Package ‘data.table’

February 29, 2024

Version 1.15.2
Title Extension of `data.frame`
Depends R (>= 3.1.0)
Imports methods
Suggests bit64 (>= 4.0.0), bit (>= 4.0.4), R.utils, xts, zoo (>= 1.8-1), yaml, knitr, markdown
Description Fast aggregation of large data (e.g. 100GB in RAM), fast ordered joins, fast add/modify/delete of columns by group using no copies at all, list columns, friendly and fast character-separated-value read/write. Offers a natural and flexible syntax, for faster development.

**data.table-package**

Enhanced data.frame

**Description**

`data.table` inherits from `data.frame`. It offers fast and memory efficient: file reader and writer, aggregations, updates, equi, non-equi, rolling, range and interval joins, in a short and flexible syntax, for faster development.

It is inspired by A[B] syntax in R where A is a matrix and B is a 2-column matrix. Since a `data.table` is a `data.frame`, it is compatible with R functions and packages that accept only `data.frame`.

Type vignette(package="data.table") to get started. The Introduction to data.table vignette introduces data.table’s x[i, j, by] syntax and is a good place to start. If you have read the vignettes and the help page below, please read the data.table support guide.

Please check the homepage for up to the minute live NEWS.

Tip: one of the quickest ways to learn the features is to type example(data.table) and study the output at the prompt.

Usage

data.table(..., keep.rownames=FALSE, check.names=FALSE, key=NULL, stringsAsFactors=FALSE)

## S3 method for class 'data.table'
x[i, j, by, keyby, with = TRUE,
  nomatch = NA,
  mult = "all",
  roll = FALSE,
  rollends = if (roll=="nearest") c(TRUE,TRUE)
    else if (roll>=0) c(FALSE,TRUE)
    else c(TRUE,FALSE),
  which = FALSE,
  .SDcols,
  verbose =getOption("datatable.verbose"),
  # default: FALSE
  allow.cartesian = getOption("datatable.allow.cartesian"),
  # default: FALSE
  drop = NULL, on = NULL, env = NULL]

Arguments

... Just as ... in data.frame. Usual recycling rules are applied to vectors of different lengths to create a list of equal length vectors.

keep.rownames If ... is a matrix or data.frame, TRUE will retain the rownames of that object in a column named rn.

check.names Just as check.names in data.frame.

key Character vector of one or more column names which is passed to setkey. It may be a single comma separated string such as key="x,y,z", or a vector of names such as key=c("x","y","z").

stringsAsFactors Logical (default is FALSE). Convert all character columns to factors?

x A data.table.

i Integer, logical or character vector, single column numeric matrix, expression of column names, list, data.frame or data.table. integer and logical vectors work the same way they do in [.data.frame except logical NAs are treated as FALSE. expression is evaluated within the frame of the data.table (i.e. it sees column names as if they are variables) and can evaluate to any of the other types. character, list and data.frame input to i is converted into a data.table internally using as.data.table.
If `i` is a `data.table`, the columns in `i` to be matched against `x` can be specified using one of these ways:

- on argument (see below). It allows for both equi- and the newly implemented non-equijoins.
- If not, `x` must be keyed. Key can be set using `setkey`. If `i` is also keyed, then first key column of `i` is matched against first key column of `x`, second against second, etc.
  - If `i` is not keyed, then first column of `i` is matched against first key column of `x`, second column of `i` against second key column of `x`, etc...
  - This is summarised in code as `min(length(key(x)), if (haskey(i)) length(key(i)) else ncol(i))`.

Using `on=` is recommended (even during keyed joins) as it helps understand the code better and also allows for non-equijoins.

When the binary operator `==` alone is used, an equi join is performed. In SQL terms, `x[i]` then performs a right join by default. `i` prefixed with `!` signals a not-join or not-select.

Support for non-equijoin was recently implemented, which allows for other binary operators `>=`, `>`, `<=` and `<`. See vignette("datatable-keys-fast-subset") and vignette("datatable-secondary-indices-and-auto-indexing").

**Advanced:** When `i` is a single variable name, it is not considered an expression of column names and is instead evaluated in calling scope.

When `with=TRUE` (default), `j` is evaluated within the frame of the `data.table`; i.e., it sees column names as if they are variables. This allows to not just select columns in `j`, but also compute on them e.g., `x[, a]` and `x[, sum(a)]` returns `x$a` and `sum(x$a)` as a vector respectively. `x[, .(a, b)]` and `x[, .(sa=sum(a), sb=sum(b))]` returns a two column `data.table` each, the first simply selecting columns `a`, `b` and the second computing their sums.

As long as `j` returns a list, each element of the list becomes a column in the resulting `data.table`. When the output of `j` is not a list, the output is returned as-is (e.g. `x[, a]` returns the column vector `a`, unless by is used, in which case it is implicitly wrapped in list for convenience (e.g. `x[, .(sum(a), by=b)]` will create a column named `V1` with value `sum(a)` for each group).

The expression `.()` is a shorthand alias to `list()`: they both mean the same. (An exception is made for the use of `.()` within a call to `bquote`, where `.()` is left unchanged.)

When `j` is a vector of column names or positions to select (as in `data.frame`). There is no need to use `with=FALSE` anymore. Note that `with=FALSE` is still necessary when using a logical vector with length `ncol(x)` to include/exclude columns. Note: if a logical vector with length `k < ncol(x)` is passed, it will be filled to length `ncol(x)` with FALSE, which is different from `data.frame`, where the vector is recycled.

**Advanced:** `j` also allows the use of special read-only symbols: `.SD`, `.N`, `.I`, `.GRP`, `.BY`. See `special-symbols` and the Examples below for more.

**Advanced:** When `i` is a `data.table`, the columns of `i` can be referred to in `j` by using the prefix `i.`, e.g., `X[Y, .(val, i.val)]`. Here `val` refers to `X`'s column and `i.val` `Y`'s.
Advanced: Columns of x can now be referred to using the prefix x. and is particularly useful during joining to refer to x’s join columns as they are otherwise masked by i’s. For example, X[Y, .(x.a=i.a, b), on="a"]. See vignette("datatable-intro") and example(data.table).

by

Column names are seen as if they are variables (as in j when with=TRUE). The data.table is then grouped by the by and j is evaluated within each group. The order of the rows within each group is preserved, as is the order of the groups. by accepts:

- A single unquoted column name: e.g., DT[, .(sa=sum(a)), by=x]
- a list() of expressions of column names: e.g., DT[, .(sa=sum(a)), by=.x=x>0, y]
- a single character string containing comma separated column names (where spaces are significant since column names may contain spaces even at the start or end): e.g., DT[, sum(a), by="x,y,z"]
- a character vector of column names: e.g., DT[, sum(a), by=c("x", "y")]
- or of the form startcol:endcol: e.g., DT[, sum(a), by=x:z]

Advanced: When i is a list (or data.frame or data.table), DT[i, j, by=.EACHI] evaluates j for the groups in ‘DT’ that each row in i joins to. That is, you can join (in i) and aggregate (in j) simultaneously. We call this grouping by each i. See this StackOverflow answer for a more detailed explanation until we roll out vignettes.

keyby

Same as by, but with an additional setkey() run on the by columns of the result, for convenience. It is common practice to use ‘keyby=’ routinely when you wish the result to be sorted. May also be TRUE or FALSE when by is provided as an alternative way to accomplish the same operation.

with

By default with=TRUE and j is evaluated within the frame of x; column names can be used as variables. In case of overlapping variables names inside dataset and in parent scope you can use double dot prefix ..cols to explicitly refer to ‘cols variable parent scope and not from your dataset.

When j is a character vector of column names, a numeric vector of column positions to select or of the form startcol:endcol, and the value returned is always a data.table. with=FALSE is not necessary anymore to select columns dynamically. Note that x[,cols] is equivalent to x[, ..cols] and to x[, cols, with=FALSE] and to x[, .SD, .SDcols=cols].

nomatch

When a row in i has no match to x, nomatch=NA (default) means NA is returned. NULL (or 0 for backward compatibility) means no rows will be returned for that row of i.

mult

When i is a list (or data.frame or data.table) and multiple rows in x match to the row in i, mult controls which are returned: "all" (default), "first" or "last".
roll

When i is a data.table and its row matches to all but the last x join column, and its value in the last i join column falls in a gap (including after the last observation in x for that group), then:

- $+\infty$ (or TRUE) rolls the prevailing value in x forward. It is also known as last observation carried forward (LOCF).
- $-\infty$ rolls backwards instead; i.e., next observation carried backward (NOCB).
- finite positive or negative number limits how far values are carried forward or backward.
- "nearest" rolls the nearest value instead.

Rolling joins apply to the last join column, generally a date but can be any variable. It is particularly fast using a modified binary search.

A common idiom is to select a contemporaneous regular time series (dts) across a set of identifiers (ids): `DT[CJ(ids,dts),roll=TRUE]` where DT has a 2-column key (id,date) and CJ stands for cross join.

rollends

A logical vector length 2 (a single logical is recycled) indicating whether values falling before the first value or after the last value for a group should be rolled as well.

- If rollends[2]=TRUE, it will roll the last value forward. TRUE by default for LOCF and FALSE for NOCB rolls.
- If rollends[1]=TRUE, it will roll the first value backward. TRUE by default for NOCB and FALSE for LOCF rolls.

When roll is a finite number, that limit is also applied when rolling the ends.

which

TRUE returns the row numbers of x that i matches to. If NA, returns the row numbers of i that have no match in x. By default FALSE and the rows in x that match are returned.

.SDcols

Specifies the columns of x to be included in the special symbol .SD which stands for Subset of data.table. May be character column names, numeric positions, logical, a function name such as ‘is.numeric’, or a function call such as ‘patterns()’. .SDcols is particularly useful for speed when applying a function through a subset of (possible very many) columns by group; e.g., `DT[, lapply(.SD, sum), by="x,y", .SDcols=301:350]`. For convenient interactive use, the form `startcol:endcol` is also allowed (as in by), e.g., `DT[, lapply(.SD, sum), by="x:y", .SDcols=a:f]`. Inversion (column dropping instead of keeping) can be accomplished by prepending the argument with ! or ~ (there’s no difference between these), e.g. `.SDcols=!c('x','y')`.

Finally, you can filter columns to include in .SD based on their names according to regular expressions via `.SDcols=patterns(regex1, regex2, ...)`. The included columns will be the intersection of the columns identified by each pattern; pattern unions can easily be specified with | in a regex. You can filter columns on values by passing a function, e.g. `.SDcols=is.numeric`. You can also invert a pattern as usual with `.SDcols=!patterns(...)` or `.SDcols=!is.numeric`.

verbose

TRUE turns on status and information messages to the console. Turn this on by default using `options(datatable.verbose=TRUE)`. The quantity and types of verbosity may be expanded in future.
allow.cartesian
FALSE prevents joins that would result in more than \( \text{nrow}(x) \times \text{nrow}(i) \) rows. This is usually caused by duplicate values in \( i \)'s join columns, each of which join to the same group in \( x \) over and over again: a misspecified join. Usually this was not intended and the join needs to be changed. The word 'cartesian' is used loosely in this context. The traditional cartesian join is (deliberately) difficult to achieve in \data.table\: where every row in \( i \) joins to every row in \( x \) (a \( \text{nrow}(x) \times \text{nrow}(i) \) row result). 'cartesian' is just meant in a 'large multiplicative' sense, so FALSE does not always prevent a traditional cartesian join.

drop
Never used by \data.table\. Do not use. It needs to be here because \data.table\ inherits from \data.frame\. See vignette("datatable-faq").

on
Indicate which columns in \( x \) should be joined with which columns in \( i \) along with the type of binary operator to join with (see non-equi joins below on this). When specified, this overrides the keys set on \( x \) and \( i \). When .NATURAL keyword provided then natural join is made (join on common columns). There are multiple ways of specifying the on argument:

- As an unnamed character vector, e.g., \( X[Y, \text{on}=c("a", "b") ] \), used when columns a and b are common to both \( X \) and \( Y \).

- Foreign key joins: As a named character vector when the join columns have different names in \( X \) and \( Y \). For example, \( X[Y, \text{on}=c(x1="y1", x2="y2") ] \) joins \( X \) and \( Y \) by matching columns \( x1 \) and \( x2 \) in \( X \) with columns \( y1 \) and \( y2 \) in \( Y \), respectively.

  From v1.9.8, you can also express foreign key joins using the binary operator ==, e.g. \( X[Y, \text{on}=c("x1==y1", "x2==y2") ] \).

  NB: shorthand like \( X[Y, \text{on}=c(\"a\", \"V2=\"b\") ] \) is also possible if, e.g., column "a" is common between the two tables.

- For convenience during interactive scenarios, it is also possible to use \( .() \) syntax as \( X[Y, \text{on}=.(a, b)] \).

- From v1.9.8, (non-equi) joins using binary operators \( >=, >, <=, < \) are also possible, e.g., \( X[Y, \text{on}=c("x>=a", "y<b") ] \), or for interactive use as \( X[Y, \text{on}=.(x>=a, y<b)] \).

See examples as well as vignette("datatable-secondary-indices-and-auto-indexing").

env
List or an environment, passed to substitute2 for substitution of parameters in \( i \), \( j \) and by (or keyby). Use verbose to preview constructed expressions. For more details see vignette("datatable-programming").

**Details**

\data.table\ builds on base R functionality to reduce 2 types of time:

1. programming time (easier to write, read, debug and maintain), and
2. compute time (fast and memory efficient).

The general form of \data.table\ syntax is:
DT[i, j, by] # + extra arguments
| | | |
| | ----------- grouped by what? |
| ------------ what to do? |
---> on which rows?

The way to read this out loud is: “Take DT, subset rows by i, then compute j grouped by by. Here are some basic usage examples expanding on this definition. See the vignette (and examples) for working examples.

X[, a] # return col 'a' from X as vector. If not found, search in parent frame.
X[, .(a)] # same as above, but return as a data.table.
X[, sum(a)] # return sum(a) as a vector (with same scoping rules as above)
X[, .(sum(a)), by=c] # get sum(a) grouped by 'c'.
X[, sum(a), by=c] # same as above, .() can be omitted in j and by on single expression for convenience
X[, sum(a), by=c:f] # get sum(a) grouped by all columns in between 'c' and 'f' (both inclusive)
X[, sum(a), keyby=b] # get sum(a) grouped by 'b', and sort that result by the grouping column 'b'.
X[, sum(a), by=b, keyby=TRUE] # same order as above, but using sorting flag
X[, sum(a), by=b][order(b)] # same order as above, but by chaining compound expressions
X[c>1, sum(a), by=c] # get rows where c>1 is TRUE, and on those rows, get sum(a) grouped by 'c'
X[Y, .(a, b), on="c"] # get rows where Y$c == X$c, and select columns 'X$a' and 'X$b' for those rows
X[Y, .(a, i.a), on="c"] # get rows where Y$c == X$c, and then select 'X$a' and 'Y$a' (=i.a)
X[Y, sum(a*i.a), on="c", by=.EACHI] # for *each* 'Y$c', get sum(a*i.a) on matching rows in 'X$c'
X[, plot(a, b), by=c] # j accepts any expression, generates plot for each group and returns no data
# see ?assign to add/update/delete columns by reference using the same consistent interface

A data.table query may be invoked on a data.frame using functional form DT(...), see examples. The class of the input is retained.

A data.table is a list of vectors, just like a data.frame. However:

1. it never has or uses rownames. Rownames based indexing can be done by setting a key of one or more columns or done ad-hoc using the on argument (now preferred).
2. it has enhanced functionality in [.data.table for fast joins of keyed tables, fast aggregation, fast last observation carried forward (LOCF) and fast add/modify/delete of columns by reference with no copy at all.

See the see also section for the several other methods that are available for operating on data.tables efficiently.

Note

If keep.rownames or check.names are supplied they must be written in full because R does not allow partial argument names after ... For example, data.table(DF, keep=TRUE) will create a column called keep containing TRUE and this is correct behaviour; data.table(DF, keep.rownames=TRUE) was intended.

POSIXlt is not supported as a column type because it uses 40 bytes to store a single datetime. They are implicitly converted to POSIXct type with warning. You may also be interested in IDateTime instead; it has methods to convert to and from POSIXlt.

### .Last.updated

#### Number of rows affected by last update

**Description**

Returns number of rows affected by last := or set().

**Usage**

```
.Last.updated
```

**Details**

Be aware that in the case of duplicate indices, multiple updates occur (duplicates are overwritten); `.Last.updated` will include all of the updates performed, including duplicated ones. See examples.

**Value**

Integer.

**See Also**

`:=`

**Examples**

```r
d = data.table(a=1:4, b=2:5)
d[2:3, z:=5L]
.Last.updated

# updated count takes duplicates into account #2837
DT = data.table(a = 1L)
DT[c(1L, 1L), a := 2:3]
.Last.updated
```
Description

Fast add, remove and update subsets of columns, by reference. := operator can be used in two ways: LHS := RHS form, and Functional form. See Usage.

set is a low-overhead loop-able version of :=. It is particularly useful for repetitively updating rows of certain columns by reference (using a for-loop). See Examples. It can not perform grouping operations.

let is an alias for the functional form and behaves exactly like `:=`.

Usage

# 1. LHS := RHS form
# DT[i, LHS := RHS, by = ...]
# DT[i, c("LHS1", "LHS2") := list(RHS1, RHS2), by = ...]

# 2a. Functional form with :=
# DT[i, :=(LHS1 = RHS1,
#     LHS2 = RHS2,
#     ...), by = ...]

# 2b. Functional form with let
# DT[i, let(LHS1 = RHS1,
#     LHS2 = RHS2,
#     ...), by = ...]

set(x, i = NULL, j, value)

Arguments

<table>
<thead>
<tr>
<th>LHS</th>
<th>A character vector of column names (or numeric positions) or a variable that evaluates as such. If the column doesn’t exist, it is added, by reference.</th>
</tr>
</thead>
<tbody>
<tr>
<td>RHS</td>
<td>A list of replacement values. It is recycled in the usual way to fill the number of rows satisfying i, if any. To remove a column use NULL.</td>
</tr>
<tr>
<td>x</td>
<td>A data.table. Or, set() accepts data.frame, too.</td>
</tr>
<tr>
<td>i</td>
<td>Optional. Indicates the rows on which the values must be updated with. If not provided, implies all rows. The := form is more powerful as it allows subsets and joins based add/update columns by reference. See Details.</td>
</tr>
<tr>
<td>j</td>
<td>Column name(s) (character) or number(s) (integer) to be assigned value when column(s) already exist, and only column name(s) if they are to be created.</td>
</tr>
<tr>
<td>value</td>
<td>A list of replacement values to assign by reference to x[i, j].</td>
</tr>
</tbody>
</table>
Details

`:=` is defined for use in `j` only. It adds or updates or removes column(s) by reference. It makes no copies of any part of memory at all. Please read vignette("datatable-reference-semantics") and follow with examples. Some typical usages are:

```r
DT[, col := val] # update (or add at the end if doesn't exist) a column called "col" with value "val" (recycled if necessary).
DT[i, col := val] # same as above, but only for those rows specified in i and (for new columns) NA elsewhere.
DT[i, "col a" := val] # update existing columns 3:6 with value. Aside: parens are not required here since : already makes LHS a call rather than a symbol.
DT[i, (colvector) := val] # OLD syntax. The contents of "colvector" in calling scope determine the column(s).
DT[i, colC := mean(colB), by = colA] # update (or add) column called "colC" by reference by group.
DT[, let(new1 = sum(colB), new2 = sum(colC))] # New alias for functional form.
```

The `.Last.updated` variable contains the number of rows updated by the most recent `:=` or `set` calls, which may be useful, for example, in production settings for testing assumptions about the number of rows affected by a statement; see `.Last.updated` for details.

Note that for efficiency no check is performed for duplicate assignments, i.e. if multiple values are passed for assignment to the same index, assignment to this index will occur repeatedly and sequentially; for a given use case, consider whether it makes sense to create your own test for duplicates, e.g. in production code.

All of the following result in a friendly error (by design):

```r
x := 1L
DT[i, col] := val
DT[i]$col := val
DT[, {col1 := 1L; col2 := 2L}] # Use the functional form, `:=`(), instead (see above).
```

For additional resources, please read vignette("datatable-faq"). Also have a look at Stack-Overflow’s data.table tag.

`:=` in `j` can be combined with all types of `i` (such as binary search), and all types of `by`. This a one reason why `:=` has been implemented in `j`. Please see vignette("datatable-reference-semantics") and also FAQ 2.16 for analogies to SQL.

When LHS is a factor column and RHS is a character vector with items missing from the factor levels, the new level(s) are automatically added (by reference, efficiently), unlike base methods.

Unlike `<-` for `data.frame`, the (potentially large) LHS is not coerced to match the type of the (often small) RHS. Instead the RHS is coerced to match the type of the LHS, if necessary. Where this involves double precision values being coerced to an integer column, a warning is given when fractional data is truncated. It is best to get the column types correct up front and stick to them.

Changing a column type is possible but deliberately harder: provide a whole column as the RHS. This RHS is then plonked into that column slot and we call this plonk syntax, or replace column syntax if you prefer. By needing to construct a full length vector of a new type, you as the user are more aware of what is happening and it is clearer to readers of your code that you really do intend to change the column type; e.g., `DT[, colA := as.integer(colA)]`. A plonk occurs whenever you provide a RHS value to `:=` which is `nrow` long. When a column is plonked, the original column
is not updated by reference because that would entail updating every single element of that column whereas the plonk is just one column pointer update.

**Value**

DT is modified by reference and returned invisibly. If you require a copy, take a copy first (using DT2 = copy(DT)).

**Advanced (internals):**

It is easy to see how sub-assigning to existing columns is done internally. Removing columns by reference is also straightforward by modifying the vector of column pointers only (using memmove in C). However adding (new) columns is more tricky as to how the data.table can be grown by reference: the list vector of column pointers is over-allocated, see truelength. By defining := in j we believe update syntax is natural, and scales, but it also bypasses [<- dispatch and allows := to update by reference with no copies of any part of memory at all.

Since [.data.table incurs overhead to check the existence and type of arguments (for example), set() provides direct (but less flexible) assignment by reference with low overhead, appropriate for use inside a for loop. See examples. := is more powerful and flexible than set() because := is intended to be combined with i and by in single queries on large datasets.

**Note**

DT[a > 4, b := c] is different from DT[a > 4][, b := c]. The first expression updates (or adds) column b with the value c on those rows where a > 4 evaluates to TRUE. X is updated by reference, therefore no assignment needed.

The second expression on the other hand updates a new data.table that’s returned by the subset operation. Since the subsetted data.table is ephemeral (it is not assigned to a symbol), the result would be lost; unless the result is assigned, for example, as follows: ans <- DT[a > 4][, b := c].

