just those list elements to retain in the transposed result. Default is to return all.
- **names** `TRUE` auto names the list with `V1, V2` etc. Default (FALSE) is to return an unnamed list.

Details

It internally calls `strsplit` first, and then `transpose` on the result.

names argument can be used to return an auto named list, although this argument does not have any effect when used with `:=`, which requires names to be provided explicitly. It might be useful in other scenarios.

Value

A transposed list after splitting by the pattern provided.
See Also

`data.table`, `transpose`

Examples

```r
x = c("abcde", "ghij", "klmnopq")
strsplit(x, "", fixed=TRUE)
tstrsplit(x, "", fixed=TRUE)
tstrsplit(x, "", fixed=TRUE, fill="<NA>")

# using keep to return just 1,3,5
tstrsplit(x, "", fixed=TRUE, keep=c(1,3,5))

# names argument
tstrsplit(x, "", fixed=TRUE, keep=c(1,3,5), names=LETTERS[1:3])

DT = data.table(x=c("A/B", "A", "B"), y=1:3)
DT[, c("c1") := tstrsplit(x, "/", fixed=TRUE, keep=1L)][]
DT[, c("c1", "c2") := tstrsplit(x, "/", fixed=TRUE)][]
```

update.dev.pkg

Perform update of development version of a package

Description

It will download and install package from devel repository only when new commit is available there, otherwise only PACKAGES file is transferred. Defaults are set to update `data.table`, other packages can be used. Their repository has to include git commit information in PACKAGES file.

Usage

```r
## S3 method for class 'dev.pkg'
update(object="data.table",
repo="https://Rdatatable.github.io/data.table", field="Revision", ...)
```

Arguments

- `object` character scalar, package name.
- `repo` character scalar, url of package devel repository.
- `field` character scalar, metadata field to use in PACKAGES file and DESCRIPTION file, default "Revision".
- `...` passed to `install.packages`.

Details

In case if devel repository does not provide package binaries user has have development tools installed for package compilation to use this function.
Value

NULL.