**See Also**

data.table, copy, setalloccol, truelength, set, .Last.updated

**Examples**

```r
DT = data.table(a = LETTERS[c(3L,1:3)], b = 4:7)
DT[, c := 8]            # add a numeric column, 8 for all rows
DT[, d := 9L]          # add an integer column, 9L for all rows
DT[, c := NULL]        # remove column c
DT[2, d := -8L]        # subassign by reference to d; 2nd row is -8L now
DT                    # DT changed by reference
DT[2, d := 10L][]      # shorthand for update and print
DT[b > 4, b := d * 2L] # subassign to b with d*2L on those rows where b > 4 is TRUE
DT[b > 4][, b := d * 2L] # different from above. [], := [] is performed on the subset
# which is an new (ephemeral) data.table. Result needs to be
# assigned to a variable (using `<-`).
```
DT[, e := mean(d), by = a] # add new column by group by reference
DT["A", b := 0L, on = "a"] # ad-hoc update of column b for group "A" using
  # joins-as-subsets with binary search and 'on'=
# same as above but using keys
setkey(DT, a)
DT["A", b := 0L] # binary search for group "A" and set column b using keys
DT["B", f := mean(d)] # subassign to new column, NA initialized

# Adding multiple columns
## by name
DT[, c('sin_d', 'log_e', 'cos_d') :=
    (.sin(d), log(e), cos(d))]
## by patterned name
DT[, paste(c('sin', 'cos'), 'b', sep = '_') :=
    (.sin(b), cos(b))]
## using lapply & .SD
DT[, paste0('tan_', c('b', 'd', 'e')) :=
    lapply(.SD, tan), .SDcols = c('b', 'd', 'e')]
## using forced evaluation to disambiguate a vector of names
## and overwrite existing columns with their squares
sq_cols = c('b', 'd', 'e')
DT[, (sq_cols) := lapply(.SD, '^2L), .SDcols = sq_cols]
## by integer (NB: for robustness, it is not recommended
## to use explicit integers to update/define columns)
DT[, c(2L, 3L, 4L) := (.sqrt(b), sqrt(d), sqrt(e))]
## by implicit integer
DT[, grep('a$', names(DT)) := tolower(a)]
## by implicit integer, using forced evaluation
sq_col_idx = grep('d$', names(DT))
DT[, (sq_col_idx) := lapply(.SD, dnorm),
    .SDcols = sq_col_idx]

## Not run:
# Speed example:

m = matrix(1, nrow = 2e6L, ncol = 100L)
DF = as.data.frame(m)
DT = as.data.table(m)

system.time(for (i in 1:1000) DF[i, 1] = i)
# 15.856 seconds
system.time(for (i in 1:1000) DT[i, V1 := i])
# 0.279 seconds (57 times faster)
system.time(for (i in 1:1000) set(DT, i, 1L, i))
# 0.002 seconds (7930 times faster, overhead of [.data.table is avoided)

# However, normally, we call [.data.table once on *large* data, not many times on small data.
# The above is to demonstrate overhead, not to recommend looping in this way. But the option
# of set() is there if you need it.
## End(Not run)
address

Address in RAM of a variable

Description

Returns the pointer address of its argument.

Usage

    address(x)

Arguments

    x  Anything.

Details

Sometimes useful in determining whether a value has been copied or not, programmatically.

Value

A character vector length 1.

References

https://stackoverflow.com/a/10913296/403310 (but implemented in C without using .Internal(inspect()))

See Also

    copy

Examples

    x=1
    address(x)
all.equal  

Equality Test Between Two Data Tables

Description

Convenient test of data equality between data.table objects. Performs some factor level *stripping*.

Usage

```r
## S3 method for class 'data.table'
all.equal(target, current, trim.levels=TRUE, check.attributes=TRUE,
          ignore.col.order=FALSE, ignore.row.order=FALSE, tolerance=sqrt(.Machine$double.eps),
          ...)
```

Arguments

- **target, current**: data.tables to compare. If `current` is not a data.table but `check.attributes` is FALSE, it will be coerced to one via `as.data.table`.
- **trim.levels**: A logical indicating whether or not to remove all unused levels in columns that are factors before running equality check. It effect only when `check.attributes` is TRUE and `ignore.row.order` is FALSE.
- **check.attributes**: A logical indicating whether or not to check attributes, will apply not only to `data.table` but also attributes of the columns. It will skip `c("row.names",".internal.selfref")` data.table attributes.
- **ignore.col.order**: A logical indicating whether or not to ignore columns order in `data.table`.
- **ignore.row.order**: A logical indicating whether or not to ignore rows order in `data.table`. This option requires datasets to use data types on which join can be made, so no support for `list, complex, raw`, but still supports `integer64`.
- **tolerance**: A numeric value used when comparing numeric columns, by default `sqrt(.Machine$double.eps)`. Unless non-default value provided it will be forced to 0 if used together with `ignore.row.order` and duplicate rows detected or factor columns present.
- **...**: Passed down to internal call of `all.equal`.

Details

For efficiency `data.table` method will exit on detected non-equality issues, unlike most `all.equal` methods which process equality checks further. Besides that fact it also handles the most time consuming case of `ignore.row.order = TRUE` very efficiently.

Value

Either `TRUE` or a vector of mode "character" describing the differences between `target` and `current`. 
See Also

all.equal

Examples

dt1 <- data.table(A = letters[1:10], X = 1:10, key = "A")
dt2 <- data.table(A = letters[5:14], Y = 1:10, key = "A")

isTRUE(all.equal(dt1, dt1))
is.character(all.equal(dt1, dt2))

# ignore.col.order
x <- copy(dt1)
y <- dt1[, .(X, A)]
all.equal(x, y)
all.equal(x, y, ignore.col.order = TRUE)

# ignore.row.order
x <- setkeyv(copy(dt1), NULL)
y <- dt1[sample(nrow(dt1))]  
all.equal(x, y)
all.equal(x, y, ignore.row.order = TRUE)

# check.attributes
x = copy(dt1)
y = setkeyv(copy(dt1), NULL)
all.equal(x, y)
all.equal(x, y, check.attributes = FALSE)

x = data.table(1L)
y = 1L
all.equal(x, y)
all.equal(x, y, check.attributes = FALSE)

# trim.levels
x <- data.table(A = factor(letters[1:10])[1:4]) # 10 levels
y <- data.table(A = factor(letters[1:5])[1:4]) # 5 levels

all.equal(x, y, trim.levels = FALSE)
all.equal(x, y, trim.levels = FALSE, check.attributes = FALSE)
all.equal(x, y)

---

as.data.table  

Coerce to data.table

Description

Functions to check if an object is data.table, or coerce it if possible.

Usage

as.data.table(x, keep.rownames=FALSE, ...)
as.data.table

## S3 method for class 'data.table'
as.data.table(x, ...)

## S3 method for class 'array'
as.data.table(x, keep.rownames=FALSE, key=NULL, sorted=TRUE, value.name="value", na.rm=TRUE, ...)

is.data.table(x)

Arguments

x        An R object.
keep.rownames Default is FALSE. If TRUE, adds the input object’s names as a separate column named "rn". keep.rownames = "id" names the column "id" instead.
key      Character vector of one or more column names which is passed to setkeyv.
sorted   logical used in array method, default TRUE is overridden when key is provided.
value.name character scalar used in array method, default "value".
na.rm    logical used in array method, default TRUE will remove rows with NA values.
...      Additional arguments to be passed to or from other methods.

Details

as.data.table is a generic function with many methods, and other packages can supply further methods.

If a list is supplied, each element is converted to a column in the data.table with shorter elements recycled automatically. Similarly, each column of a matrix is converted separately.
character objects are not converted to factor types unlike as.data.frame.

If a data.frame is supplied, all classes preceding "data.frame" are stripped. Similarly, for data.table as input, all classes preceding "data.table" are stripped. as.data.table methods returns a copy of original data. To modify by reference see setDT and setDF.

keep.rownames argument can be used to preserve the (row)names attribute in the resulting data.table.

---

as.data.table.xts  Efficient xts to as.data.table conversion

Description

Efficient conversion xts to data.table.

Usage

## S3 method for class 'xts'
as.data.table(x, keep.rownames = TRUE, key=NULL, ...)

Arguments

x  xts to convert to data.table
keep.rownames  Default is TRUE. If TRUE, adds the xts input's index as a separate column named "index". keep.rownames = "id" names the index column "id" instead.
key  Character vector of one or more column names which is passed to setkeyv.
...  ignored, just for consistency with as.data.table
as.matrix

Convert a data.table to a matrix

Description

Converts a data.table into a matrix, optionally using one of the columns in the data.table as the matrix rownames.

Usage

```r
## S3 method for class 'data.table'
as.matrix(x, rownames=NULL, rownames.value=NULL, ...)
```

Arguments

- `x`: a data.table
- `rownames`: optional, a single column name or column number to use as the rownames in the returned matrix. If TRUE the key of the data.table will be used if it is a single column, otherwise the first column in the data.table will be used.
- `rownames.value`: optional, a vector of values to be used as the rownames in the returned matrix. It must be the same length as nrow(x).
- `...`: Required to be present because the generic ‘as.matrix’ generic has it. Arguments here are not currently used or passed on by this method.

Details

`as.matrix` is a generic function in base R. It dispatches to `as.matrix.data.table` if its `x` argument is a data.table.

The method for data.tables will return a character matrix if there are only atomic columns and any non-(numeric/logical/complex) column, applying `as.vector` to factors and `format` to other non-character columns. Otherwise, the usual coercion hierarchy (logical < integer < double < complex) will be used, e.g., all-logical data frames will be coerced to a logical matrix, mixed logical-integer will give an integer matrix, etc.

See Also

- `as.xts.data.table`
Value

A new matrix containing the contents of x.

See Also

data.table, as.matrix, data.matrix array

Examples

DT <- data.table(A = letters[1:10], X = 1:10, Y = 11:20)
as.matrix(DT) # character matrix
as.matrix(DT, rownames = "A")
as.matrix(DT, rownames = 1)
as.matrix(DT, rownames = TRUE)

setkey(DT, A)
as.matrix(DT, rownames = TRUE)

as.xts.data.table Efficient data.table to xts conversion

Description

Efficient conversion of data.table to xts, data.table must have a time based type in first column. See ?xts::timeBased for supported types

Usage

as.xts.data.table(x, numeric.only = TRUE, ...)

Arguments

x data.table to convert to xts, must have a time based first column. As xts objects are indexed matrixes, all columns must be of the same type. If columns of multiple types are selected, standard as.matrix rules are applied during the conversion.

numeric.only If TRUE, only include numeric columns in the conversion and all non-numeric columns will be omitted with warning

... ignored, just for consistency with generic method.

See Also

as.data.table.xts
Examples

```r
if (requireNamespace("xts", quietly = TRUE)) {
  sample.dt <- data.table(date = as.Date((Sys.Date()-999):Sys.Date(),origin="1970-01-01"),
                           quantity = sample(10:50,1000,TRUE),
                           value = sample(100:1000,1000,TRUE))

  # print data.table
  print(sample.dt)
  # print head of xts
  print(head(as.xts.data.table(sample.dt))) # xts might not be attached on search path
}
```

between

Convenience functions for range subsets.

Description

Intended for use in `in [.data.table`. between is equivalent to `lower<=x & x<=upper` when `incbounds=TRUE`, or `lower<x & y<upper` when `FALSE`. With a caveat that `NA` in `lower` or `upper` are taken as unlimited bounds not `NA`. This can be changed by setting `NAbounds` to `NA`.

inrange checks whether each value in `x` is in between any of the intervals provided in `lower, upper`.

Usage

```r
between(x, lower, upper, incbounds=TRUE, NAbounds=TRUE, check=FALSE)

x %between% y

inrange(x, lower, upper, incbounds=TRUE)

x %inrange% y
```

Arguments

- `x`: Any orderable vector, i.e., those with relevant methods for `\`<=\`, such as numeric, character, Date, etc. in case of `between` and a numeric vector in case of `inrange`.
- `lower`: Lower range bound. Either length 1 or same length as `x`.
- `upper`: Upper range bound. Either length 1 or same length as `x`.
- `y`: A length-2 vector or list, with `y[[1]]` interpreted as `lower` and `y[[2]]` as `upper`.
- `incbounds`: TRUE means inclusive bounds, i.e., `[lower,upper]`. FALSE means exclusive bounds, i.e., `(lower,upper)`. It is set to TRUE by default for infix notations.
- `NAbounds`: If `lower (upper)` contains an `NA` what should `lower<=x (x<=upper)` return? By default TRUE so that a missing bound is interpreted as unlimited.
- `check`: Produce error if any(`lower>upper`)? FALSE by default for efficiency, in particular type character.
Details

`non-equi` joins were implemented in v1.9.8. They extend binary search based joins in `data.table` to other binary operators including `>=, <=, >, <`. `inrange` makes use of this new functionality and performs a range join.

Value

Logical vector the same length as `x` with value TRUE for those that lie within the specified range.

Note

Current implementation does not make use of ordered keys for `%between%`.

See Also

`data.table, like, %chin%`

Examples

```r
X = data.table(a=1:5, b=6:10, c=c(5:1))
X[b %between% c(7,9)]
X[between(b, 7, 9)] # same as above
# NEW feature in v1.9.8, vectorised between
X[c %between% list(a,b)]
X[between(c, a, b)] # same as above
X[between(c, a, b, incbounds=FALSE)] # open interval

# inrange()
Y = data.table(a=c(8,3,10,7,-10), val=runif(5))
rang = data.table(start = 1:5, end = 6:10)
Y[a %inrange% range]
Y[inrange(a, range$start, range$end)] # same as above
Y[inrange(a, range$start, range$end, incbounds=FALSE)] # open interval
```

cdt

data.table exported C routines

Description

Some of internally used C routines are now exported. This interface should be considered experimental. List of exported C routines and their signatures are provided below in the usage section.

Usage

```r
# SEXP DT_subsetDT(SEXP x, SEXP rows, SEXP cols);
# p_DT_subsetDT = R_GetCCallable("data.table", "DT_subsetDT");
```
Details

Details how to use those can be found in Writing R Extensions manual Linking to native routines in other packages section. An example use with Rcpp:

```r
dt = data.table::as.data.table(iris)
Rcpp::cppFunction("SEXP mysub2(SEXP x, SEXP rows, SEXP cols) { return DT_subsetDT(x,rows,cols); }",
  include="#include <datatableAPI.h>",
  depends="data.table")
mysub2(dt, 1:4, 1:4)
```

Note

Be aware C routines are likely to have less input validation than their corresponding R interface. For example one should not expect DT[-5L] will be equal to .Call(DT_subsetDT, DT, -5L, seq_along(DT)) because translation of i=-5L to seq_len(nrow(DT))[-5L] might be happening on R level. Moreover checks that i argument is in range of 1:nrow(DT), missingness, etc. might be happening on R level too.

### chmatch

**Faster match of character vectors**

**Description**

chmatch returns a vector of the positions of (first) matches of its first argument in its second. Both arguments must be character vectors.

%chin% is like %in%, but for character vectors.

**Usage**

```r
chmatch(x, table, nomatch=NA_integer_)
x %chin% table
chorder(x)
chgroup(x)
```

**Arguments**

- `x` character vector: the values to be matched, or the values to be ordered or grouped
- `table` character vector: the values to be matched against.
- `nomatch` the value to be returned in the case when no match is found. Note that it is coerced to integer.
Details

Fast versions of `match`, `%in%` and `order`, optimised for character vectors. `chgroup` groups together duplicated values but retains the group order (according the first appearance order of each group), efficiently. They have been primarily developed for internal use by `data.table`, but have been exposed since that seemed appropriate.

Strings are already cached internally by R (CHARSXP) and that is utilised by these functions. No hash table is built or cached, so the first call is the same speed as subsequent calls. Essentially, a counting sort (similar to `base::sort.list(x, method="radix")`, see `setkey`) is implemented using the (almost) unused truelength of CHARSXP as the counter. Where R has used truelengths of CHARSXP (where a character value is shared by a variable name), the non zero truelengths are stored first and reinstated afterwards. Each of the ch* functions implements a variation on this theme. Remember that internally in R, length of a CHARSXP is the nchar of the string and DATAPTR is the string itself.

Methods that do build and cache a hash table (such as the fastmatch package) are much faster on subsequent calls (almost instant) but a little slower on the first. Therefore `chmatch` may be particularly suitable for ephemeral vectors (such as local variables in functions) or tasks that are only done once. Much depends on the length of x and table, how many unique strings each contains, and whether the position of the first match is all that is required.

It may be possible to speed up fastmatch’s hash table build time by using the technique in `data.table`, and we have suggested this to its author. If successful, fastmatch would then be fastest in all cases.

Value

As `match` and `%in%`. `chorder` and `chgroup` return an integer index vector.

Note

The name `charmatch` was taken by `chartmatch`, hence `chmatch`.

`match`, `%in%`

Examples

# Please type 'example(chmatch)' to run this and see timings on your machine

N = 1e5
# N is set small here (1e5) to reduce runtime because every day CRAN runs and checks
# all documentation examples in addition to the package's test suite.
# The comments here apply when N has been changed to 1e8 and were run on 2018-05-13
# with R 3.5.0 and data.table 1.11.2.

u = as.character(as.hexmode(1:10000))
y = sample(u,N,replace=TRUE)
x = sample(u)

# With N=1e8 ...

system.time(a <- match(x,y)) # 4.6s
system.time(b <- chmatch(x,y)) # 1.8s
identical(a,b)

system.time(a <- x %in% y)  # 4.5s
system.time(b <- x %chin% y) # 1.7s
identical(a,b)

# Different example with more unique strings ...
u = as.character(as.hexmode(1:(N/10)))
y = sample(u,N,replace=TRUE)
x = sample(u,N,replace=TRUE)

system.time(a <- match(x,y))  # 46s
system.time(b <- chmatch(x,y)) # 16s
identical(a,b)

---

**copy**

*Copy an entire object*

---

**Description**

In `data.table` parlance, all `set*` functions change their input *by reference*. That is, no copy is made at all, other than temporary working memory, which is as large as one column. The only other `data.table` operator that modifies input by reference is `:=`. Check out the See Also section below for other `set*` function `data.table` provides.

`copy()` copies an entire object.

**Usage**

`copy(x)`

**Arguments**

- `x` A `data.table`.

**Details**

data.table provides functions that operate on objects *by reference* and minimise full object copies as much as possible. Still, it might be necessary in some situations to work on an object’s copy which can be done using `DT.copy <- copy(DT)`. It may also be sometimes useful before `:=` (or `set`) is used to subassign to a column by reference.

A `copy()` may be required when doing `dt_names = names(DT)`. Due to R’s *copy-on-modify*, `dt_names` still points to the same location in memory as `names(DT)`. Therefore modifying `DT` *by reference* now, say by adding a new column, `dt_names` will also get updated. To avoid this, one has to explicitly copy: `dt_names <- copy(names(DT))`.

**Value**

Returns a copy of the object.
Note
To confirm precisely whether an object is a copy of another, compare their exact memory address with address.

data.table, address, setkey, setDT, setDF, set :=, setorder, setattr, setnames

Examples
# Type 'example(copy)' to run these at prompt and browse output

DT = data.table(A=5:1, B=letters[5:1])
DT2 = copy(DT)  # explicit copy() needed to copy a data.table
setkey(DT2, B)  # now just changes DT2
identical(DT, DT2)  # FALSE. DT and DT2 are now different tables

DT = data.table(A=5:1, B=letters[5:1])
nm1 = names(DT)
nm2 = copy(names(DT))
DT[, C := 1L]
identical(nm1, names(DT))  # TRUE, nm1 is also changed by reference
identical(nm2, names(DT))  # FALSE, nm2 is a copy, different from names(DT)

Description
A data.table can be used in S4 class definitions as either a parent class (inside a contains argument of setClass), or as an element of an S4 slot.

## Used in a slot
setClass("Something", representation(x="character", dt="data.table"))
x <- new("Something", x="check", dt=data.table(a=1:10, b=11:20))
**dataTable.optimize**  

**Optimisations in data.table**

---

### Description

data.table internally optimises certain expressions in order to improve performance. This section briefly summarises those optimisations.

Note that there’s no additional input needed from the user to take advantage of these optimisations. They happen automatically.

Run the code under the example section to get a feel for the performance benefits from these optimisations.

Note that for all optimizations involving efficient sorts, the caveat mentioned in setorder applies – whenever data.table does the sorting, it does so in "C-locale". This has some subtle implications; see Examples.

### Details

data.table reads the global option metaData.optimize to figure out what level of optimisation is required. The default value Inf activates all available optimisations.

At optimisation level $\geq 1$, i.e., getOption("datatable.optimize") $\geq 1$, these are the optimisations:

- The base function order is internally replaced with data.table’s fast ordering. That is, `DT[order(...)]` gets internally optimised to `DT[forder(...)]`.

- The expression `DT[, lapply(.SD, fun), by=.]` gets optimised to `DT[, list(fun(a), fun(b), ...), by=.]` where `a`, `b`, ... are columns in `.SD`. This improves performance tremendously.

- Similarly, the expression `DT[, c(.N, lapply(.SD, fun)), by=.]` gets optimised to `DT[, list(.N, fun(a), fun(b), ...)]`. `.N` is just for example here.

- `base::mean` function is internally optimised to use data.table’s fastmean function. `mean()` from base is an S3 generic and gets slow with many groups.

At optimisation level $\geq 2$, i.e., getOption("datatable.optimize") $\geq 2$, additional optimisations are implemented on top of the optimisations already shown above:

- Expressions in `j` which contain only the functions `min`, `max`, `mean`, `median`, `var`, `sd`, `sum`, `prod`, `first`, `last`, `head`, `tail` (for example, `DT[, list(mean(x), median(x), min(y), max(y)), by=z]`), they are very effectively optimised using what we call GForce. These functions are automatically replaced with a corresponding GForce version with pattern `g*`, e.g., `prod` becomes `gprod`.

Normally, once the rows belonging to each group are identified, the values corresponding to the group are gathered and the `j`-expression is evaluated. This can be improved by computing the result directly without having to gather the values or evaluating the expression for each group (which can get costly with large number of groups) by implementing it specifically for a particular function. As a result, it is extremely fast.
• In addition to all the functions above, `.N` is also optimised to use GForce, when used separately or when combined with the functions mentioned above. Note further that GForce-optimized functions must be used separately, i.e., code like `DT[ , max(x) - min(x), by=z]` will **not** currently be optimized to use `gmax, gmin`.

• Expressions of the form `DT[i, j, by]` are also optimised when `i` is a *subset* operation and `j` is any/all of the functions discussed above.

At optimisation level \(\geq 3\), i.e., `getOption("datatable.optimize") \geq 3`, additional optimisations for subsets in `i` are implemented on top of the optimisations already shown above. Subsetting operations are - if possible - translated into joins to make use of blazing fast binary search using indices and keys. The following queries are optimized:

• Supported operators: `==`, `%in%`. Non-equi operators(`>`, `<`, etc.) are not supported yet because non-equi joins are slower than vector based subsets.

• Queries on multiple columns are supported, if the connector is `&`, e.g. `DT[x == 2 & y == 3]` is supported, but `DT[x == 2 | y == 3]` is not.

• Optimization will currently be turned off when doing subset when cross product of elements provided to filter on exceeds \(> 1e4\). This most likely happens if multiple `%in%`, or `%chin%` queries are combined, e.g. `DT[x %in% 1:100 & y %in% 1:200]` will not be optimized since \(100 \times 200 = 2e4 > 1e4\).

• Queries with multiple criteria on one column are **not** supported, e.g. `DT[x == 2 & x %in% c(2,5)]` is not supported.

• Queries with non-missing `j` are supported, e.g. `DT[x == 3 & y == 5, .(new = x-y)]` or `DT[x == 3 & y == 5, new := x-y]` are supported. Also extends to queries using `with = FALSE`.

• "notjoin" queries, i.e. queries that start with `!`, are only supported if there are no & connections, e.g. `DT[!x==3]` is supported, but `DT[!x==3 & y == 4]` is not.

If in doubt, whether your query benefits from optimization, call it with the `verbose = TRUE` argument. You should see "Optimized subsetting...". 

**Auto indexing:** In case a query is optimized, but no appropriate key or index is found, data.table automatically creates an **index** on the first run. Any successive subsets on the same column then reuse this index to **binary search** (instead of **vector scan**) and is therefore fast. Auto indexing can be switched off with the global option `options(datatable.auto.index = FALSE)`. To switch off using existing indices set global option `options(datatable.use.index = FALSE)`.

## End(Not run)

## S3 method for class 'data.table'
dcast(data, formula, fun.aggregate = NULL, sep = "_",
..., margins = NULL, subset = NULL, fill = NULL,
drop = TRUE, value.var = guess(data),
verbose =getOption("datatable.verbose"))

Arguments

- **data** A data.table.
- **formula** A formula of the form LHS ~ RHS to cast, see Details.
- **fun.aggregate** Should the data be aggregated before casting? If the formula doesn’t identify a single observation for each cell, then aggregation defaults to length with a message.
- **sep** Character vector of length 1, indicating the separating character in variable names generated during casting. Default is _ for backwards compatibility.
- **...** Any other arguments that may be passed to the aggregating function.
- **margins** Not implemented yet. Should take variable names to compute margins on. A value of TRUE would compute all margins.
**dcast.data.table**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>subset</td>
<td>Specified if casting should be done on a subset of the data. Ex: subset = .(col1 &lt;= 5) or subset = .(variable != &quot;January&quot;).</td>
</tr>
<tr>
<td>fill</td>
<td>Value with which to fill missing cells. If fun.aggregate is present, takes the value by applying the function on a 0-length vector.</td>
</tr>
<tr>
<td>drop</td>
<td>FALSE will cast by including all missing combinations. c(FALSE, TRUE) will only include all missing combinations of formula LHS; c(TRUE, FALSE) will only include all missing combinations of formula RHS. See Examples.</td>
</tr>
<tr>
<td>value.var</td>
<td>Name of the column whose values will be filled to cast. Function guess() tries to, well, guess this column automatically, if none is provided. Cast multiple value.var columns simultaneously by passing their names as a character vector. See Examples.</td>
</tr>
<tr>
<td>verbose</td>
<td>Not used yet. May be dropped in the future or used to provide informative messages through the console.</td>
</tr>
</tbody>
</table>

**Details**

The cast formula takes the form LHS ~ RHS, ex: var1 + var2 ~ var3. The order of entries in the formula is essential. There are two special variables: . represents no variable, while ... represents all variables not otherwise mentioned in formula; see Examples.

When not all combinations of LHS & RHS values are present in the data, some or all (in accordance with drop) missing combinations will replaced with the value specified by fill. Note that fill will be converted to the class of value.var; see Examples.

dcast also allows value.var columns of type list.

When variable combinations in formula don't identify a unique value, fun.aggregate will have to be specified, which defaults to length. For the formula var1 ~ var2, this means there are some (var1, var2) combinations in the data corresponding to multiple rows (i.e. x is not unique by (var1, var2).

The aggregating function should take a vector as input and return a single value (or a list of length one) as output. In cases where value.var is a list, the function should be able to handle a list input and provide a single value or list of length one as output.

If the formula's LHS contains the same column more than once, ex: dcast(DT, x+x~ y), then the answer will have duplicate names. In those cases, the duplicate names are renamed using make.unique so that key can be set without issues.

Names for columns that are being cast are generated in the same order (separated by an underscore, _) from the (unique) values in each column mentioned in the formula RHS.

From v1.9.4, dcast tries to preserve attributes wherever possible.

From v1.9.6, it is possible to cast multiple value.var columns and also cast by providing multiple fun.aggregate functions. Multiple fun.aggregate functions should be provided as a list, for e.g., list(mean, sum, function(x) paste(x, collapse="")), value.var can be either a character vector or list of length one, or a list of length equal to length(fun.aggregate). When value.var is a character vector or a list of length one, each function mentioned under fun.aggregate is applied to every column specified under value.var column. When value.var is a list of length equal to length(fun.aggregate) each element of fun.aggregate is applied to each element of value.var column.
Historical note: `dcast.data.table` was originally designed as an enhancement to `reshape2::dcast` in terms of computing and memory efficiency. `reshape2` has since been superseded in favour of `tidyr`, and `dcast` has had a generic defined within `data.table` since v1.9.6 in 2015, at which point the dependency between the packages became more etymological than programmatic. We thank the `reshape2` authors for the inspiration.

**Value**

A keyed `data.table` that has been cast. The key columns are equal to the variables in the formula `LHS` in the same order.

**See Also**

`melt.data.table`, `rowid`, [https://cran.r-project.org/package=reshape](https://cran.r-project.org/package=reshape)

**Examples**

```r
ChickWeight = as.data.table(ChickWeight)
setnames(ChickWeight, tolower(names(ChickWeight)))
DT <- melt(as.data.table(ChickWeight), id.vars=2:4) # calls melt.data.table
# dcast is an S3 method in data.table from v1.9.6
dcast(DT, time ~ variable, fun.aggregate=mean)
dcast(DT, diet ~ variable, fun.aggregate=mean)
dcast(DT, diet+chick ~ time, drop=FALSE)
dcast(DT, diet+chick ~ time, drop=FALSE, fill=0)
# using subset
dcast(DT, chick ~ time, fun.aggregate=mean, subset=.(time < 10 & chick < 20))
# drop argument, #1512
DT <- data.table(v1 = c(1.1, 1.1, 1.1, 2.2, 2.2, 2.2),
                 v2 = factor(c(1L, 1L, 1L, 3L, 3L, 3L), levels=1:3),
                 v3 = factor(c(2L, 3L, 5L, 1L, 2L, 6L), levels=1:6),
                 v4 = c(3L, 2L, 2L, 5L, 4L, 3L))
# drop=TRUE
dcast(DT, v1+v2~v3, value.var='v4') # default is drop=TRUE
dcast(DT, v1+v2~v3, value.var='v4', drop=FALSE)  # all missing combinations of LHS and RHS
dcast(DT, v1+v2~v3, value.var='v4', drop=c(FALSE, TRUE))  # all missing combinations of LHS only
dcast(DT, v1+v2~v3, value.var='v4', drop=c(TRUE, FALSE)) # all missing combinations of RHS only
# using . and ...
DT <- data.table(v1 = rep(1:2, each = 6),
                 v2 = rep(rep(1:3, 2), each = 2),
                 v3 = rep(1:2, 6),
                 v4 = rnorm(6))
dcast(DT, ..., v3, value.var="v4") # same as v1+v2 ~ v3, value.var="v4"
dcast(DT, v1+v2+v3 ~ ., value.var="v4")
## for each combination of (v1, v2), add up all values of v4
dcast(DT, v1+v2 ~ ., value.var="v4", fun.aggregate=sum)
```
duplicated returns a logical vector indicating which rows of a data.table are duplicates of a row with smaller subscripts.

unique returns a data.table with duplicated rows removed, by columns specified in by argument. When no by then duplicated rows by all columns are removed.

anyDuplicated returns the index i of the first duplicated entry if there is one, and 0 otherwise.

uniqueN is equivalent to length(unique(x)) when x is an atomic vector, and nrow(unique(x)) when x is a data.frame or data.table. The number of unique rows are computed directly without materialising the intermediate unique data.table and is therefore faster and memory efficient.

Usage

```r
## S3 method for class 'data.table'
duplicated(x, incomparables=FALSE, fromLast=FALSE, by=seq_along(x), ...)

## S3 method for class 'data.table'
unique(x, incomparables=FALSE, fromLast=FALSE, by=seq_along(x), cols=NULL, ...)

## S3 method for class 'data.table'
anyDuplicated(x, incomparables=FALSE, fromLast=FALSE, by=seq_along(x), ...)

uniqueN(x, by=if (is.list(x)) seq_along(x) else NULL, na.rm=FALSE)
```
Arguments

x A data.table. uniqueN accepts atomic vectors and data.frames as well.

... Not used at this time.

incomparables Not used. Here for S3 method consistency.

fromLast logical indicating if duplication should be considered from the reverse side, i.e., the last (or rightmost) of identical elements would correspond to duplicated = FALSE.

by character or integer vector indicating which combinations of columns from x to use for uniqueness checks. By default all columns are being used. That was changed recently for consistency to data.frame methods. In version < 1.9.8 default was key(x).

cols Columns (in addition to by) from x to include in the resulting data.table.

na.rm Logical (default is FALSE). Should missing values (including NaN) be removed?

Details

Because data.tables are usually sorted by key, tests for duplication are especially quick when only the keyed columns are considered. Unlike unique.data.frame, paste is not used to ensure equality of floating point data. It is instead accomplished directly and is therefore quite fast. data.table provides setNumericRounding to handle cases where limitations in floating point representation is undesirable.

v1.9.4 introduces anyDuplicated method for data.tables and is similar to base in functionality. It also implements the logical argument fromLast for all three functions, with default value FALSE.

Note: When cols is specified, the resulting table will have columns c(by, cols), in that order.

Value

duplicated returns a logical vector of length nrow(x) indicating which rows are duplicates.
unique returns a data table with duplicated rows removed.
anyDuplicated returns a integer value with the index of first duplicate. If none exists, 0L is returned.
uniqueN returns the number of unique elements in the vector, data.frame or data.table.

Examples

DT <- data.table(A = rep(1:3, each=4), B = rep(1:4, each=3),
                  C = rep(1:2, 6), key = "A,B")
duplicated(DT)
unique(DT)

duplicated(DT, by="B")
unique(DT, by="B")

duplicated(DT, by=c("A", "C"))
unique(DT, by=c("A", "C"))

DT = data.table(a=c(2L,1L,2L), b=c(1L,2L,1L))  # no key
unique(DT)  # rows 1 and 2 (row 3 is a duplicate of row 1)

DT = data.table(a=c(3.142, 4.2, 4.2, 3.142, 1.223, 1.223), b=rep(1,6))
unique(DT)  # rows 1, 2 and 5

DT = data.table(a=tan(pi*(1/4 + 1:10)), b=rep(1,10))  # example from ?all.equal
length(unique(DT$a))  # 10 strictly unique floating point values
all.equal(DT$a,rep(1,10))  # TRUE, all within tolerance of 1.0

DT[,which.min(a)]  # row 10, the strictly smallest floating point value
identical(unique(DT),DT[1])  # TRUE, stable within tolerance
identical(unique(DT),DT[10])  # FALSE

# fromLast=TRUE
DT <- data.table(A = rep(1:3, each=4), B = rep(1:4, each=3),
                 C = rep(1:2, 6), key = "A,B")
duplicated(DT, by="B", fromLast=TRUE)
unique(DT, by="B", fromLast=TRUE)

# anyDuplicated
anyDuplicated(DT, by=c("A", "B"))  # 3L
any(duplicated(DT, by=c("A", "B")))  # TRUE

# uniqueN, unique rows on key columns
uniqueN(DT, by = key(DT))
# uniqueN, unique rows on all columns
uniqueN(DT)
# uniqueN while grouped by "A"
DT[, .(uN=uniqueN(.SD)), by=A]

# uniqueN's na.rm=TRUE
x = sample(c(NA, NaN, runif(3)), 10, TRUE)
uniqueN(x, na.rm = FALSE)  # 5, default
uniqueN(x, na.rm=TRUE)  # 3

---

**Description**

*fcase* is a fast implementation of SQL CASE WHEN statement for R. Conceptually, *fcase* is a nested version of *ifelse* (with smarter implementation than manual nesting). It is comparable to *dplyr::case_when* and supports bit64's integer64 and nanotime classes.
Usage

fcase(..., default=NA)

Arguments

... A sequence consisting of logical condition (when)-resulting value (value) pairs in the following order when1, value1, when2, value2, ..., whenN, valueN. Logical conditions when1, when2, ..., whenN must all have the same length, type and attributes. Each value may either share length with when or be length 1. Please see Examples section for further details.

default Default return value, NA by default, for when all of the logical conditions when1, when2, ..., whenN are FALSE or missing for some entries.

Value

Vector with the same length as the logical conditions (when) in ..., filled with the corresponding values (value) from ..., or eventually default. Attributes of output values value1, value2, ...valueN in ... are preserved.

See Also

fifelse

Examples

x = 1:10
fcase(
  x < 5L, 1L,
  x > 5L, 3L
)
fcase(
  x < 5L, 1L:10L,
  x > 5L, 3L:12L
)

# Lazy evaluation example
fcase(
  x < 5L, 1L,
  x >= 5L, 3L,
  x == 5L, stop("provided value is an unexpected one!"
)
)

# fcase preserves attributes, example with dates
fcase(
  x < 5L, as.Date("2019-10-11"),
  x > 5L, as.Date("2019-10-14")
)

# fcase example with factor; note the matching levels
fcase("
fcoalesce

x < 5L, factor("a", levels=letters[1:3]),
  x > 5L, factor("b", levels=letters[1:3])
)

# Example of using the 'default' argument
fcase(
  x < 5L, 1L,
  x > 5L, 3L,
  default = 5L
)

---

fcoalesce  Coalescing missing values

Description

Fill in missing values in a vector by successively pulling from candidate vectors in order. As per the ANSI SQL function COALESCE, dplyr::coalesce and hutils::coalesce. Unlike BBmisc::coalesce which just returns the first non-NULL vector. Written in C, and multithreaded for numeric and factor types.

Usage

fcoalesce(...)

Arguments

...  A set of same-class vectors. These vectors can be supplied as separate arguments or as a single plain list, data.table or data.frame, see examples.

Details

Factor type is supported only when the factor levels of each item are equal.

NaN is considered missing (note is.na(NaN) and all.equal(NA_real_, NaN) are both TRUE).

Value

Atomic vector of the same type and length as the first vector, having NA values replaced by corresponding non-NA values from the other vectors. If the first item is NULL, the result is NULL.

See Also

fifelse
Examples

```r
x = c(11L, NA, 13L, NA, 15L, NA)
y = c(NA, 12L, 5L, NA, NA, NA)
z = c(11L, NA, 1L, 14L, NA, NA)
fcoalesce(x, y, z)
fcoalesce(list(x, y, z))  # same
fcoalesce(x, list(y, z))  # same
```

fdroplevels

**Fast droplevels**

Description

Similar to base::droplevels but much faster.

Usage

```r
fdroplevels(x, exclude = if (anyNA(levels(x))) NULL else NA, ...)
```

## S3 method for class 'data.table'

```r
droplevels(x, except = NULL, exclude, in.place = FALSE, ...)
```

Arguments

- `x` factor or data.table where unused levels should be dropped.
- `exclude` A character vector of factor levels which are dropped no matter of presented or not.
- `except` An integer vector of indices of data.table columns which are not modified by dropping levels.
- `in.place` logical (default is FALSE). If TRUE levels of factors of data.table are modified in-place.
- `...` further arguments passed to methods

Value

- fdroplevels returns a factor.
- droplevels returns a data.table where levels are dropped at factor columns.

See Also

data.table, duplicated, unique
Examples

# on vectors
x = factor(letters[1:10])
fdroplevels(x[1:5])
# exclude levels from drop
fdroplevels(x[1:5], exclude = c("a", "c"))

# on data.table
DT = data.table(a = factor(1:10), b = factor(letters[1:10]))
droplevels(head(DT))[["b"]]
# exclude levels
droplevels(head(DT), exclude = c("b", "c"))[["b"]]
# except columns from drop
droplevels(head(DT), except = 2)[["b"]]
droplevels(head(DT), except = 1)[["b"]]

fifelse

Description

fifelse is a faster and more robust replacement of ifelse. It is comparable to dplyr::if_else and hutils::if_else. It returns a value with the same length as test filled with corresponding values from yes, no or eventually na, depending on test. Supports bit64’s integer64 and nanotime classes.

Usage

fifelse(test, yes, no, na=NA)

Arguments

test: A logical vector.
yes, no: Values to return depending on TRUE/FALSE element of test. They must be the same type and be either length 1 or the same length of test.
na: Value to return if an element of test is NA. It must be the same type as yes and no and its length must be either 1 or the same length of test. Default value NA. NULL is treated as NA.

Details

In contrast to ifelse attributes are copied from the first non-NA argument to the output. This is useful when returning Date, factor or other classes.

Value

A vector of the same length as test and attributes as yes. Data values are taken from the values of yes and no, eventually na.
See Also

fcoalesce

Examples

```r
x = c(1:4, 3:2, 1:4)
fifelse(x > 2L, x, x - 1L)
# unlike ifelse, fifelse preserves attributes, taken from the 'yes' argument
dates = as.Date(c("2011-01-01","2011-01-02","2011-01-03","2011-01-04","2011-01-05"))
ifelse(dates == "2011-01-01", dates - 1, dates)
yes = factor(c("a","b","c"))
no = yes[1L]
ifelse(c(TRUE, FALSE, TRUE), yes, no)
ifelse(c(TRUE, FALSE, TRUE), yes, no)
# Example of using the 'na' argument
fifelse(test = c(-5L:5L < 0L, NA), yes = 1L, no = 0L, na = 2L)
```

Description

A fast binary-search based overlap join of two data.tables. This is very much inspired by findOverlaps function from the Bioconductor package IRanges (see link below under See Also).

Usually, x is a very large data.table with small interval ranges, and y is much smaller keyed data.table with relatively larger interval spans. For a usage in genomics, see the examples section.

NOTE: This is still under development, meaning it is stable, but some features are yet to be implemented. Also, some arguments and/or the function name itself could be changed.

Usage

```r
foverlaps(x, y, by.x = if (!is.null(key(x))) key(x) else key(y),
by.y = key(y), maxgap = 0L, minoverlap = 1L,
type = c("any", "within", "start", "end", "equal"),
mult = c("all", "first", "last"),
nomatch = NA,
which = FALSE, verbose = getOption("datatable.verbose"))
```

Arguments

x, y data.tables. y needs to be keyed, but not necessarily x. See examples.
A vector of column names (or numbers) to compute the overlap joins. The last two columns in both by.x and by.y should each correspond to the start and end interval columns in x and y respectively. And the start column should always be <= end column. If x is keyed, by.x is equal to key(x), else key(y). by.y defaults to key(y).

maxgap
It should be a non-negative integer value, >= 0. Default is 0 (no gap). For intervals \([a,b]\) and \([c,d]\), where \(a<=b\) and \(c<=d\), when \(c > b\) or \(d < a\), the two intervals don’t overlap. If the gap between these two intervals is \(<=\) maxgap, these two intervals are considered as overlapping. Note: This is not yet implemented.

minoverlap
It should be a positive integer value, > 0. Default is 1. For intervals \([a,b]\) and \([c,d]\), where \(a<=b\) and \(c<=d\), when \(c<=b\) and \(d>=a\), the two intervals overlap. If the length of overlap between these two intervals is \(>=\) minoverlap, then these two intervals are considered to be overlapping. Note: This is not yet implemented.

type
Default value is any. Allowed values are any, within, start, end and equal. The types shown here are identical in functionality to the function findOverlaps in the bioconductor package IRanges. Let \([a,b]\) and \([c,d]\) be intervals in x and y with \(a<=b\) and \(c<=d\). For type="start", the intervals overlap iff \(a == c\). For type="end", the intervals overlap iff \(b == d\). For type="within", the intervals overlap iff \(a>=c\) and \(b<=d\). For type="equal", the intervals overlap iff \(a==c\) and \(b==d\). For type="any", as long as \(c<=b\) and \(d>=a\), they overlap. In addition to these requirements, they also have to satisfy the minoverlap argument as explained above.

NB: maxgap argument, when > 0, is to be interpreted according to the type of the overlap. This will be updated once maxgap is implemented.

mult
When multiple rows in y match to the row in x, mult=. controls which values are returned - "all" (default), "first" or "last".

nomatch
When a row (with interval say, \([a,b]\)) in x has no match in y, nomatch=NA (default) means NA is returned for y’s non-by.y columns for that row of x. nomatch=NULL (or 0 for backward compatibility) means no rows will be returned for that row of x.

which
When TRUE, if mult="all" returns a two column data.table with the first column corresponding to x’s row number and the second corresponding to y’s. When nomatch=NA, no matches return NA for y, and if nomatch=NULL, those rows where no match is found will be skipped; if mult="first" or "last", a vector of length equal to the number of rows in x is returned, with no-match entries filled with NA or 0 corresponding to the nomatch argument. Default is FALSE, which returns a join with the rows in y.

verbose
TRUE turns on status and information messages to the console. Turn this on by default using options(datatable.verbose=TRUE). The quantity and types of verbosity may be expanded in future.

Details
Very briefly, foverlaps() collapses the two-column interval in y to one-column of unique values to generate a lookup table, and then performs the join depending on the type of overlap, using the...
already available binary search feature of data.table. The time (and space) required to generate the lookup is therefore proportional to the number of unique values present in the interval columns of y when combined together.

Overlap joins takes advantage of the fact that y is sorted to speed-up finding overlaps. Therefore y has to be keyed (see ?setkey) prior to running foverlaps(). A key on x is not necessary, although it might speed things further. The columns in by.x argument should correspond to the columns specified in by.y. The last two columns should be the interval columns in both by.x and by.y. The first interval column in by.x should always be <= the second interval column in by.x, and likewise for by.y. The storage.mode of the interval columns must be either double or integer. It therefore works with bit64::integer64 type as well.

The lookup generation step could be quite time consuming if the number of unique values in y are too large (ex: in the order of tens of millions). There might be improvements possible by constructing lookup using RLE, which is a pending feature request. However most scenarios will not have too many unique values for y.

### Value

A new data.table by joining over the interval columns (along with other additional identifier columns) specified in by.x and by.y.

NB: When which=TRUE: a) mult="first" or "last" returns a vector of matching row numbers in y, and b) when mult="all" returns a data.table with two columns with the first containing row numbers of x and the second column with corresponding row numbers of y.

nomatch=NA|NULL also influences whether non-matching rows are returned or not, as explained above.

### See Also

### Examples

```r
require(data.table)
## simple example:
x = data.table(start=c(5,31,22,16), end=c(8,50,25,18), val2 = 7:10)
y = data.table(start=c(10, 20, 30), end=c(15, 35, 45), val1 = 1:3)
setkey(y, start, end)
foverlaps(x, y, type="any", which=TRUE) ## return overlap indices
foverlaps(x, y, type="any") ## return overlap join
foverlaps(x, y, type="any", mult="first") ## returns only first match
foverlaps(x, y, type="within") ## matches iff 'x' is within 'y'

## with extra identifiers (ex: in genomics)
x = data.table(chr=c("Chr1", "Chr1", "Chr2", "Chr2"),
    start=c(5,10,1,25), end=c(11,20,4,52))
y = data.table(chr=c("Chr1", "Chr1", "Chr2"), start=c(1,15,1),
    end=c(4, 18, 55), geneid=letters[1:3])
setkey(y, chr, start, end)
foverlaps(x, y, type="any", which=TRUE)
```
frank

foroverlaps(x, y, type="any")
foroverlaps(x, y, type="any", nomatch=NULL)
foroverlaps(x, y, type="within", which=TRUE)
foroverlaps(x, y, type="within")
foroverlaps(x, y, type="start")

## x and y have different column names - specify by.x
x = data.table(seq=c("Chr1", "Chr1", "Chr2", "Chr2", "Chr2"),
               start=c(5,10, 1, 25, 50), end=c(11,20,4,52,60))
y = data.table(chr=c("Chr1", "Chr1", "Chr2"), start=c(1, 15,1),
               end=c(4, 18, 55), geneid=letters[1:3])
setkey(y, chr, start, end)
foroverlaps(x, y, by.x=c("seq", "start", "end"),
            type="any", which=TRUE)

---

Description

Similar to base::rank but much faster. And it accepts vectors, lists, data.frames or data.tables as input. In addition to the ties.method possibilities provided by base::rank, it also provides ties.method="dense".

Like forder, sorting is done in "C-locale"; in particular, this may affect how capital/lowercase letters are ranked. See Details on forder for more.

bit64::integer64 type is also supported.

Usage

frank(x, ..., na.last=TRUE, ties.method=c("average",
"first", "last", "random", "max", "min", "dense"))

frankv(x, cols=seq_along(x), order=1L, na.last=TRUE,
ties.method=c("average", "first", "last", "random",
"max", "min", "dense"))

Arguments

x A vector, or list with all its elements identical in length or data.frame or data.table.

... Only for lists, data.frames and data.tables. The columns to calculate ranks based on. Do not quote column names. If ... is missing, all columns are considered by default. To sort by a column in descending order prefix "-", e.g., frank(x, a, -b, c). -b works when b is of type character as well.

cols A character vector of column names (or numbers) of x, for which to obtain ranks.
order  An integer vector with only possible values of 1 and -1, corresponding to ascending and descending order. The length of order must be either 1 or equal to that of cols. If length(order) == 1, it is recycled to length(cols).

na.last  Control treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed; if "keep" they are kept with rank NA.

ties.method  A character string specifying how ties are treated, see Details.

Details
To be consistent with other data.table operations, NAs are considered identical to other NAs (and NaNs to other NaNs), unlike base::rank. Therefore, for na.last=TRUE and na.last=FALSE, NAs (and NaNs) are given identical ranks, unlike rank.

frank is not limited to vectors. It accepts data.tables (and lists and data.frames) as well. It accepts unquoted column names (with names preceded with a - sign for descending order, even on character vectors), for e.g., frank(DT, a, -b, c, ties.method="first") where a,b,c are columns in DT. The equivalent in frankv is the order argument.

In addition to the ties.method values possible using base's rank, it also provides another additional argument "dense" which returns the ranks without any gaps in the ranking. See examples.

Value
A numeric vector of length equal to NROW(x) (unless na.last = NA, when missing values are removed). The vector is of integer type unless ties.method = "average" when it is of double type (irrespective of ties).

See Also
data.table, setkey, setorder

Examples

# on vectors
x = c(4, 1, 4, NA, 1, NA, 4)
# NAs are considered identical (unlike base R)
# default is average
frankv(x) # na.last=TRUE
frankv(x, na.last=FALSE)

# ties.method = min
frankv(x, ties.method="min")
# ties.method = dense
frankv(x, ties.method="dense")

# on data.table
DT = data.table(x, y=c(1, 1, 1, 0, NA, 0, 2))
frankv(DT, cols="x") # same as frankv(x) from before
frankv(DT, cols="x", na.last="keep")
frankv(DT, cols="x", ties.method="dense", na.last=NA)
frank(DT, x, ties.method="dense", na.last=NA) # equivalent of above using frank
# on both columns
frankv(DT, ties.method="first", na.last="keep")
frank(DT, ties.method="first", na.last="keep") # equivalent of above using frank

# order argument
frank(DT, x, -y, ties.method="first")
# equivalent of above using frankv
frankv(DT, order=c(1L, -1L), ties.method="first")

---

**fread**  
*Fast and friendly file finagler*

Description

Similar to `read.table` but faster and more convenient. All controls such as `sep`, `colClasses` and `nrows` are automatically detected.

`bit64::integer64`, `IDate`, and `POSIXct` types are also detected and read directly without needing to read as character before converting.

`fread` is for regular delimited files; i.e., where every row has the same number of columns. In future, secondary separator (`sep2`) may be specified within each column. Such columns will be read as type `list` where each cell is itself a vector.

Usage

```r
fread(input, file, text, cmd, sep="auto", sep2="auto", dec=".", quote="\",
nrows=Inf, header="auto",
na.strings=getOption("datatable.na.strings", "NA"), # due to change to "; see NEWS
stringsAsFactors=FALSE, verbose=getOption("datatable.verbose", FALSE),
skip="__auto__", select=NULL, drop=NULL, colClasses=NULL,
integer64=getOption("datatable.integer64", "integer64"),
col.names,
check.names=FALSE, encoding="unknown",
strip.white=TRUE, fill=FALSE, blank.lines.skip=FALSE,
key=NULL, index=NULL,
showProgress=getOption("datatable.showProgress", interactive()),

yaml=FALSE, autostart=NA, tempdir=tempdir(), tz="UTC"
)
```

Arguments

- **input**  
  A single character string. The value is inspected and deferred to either `file=` (if no `\n` present), `text=` (if at least one `\n` is present) or `cmd=` (if no `\n` is present, at least one space is present, and it isn’t a file name). Exactly one of `input=`, `file=`, `text=`, or `cmd=` should be used in the same call.
file
File name in working directory, path to file (passed through \texttt{path.expand} for convenience), or a URL starting http://, file://, etc. Compressed files with extension `.gz` and `.bz2` are supported if the \texttt{R.utils} package is installed.

text
The input data itself as a character vector of one or more lines, for example as returned by \texttt{readLines()}.

cmd
A shell command that pre-processes the file; e.g. \texttt{fread(cmd=paste("grep",word,"filename")}). See Details.

sep
The separator between columns. Defaults to the character in the set \[,\t |;:\] that separates the sample of rows into the most number of lines with the same number of fields. Use \texttt{NULL} or "" to specify no separator; i.e. each line a single character column like \texttt{base::readLines} does.

sep2
The separator \textit{within} columns. A list column will be returned where each cell is a vector of values. This is much faster using less working memory than \texttt{strsplit} afterwards or similar techniques. For each column \texttt{sep2} can be different and is the first character in the same set above \[,\t |;:], other than \texttt{sep}, that exists inside each field outside quoted regions in the sample. NB: \texttt{sep2} is not yet implemented.

nrows
The maximum number of rows to read. Unlike \texttt{read.table}, you do not need to set this to an estimate of the number of rows in the file for better speed because that is already automatically determined by \texttt{fread} almost instantly using the large sample of lines. \texttt{nrows=0} returns the column names and typed empty columns determined by the large sample; useful for a dry run of a large file or to quickly check format consistency of a set of files before starting to read any of them.

header
Does the first data line contain column names? Defaults according to whether every non-empty field on the first data line is type character. If so, or TRUE is supplied, any empty column names are given a default name.

na.strings
A character vector of strings which are to be interpreted as NA values. By default, \"","\" for columns of all types, including type character is read as NA for consistency. \""\", is unambiguous and read as an empty string. To read ,NA, as NA, set \texttt{na.strings="NA"}. To read , , as blank string ",", set \texttt{na.strings=NULL}. When they occur in the file, the strings in \texttt{na.strings} should not appear quoted since that is how the string literal ,"NA", is distinguished from ,NA,, for example, when \texttt{na.strings="NA"}.

stringsAsFactors
Convert all or some character columns to factors? Acceptable inputs are TRUE, FALSE, or a decimal value between 0.0 and 1.0. For \texttt{stringsAsFactors = FALSE}, all string columns are stored as character vs. all stored as factor when \texttt{TRUE}. When \texttt{stringsAsFactors = p} for 0 \(\leq p \leq 1\), string columns \texttt{col} are stored as factor if \texttt{uniqueN(col)/nrow} \(\leq p\).

verbose
Be chatty and report timings?

skip
If 0 (default) start on the first line and from there finds the first row with a consistent number of columns. This automatically avoids irregular header information before the column names row. \texttt{skip>0} means ignore the first \texttt{skip} rows manually. \texttt{skip="string"} searches for "string" in the file (e.g. a substring of
the column names row) and starts on that line (inspired by read.xls in package gdata).

**select** A vector of column names or numbers to keep, drop the rest. `select` may specify types too in the same way as `colClasses`; i.e., a vector of `colname=type` pairs, or a list of `type=col(s)` pairs. In all forms of `select`, the order that the columns are specified determines the order of the columns in the result.

**drop** Vector of column names or numbers to drop, keep the rest.

**colClasses** As in `utils::read.csv`; i.e., an unnamed vector of types corresponding to the columns in the file, or a named vector specifying types for a subset of the columns by name. The default, `NULL` means types are inferred from the data in the file. Further, `data.table` supports a named list of vectors of column names or numbers where the list names are the class names; see examples. The list form makes it easier to set a batch of columns to be a particular class. When column numbers are used in the list form, they refer to the column number in the file not the column number after `select` or `drop` has been applied. If type coercion results in an error, introduces NAs, or would result in loss of accuracy, the coercion attempt is aborted for that column with warning and the column’s type is left unchanged. If you really desire data loss (e.g. reading 3.14 as integer) you have to truncate such columns afterwards yourself explicitly so that this is clear to future readers of your code.

**integer64** "integer64" (default) reads columns detected as containing integers larger than `2^31` as type `bit64::integer64`. Alternatively, "double" or "numeric" reads as `utils::read.csv` does; i.e., possibly with loss of precision and if so silently. Or, "character".

**dec** The decimal separator as in `utils::read.csv`. If not "," (default) then usually ".", See details.

**col.names** A vector of optional names for the variables (columns). The default is to use the header column if present or detected, or if not "V" followed by the column number. This is applied after `check.names` and before `key` and `index`.

**check.names** default is `FALSE`. If `TRUE` then the names of the variables in the `data.table` are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by `make.names`) so that they are, and also to ensure that there are no duplicates.

**encoding** default is "unknown". Other possible options are "UTF-8" and "Latin-1". Note: it is not used to re-encode the input, rather enables handling of encoded strings in their native encoding.

**quote** By default ("\""), if a field starts with a double quote, fread handles embedded quotes robustly as explained under Details. If it fails, then another attempt is made to read the field as is, i.e., as if quotes are disabled. By setting `quote=\"`, the field is always read as if quotes are disabled. It is not expected to ever need to pass anything other than \" to quote; i.e., to turn it off.

**strip.white** default is `TRUE`. Strips leading and trailing whitespaces of unquoted fields. If `FALSE`, only header trailing spaces are removed.

**fill** logical (default is `FALSE`). If `TRUE` then in case the rows have unequal length, blank fields are implicitly filled.
blank.lines.skip

logical, default is FALSE. If TRUE blank lines in the input are ignored.

key

Character vector of one or more column names which is passed to setkey. It may be a single comma separated string such as key="x,y,z", or a vector of names such as key=c("x","y","z"). Only valid when argument data.table=TRUE. Where applicable, this should refer to column names given in col.names.

index

Character vector or list of character vectors of one or more column names which is passed to setindexv. As with key, comma-separated notation like index="x,y,z" is accepted for convenience. Only valid when argument data.table=TRUE. Where applicable, this should refer to column names given in col.names.

showProgress

TRUE displays progress on the console if the ETA is greater than 3 seconds. It is produced in fread's C code where the very nice (but R level) txtProgressBar and tkProgressBar are not easily available.

data.table

TRUE returns a data.table. FALSE returns a data.frame. The default for this argument can be changed with options(data.table.fread.data.table=FALSE).

nThread

The number of threads to use. Experiment to see what works best for your data on your hardware.

logical01

If TRUE a column containing only 0s and 1s will be read as logical, otherwise as integer.

keepLeadingZeros

If TRUE a column containing numeric data with leading zeros will be read as character, otherwise leading zeros will be removed and converted to numeric.

yaml

If TRUE, fread will attempt to parse (using yaml.load) the top of the input as YAML, and further to glean parameters relevant to improving the performance of fread on the data itself. The entire YAML section is returned as parsed into a list in the yaml_metadata attribute. See Details.

autostart

Deprecated and ignored with warning. Please use skip instead.

tmpdir

Directory to use as the tmpdir argument for any tempfile calls, e.g. when the input is a URL or a shell command. The default is tempdir() which can be controlled by setting TMPDIR before starting the R session; see base::tempdir.

tz

Relevant to datetime values which have no Z or UTC-offset at the end, i.e. unmarked datetime, as written by utils::write.csv. The default tz="UTC" reads unmarked datetime as UTC POSIXct efficiently. tz="" reads unmarked datetime as type character (slowly) so that as.POSIXct can interpret (slowly) the character datetimes in local timezone; e.g. by using "POSIXct" in colClasses=.

Note that fwrite() by default writes datetime in UTC including the final Z and therefore fwrite's output will be read by fread consistently and quickly without needing to use tz= or colClasses=. If the TZ environment variable is set to "UTC" (or "" on non-Windows where unset vs ."" is significant) then the R session's timezone is already UTC and tz="" will result in unmarked datetimes being read as UTC POSIXct. For more information, please see the news items from v1.13.0 and v1.14.0.

Details

A sample of 10,000 rows is used for a very good estimate of column types. 100 contiguous rows are read from 100 equally spaced points throughout the file including the beginning, middle and the
very end. This results in a better guess when a column changes type later in the file (e.g. blank at the beginning/only populated near the end, or 001 at the start but 0A0 later on). This very good type guess enables a single allocation of the correct type up front once for speed, memory efficiency and convenience of avoiding the need to set colClasses after an error. Even though the sample is large and jumping over the file, it is almost instant regardless of the size of the file because a lazy on-demand memory map is used. If a jump lands inside a quoted field containing newlines, each newline is tested until 5 lines are found following it with the expected number of fields. The lowest type for each column is chosen from the ordered list: logical, integer, integer64, double, character. Rarely, the file may contain data of a higher type in rows outside the sample (referred to as an out-of-sample type exception). In this event fread will automatically reread just those columns from the beginning so that you don’t have the inconvenience of having to set colClasses yourself; particularly helpful if you have a lot of columns. Such columns must be read from the beginning to correctly distinguish "00" from "000" when those have both been interpreted as integer 0 due to the sample but 00A occurs out of sample. Set verbose=TRUE to see a detailed report of the logic deployed to read your file.

There is no line length limit, not even a very large one. Since we are encouraging list columns (i.e. sep2) this has the potential to encourage longer line lengths. So the approach of scanning each line into a buffer first and then rescanning that buffer is not used. There are no buffers used in fread's C code at all. The field width limit is limited by R itself: the maximum width of a character string (currently 2^31-1 bytes, 2GB).

The filename extension (such as .csv) is irrelevant for "auto" sep and sep2. Separator detection is entirely driven by the file contents. This can be useful when loading a set of different files which may not be named consistently, or may not have the extension .csv despite being csv. Some datasets have been collected over many years, one file per day for example. Sometimes the file name format has changed at some point in the past or even the format of the file itself. So the idea is that you can loop fread through a set of files and as long as each file is regular and delimited, fread can read them all. Whether they all stack is another matter but at least each one is read quickly without you needing to vary colClasses in read.table or read.csv.

If an empty line is encountered then reading stops there with warning if any text exists after the empty line such as a footer. The first line of any text discarded is included in the warning message. Unless, it is single-column input. In that case blank lines are significant (even at the very end) and represent NA in the single column. So that freadfwrite(DT)==DT. This default behaviour can be controlled using blank.lines.skip=TRUE|FALSE.

**Line endings:** All known line endings are detected automatically: \n (*NIX including Mac), \r\n (Windows CRLF), \r (old Mac) and \n\r (just in case). There is no need to convert input files first. fread running on any architecture will read a file from any architecture. Both \r and \n may be embedded in character strings (including column names) provided the field is quoted.

**Decimal separator and locale:** fread(.,...,dec="",") should just work. fread uses C function strtod to read numeric data; e.g., 1.23 or 1,23. strtod retrieves the decimal separator (., or , usually) from the locale of the R session rather than as an argument passed to the strtod function. So for fread(.,...,dec="",") to work, fread changes this (and only this) R session's locale temporarily to a locale which provides the desired decimal separator.

On Windows, "French_France.1252" is tried which should be available as standard (any locale with comma decimal separator would suffice) and on unix "fr_FR.utf8" (you may need to install this locale on unix). fread() is very careful to set the locale back again afterwards, even if the function fails with an error. The choice of locale is determined by options()$datatable.fread.dec.locale.
This may be a vector of locale names and if so they will be tried in turn until the desired dec is obtained; thus allowing more than two different decimal separators to be selected. This is a new feature in v1.9.6 and is experimental. In case of problems, turn it off with options(datatable.fread.dec.experiment=FALSE).

Quotes:

When quote is a single character,

- Spaces and other whitespace (other than sep and \n) may appear in unquoted character fields, e.g., ...,2, Joe Bloggs, 3.14, ...
- When character columns are quoted, they must start and end with that quoting character immediately followed by sep or \n, e.g., ...,2, "Joe Bloggs", 3.14, ...

In essence quoting character fields are required only if sep or \n appears in the string value. Quoting may be used to signify that numeric data should be read as text. Unescaped quotes may be present in a quoted field, e.g., ...,2, "Joe, "Bloggs"", 3.14, ..., as well as escaped quotes, e.g., ...,2, "Joe \", "Bloggs"", 3.14, ... If an embedded quote is followed by the separator inside a quoted field, the embedded quotes up to that point in that field must be balanced; e.g. ..., 2, "www.blah?x="one",y="two"", 3.14, ...

On those fields that do not satisfy these conditions, e.g., fields with unbalanced quotes, fread re-attempts that field as if it isn’t quoted. This is quite useful in reading files that contains fields with unbalanced quotes as well, automatically.

To read fields as is instead, use quote = "".

CSVY Support:

Currently, the yaml setting is somewhat inflexible with respect to incorporating metadata to facilitate file reading. Information on column classes should be stored at the top level under the heading schema and subheading fields; those with both a type and a name sub-heading will be merged into colClasses. Other supported elements are as follows:

- sep (or alias delimiter)
- header
- quote (or aliases quoteChar, quote_char)
- dec (or alias decimal)
- na.strings

File Download:

When input begins with http://, https://, ftp://, ftps://, or file://, fread detects this and downloads the target to a temporary file (at tempfile()) before proceeding to read the file as usual. URLs (ftps:// and https:// as well as ftp:// and http://) paths are downloaded with download.file and method set togetOption("download.file.method"), defaulting to "auto"; and file:// is downloaded with download.file with method="internal". NB: this implies that for file://, even files found on the current machine will be "downloaded" (i.e., hard-copied) to a temporary file. See download.file for more details.

Shell commands:

fread accepts shell commands for convenience. The input command is run and its output written to a file in tmpdir (tempdir() by default) to which fread is applied "as normal". The details are platform dependent – system is used on UNIX environments, shell otherwise; see system.
Value

A `data.table` by default, otherwise a `data.frame` when argument `data.table=FALSE`.

Examples

```r
# Reads text input directly :
fread("A,B\n1,2\n3,4")

# Reads pasted input directly :
fread("A,B
1,2
3,4")

# Finds the first data line automatically :
fread(""
This is perhaps a banner line or two or ten.
A,B
1,2
3,4")

# Detects whether column names are present automatically :
fread(""
1,2
3,4")
```
# Numerical precision:

```
DT = fread("A\n1.010203040506070809010203040506\n")
```

# TODO: add numerals=c("allow.loss", "warn.loss", "no.loss") from base::read.table, +"use.Rmpfr"
typeof(DT$A)=="double"  # currently "allow.loss" with no option

```
DT = fread("A\n1.46761e-313\n")  # read as 'numeric'
DT[,sprintf("%.15E",A)] # beyond what double precision can store accurately to 15 digits
```

# For greater accuracy use colClasses to read as character, then package Rmpfr.

```
# colClasses
data = "A,B,C,D\n1,3,5,7\n2,4,6,8"
fread(data, colClasses=c(B="character",C="character",D="character")) # as read.csv
fread(data, colClasses=list(character=c("B","C","D")))  # saves typing
fread(data, colClasses=list(character=2:4))  # same using column numbers
```

# drop
```
fread(data, colClasses=c("B"="NULL","C"="NULL"))  # as read.csv
fread(data, colClasses=list(NULL=c("B","C")))  # same but less typing, easier to read
fread(data, drop=2:3)  # same using column numbers
```

# select
```
# (in read.csv you need to work out which to drop)
fread(data, select=c("A","D"))   # less typing, easier to read
fread(data, select=c(1,4))  # same using column numbers
```

# select and types combined
```
fread(data, select=c(A="numeric", D="character"))
fread(data, select=list(numeric="A", character="D"))
```

# skip blank lines
```
fread("a,b\n1,a\n2,b\n3,c\n", blank.lines.skip=TRUE)  # fill
fread("a,b\n1,a\n2\n3,c\n", fill=TRUE)
fread("a,b\n1,a\n2\n3\n4\n5\n6\n", fill=TRUE)
```

# check.names usage
```
fread("a b,a b\n1,2\n")
fread("a b,a b1,2\n", check.names=TRUE) # no duplicates + syntactically valid names
```

# Decompresses .gz and .bz2 automatically:  
**fsort**

---

**Fast parallel sort**

**Description**

Similar to base::sort but fast using parallelism. Experimental.

**Usage**

```r
fsort(x, decreasing = FALSE, na.last = FALSE, internal=FALSE, verbose=FALSE, ...)```

**Arguments**

- `x` A vector. Type double, currently.
- `decreasing` Decreasing order?
- `na.last` Control treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed; if "keep" they are kept with rank NA.
- `internal` Internal use only. Temporary variable. Will be removed.
- `verbose` Print tracing information.
- `...` Not sure yet. Should be consistent with base R.

**Details**

Process will raise error if x contains negative values. Unless x is already sorted fsort will redirect processing to slower single threaded order followed by subset in following cases:

- data type other than double (numeric)
- data having NAs
- decreasing==FALSE

**Value**

The input in sorted order.

**Examples**

```r
x = runif(1e6)
system.time(ans1 <- sort(x, method="quick"))
system.time(ans2 <- fsort(x))
identical(ans1, ans2)
```
fwrite

Fast CSV writer

Description

As write.csv but much faster (e.g. 2 seconds versus 1 minute) and just as flexible. Modern machines almost surely have more than one CPU so fwrite uses them; on all operating systems including Linux, Mac and Windows.

Usage

fwrite(x, file = "", append = FALSE, quote = "auto", sep=getOption("datatablefwrite.sep", ","),
sep2 = c("","|",""),
eol = if (.Platform$OS.type="windows") "\r\n" else "\n",
na = "", dec = ".", row.names = FALSE, col.names = TRUE,
qmethod = c("double","escape"),
logical01 = getOption("datatable.logical01", FALSE), # due to change to TRUE; see NEWS
logicalAsInt = logical01, # deprecated
scipen = getOption('scipen', 0L),
dateTimeAs = c("ISO","squash","epoch","write.csv"),
buffMB = 8L, nThread = getDTthreads(verbos),
showProgress = getOption("datatable.showProgress", interactive()),
compress = c("auto", "none", "gzip"),
yaml = FALSE,
bom = FALSE,
verbose = getOption("datatable.verbose", FALSE),
encoding = "")

Arguments

x
Any list of same length vectors; e.g. data.frame and data.table. If matrix, it gets internally coerced to data.table preserving col names but not row names.

file
Output file name. "" indicates output to the console.

append
If TRUE, the file is opened in append mode and column names (header row) are not written.

quote
When "auto", character fields, factor fields and column names will only be surrounded by double quotes when they need to be; i.e., when the field contains the separator sep, a line ending \n, the double quote itself or (when list columns are present) sep2[2] (see sep2 below). If FALSE the fields are not wrapped with quotes even if this would break the CSV due to the contents of the field. If TRUE double quotes are always included other than around numeric fields, as write.csv.

sep
The separator between columns. Default is ",".
For columns of type `list` where each item is an atomic vector, `sep2` controls how to separate items within the column. `sep2[1]` is written at the start of the output field, `sep2[2]` is placed between each item and `sep2[3]` is written at the end. `sep2[1]` and `sep2[3]` may be any length strings including empty "" (default). `sep2[2]` must be a single character and (when list columns are present and therefore `sep2` is used) different from both `sep` and `dec`. The default (\(1\)) is chosen to visually distinguish from the default `sep`. In speaking, writing and in code comments we may refer to `sep2[2]` as simply "sep2".

eol
Line separator. Default is "\r\n" for Windows and "\n" otherwise.

na
The string to use for missing values in the data. Default is a blank string "".

dec
The decimal separator, by default ".". See link in references. Cannot be the same as `sep`.

row.names
Should row names be written? For compatibility with `data.frame` and `write.csv` since `data.table` never has row names. Hence default `FALSE` unlike `write.csv`.

col.names
Should the column names (header row) be written? The default is `TRUE` for new files and when overwriting existing files (`append=FALSE`). Otherwise, the default is `FALSE` to prevent column names appearing again mid-file when stacking a set of `data.tables` or appending rows to the end of a file.

qmethod
A character string specifying how to deal with embedded double quote characters when quoting strings.
- "escape" - the quote character (as well as the backslash character) is escaped in C style by a backslash, or
- "double" (default, same as `write.csv`), in which case the double quote is doubled with another one.

logical01
Should logical values be written as 1 and 0 rather than "TRUE" and "FALSE"?

logicalAsInt
Deprecated. Old name for 'logical01'. Name change for consistency with 'fwrite' for which 'logicalAsInt' would not make sense.

scipen
integer In terms of printing width, how much of a bias should there be towards printing whole numbers rather than scientific notation? See Details.

dateTimeAs
How `Date/IDate`, `ITime` and `POSIXct` items are written.
- "ISO" (default) - 2016-09-12, 12:12:16 and 2016-09-12T12:12:16.999999Z. 0, 3 or 6 digits of fractional seconds are printed if and when present for convenience, regardless of any R options such as `digits.secs`. The idea being that if milli and microseconds are present then you most likely want to retain them. R’s internal UTC representation is written faithfully to encourage ISO standards, stymie timezone ambiguity and for speed. An option to consider is to start R in the UTC timezone simply with "$ TZ='UTC' R" at the shell (NB: it must be one or more spaces between `TZ='UTC'` and R, anything else will be silently ignored; this TZ setting applies just to that R process) or Sys.setenv(TZ='UTC') at the R prompt and then continue as if UTC were local time.
- "squash" - 20160912, 181216 and 20160912181216999. This option allows fast and simple extraction of `yyyy, mm, dd` and (most commonly to group by) `yyyymm` parts using integer div and mod operations. In R for example, one line helper functions could use `%%10000`, `%%%100%100`, `%%%100` and
fwrite

%/%100 respectively. POSIXct UTC is squashed to 17 digits (including 3
digits of milliseconds always, even if 000) which may be read comfortably
as integer64 (automatically by fread()).

• "epoch" - 17056, 65536 and 1473703936.999999. The underlying num-
ber of days or seconds since the relevant epoch (1970-01-01, 00:00:00 and
1970-01-01T00:00:00Z respectively), negative before that (see ?date). 0,
3 or 6 digits of fractional seconds are printed if and when present.

• "write.csv" - this currently affects POSIXct only. It is written as write.csv
does by using the as.character method which heeds digits.secs and
converts from R’s internal UTC representation back to local time (or the
"tzone" attribute) as of that historical date. Accordingly this can be slow.
All other column types (including Date, IDate and ITime which are in-
dependent of timezone) are written as the "ISO" option using fast C code
which is already consistent with write.csv.

The first three options are fast due to new specialized C code. The epoch to
date-part conversion uses a fast approach by Howard Hinnant (see references)
using a day-of-year starting on 1 March. You should not be able to notice any
difference in write speed between those three options. The date range supported
for Date and IDate is [0000-03-01, 9999-12-31]. Every one of these 3,652,365
dates have been tested and compared to base R including all 2,790 leap days in
this range.

This option applies to vectors of date/time in list column cells, too.

A fully flexible format string (such as "%m/%d/%Y") is not supported. This is
to encourage use of ISO standards and because that flexibility is not known how
to make fast at C level. We may be able to support one or two more specific
options if required.

buffMB The buffer size (MB) per thread in the range 1 to 1024, default 8MB. Experiment
to see what works best for your data on your hardware.

nThread The number of threads to use. Experiment to see what works best for your data
on your hardware.

showProgress Display a progress meter on the console? Ignored when file="".

compress If compress = "auto" and if file ends in .gz then output format is gzipped
csv else csv. If compress = "none", output format is always csv. If compress =
"gzip" then format is gzipped csv. Output to the console is never gzipped even
if compress = "gzip". By default, compress = "auto".

yaml If TRUE, fwrite will output a CSVY file, that is, a CSV file with metadata stored
as a YAML header, using as.yaml. See Details.

bom If TRUE a BOM (Byte Order Mark) sequence (EF BB BF) is added at the begin-
ning of the file; format 'UTF-8 with BOM'.

verbose Be chatty and report timings?

encoding The encoding of the strings written to the CSV file. Default is ",", which means
writing raw bytes without considering the encoding. Other possible options are
"UTF-8" and "native".
Details

fwrite began as a community contribution with pull request #1613 by Otto Seiskari. This gave Matt Dowle the impetus to specialize the numeric formatting and to parallelize: https://h2o.ai/blog/2016/fast-csv-writing-for-r/. Final items were tracked in issue #1664 such as automatic quoting, bit64::integer64 support, decimal/scientific formatting exactly matching write.csv between 2.225074e-308 and 1.797693e+308 to 15 significant figures, row.names, dates (between 0000-03-01 and 9999-12-31), times and sep2 for list columns where each cell can itself be a vector.

To save space, fwrite prefers to write wide numeric values in scientific notation – e.g. 10000000000 takes up much more space than 1e+10. Most file readers (e.g. fread) understand scientific notation, so there's no fidelity loss. Like in base R, users can control this by specifying the scipen argument, which follows the same rules as options('scipen'). fwrite will see how much space a value will take to write in scientific vs. decimal notation, and will only write in scientific notation if the latter is more than scipen characters wider. For 10000000000, then, 1e+10 will be written whenever scipen<6.

CSVY Support:
The following fields will be written to the header of the file and surrounded by --- on top and bottom:

- source - Contains the R version and data.table version used to write the file
- creation_time_utc - Current timestamp in UTC time just before the header is written
- schema with element fields giving name-type (class) pairs for the table; multi-class objects (e.g. c('POSIXct', 'POSIXt')) will have their first class written.
- header - same as col.names (which is header on input)
- sep
- sep2
- eol
- na.strings - same as na
- dec
- qmethod
- logical01

unlink("/dev/shm/tmp1.csv")
unlink("/dev/shm/tmp2.csv")
```

## End(Not run)
groupingsets

*Grouping Set aggregation for data tables*

**Description**

Calculate aggregates at various levels of groupings producing multiple (sub-)totals. Reflects SQLs `GROUPING SETS` operations.

**Usage**

```r
rollup(x, ...)  
## S3 method for class 'data.table'
rollup(x, j, by, .SDcols, id = FALSE, ...)  
cube(x, ...)  
## S3 method for class 'data.table'
cube(x, j, by, .SDcols, id = FALSE, ...)  
groupingsets(x, ...)  
## S3 method for class 'data.table'
groupingsets(x, j, by, sets, .SDcols, id = FALSE, jj, ...)
```

**Arguments**

- `x` data.table.
- `...` argument passed to custom user methods. Ignored for `data.table` methods.
- `j` expression passed to `data.table` `j`.
- `by` character column names by which we are grouping.
- `sets` list of character vector reflecting grouping sets, used in `groupingsets` for flexibility.
- `.SDcols` columns to be used in `j` expression in `.SD` object.
- `id` logical default FALSE. If TRUE it will add leading column with bit mask of grouping sets.
- `jj` quoted version of `j` argument, for convenience. When provided function will ignore `j` argument.

**Details**

All three functions `rollup`, `cube`, `groupingsets` are generic methods, `data.table` methods are provided.

**Value**

A `data.table` with various aggregates.

set.seed(25)
DT <- data.table(
  color = sample(c("green","yellow","red"), n, TRUE),
  year = as.Date(sample(paste0(2011:2015,"-01-01"), n, TRUE)),
  status = as.factor(sample(c("removed","active","inactive","archived"), n, TRUE)),
  amount = sample(1:5, n, TRUE),
  value = sample(c(3, 3.5, 2.5, 2), n, TRUE)
)

# rollup
rollup(DT, j = sum(value), by = c("color","year","status")) # default id=FALSE
rollup(DT, j = sum(value), by = c("color","year","status"), id=TRUE)
rollup(DT, j = lapply(.SD, sum), by = c("color","year","status"), id=TRUE, .SDcols="value")
rollup(DT, j = c(list(count=.N), lapply(.SD, sum)), by = c("color","year","status"), id=TRUE)

# cube
cube(DT, j = sum(value), by = c("color","year","status"), id=TRUE)
cube(DT, j = lapply(.SD, sum), by = c("color","year","status"), id=TRUE, .SDcols="value")
cube(DT, j = c(list(count=.N), lapply(.SD, sum)), by = c("color","year","status"), id=TRUE)

# groupingsets
groupingsets(DT, j = c(list(count=.N), lapply(.SD, sum)), by = c("color","year","status"),
  sets = list("color", c("year","status"), character()), id=TRUE)
```

### IDateTime

**Integer based date class**

**Description**

Classes (IDate and ITime) with *integer* storage for fast sorting and grouping.

IDate inherits from the base class Date; the main difference is that the latter uses double storage, allowing e.g. for fractional dates at the cost of storage & sorting inefficiency.

Using IDate, if sub-day granularity is needed, use a second ITime column. IDateTime() facilitates building such paired columns.

Lastly, there are date-time helpers for extracting parts of dates as integers, for example the year (year()), month (month()), or day in the month (mday()); see Usage and Examples.

**Usage**

```r
as.IDate(x, ...)
## Default S3 method:
as.IDate(x, ..., tz = attr(x, "tzone", exact=TRUE))
```
## Arguments

- **x**: an object
arguments to be passed to or from other methods. For as.IDate.default, arguments are passed to as.Date. For as.ITime.default, arguments are passed to as.POSIXlt.

tz
time zone (see strptime).

date
date object convertible with as.IDate.

time
time-of-day object convertible with as.ITime.

digits
really units; one of the units listed for rounding. May be abbreviated. Named digits for consistency with the S3 generic.

units
one of the units listed for truncating. May be abbreviated.

ms
For as.ITime methods, what should be done with sub-second fractions of input? Valid values are 'truncate' (floor), 'nearest' (round), and 'ceil' (ceiling). See Details.

Details

IDate is a date class derived from Date. It has the same internal representation as the Date class, except the storage mode is integer. IDate is a relatively simple wrapper, and it should work in almost all situations as a replacement for Date. The main limitations of integer storage are (1) fractional dates are not supported (use IDateTime() instead) and (2) the range of supported dates is bounded by .Machine$integer.max dates away from January 1, 1970 (a rather impractical limitation as these dates are roughly 6 million years in the future/past, but consider this your caveat).

Functions that use Date objects generally work for IDate objects. This package provides specific methods for IDate objects for mean, cut, seq, c, rep, and split to return an IDate object.

ITime is a time-of-day class stored as the integer number of seconds in the day. as.ITime does not allow days longer than 24 hours. Because ITime is stored in seconds, you can add it to a POSIXct object, but you should not add it to a Date object.

We also provide S3 methods to convert to and from Date and POSIXct.

ITime is time zone-agnostic. When converting ITime and IDate to POSIXct with as.POSIXct, a time zone may be specified.

Inputs like '2018-05-15 12:34:56.789' are ambiguous from the perspective of an ITime object – the method of coercion of the 789 milliseconds is controlled by the ms argument to relevant methods. The default behavior (ms = 'truncate') is to use as.integer, which has the effect of truncating anything after the decimal. Alternatives are to round to the nearest integer (ms = 'nearest') or to round up (ms = 'ceil').

In as.POSIXct methods for ITime and IDate, the second argument is required to be tz based on the generic template, but to make converting easier, the second argument is interpreted as a date instead of a time zone if it is of type IDate or ITime. Therefore, you can use either of the following: as.POSIXct(time, date) or as.POSIXct(date, time).

IDateTime takes a date-time input and returns a data table with columns date and time.

Using integer storage allows dates and/or times to be used as data table keys. With positive integers with a range less than 100,000, grouping and sorting is fast because radix sorting can be used (see sort.list).

Several convenience functions like hour and quarter are provided to group or extract by hour, month, and other date-time intervals. as.POSIXlt is also useful. For example, as.POSIXlt(x)$mon
is the integer month. The R base convenience functions weekdays, months, and quarters can also be used, but these return character values, so they must be converted to factors for use with data.table. isoweek is ISO 8601-consistent.

The round method for IDate’s is useful for grouping and plotting. It can round to weeks, months, quarters, and years. Similarly, the round and trunc methods for ITime’s are useful for grouping and plotting. They can round or truncate to hours and minutes. Note for ITime’s with 30 seconds, rounding is inconsistent due to rounding off a 5. See ’Details’ in round for more information.

Value

For as.IDate, a class of IDate and Date with the date stored as the number of days since some origin.

For as.ITime, a class of ITime stored as the number of seconds in the day.

For IDateTime, a data table with columns idate and itime in IDate and ITime format.

second, minute, hour, yday, wday, mday, week, month, quarter, and year return integer values for second, minute, hour, day of year, day of week, day of month, week, month, quarter, and year, respectively. yearmon and yearqtr return double values representing respectively ’year + (month-1)/12’ and ’year + (quarter-1)/4’.

second, minute, hour are taken directly from the POSIXlt representation. All other values are computed from the underlying integer representation and comparable with the values of their POSIXlt representation of x, with the notable difference that while yday, wday, and mon are all 0-based, here they are 1-based.

J

*Creates a join* data.table

**Description**

Creates a data.table for use in i in a [.data.table join.

**Usage**

```r
# DT[J(...)]         # J() only for use inside DT[...]
# DT[.(...)]         # .() only for use inside DT[...]
# DT[|list(...)]     # same; .(), list() and J() are identical
SJ(...)             # DT[SJ(...)]
CJ(..., sorted=TRUE, unique=FALSE) # DT[CJ(...)]
```
Arguments

... Each argument is a vector. Generally each vector is the same length, but if they are not then the usual silent recycling is applied.

sorted logical. Should setkey() be called on all the columns in the order they were passed to CJ?

unique logical. When TRUE, only unique values of each vectors are used (automatically).

Details

SJ and CJ are convenience functions to create a data.table to be used in i when performing a data.table 'query' on x.

x[data.table(id)] is the same as x[J(id)] but the latter is more readable. Identical alternatives are x[list(id)] and x[.(id)].

When using a join table in i, x must either be keyed or the on argument be used to indicate the columns in x and i which should be joined. See [.data.table].

Value

J: the same result as calling list, for which J is a direct alias.
SJ: Sorted Join. The same value as J() but additionally setkey() is called on all columns in the order they were passed to SJ. For efficiency, to invoke a binary merge rather than a repeated binary full search for each row of i.

CJ: Cross Join. A data.table is formed from the cross product of the vectors. For example, CJ on 10 ids and 100 dates, returns a 1000 row table containing all dates for all ids. If sorted = TRUE (default), setkey() is called on all columns in the order they were passed in to CJ. If sorted = FALSE, the result is unkeyed and input order is retained.

See Also

data.table, test.data.table

Examples

DT = data.table(A=5:1, B=letters[5:1])
setkey(DT, B) # reorders table and marks it sorted
DT[J("b")]] # returns the 2nd row
DT[list("b")]] # same
DT[.("b")]] # same using the dot alias for list

# CJ usage examples
CJ(c(5, NA, 1), c(1, 3, 2)) # sorted and keyed data.table
do.call(CJ, list(c(5, NA, 1), c(1, 3, 2))) # same as above
CJ(c(5, NA, 1), c(1, 3, 2), sorted=FALSE) # same order as input, unkeyed
# use for 'unique=' argument
x = c(1, 1, 2)
y = c(4, 6, 4)
CJ(x, y) # output columns are automatically named 'x' and 'y'
CJ(x, y, unique=TRUE) # unique(x) and unique(y) are computed automatically
last

Description

Returns the first/last item of a vector or list, or the first/last row of a data.frame or data.table. The main difference to head/tail is that the default for n is 1 rather than 6.

Usage

```r
first(x, n=1L, ...) 
last(x, n=1L, ...)
```

Arguments

- `x`: A vector, list, data.frame or data.table. Otherwise the S3 method of `xts::first` is deployed.
- `n`: A numeric vector length 1. How many items to select.
- `...`: Not applicable for `data.table` first/last. Any arguments here are passed through to `xts`'s first/last.

Value

If no other arguments are supplied it depends on the type of `x`. The first/last item of a vector or list. The first/last row of a `data.frame` or `data.table`. For other types, or if any argument is supplied in addition to `x` (such as `n`, or keep in `xts`) regardless of `x`'s type, then `xts::first/xts::last` is called if `xts` has been loaded, otherwise `utils::head/utils::tail`.

See Also

- `NROW`, `head`, `tail`

Examples

```r
first(1:5) # [1] 1
x = data.table(x=1:5, y=6:10)
first(x) # same as head(x, 1)

last(1:5) # [1] 5
x = data.table(x=1:5, y=6:10)
last(x) # same as tail(x, 1)
```
like  

Convenience function for calling grep.

Description

Intended for use in i in [.data.table, i.e., for subsetting/filtering.

Syntax should be familiar to SQL users, with interpretation as regex.

Usage

like(vector, pattern, ignore.case = FALSE, fixed = FALSE, perl = FALSE)

vector %like% pattern
vector %ilike% pattern
vector %flike% pattern
vector %plike% pattern

Arguments

vector  Either a character or a factor vector.
pattern  Pattern to be matched
ignore.case  logical; is pattern case-sensitive?
fixed  logical; should pattern be interpreted as a literal string (i.e., ignoring regular expressions)?
perl  logical; is pattern Perl-compatible regular expression?

Details

Internally, like is essentially a wrapper around base::grepl, except that it is smarter about handling factor input (base::grep uses slow as.character conversion).

Value

Logical vector, TRUE for items that match pattern.

Note

Current implementation does not make use of sorted keys.

See Also

base::grepl
Examples

```r
DT = data.table(Name=c("Mary","George","Martha"), Salary=c(2,3,4))
DT[Name %like% "^Mar"]
DT[Name %ilike% "mar"]
DT[Name %flike% "Mar"]
DT[Name %plike% "(?=Ma)(?=.*y)"]
```

**Description**

These functions compute an integer vector or list for use as the `measure.vars` argument to `melt`. Each measured variable name is converted into several groups that occupy different columns in the output melted data. `measure` allows specifying group names/conversions in R code (each group and conversion specified as an argument) whereas `measurev` allows specifying group names/conversions using data values (each group and conversion specified as a list element). See vignette("datatable-reshape") for more info.

**Usage**

```r
measure(..., sep, pattern, cols, multiple.keyword="value.name")
measurev(fun.list, sep, pattern, cols, multiple.keyword="value.name",
                     group.desc="elements of fun.list")
```

**Arguments**

- `...`: One or more (1) symbols (without argument name; symbol is used for group name) or (2) functions to convert the groups (with argument name that is used for group name). Must have same number of arguments as groups that are specified by either `sep` or `pattern` arguments.
- `fun.list`: Named list which must have the same number of elements as groups that are specified by either `sep` or `pattern` arguments. Each name used for a group name, and each value must be either a function (to convert the group from a character vector to an atomic vector of the same size) or NULL (no conversion).
- `sep`: Separator to split each element of `cols` into groups. Columns that result in the maximum number of groups are considered measure variables.
- `pattern`: Perl-compatible regex with capture groups to match to `cols`. Columns that match the regex are considered measure variables.
- `cols`: A character vector of column names.
- `multiple.keyword`: A string, if used as a group name, then `measure` returns a list and `melt` returns multiple value columns (with names defined by the unique values in that group). Otherwise if the string not used as a group name, then `measure` returns a vector and `melt` returns a single value column.
- `group.desc`: Internal, used in error messages.

melt, https://github.com/Rdatatable/data.table/wiki/Getting-started

Examples

```r
(two.iris = data.table(datasets::iris)[c(1,150)])
# melt into a single value column.
melt(two.iris, measure.vars = measure(part, dim, sep="."))
# do the same, programmatically with measurev
my.list = list(part=NULL, dim=NULL)
melt(two.iris, measure.vars=measurev(my.list, sep="."))
# melt into two value columns, one for each part.
melt(two.iris, measure.vars = measure(value.name, dim, sep="."))
# melt into two value columns, one for each dim.
melt(two.iris, measure.vars = measure(part, value.name, sep="."))
# melt using sep, converting child number to integer.
(two.families = data.table(sex_child1="M", sex_child2="F", age_child1=10, age_child2=20))
print(melt(two.families, measure.vars = measure(
    value.name, child=as.integer,
    sep="_child")))
# same melt using pattern.
print(melt(two.families, measure.vars = measure(
    value.name, child=as.integer,
    pattern="(.*)_child(.)"))
# same melt with pattern and measurev function list.
print(melt(two.families, measure.vars = measurev(
    list(value.name=NULL, child=as.integer),
    pattern="(.*)_child(.)"))
# inspired by data(who, package="tidyr")
(who <- data.table(id=1, new_sp_m5564=2, newrel_f65=3))
# melt to three variable columns, all character.
melt(who, measure.vars = measure(diagnosis, gender, ages, pattern="new_.?(.*)_(.)(.*)"))
# melt to five variable columns, two numeric (with custom conversion).
print(melt(who, measure.vars = measure(
    diagnosis, gender, ages,
    ymin=as.numeric,
    ymax=function(y)ifelse(y=="", Inf, as.numeric(y)),
    pattern="new_.?(.*)_.?([0-9][2])([0-9][0,2])"
))
```

melt.data.table

Fast melt for data.table

Description

melt is data.table’s wide-to-long reshaping tool. We provide an S3 method for melting data.tables. It is written in C for speed and memory efficiency. Since v1.9.6, melt.data.table allows melting into multiple columns simultaneously.
Usage

```r
## fast melt a data.table
## S3 method for class 'data.table'
melt(data, id.vars, measure.vars,
     variable.name = "variable", value.name = "value",
     ..., na.rm = FALSE, variable.factor = TRUE,
     value.factor = FALSE,
     verbose = getOption("datatable.verbose"))
```

Arguments

data A `data.table` object to melt.

id.vars vector of id variables. Can be integer (corresponding id column numbers) or character (id column names) vector. If missing, all non-measure columns will be assigned to it. If integer, must be positive; see Details.

measure.vars Measure variables for melting. Can be missing, vector, list, or pattern-based.

- When missing, `measure.vars` will become all columns outside `id.vars`.
- Vector can be integer (implying column numbers) or character (column names).
- list is a generalization of the vector version – each element of the list (which should be integer or character as above) will become a melted column.
- Pattern-based column matching can be achieved with the regular expression-based `patterns` syntax; multiple patterns will produce multiple columns.

For convenience/clarity in the case of multiple melted columns, resulting column names can be supplied as names to the elements `measure.vars` (in the list and patterns usages). See also Examples.

variable.name name (default 'variable') of output column containing information about which input column(s) were melted. If `measure.vars` is an integer/character vector, then each entry of this column contains the name of a melted column from `data`. If `measure.vars` is a list of integer/character vectors, then each entry of this column contains an integer indicating an index/position in each of those vectors. If `measure.vars` has attribute `variable_table` then it must be a data.table with `nrow = length of measure.vars` vector(s), each row describing the corresponding measured variables(s), (typically created via `measure`) and its columns will be output instead of the `variable.name` column.

value.name name for the molten data values column(s). The default name is 'value'. Multiple names can be provided here for the case when `measure.vars` is a list, though note well that the names provided in `measure.vars` take precedence.

na.rm If TRUE, NA values will be removed from the molten data.

variable.factor If TRUE, the variable column will be converted to factor, else it will be a character column.

value.factor If TRUE, the value column will be converted to factor, else the molten value type is left unchanged.
melt.data.table

verbose TRUE turns on status and information messages to the console. Turn this on by default using options(datatable.verbose=TRUE). The quantity and types of verbosity may be expanded in future.

... any other arguments to be passed to/from other methods.

Details

If id.vars and measure.vars are both missing, all non-numeric/integer/logical columns are assigned as id variables and the rest as measure variables. If only one of id.vars or measure.vars is supplied, the rest of the columns will be assigned to the other. Both id.vars and measure.vars can have the same column more than once and the same column can be both as id and measure variables.

melt.data.table also accepts list columns for both id and measure variables.

When all measure.vars are not of the same type, they’ll be coerced according to the hierarchy list > character > numeric > integer > logical. For example, if any of the measure variables is a list, then entire value column will be coerced to a list.

From version 1.9.6, melt gains a feature with measure.vars accepting a list of character or integer vectors as well to melt into multiple columns in a single function call efficiently. If a vector in the list contains missing values, or is shorter than the max length of the list elements, then the output will include runs of missing values at the specified position, or at the end. The function patterns can be used to provide regular expression patterns. When used along with melt, if cols argument is not provided, the patterns will be matched against names(data), for convenience.

Attributes are preserved if all value columns are of the same type. By default, if any of the columns to be melted are of type factor, it’ll be coerced to character type. To get a factor column, set value.factor = TRUE. melt.data.table also preserves ordered factors.

Historical note: melt.data.table was originally designed as an enhancement to reshape2::melt in terms of computing and memory efficiency. reshape2 has since been superseded in favour of tidyr, and melt has had a generic defined within data.table since v1.9.6 in 2015, at which point the dependency between the packages became more etymological than programmatic. We thank the reshape2 authors for the inspiration.

Value

An unkeyed data.table containing the molten data.

dcast, https://cran.r-project.org/package=reshape

Examples

set.seed(45)
require(data.table)
DT <- data.table(
  i_1 = c(1:5, NA),
  n_1 = c(NA, 6, 7, 8, 9, 10),
  f_1 = factor(sample(c(letters[1:3], NA), 6L, TRUE)),
  f_2 = factor(c("z", "a", "x", "c", "x", "x"), ordered=TRUE),
c_1 = sample(c(letters[1:3], NA), 6L, TRUE),
c_2 = sample(c(LETTERS[1:2], NA), 6L, TRUE),
d_1 = as.Date(c(1:3,NA,4:5), origin="2013-09-01"),
d_2 = as.Date(6:1, origin="2012-01-01")
)
# add a couple of list cols
DT[, l_1 := DT[, list(c=list(rep(i_1, sample(5, 1L)))), by = i_1]]
DT[, l_2 := DT[, list(c=list(rep(c_1, sample(5, 1L)))), by = i_1]]
# id.vars, measure.vars as character/integer/numeric vectors
melt(DT, id.vars=1:2, measure.vars="f_1")
melt(DT, id.vars=c("i_1", "n_1"), measure.vars=3) # same as above
melt(DT, id.vars=1:2, measure.vars=3L, value.factor=TRUE) # 'value' is *ordered* factor
melt(DT, id.vars=1:2, measure.vars=3:4, value.factor=TRUE) # 'value' is factor
# preserves attribute when types are identical, ex: Date
melt(DT, id.vars=3:4, measure.vars=c("d_1", "d_2"))
melt(DT, id.vars=3:4, measure.vars=c("n_1", "d_1")) # attribute not preserved
# on list
melt(DT, id.vars=1, measure.vars=c("l_1", "l_2")) # value is a list
suppressWarnings(
melt(DT, id.vars=1, measure.vars=c("c_1", "l_1")) # c1 coerced to list, with warning
)
# on character
melt(DT, id.vars=1, measure.vars=c("c_1", "f_1")) # value is char
suppressWarnings(
melt(DT, id.vars=1, measure.vars=c("c_1", "n_1")) # n_1 coerced to char, with warning
)
# on na.rm=TRUE. NAs are removed efficiently, from within C
melt(DT, id.vars=1, measure.vars=c("c_1", "c_2"), na.rm=TRUE) # remove NA
# measure.vars can be also a list
# melt "f_1,f_2" and "d_1,d_2" simultaneously, retain 'factor' attribute
# convenient way using internal function patterns()
melt(DT, id.vars=1:2, measure.vars=patterns("^f_", "^d_"), value.factor=TRUE)
# same as above, but provide list of columns directly by column names or indices
melt(DT, id.vars=1:2, measure.vars=list(3:4, c("d_1", "d_2")), value.factor=TRUE)
# same as above, but provide names directly:
melt(DT, id.vars=1:2, measure.vars=patterns(f="^f_", d="^d_"), value.factor=TRUE)
# na.rm=TRUE removes rows with NAs in any 'value' columns
melt(DT, id.vars=1:2, measure.vars=patterns("^f_", "^d_"), value.factor=TRUE, na.rm=TRUE)
# 'na.rm=TRUE' also works with list column, but note that is.na only
# returns TRUE if the list element is a length=1 vector with an NA.
is.na(list(one.NA=NA, two.NA=c(NA,NA)))
melt(DT, id.vars=1:2, measure.vars=patterns("^l_", "^d_"), na.rm=FALSE)
melt(DT, id.vars=1:2, measure.vars=patterns("^l_", "^d_"), na.rm=TRUE)
# measure list with missing/short entries results in output with runs of NA
merge

Merge two data.tables

Description

Fast merge of two data.tables. The data.table method behaves similarly to data.frame except that row order is specified, and by default the columns to merge on are chosen:

• at first based on the shared key columns, and if there are none,
• then based on key columns of the first argument x, and if there are none,
• then based on the common columns between the two data.tables.

Use the by, by.x and by.y arguments explicitly to override this default.

Usage

```r
## S3 method for class 'data.table'
merge(x, y, by = NULL, by.x = NULL, by.y = NULL, all = FALSE,
all.x = all, all.y = all, sort = TRUE, suffixes = c(".x", ".y"), no.dups = TRUE,
allow.cartesian=getOption("datatable.allow.cartesian"), # default FALSE
incomparables = NULL, ...)
```

Arguments

- `x, y`  
  data tables. `y` is coerced to a `data.table` if it isn’t one already.
- `by`  
  A vector of shared column names in `x` and `y` to merge on. This defaults to the shared key columns between the two tables. If `y` has no key columns, this defaults to the key of `x`.
- `by.x, by.y`  
  Vectors of column names in `x` and `y` to merge on.
- `all`  
  logical; `all = TRUE` is shorthand to save setting both `all.x = TRUE` and `all.y = TRUE`.
- `all.x`  
  logical; if `TRUE`, rows from `x` which have no matching row in `y` are included. These rows will have ‘NA’s in the columns that are usually filled with values from `y`. The default is `FALSE` so that only rows with data from both `x` and `y` are included in the output.
- `all.y`  
  logical; analogous to `all.x` above.
merge

sort logical. If TRUE (default), the rows of the merged data.table are sorted by setting the key to the by / by.x columns. If FALSE, unlike base R’s merge for which row order is unspecified, the row order in x is retained (including retaining the position of missings when all.x=TRUE), followed by y rows that don’t match x (when all.y=TRUE) retaining the order those appear in y.

suffixes A character(2) specifying the suffixes to be used for making non-by column names unique. The suffix behaviour works in a similar fashion as the merge.data.frame method does.

no.dups logical indicating that suffixes are also appended to non-by.y column names in y when they have the same column name as any by.x.

allow.cartesian See allow.cartesian in [.data.table.

incomparables values which cannot be matched and therefore are excluded from by columns.

... Not used at this time.

Details

merge is a generic function in base R. It dispatches to either the merge.data.frame method or merge.data.table method depending on the class of its first argument. Note that, unlike SQL join, NA is matched against NA (and NaN against NaN) while merging.

For a more data.table-centric way of merging two data.tables, see [.data.table; e.g., x[y, ...]. See FAQ 1.11 for a detailed comparison of merge and x[y, ...].

Value

A new data.table based on the merged data tables, and sorted by the columns set (or inferred for) the by argument if argument sort is set to TRUE.

See Also
data.table, setkey, [.data.table, merge.data.frame

Examples

(dt1 <- data.table(A = letters[1:10], X = 1:10, key = "A"))
(dt2 <- data.table(A = letters[5:14], Y = 1:10, key = "A"))
merge(dt1, dt2)
merge(dt1, dt2, all = TRUE)

(dt1 <- data.table(A = letters[rep(1:3, 2)], X = 1:6, key = "A"))
(dt2 <- data.table(A = letters[rep(2:4, 2)], Y = 6:1, key = "A"))
merge(dt1, dt2, all.cartesian=TRUE)

(dt1 <- data.table(A = c(rep(1L, 5), 2L), B = letters[rep(1:3, 2)], X = 1:6, key = "A,B"))
(dt2 <- data.table(A = c(rep(1L, 5), 2L), B = letters[rep(2:4, 2)], Y = 6:1, key = "A,B"))
merge(dt1, dt2)
merge(dt1, dt2, by="B", allow.cartesian=TRUE)

# test it more:
d1 <- data.table(a=rep(1:2,each=3), b=1:6, key="a,b")
d2 <- data.table(a=0:1, bb=10:11, key="a")
d3 <- data.table(a=0:1, key="a")
d4 <- data.table(a=0:1, b=0:1, key="a,b")
merge(d1, d2)
merge(d2, d1)
merge(d1, d2, all=TRUE)
merge(d2, d1, all=TRUE)
merge(d3, d1)
merge(d1, d3)
merge(d1, d3, all=TRUE)
merge(d3, d1, all=TRUE)
merge(d1, d4)
merge(d1, d4, by="a", suffixes=c("d1", "d4"))
merge(d4, d1)
merge(d1, d4, all=TRUE)
merge(d4, d1, all=TRUE)

# setkey is automatic by default
set.seed(1L)
d1 <- data.table(a=sample(rep(1:3,each=2)), z=1:6)
d2 <- data.table(a=2:0, z=10:12)
merge(d1, d2, by="a")
merge(d1, d2, by="a", all=TRUE)

# using by.x and by.y
setnames(d2, "a", "b")
merge(d1, d2, by.x="a", by.y="b")
merge(d1, d2, by.x="a", by.y="b", all=TRUE)
merge(d2, d1, by.x="b", by.y="a")

# using incomparables values
d1 <- data.table(a=c(1,2,NA,NA,3,1), z=1:6)
d2 <- data.table(a=c(1,2,NA), z=10:12)
merge(d1, d2, by="a")
merge(d1, d2, by="a", incomparables=NA)

---

na.omit.data.table  
Remove rows with missing values on columns specified

Description

This is a data.table method for the S3 generic stats::na.omit. The internals are written in C for speed. See examples for benchmark timings.

bit64::integer64 type is also supported.
Usage

## S3 method for class 'data.table'
na.omit(object, cols=seq_along(object), invert=FALSE, ...)

Arguments

object       A data.table.
cols         A vector of column names (or numbers) on which to check for missing values. Default is all the columns.
invert       logical. If FALSE omits all rows with any missing values (default). TRUE returns just those rows with missing values instead.
...
Further arguments special methods could require.

Details

The data.table method consists of an additional argument cols, which when specified looks for missing values in just those columns specified. The default value for cols is all the columns, to be consistent with the default behaviour of stats::na.omit.

It does not add the attribute na.action as stats::na.omit does.

Value

A data.table with just the rows where the specified columns have no missing value in any of them.

See Also

data.table

Examples

DT = data.table(x=c(1,NaN,NA,3), y=c(NA_integer_, 1:3), z=c("a", NA_character_, "b", "c"))
# default behaviour
na.omit(DT)
# omit rows where 'x' has a missing value
na.omit(DT, cols="x")
# omit rows where either 'x' or 'y' have missing values
na.omit(DT, cols=c("x", "y"))

## Not run:
# Timings on relatively large data
set.seed(1L)
DT = data.table(x = sample(c(1:100, NA_integer_), 5e7L, TRUE),
                y = sample(c(rnorm(100), NA), 5e7L, TRUE))
system.time(ans1 <- na.omit(DT)) ## 2.6 seconds
system.time(ans2 <- stats:::na.omit.data.frame(DT)) ## 29 seconds
# identical? check each column separately, as ans2 will have an additional attribute
all(sapply(1:2, function(i) identical(ans1[[i]], ans2[[i]]))) ## TRUE

## End(Not run)
**nafill**

*Fill missing values*

**Description**

Fast fill missing values using constant value, *last observation carried forward* or *next observation carried backward*.

**Usage**

```r
nafill(x, type=c("const","locf","nocb"), fill=NA, nan=NA)
setnafill(x, type=c("const","locf","nocb"), fill=NA, nan=NA, cols=seq_along(x))
```

**Arguments**

- **x**: vector, list, data.frame or data.table of numeric columns.
- **type**: character, one of "const", "locf" or "nocb". Defaults to "const".
- **fill**: numeric or integer, value to be used to fill.
- **nan**: (numeric x only) Either NaN or NA; if the former, NaN is treated as distinct from NA, otherwise, they are treated the same during replacement?
- **cols**: numeric or character vector specifying columns to be updated.

**Details**

Only *double* and *integer* data types are currently supported.

Note that both nafill and setnafill provide some verbose output when `getOption('datatable.verbose')` is TRUE.

**Value**

A list except when the input is a vector in which case a vector is returned. For setnafill the input argument is returned, updated by reference.

**See Also**

`shift, data.table`

**Examples**

```r
x = 1:10
x[c(1:2, 5:6, 9:10)] = NA
nafill(x, "locf")

dt = data.table(v1=x, v2=shift(x)/2, v3=shift(x, -1L)/2)
nafill(dt, "nocb")

setnafill(dt, "locf", cols=c("v2","v3"))
dt
```
Convenience operator for checking if an example is not in a set of elements

Description

Check whether an object is absent from a table, i.e., the logical inverse of `in`. See examples on how missing values are being handled.

Usage

```r
x %notin% table
```

Arguments

- `x`: Vector or `NULL`: the values to be matched.
- `table`: Vector or `NULL`: the values to be matched against.

Value

Logical vector, `TRUE` for each element of `x` absent from `table`, and `FALSE` for each element of `x` present in `table`.

See Also

`match`, `chmatch`

Examples

```r
11 %notin% 1:10 # TRUE
"a" %notin% c("a", "b") # FALSE

## NAs on the LHS
NA %in% 1:2
NA %notin% 1:2
## NAs on the RHS
NA %in% c(1:2,NA)
NA %notin% c(1:2,NA)
```
patterns

Obtain matching indices corresponding to patterns

Description

patterns returns the matching indices in the argument cols corresponding to the regular expression patterns provided. The patterns must be supported by grep.

From v1.9.6, melt.data.table has an enhanced functionality in which measure.vars argument can accept a list of column names and melt them into separate columns. See the Efficient reshaping using data.tables vignette linked below to learn more.

Usage

patterns(..., cols=character(0))

Arguments

... A set of regular expression patterns.

cols A character vector of names to which each pattern is matched.

See Also

melt, https://github.com/Rdatatable/data.table/wiki/Getting-started

Examples

DT = data.table(x1 = 1:5, x2 = 6:10, y1 = letters[1:5], y2 = letters[6:10])
# melt all columns that begin with 'x' & 'y', respectively, into separate columns
melt(DT, measure.vars = patterns("^x", "^y", cols=names(DT)))
# when used with melt, 'cols' is implicitly assumed to be names of input
data.table, if not provided.
melt(DT, measure.vars = patterns("^x", "^y"))

print.data.table

data.table Printing Options

Description

print.data.table extends the functionalities of print.data.frame.

Key enhancements include automatic output compression of many observations and concise column-wise class summary.

format_col and format_list_item generics provide flexibility for end-users to define custom printing methods for generic classes.
Usage

```r
## S3 method for class 'data.table'
print(x,
     topn=getOption("datatable.print.topn"), # default: 5
     nrows=getOption("datatable.print.nrows"), # default: 100
     class=getOption("datatable.print.class"), # default: TRUE
     row.names=getOption("datatable.print.rownames"), # default: TRUE
     col.names=getOption("datatable.print.colnames"), # default: "auto"
     print.keys=getOption("datatable.print.keys"), # default: TRUE
     trunc.cols=getOption("datatable.print.trunc.cols"), # default: FALSE
     quote=FALSE,
     timezone=FALSE, ...)
```

```r
format_col(x, ...)
## Default S3 method:
format_col(x, ...)
## S3 method for class 'POSIXct'
format_col(x, ..., timezone=FALSE)
## S3 method for class 'expression'
format_col(x, ...)
```

```r
format_list_item(x, ...)
## Default S3 method:
format_list_item(x, ...)
```

Arguments

- **x**: A data.table.
- **topn**: The number of rows to be printed from the beginning and end of tables with more than `nrows` rows.
- **nrows**: The number of rows which will be printed before truncation is enforced.
- **class**: If TRUE, the resulting output will include above each column its storage class (or a self-evident abbreviation thereof).
- **row.names**: If TRUE, row indices will be printed alongside `x`.
- **col.names**: One of three flavours for controlling the display of column names in output. "auto" includes column names above the data, as well as below the table if `nrow(x) > 20`. "top" excludes this lower register when applicable, and "none" suppresses column names altogether (as well as column classes if `class` = TRUE).
- **print.keys**: If TRUE, any key and/or index currently assigned to `x` will be printed prior to the preview of the data.
- **trunc.cols**: If TRUE, only the columns that can be printed in the console without wrapping the columns to new lines will be printed (similar to tibbles).
- **quote**: If TRUE, all output will appear in quotes, as in print.default.
- **timezone**: If TRUE, time columns of class POSIXct or POSIXlt will be printed with their timezones (if attribute is available).
- **...**: Other arguments ultimately passed to format.
Details

By default, with an eye to the typically large number of observations in a data.table, only the beginning and end of the object are displayed (specifically, head(x, topn) and tail(x, topn) are displayed unless nrow(x) < nrows, in which case all rows will print).

format_col is applied at a column level; for example, format_col.POSIXct is used to tag the time zones of POSIXct columns. format_list_item is applied to the elements (rows) of list columns; see Examples. The default format_col method uses getS3method to test if a format method exists for the column, and if so uses it. Otherwise, the default format_list_item method uses the S3 format method (if one exists) for each item of a list column.

Value

print.data.table returns x invisibly.

format_col returns a length(x)-size character vector.

format_list_item returns a length-1 character scalar.

See Also

print.default

Examples

#output compression
DT <- data.table(a = 1:1000)
print(DT, nrows = 100, topn = 4)

#'quote' can be used to identify whitespace
DT <- data.table(blanks = c(" 12", " .34"),
                 noblocks = c("12", "34"))
print(DT, quote = TRUE)

#'class' provides handy column type summaries at a glance
DT <- data.table(a = vector("integer", 3),
                 b = vector("complex", 3),
                 c = as.IDate(paste0("2016-02-0", 1:3)))
print(DT, class = TRUE)

#'row.names' can be eliminated to save space
DT <- data.table(a = 1:3)
print(DT, row.names = FALSE)

#'print.keys' can alert which columns are currently keys
DT <- data.table(a=1:3, b=4:6, c=7:9, key="b,a")
setindexv(DT, c("a", "b"))
setindexv(DT, "a")
print(DT, print.keys=TRUE)

# `trunc.cols` will make it so only columns that fit in console will be printed
# with a message that states the variables not shown
old_width = options("width" = 48)
rbindlist

Constructs a single data.table from a list of data.tables, data.frames, or lists.

**Usage**

```r
library(tidyverse)
library(data.table)

# Example data
thing_11 <- vector("integer", 3)
thing_21 <- vector("complex", 3)
thing_31 <- as.IDate(paste0("2016-02-0", 1:3)),
thing_41 <- "aasdfasdfasdfasdfasdfasdfasdfasdfasdfasdf",
thing_51 <- vector("integer", 3),
thing_61 <- vector("complex", 3)

DT <- data.table(thing_11 = vector("integer", 3),
                 thing_21 = vector("complex", 3),
                 thing_31 = as.IDate(paste0("2016-02-0", 1:3)),
                 thing_41 = "aasdfasdfasdfasdfasdfasdfasdfasdfasdfasdf",
                 thing_51 = vector("integer", 3),
                 thing_61 = vector("complex", 3))

print(DT, trunc.cols=TRUE)
```

**Arguments**

- `l`: A list containing `data.table`, `data.frame` or `list` objects. ... is the same but you pass the objects by name separately.
- `use.names`: TRUE binds by matching column name, FALSE by position. ‘check’ (default) warns if all items don’t have the same names in the same order and then currently proceeds as if ‘use.names=FALSE’ for backwards compatibility (TRUE in future); see news for v1.12.2.
- `fill`: TRUE fills missing columns with NAs. By default FALSE.
- `idcol`: Creates a column in the result showing which list item those rows came from. TRUE names this column ".id". idcol="file" names this column "file". If the input list has names, those names are the values placed in this id column, otherwise the values are an integer vector 1:length(l). See examples.
Details

Each item of l can be a data.table, data.frame or list, including NULL (skipped) or an empty object (0 rows). rbindlist is most useful when there are an unknown number of (potentially many) objects to stack, such as returned by lapply(fileNames, fread). rbind is most useful to stack two or three objects which you know in advance. . . . should contain at least one data.table for rbind(...) to call the fast method and return a data.table, whereas rbindlist(l) always returns a data.table even when stacking a plain list with a data.frame, for example.

Columns with duplicate names are bound in the order of occurrence, similar to base. The position (column number) that each duplicate name occurs is also retained.

If column i does not have the same type in each of the list items; e.g., the column is integer in item 1 while others are numeric, they are coerced to the highest type.

If a column contains factors then a factor is created. If any of the factors are also ordered factors then the longest set of ordered levels are found (the first if this is tied). Then the ordered levels from each list item are checked to be an ordered subset of these longest levels. If any ambiguities are found (e.g. blue<green vs green<blue), or any ordered levels are missing from the longest, then a regular factor is created with warning. Any strings in regular factor and character columns which are missing from the longest ordered levels are added at the end.

Value

An unkeyed data.table containing a concatenation of all the items passed in.

Examples

# default case
DT1 = data.table(A=1:3,B=letters[1:3])
DT2 = data.table(A=4:5,B=letters[4:5])
l = list(DT1,DT2)
rbindlist(l)

# bind correctly by names
DT1 = data.table(A=1:3,B=letters[1:3])
DT2 = data.table(B=letters[4:5],A=4:5)
l = list(DT1,DT2)
rbindlist(l, use.names=TRUE)

# fill missing columns, and match by col names
DT1 = data.table(A=1:3,B=letters[1:3])
DT2 = data.table(B=letters[4:5],C=factor(1:2))
l = list(DT1,DT2)
rbindlist(l, use.names=TRUE, fill=TRUE)

# generate index column, auto generates indices
rbindlist(l, use.names=TRUE, fill=TRUE, idcol=TRUE)
# let’s name the list
rleid

Generate run-length type group id

Description

A convenience function for generating a run-length type id column to be used in grouping operations. It accepts atomic vectors, lists, data.frames or data.tables as input.

Usage

rleid(..., prefix=NULL)

rleidv(x, cols=seq_along(x), prefix=NULL)

Arguments

x
A vector, list, data.frame or data.table.

... A sequence of numeric, integer64, character or logical vectors, all of same length. For interactive use.

cols Only meaningful for lists, data.frames or data.tables. A character vector of column names (or numbers) of x.

prefix Either NULL (default) or a character vector of length=1 which is prefixed to the row ids, returning a character vector (instead of an integer vector).

Details

At times aggregation (or grouping) operations need to be performed where consecutive runs of identical values should belong to the same group (See rle). The use for such a function has come up repeatedly on StackOverflow, see the See Also section. This function allows to generate “run-length” groups directly.

rleid is designed for interactive use and accepts a sequence of vectors as arguments. For programming, rleidv might be more useful.

Value

When prefix = NULL, an integer vector with same length as NROW(x), else a character vector with the value in prefix prefixed to the ids obtained.

data.table, rowid, https://stackoverflow.com/q/21421047/559784
**Examples**

DT = data.table(grp=rep(c("A", "B", "C", "A", "B"), c(2,2,3,1,2)), value=1:10)

rleid(DT$grp) # get run-length ids
rleidv(DT, "grp") # same as above

rleid(DT$grp, prefix="grp") # prefix with 'grp'

# get sum of value over run-length groups
DT[, sum(value), by=(grp, rleid(grp))]
DT[, sum(value), by=(grp, rleid(grp, prefix="grp"))]

---

**roll**  
**Rolling functions**

**Description**

Fast rolling functions to calculate aggregates on sliding windows. Function name and arguments are experimental.

**Usage**

frollmean(x, n, fill=NA, algo=c("fast", "exact"),  
align=c("right", "left", "center"), na.rm=FALSE, hasNA=NA, adaptive=FALSE)

frollsum(x, n, fill=NA, algo=c("fast", "exact"),  
align=c("right", "left", "center"), na.rm=FALSE, hasNA=NA, adaptive=FALSE)

frollapply(x, n, FUN, ..., fill=NA, align=c("right", "left", "center"))

**Arguments**

- **x**: Vector, data.frame or data.table of integer, numeric or logical columns over which to calculate the windowed aggregations. May also be a list, in which case the rolling function is applied to each of its elements.
- **n**: Integer vector giving rolling window size(s). This is the total number of included values. Adaptive rolling functions also accept a list of integer vectors.
- **fill**: Numeric; value to pad by. Defaults to NA.
- **algo**: Character, default "fast". When set to "exact", a slower (but more accurate) algorithm is used. It suffers less from floating point rounding errors by performing an extra pass, and carefully handles all non-finite values. It will use multiple cores where available. See Details for more information.
- **align**: Character, specifying the "alignment" of the rolling window, defaulting to "right". "right" covers preceding rows (the window ends on the current value); "left" covers following rows (the window starts on the current value); "center" is halfway in between (the window is centered on the current value, biased towards "left" when n is even).
roll

na.rm Logical, default FALSE. Should missing values be removed when calculating window? For details on handling other non-finite values, see Details.

hasNA Logical. If it is known that x contains NA then setting this to TRUE will speed up calculation. Defaults to NA.

adaptive Logical, default FALSE. Should the rolling function be calculated adaptively? See Details below.

FUN The function to be applied to the rolling window; see Details for restrictions.

... Extra arguments passed to FUN in frollapply.

Details

froll* functions accept vectors, lists, data.frames or data.tables. They always return a list except when the input is a vector and length(n)==1, in which case a vector is returned, for convenience. Thus, rolling functions can be used conveniently within data.table syntax.

Argument n allows multiple values to apply rolling functions on multiple window sizes. If adaptive=TRUE, then n must be a list. Each list element must be integer vector of window sizes corresponding to every single observation in each column; see Examples.

When algo="fast" an "on-line" algorithm is used, and all of NaN, +Inf, -Inf are treated as NA. Setting algo="exact" will make rolling functions to use a more computationally-intensive algorithm that suffers less from floating point rounding error (the same consideration applies to mean). algo="exact" also handles NaN, +Inf, -Inf consistently to base R. In case of some functions (like mean), it will additionally make extra pass to perform floating point error correction. Error corrections might not be truly exact on some platforms (like Windows) when using multiple threads.

Adaptive rolling functions are a special case where each observation has its own corresponding rolling window width. Due to the logic of adaptive rolling functions, the following restrictions apply:

- align only "right".
- if list of vectors is passed to x, then all vectors within it must have equal length.

When multiple columns or multiple windows width are provided, then they are run in parallel. The exception is for algo="exact", which runs in parallel already.

frollapply computes rolling aggregate on arbitrary R functions. The input x (first argument) to the function FUN is coerced to numeric beforehand and FUN has to return a scalar numeric value. Checks for that are made only during the first iteration when FUN is evaluated. Edge cases can be found in examples below. Any R function is supported, but it is not optimized using our own C implementation – hence, for example, using frollapply to compute a rolling average is inefficient. It is also always single-threaded because there is no thread-safe API to R’s C eval. Nevertheless we’ve seen the computation speed up vis-a-vis versions implemented in base R.

Value

A list except when the input is a vector and length(n)==1 in which case a vector is returned.
Note

Users coming from most popular package for rolling functions zoo might expect following differences in data.table implementation.

- rolling function will always return result of the same length as input.
- fill defaults to NA.
- fill accepts only constant values. It does not support for na.locf or other functions.
- align defaults to "right".
- na.rm is respected, and other functions are not needed when input contains NA.
- integers and logical are always coerced to double.
- when adaptive=FALSE (default), then n must be a numeric vector. List is not accepted.
- when adaptive=TRUE, then n must be vector of length equal to nrow(x), or list of such vectors.
- partial window feature is not supported, although it can be accomplished by using adaptive=TRUE, see examples. NA is always returned for incomplete windows.

Be aware that rolling functions operates on the physical order of input. If the intent is to roll values in a vector by a logical window, for example an hour, or a day, one has to ensure that there are no gaps in input. For details see issue #3241.

rowid rowid

Generate unique row ids within each group

Description

Convenience functions for generating a unique row ids within each group. It accepts atomic vectors, lists, data.frames or data.tables as input.

rowid is intended for interactive use, particularly along with the function dcast to generate unique ids directly in the formula.

rowidv(DT, cols=c("x", "y")) is equivalent to column N in the code DT[, N := seq_len(.N), by=c("x", "y")].

See examples for more.

Usage

rowid(..., prefix=NULL)
rowidv(x, cols=seq_along(x), prefix=NULL)

Arguments

x A vector, list, data.frame or data.table.
...
A sequence of numeric, integer64, character or logical vectors, all of same length. For interactive use.

cols Only meaningful for lists, data.frames or data.tables. A character vector of column names (or numbers) of x.

prefix Either NULL (default) or a character vector of length=1 which is prefixed to the row ids, returning a character vector (instead of an integer vector).

Value

When prefix = NULL, an integer vector with same length as NROW(x), else a character vector with the value in prefix prefixed to the ids obtained.
setattr

See Also
dcast.data.table, rleid

Examples

```r
DT = data.table(x=c(20,10,10,30,30,20), y=c("a", "a", "a", "b", "b", "b"), z=1:6)

rowid(DT$x) # 1,1,2,1,2,2
rowidv(DT, cols="x") # same as above

rowid(DT$x, prefix="group") # prefixed with 'group'

rowid(DT$x, DT$y) # 1,1,2,1,2,1
rowidv(DT, cols=c("x","y")) # same as above
DT[, .(N=seq_len(.N)), by=(x,y)]$N # same as above

# convenient usage with dcast
dcast(DT, x ~ rowid(x, prefix="group"), value.var="z")
#    x  group1 group2
# 1: 10  2  3
# 2: 20  1  6
# 3: 30  4  5
```

setattr: Set attributes of objects by reference

Description

In `data.table`, all `set*` functions change their input by reference. That is, no copy is made at all, other than temporary working memory which is as large as one column. The only other `data.table` operator that modifies input by reference is `:=`. Check out the See Also section below for other `set*` function that `data.table` provides.

Usage

```r
setattr(x, name, value)
setnames(x, old, new, skip_absent=FALSE)
```

Arguments

- **x**
  - `setnames` accepts `data.frame` and `data.table`. `setattr` accepts any input; e.g., list, columns of a `data.frame` or `data.table`.

- **name**
  - The character attribute name.

- **value**
  - The value to assign to the attribute or `NULL` removes the attribute, if present.

- **old**
  - When `new` is provided, character names or numeric positions of column names to change. When `new` is not provided, a function or the new column names (i.e., it's implicitly treated as `new`; excluding `old` and explicitly naming `new` is
setattr equivalent). If a function, it will be called with the current column names and is supposed to return the new column names. The new column names must be the same length as the number of columns. See examples.

new Optional. It can be a function or the new column names. If a function, it will be called with old and expected to return the new column names. The new column names must be the same length as columns provided to old argument.

skip_absent Skip items in old that are missing (i.e. absent) in 'names(x)'. Default FALSE halts with error if any are missing.

Details

setnames operates on data.table and data.frame not other types like list and vector. It can be used to change names by name with built-in checks and warnings (e.g., if any old names are missing or appear more than once).

setattr is a more general function that allows setting of any attribute to an object by reference.

A very welcome change in R 3.1+ was that 'names<-' and 'colnames<-' no longer copy the entire object as they used to (up to 4 times), see examples below. They now take a shallow copy. The 'set*' functions in data.table are still useful because they don’t even take a shallow copy. This allows changing names and attributes of a (usually very large) data.table in the global environment from within functions. Like a database.

Value

The input is modified by reference, and returned (invisibly) so it can be used in compound statements; e.g., setnames(DT,"V1", "Y")[, .N, by=Y]. If you require a copy, take a copy first (using DT2=copy(DT)). See ?copy.

Note that setattr is also in package bit. Both packages merely expose R’s internal setAttrib function at C level but differ in return value. bit::setattr returns NULL (invisibly) to remind you the function is used for its side effect. data.table::setattr returns the changed object (invisibly) for use in compound statements.

See Also

data.table, setkey, setorder, setcolorder, set, :=, setDT, setDF, copy

Examples

DT <- data.table(a = 1, b = 2, d = 3)
old <- c("a", "b", "c", "d")
new <- c("A", "B", "C", "D")

setnames(DT, old, new, skip_absent = TRUE) # skips old[3] because "c" is not a column name of DT

DF = data.frame(a=1:2,b=3:4) # base data.frame to demo copies and syntax
if (capabilities()["profmem"])
  tracemem(DF)
  colnames(DF)[1] <- "A" # 4 shallow copies (R >= 3.1, was 4 deep copies before)
setcolorder

Fast column reordering of a data.table by reference

Description

In data.table parlance, all set* functions change their input by reference. That is, no copy is made at all, other than temporary working memory, which is as large as one column. The only other data.table operator that modifies input by reference is :=. Check out the See Also section below for other set* function data.table provides.

setcolorder reorders the columns of data.table, by reference, to the new order provided.

Usage

setcolorder(x, neworder=key(x), before=NULL, after=NULL)
Arguments

- `x`: A data.table.
- `neworder`: Character vector of the new column name ordering. May also be column numbers. If `length(neworder) < length(x)`, the specified columns are moved in order to the “front” of `x`. By default, `setcolorder` without a specified `neworder` moves the key columns in order to the “front” of `x`.
- `before, after`: If one of them (not both) was provided with a column name or number, `neworder` will be inserted before or after that column.

Details

To reorder data.table columns, the idiomatic way is to use `setcolorder(x, neworder)`, instead of doing `x <- x[,..neworder]` (or `x <- x[, neworder, with=FALSE]`). This is because the latter makes an entire copy of the data.table, which maybe unnecessary in most situations. `setcolorder` also allows column numbers instead of names for `neworder` argument, although we recommend using names as a good programming practice.

Value

The input is modified by reference, and returned (invisibly) so it can be used in compound statements. If you require a copy, take a copy first (using `DT2 = copy(DT)`). See ?copy.

See Also

- `setkey`, `setorder`, `setattr`, `setnames`, `set`, `:=`, `setDT`, `setDF`, `copy`, `getNumericRounding`, `setNumericRounding`

Examples

```r
set.seed(45L)
DT = data.table(A=sample(3, 10, TRUE),
       B=sample(letters[1:3], 10, TRUE), C=sample(10))

setcolorder(DT, c("C", "A", "B"))

# incomplete specification
setcolorder(DT, "A")

# insert new column as first column
set(DT, j="D", value=sample(10))
setcolorder(DT, "D", before=1)

# move column to last column place
setcolorder(DT, "A", after=ncol(DT))
```
setDF

Coerce a `data.table` to `data.frame` by reference

Description

In `data.table` parlance, all `set*` functions change their input *by reference*. That is, no copy is made at all, other than temporary working memory, which is as large as one column. The only other `data.table` operator that modifies input by reference is `:=`. Check out the `See Also` section below for other `set*` function `data.table` provides.

A helper function to convert a `data.table` or list of equal length to `data.frame` by reference.

Usage

```r
setDF(x, rownames=NULL)
```

Arguments

- `x`  
  A `data.table`, `data.frame` or list of equal length.

- `rownames`  
  A character vector to assign as the row names of `x`.

Details

All `data.table` attributes including any keys and indices of the input `data.table` are stripped off.

When using `rownames`, recall that the row names of a `data.frame` must be unique. By default, the assigned set of row names is simply the sequence `1,...,nrow(x)` (or `length(x)` for lists).

Value

The input `data.table` is modified by reference to a `data.frame` and returned (invisibly). If you require a copy, take a copy first (using `DT2 = copy(DT)`). See `?copy`.

See Also

- `data.table`
- `as.data.table`
- `setDT`
- `copy`
- `setkey`
- `setcolorder`
- `setattr`
- `setnames`
- `set`
- `:=`
- `setorder`

Examples

```r
X = data.table(x=1:5, y=6:10)
## convert 'X' to data.frame, without any copy.
setDF(X)

X = data.table(x=1:5, y=6:10)
## idem, assigning row names
setDF(X, rownames = LETTERS[1:5])

X = list(x=1:5, y=6:10)
# X is converted to a data.frame without any copy.
setDF(X)
```
Description

In `data.table` parlance, all `set*` functions change their input by reference. That is, no copy is made at all, other than temporary working memory, which is as large as one column. The only other `data.table` operator that modifies input by reference is `:=`. Check out the `See Also` section below for other `set*` function `data.table` provides.

`setDT` converts lists (both named and unnamed) and `data.frame`s to `data.tables` by reference. This feature was requested on Stackoverflow.

Usage

```r
setDT(x, keep.rownames=FALSE, key=NULL, check.names=FALSE)
```

Arguments

- **x**: A named or unnamed `list`, `data.frame` or `data.table`.
- **keep.rownames**: For `data.frame`s, `TRUE` retains the `data.frame`'s row names under a new column `rn`. `keep.rownames = "id"` names the column "id" instead.
- **key**: Character vector of one or more column names which is passed to `setkeyv`. It may be a single comma separated string such as `key="x,y,z"`, or a vector of names such as `key=c("x","y","z")`.
- **check.names**: Just as `check.names` in `data.frame`.

Details

When working on large `lists` or `data.frame`s, it might be both time and memory consuming to convert them to a `data.table` using `as.data.table(.)`, as this will make a complete copy of the input object before to convert it to a `data.table`. The `setDT` function takes care of this issue by allowing to convert `lists` - both named and unnamed `lists` and `data.frames` by reference instead. That is, the input object is modified in place, no copy is being made.

Value

The input is modified by reference, and returned (invisibly) so it can be used in compound statements; e.g., `setDT(X)[, sum(B), by=A]`. If you require a copy, take a copy first (using `DT2 = copy(DT)`). See ?copy.

See Also

`data.table`, `as.data.table`, `setDF`, `copy`, `setkey`, `setcolorder`, `setattr`, `setnames`, `set`, `:=`, `setorder`
Examples

```r
set.seed(45L)
X = data.frame(A=sample(3, 10, TRUE),
               B=sample(letters[1:3], 10, TRUE),
               C=sample(10), stringsAsFactors=FALSE)

# Convert X to data.table by reference and
# get the frequency of each "A,B" combination
setDT(X)[, .N, by=(A,B)]

# convert list to data.table
# autofill names
X = list(1:4, letters[1:4])
setDT(X)
# don't provide names
X = list(a=1:4, letters[1:4])
setDT(X, FALSE)

# setkey directly
X = list(a = 4:1, b=runif(4))
setDT(X, key="a")[]

# check.names argument
X = list(a=1:5, a=6:10)
setDT(X, check.names=TRUE)[]
```

---

**setDTthreads**  Set or get number of threads that data.table should use

**Description**

Set and get number of threads to be used in *data.table* functions that are parallelized with OpenMP. The number of threads is initialized when *data.table* is first loaded in the R session using optional environment variables. Thereafter, the number of threads may be changed by calling *setDTthreads*. If you change an environment variable using *Sys.setenv* you will need to call *setDTthreads* again to reread the environment variables.

**Usage**

```r
setDTthreads(threads = NULL, restore_after_fork = NULL, percent = NULL, throttle = NULL)
getDTthreads(verbos = getOption("datatable.verbos"))
```

**Arguments**

- `threads` NULL (default) rereads environment variables. 0 means to use all logical CPUs available. Otherwise a number >= 1
setDTthreads

**restore_after_fork**
Should data.table be multi-threaded after a fork has completed? NULL leaves the current setting unchanged which by default is TRUE. See details below.

**percent**
If provided it should be a number between 2 and 100; the percentage of logical CPUs to use. By default on startup, 50%.

**throttle**
1024 (default) means that, roughly speaking, a single thread will be used when nrow(DT)<=1024, 2 threads when nrow(DT)<=2048, etc. The throttle is to speed up small data tasks (especially when repeated many times) by not incurring the overhead of managing multiple threads. Hence the number of threads is throttled (restricted) for small tasks.

**verbose**
Display the value of relevant OpenMP settings plus the `restore_after_fork` internal option.

**Details**
data.table automatically switches to single threaded mode upon fork (the mechanism used by `parallel::mclapply` and the foreach package). Otherwise, nested parallelism would very likely overload your CPUs and result in much slower execution. As data.table becomes more parallel internally, we expect explicit user parallelism to be needed less often. The `restore_after_fork` option controls what happens after the explicit fork parallelism completes. It needs to be at C level so it is not a regular R option using `options()`.

By default data.table will be multi-threaded again; restoring the prior setting of `getDTthreads()`. But problems have been reported in the past on Mac with Intel OpenMP libraries whereas success has been reported on Linux. If you experience problems after fork, start a new R session and change the default behaviour by calling `setDTthreads(restore_after_fork=FALSE)` before retrying. Please raise issues on the data.table GitHub issues page.

The number of logical CPUs is determined by the OpenMP function `omp_get_num_procs()` whose meaning may vary across platforms and OpenMP implementations. `setDTthreads()` will not allow more than this limit. Neither will it allow more than `omp_get_thread_limit()` nor the current value of `Sys.getenv("OMP_THREAD_LIMIT")`. Note that CRAN’s daily test system (results for data.table here) sets `OMP_THREAD_LIMIT` to 2 and should always be respected; e.g., if you have written a package that uses data.table and your package is to be released on CRAN, you should not change `OMP_THREAD_LIMIT` in your package to a value greater than 2.

Some hardware allows CPUs to be removed and/or replaced while the server is running. If this happens, our understanding is that `omp_get_num_procs()` will reflect the new number of processors available. But if this happens after data.table started, `setDTthreads(...)` will need to be called again by you before data.table will reflect the change. If you have such hardware, please let us know your experience via GitHub issues / feature requests.

Use `getDTthreads( verbose=TRUE)` to see the relevant environment variables, their values and the current number of threads data.table is using. For example, the environment variable `R_DATATABLE_NUM_PROCS_PERCENT` can be used to change the default number of logical CPUs from 50% to another value between 2 and 100. If you change these environment variables using ‘Sys.setenv()’ after data.table and/or OpenMP has initialized then you will need to call `setDTthreads(threads=NULL)` to reread their current values. `getDTthreads()` merely retrieves the internal value that was set by the last call to `setDTthreads()`. `setDTthreads(threads=NULL)` is called when data.table is first loaded and is not called again unless you call it.
setDTthreads() affects data.table only and does not change R itself or other packages using OpenMP. We have followed the advice of section 1.2.1.1 in the R-exts manual: "...or, better, for the regions in your code as part of their specification... num_threads(nthreads)... That way you only control your own code and not that of other OpenMP users." Every parallel region in data.table contain a num_threads(getDTthreads()) directive. This is mandated by a grep in data.table’s quality control script.

setDTthreads(0) is the same as setDTthreads(percent=100); i.e. use all logical CPUs, subject to Sys.getenv("OMP_THREAD_LIMIT"). Please note again that CRAN’s daily test system sets OMP_THREAD_LIMIT to 2, so developers of CRAN packages should never change OMP_THREAD_LIMIT inside their package to a value greater than 2.

Internally parallelized code is used in the following places:

- ‘between.c’ - between()
- ‘cj.c’ - CJ()
- ‘coalesce.c’ - fcoalesce()
- ‘fifelse.c’ - fifelse()
- ‘fread.c’ - fread()
- ‘forder.c’, ‘fsort.c’, and ‘reorder.c’ - forder() and related
- ‘froll.c’, ‘frolladaptive.c’, and ‘frollR.c’ - froll() and family
- ‘fwrite.c’ - fwrite()
- ‘gsumm.c’ - GForce in various places, see GForce
- ‘nafill.c’ - nafill()
- ‘subset.c’ - Used in [.data.table subsetting
- ‘types.c’ - Internal testing usage

**Value**

A length 1 integer. The old value is returned by setDTthreads so you can store that prior value and pass it to setDTthreads() again after the section of your code where you control the number of threads.

**Examples**

getDTthreads(verbos=TRUE)
Description

setkey sorts a data.table and marks it as sorted with an attribute "sorted". The sorted columns are the key. The key can be any number of columns. The data is always sorted in ascending order with NAs (if any) always first. The table is changed by reference and there is no memory used for the key (other than marking which columns the data is sorted by).

There are three reasons setkey is desirable:

- binary search and joins are faster when they detect they can use an existing key
- grouping by a leading subset of the key columns is faster because the groups are already gathered contiguously in RAM
- simpler shorter syntax; e.g. DT["id",] finds the group "id" in the first column of DT's key using binary search. It may be helpful to think of a key as super-charged rownames: multi-column and multi-type.

NAs are always first because:

- NA is internally INT_MIN (a large negative number) in R. Keys and indexes are always in increasing order so if NAs are first, no special treatment or branch is needed in many data.table internals involving binary search. It is not optional to place NAs last for speed, simplicity and robustness of internals at C level.
- if any NAs are present then we believe it is better to display them up front (rather than hiding them at the end) to reduce the risk of not realizing NAs are present.

In data.table parlance, all set* functions change their input by reference. That is, no copy is made at all other than for temporary working memory, which is as large as one column. The only other data.table operator that modifies input by reference is :=. Check out the See Also section below for other set* functions data.table provides.

setindex creates an index for the provided columns. This index is simply an ordering vector of the dataset’s rows according to the provided columns. This order vector is stored as an attribute of the data.table and the dataset retains the original order of rows in memory. See the vignette("datatable-secondary-indices-and-auto-indexing") for more details.

key returns the data.table’s key if it exists; NULL if none exists.

haskey returns TRUE/FALSE if the data.table has a key.

Usage

setkey(x, ..., verbose=getOption("datatable.verbose"), physical = TRUE)
setkeyv(x, cols, verbose=getOption("datatable.verbose"), physical = TRUE)
setindex(...)
setindexv(x, cols, verbose=getOption("datatable.verbose"))
key(x)
indices(x, vectors = FALSE)
haskey(x)

Arguments

x A data.table.
... The columns to sort by. Do not quote the column names. If ... is missing (i.e. setkey(DT)), all the columns are used. NULL removes the key.

cols A character vector of column names. For setindexv, this can be a list of character vectors, in which case each element will be applied as an index in turn.

verbose Output status and information.

physical TRUE changes the order of the data in RAM. FALSE adds an index.

vectors logical scalar, default FALSE; when set to TRUE, a list of character vectors is returned, each referring to one index.

Details

setkey reorders (i.e. sorts) the rows of a data.table by the columns provided. The sort method used has developed over the years and we have contributed to base R too; see sort. Generally speaking we avoid any type of comparison sort (other than insert sort for very small input) preferring instead counting sort and forwards radix. We also avoid hash tables.

Note that setkey always uses "C-locale"; see the Details in the help for setorder for more on why. The sort is stable; i.e., the order of ties (if any) is preserved.

For character vectors, data.table takes advantage of R’s internal global string cache, also exported as chorder.

Value

The input is modified by reference and returned (invisibly) so it can be used in compound statements; e.g., setkey(DT,a)[.(“foo”)]. If you require a copy, take a copy first (using DT2=copy(DT)). copy may also sometimes be useful before := is used to subassign to a column by reference.

Good practice

In general, it’s good practice to use column names rather than numbers. This is why setkey and setkeyv only accept column names. If you use column numbers then bugs (possibly silent) can more easily creep into your code as time progresses if changes are made elsewhere in your code; e.g., if you add, remove or reorder columns in a few months time, a setkey by column number will then refer to a different column, possibly returning incorrect results with no warning. (A similar concept exists in SQL, where "select * from ..." is considered poor programming style when a robust, maintainable system is required.)

If you really wish to use column numbers, it is possible but deliberately a little harder; e.g., setkeyv(DT,names(DT)[1:2]).

If you wanted to use grep to select key columns according to a pattern, note that you can just set value = TRUE to return a character vector instead of the default integer indices.

Examples

# Type 'example(setkey)' to run these at the prompt and browse output

```
DT = data.table(A=5:1,B=letters[5:1])
DT # before
setkey(DT,B) # re-orders table and marks it sorted.
DT # after
tables() # KEY column reports the key'd columns
key(DT)
keycols = c("A","B")
setkeyv(DT, keycols)

DT = data.table(A=5:1,B=letters[5:1])
DT2 = DT # does not copy
setkey(DT2,B) # does not copy-on-write to DT2
identical(DT,DT2) # TRUE. DT and DT2 are two names for the same keyed table

DT = data.table(A=5:1,B=letters[5:1])
DT2 = copy(DT) # explicit copy() needed to copy a data.table
setkey(DT2,B) # now just changes DT2
identical(DT,DT2) # FALSE. DT and DT2 are now different tables

DT = data.table(A=5:1,B=letters[5:1])
setindex(DT) # set indices
setindex(DT, A)
setindex(DT, B)
indices(DT) # get indices single vector
indices(DT, vectors = TRUE) # get indices list
```

setNumericRounding  Change or turn off numeric rounding

Description

Change rounding to 0, 1 or 2 bytes when joining, grouping or ordering numeric (i.e. double, POSIXct) columns.

Usage

```
setNumericRounding(x)
getNumericRounding()
```
setNumericRounding

Arguments

x integer or numeric vector: 0 (default), 1 or 2 byte rounding

Details

Computers cannot represent some floating point numbers (such as 0.6) precisely, using base 2. This leads to unexpected behaviour when joining or grouping columns of type 'numeric'; i.e. 'double', see example below. In cases where this is undesirable, data.table allows rounding such data up to approximately 11 s.f. which is plenty of digits for many cases. This is achieved by rounding the last 2 bytes off the significand. Other possible values are 1 byte rounding, or no rounding (full precision, default).

It is bytes rather than bits because it is tied in with the radix sort algorithm for sorting numerics which sorts byte by byte. With the default rounding of 0 bytes, at most 8 passes are needed. With rounding of 2 bytes, at most 6 passes are needed (and therefore might be a tad faster).

For large numbers (integers > 2^31), we recommend using bit64::integer64, even though the default is to round off 0 bytes (full precision).

Value

setNumericRounding returns no value; the new value is applied. getNumericRounding returns the current value: 0, 1 or 2.

See Also

datatable-optimize
https://en.wikipedia.org/wiki/Floating_point
https://docs.oracle.com/cd/E19957-01/806-3568/ncg_goldberg.html

Examples

DT = data.table(a=seq(0,1,by=0.2),b=1:2, key="a")
DT
setNumericRounding(0) # By default, rounding is turned off
DT[.(0.4)] # works
DT[.(0.6)] # no match, can be confusing since 0.6 is clearly there in DT # happens due to floating point representation limitations

setNumericRounding(2) # round off last 2 bytes
DT[.(0.6)] # works

# using type 'numeric' for integers > 2^31 (typically ids)
DT = data.table(id = c(1234567890123, 1234567890124, 1234567890125), val=1:3)
print(DT, digits=15)
DT[.,N,by=id] # 1 row, (last 2 bytes rounded)
setNumericRounding(0)
DT[.,N,by=id] # 3 rows, (no rounding, default) # better to use bit64::integer64 for such ids
Set operations for data tables

Description

Similar to base R set functions, union, intersect, setdiff and setequal but for data.tables. Additional all argument controls how duplicated rows are handled. Functions fintersect, fsetdiff (MINUS or EXCEPT in SQL) and funion are meant to provide functionality of corresponding SQL operators. Unlike SQL, data.table functions will retain row order.

Usage

fintersect(x, y, all = FALSE)
fsetdiff(x, y, all = FALSE)
funion(x, y, all = FALSE)
fsetequal(x, y, all = TRUE)

Arguments

x, y       data.tables.
all       Logical. Default is FALSE and removes duplicate rows on the result. When TRUE, if there are xn copies of a particular row in x and yn copies of the same row in y, then:
          • fintersect will return min(xn, yn) copies of that row.
          • fsetdiff will return max(0, xn-yn) copies of that row.
          • funion will return xn+yn copies of that row.
          • fsetequal will return FALSE unless xn == yn.

Details

bit64::integer64 columns are supported but not complex and list, except for funion.

Value

A data.table in case of fintersect, funion and fsetdiff. Logical TRUE or FALSE for fsetequal.

setorder  

**Fast row reordering of a data.table by reference**

Description

In data.table parlance, all set* functions change their input by reference. That is, no copy is made at all, other than temporary working memory, which is as large as one column. The only other data.table operator that modifies input by reference is :=. Check out the See Also section below for other set* function data.table provides.

setorder (and setorderv) reorders the rows of a data.table based on the columns (and column order) provided. It reorders the table by reference and is therefore very memory efficient.

Note that queries like \(x[\text{order(.)}]\) are optimised internally to use data.table’s fast order.

Also note that data.table always reorders in "C-locale" (see Details). To sort by session locale, use \(x[\text{base::order(.)}].\)

bit64::integer64 type is also supported for reordering rows of a data.table.

Usage

\[
\text{setorder}(x, ..., \text{na.last}=\text{FALSE})
\]
\[
\text{setorderv}(x, \text{cols} = \text{colnames}(x), \text{order}=1L, \text{na.last}=\text{FALSE})
\]

# optimised to use data.table’s internal fast order

# \(x[\text{order(.)}, \text{na.last}=\text{TRUE}]\)

Arguments

\[
x \quad \text{A data.table.}
\]
\[
... \quad \text{The columns to sort by. Do not quote column names. If … is missing (ex: setorder(x)), x is rearranged based on all columns in ascending order by default. To sort by a column in descending order prefix the symbol "-" which means "descending" (not "negative", in this context), i.e., setorder(x, a, \text{-b, c}). The \text{-b} works when b is of type character as well.}\]
cols  A character vector of column names of `x` by which to order. By default, sorts over all columns; `cols = NULL` will return `x` untouched. Do not add "-" here. Use order argument instead.

order  An integer vector with only possible values of 1 and -1, corresponding to ascending and descending order. The length of `order` must be either 1 or equal to that of `cols`. If `length(order) == 1`, it is recycled to `length(cols)`.

na.last  logical. If TRUE, missing values in the data are placed last; if FALSE, they are placed first; if NA they are removed. `na.last=NA` is valid only for `x[order(. , na.last)]` and its default is TRUE. setorder and setorderv only accept TRUE/FALSE with default FALSE.

Details
data.table implements its own fast radix-based ordering. See the references for some exposition on the concept of radix sort.

setorder accepts unquoted column names (with names preceded with a - sign for descending order) and reorders data.table rows by reference, for e.g., `setorder(x, a, -b, c)`. We emphasize that this means "descending" and not "negative" because the implementation simply reverses the sort order, as opposed to sorting the opposite of the input (which would be inefficient).

Note that -b also works with columns of type character unlike `order`, which requires `-xtfrm(y)` instead (which is slow). setorderv in turn accepts a character vector of column names and an integer vector of column order separately.

Note that `setkey` still requires and will always sort only in ascending order, and is different from `setorder` in that it additionally sets the sorted attribute.

na.last argument, by default, is FALSE for `setorder` and `setorderv` to be consistent with `data.table`'s `setkey` and is TRUE for `x[order(.)]` to be consistent with `base::order`. Only `x[order(.)]` can have `na.last = NA` as it is a subset operation as opposed to `setorder` or `setorderv` which reorders the data.table by reference.

data.table always reorders in "C-locale". As a consequence, the ordering may be different to that obtained by `base::order`. In English locales, for example, sorting is case-sensitive in C-locale. Thus, sorting `c("c", "a", "B")` returns `c("B", "a", "c")` in `data.table` but `c("a", "B", "c")` in `base::order`. Note this makes no difference in most cases of data; both return identical results on ids where only upper-case or lower-case letters are present ("AB123" < "AC234" is true in both), or on country names and other proper nouns which are consistently capitalized. For example, neither "America" < "Brazil" nor "america" < "brazil" are affected since the first letter is consistently capitalized.

Using C-locale makes the behaviour of sorting in `data.table` more consistent across sessions and locales. The behaviour of `base::order` depends on assumptions about the locale of the R session. In English locales, "america" < "BRAZIL" is true by default but false if you either type `Sys.setlocale(locale="C")` or the R session has been started in a C locale for you – which can happen on servers/services since the locale comes from the environment the R session was started in. By contrast, "america" < "BRAZIL" is always FALSE in `data.table` regardless of the way your R session was started.

If `setorder` results in reordering of the rows of a keyed `data.table`, then its key will be set to `NULL`. 

Value

The input is modified by reference, and returned (invisibly) so it can be used in compound statements: e.g., `setorder(DT, a, -b)[, cumsum(c), by=list(a,b)]`. If you require a copy, take a copy first (using `DT2 = copy(DT)`). See `copy`.

See Also

`setkey`, `setcolorder`, `setattr`, `setnames`, `set`, `:=`, `setDT`, `setDF`, `copy`, `setNumericRounding`

Examples

```r
set.seed(45L)
DT = data.table(A=sample(3, 10, TRUE),
    B=sample(letters[1:3], 10, TRUE), C=sample(10))

# setorder
setorder(DT, A, -B)

# same as above, but using setorderv
setorderv(DT, c("A", "B"), c(1, -1))
```

Description

1lead or 1lag vectors, lists, data.frames or data.tables implemented in C for speed.

bit64::integer64 is also supported.

Usage

```r
shift(x, n=1L, fill, type=c("lag", "lead", "shift", "cyclic"), give.names=FALSE)
```
Arguments

x  A vector, list, data.frame or data.table.
n  integer vector denoting the offset by which to lead or lag the input. To create multiple lead/lag vectors, provide multiple values to n; negative values of n will "flip" the value of type, i.e., n=-1 and type='lead' is the same as n=1 and type='lag'.
fill  default is NA. Value to use for padding when the window goes beyond the input length.

type  default is "lag" (look "backwards"). The other possible values "lead" (look "forwards"), "shift" (behave same as "lag" except given names) and "cyclic" where pushed out values are re-introduced at the front/back.
give.names  default is FALSE which returns an unnamed list. When TRUE, names are automatically generated corresponding to type and n. If answer is an atomic vector, then the argument is ignored.

Details

shift accepts vectors, lists, data.frames or data.tables. It always returns a list except when the input is a vector and length(n) == 1 in which case a vector is returned, for convenience. This is so that it can be used conveniently within data.table's syntax. For example, DT[, (cols) := shift(.SD, 1L, by=id)] would lag every column of .SD by 1 for each group and DT[, newcol := colA + shift(colB)] would assign the sum of two vectors to newcol.

Argument n allows multiple values. For example, DT[, (cols) := shift(.SD, 1:2, by=id)] would lag every column of .SD by 1 and 2 for each group. If .SD contained four columns, the first two elements of the list would correspond to lag=1 and lag=2 for the first column of .SD, the next two for second column of .SD and so on. Please see examples for more.

shift is designed mainly for use in data.tables along with := or set. Therefore, it returns an unnamed list by default as assigning names for each group over and over can be quite time consuming with many groups. It may be useful to set names automatically in other cases, which can be done by setting give.names to TRUE.

Value

A list containing the lead/lag of input x.

data.table

Examples

# on vectors, returns a vector as long as length(n) == 1, #1127
x = 1:5
# lag with n=1 and pad with NA (returns vector)
shift(x, n=1, fill=NA, type="lag")
# lag with n=1 and 2, and pad with 0 (returns list)
shift(x, n=1:2, fill=0, type="lag")
# getting a window by using positive and negative n:
shift(x, n = -1:1)
shift(x, n = -1:1, type = "shift", give.names = TRUE)
# cyclic shift where pad uses pushed out values
shift(x, n = -1:1, type = "cyclic")

# on data.tables
DT = data.table(year=2010:2014, v1=runif(5), v2=1:5, v3=letters[1:5])
# lag columns 'v1,v2,v3' DT by 1 and fill with 0
cols = c("v1","v2","v3")
anscols = paste("lead", cols, sep="_")
DT[, (anscols) := shift(.SD, 1, 0, "lead"), .SDcols=cols]

# return a new data.table instead of updating
# with names automatically set
DT = data.table(year=2010:2014, v1=runif(5), v2=1:5, v3=letters[1:5])
DT[, shift(.SD, 1:2, NA, "lead", TRUE), .SDcols=2:4]

# lag/lead in the right order
DT = data.table(year=2010:2014, v1=runif(5), v2=1:5, v3=letters[1:5])
DT = DT[sample(nrow(DT))]  
# add lag=1 for columns 'v1,v2,v3' in increasing order of 'year'
cols = c("v1","v2","v3")
anscols = paste("lag", cols, sep="_")
DT[order(year), (cols) := shift(.SD, 1, type="lag"), .SDcols=cols]
DT[order(year)]

# while grouping
DT = data.table(year=rep(2010:2011, each=3), v1=1:6)
DT[, c("lag1", "lag2") := shift(.SD, 1:2), by=year]

# on lists
ll = list(1:3, letters[4:1], runif(2))
shift(ll, 1, type="lead")
shift(ll, 1, type="lead", give.names=TRUE)
shift(ll, 1:2, type="lead")

# fill using first or last by group
DT = data.table(x=1:6, g=rep(1:2, each=3))
DT[, shift(x, fill=x[1L]), by=g]
DT[, shift(x, fill=x[N], type="lead"), by=g]

---

shouldPrint

For use by packages that mimic/divert auto printing e.g. IRkernel and knitr

Description

Not for use by users. Exported only for use by IRkernel (Jupyter) and knitr.
Usage

\texttt{shouldPrint(x)}

Arguments

\texttt{x}  \hspace{1cm} A data.table.

Details

Should IRkernel/Jupyter print a data.table returned invisibly by DT[::=] ? This is a read-once function since it resets an internal flag. If you need the value more than once in your logic, store the value from the first call.

Value

TRUE or FALSE.

References

https://github.com/IRkernel/IRkernel/issues/127
https://github.com/Rdatatable/data.table/issues/933

Examples

# dummy example section to pass release check that all .Rd files have examples

\begin{verbatim}

special-symbols  Special symbols

\end{verbatim}

Description

\texttt{.SD}, \texttt{.BY}, \texttt{.N}, \texttt{.I}, \texttt{.GRP}, and \texttt{.NGRP} are \textit{read-only} symbols for use in \texttt{j}. \texttt{.N} can be used in \texttt{i} as well. \texttt{.I} can be used in \texttt{by} as well. See the vignettes, Details and Examples here and in \texttt{data.table}. \texttt{.EACHI} is a symbol passed to \texttt{by}; i.e. \texttt{by=.EACHI}.

Details

The bindings of these variables are locked and attempting to assign to them will generate an error. If you wish to manipulate \texttt{.SD} before returning it, take a copy(\texttt{.SD}) first (see FAQ 4.5). Using \texttt{:=} in the \texttt{j} of \texttt{.SD} is reserved for future use as a (tortuously) flexible way to update \texttt{DT} by reference by group (even when groups are not contiguous in an ad hoc by).

These symbols used in \texttt{j} are defined as follows.

\begin{itemize}
  \item \texttt{.SD} is a \texttt{data.table} containing the \texttt{Subset} of \texttt{x}'s \texttt{Data} for each group, excluding any columns used in \texttt{by} (or \texttt{keyby}).
\end{itemize}
• .BY is a list containing a length 1 vector for each item in by. This can be useful when by is not known in advance. The by variables are also available to j directly by name; useful for example for titles of graphs if j is a plot command, or to branch with if() depending on the value of a group variable.

• .N is an integer, length 1, containing the number of rows in the group. This may be useful when the column names are not known in advance and for convenience generally. When grouping by i, .N is the number of rows in x matched to, for each row of i, regardless of whether nomatch is NA or NULL. It is renamed to N (no dot) in the result (otherwise a column called ".N" could conflict with the .N variable, see FAQ 4.6 for more details and example), unless it is explicitly named; e.g., DT[,list(total=.N),by=a].

• .I is an integer vector equal to seq_len(nrow(x)). While grouping, it holds for each item in the group, its row location in x. This is useful to subset in j; e.g. DT[, .I[which.max(somecol)], by=grp]. If used in by it corresponds to applying a function rowwise.

• .GRP is an integer, length 1, containing a simple group counter. 1 for the 1st group, 2 for the 2nd, etc.

• .NGRP is an integer, length 1, containing the number of groups.

.EACHI is defined as NULL but its value is not used. Its usage is by=.EACHI (or keyby=.EACHI) which invokes grouping-by-each-row-of-i; see data.table’s by argument for more details.

Note that .N in i is computed up-front, while that in j applies after filtering in i. That means that even absent grouping, .N in i can be different from .N in j. See Examples.

X[, DT[.BY, y, on="x"], by=x] # join within each group

# .N can be different in i and j
DT[(cat(sprintf('in i, .N is %d\n', .N)); a < .N/2),
   (cat(sprintf('in j, .N is %d\n', .N)); mean(a))]

# .I can be different in j and by, enabling rowwise operations in by
DT[, .(I, min(.SD[-1]))]
DT[, .(min(.SD[-1])), by=.I]

## S3 method for class 'data.table'
split(x, f, drop = FALSE,
     by, sorted = FALSE, keep.by = TRUE, flatten = TRUE,
     ..., verbose = getOption("datatable.verbose"))

Arguments

x data.table
f factor or list of factors. Same as \texttt{split.data.frame}. Use by argument instead,
   this is just for consistency with data.frame method.
drop logical. Default FALSE will not drop empty list elements caused by factor levels
   not referred by that factors. Works also with new arguments of split data.table
   method.
by character vector. Column names on which split should be made. For \texttt{length(by)}
   > 1L and flatten FALSE it will result nested lists with data.tables on leaves.
sorted When default FALSE it will retain the order of groups we are splitting on. When
     TRUE then sorted list(s) are returned. Does not have effect for \texttt{f} argument.
keep.by logical default TRUE. Keep column provided to by argument.
flatten logical default TRUE will unlist nested lists of data.tables. When using \texttt{f} results
   are always flattened to list of data.tables.
... passed to data.frame way of processing when using \texttt{f} argument.
verbose logical default FALSE. When TRUE it will print to console data.table split query
   used to split data.

Details

Argument \texttt{f} is just for consistency in usage to data.frame method. Recommended is to use by
   argument instead, it will be faster, more flexible, and by default will preserve order according to
   order in data.
Value

List of data.tables. If using flatten FALSE and length(by) > 1L then recursively nested lists having data.tables as leafs of grouping according to by argument.

See Also
data.table, rbindlist

Examples

```r
set.seed(123)
DT = data.table(x1 = rep(letters[1:2], 6),
               x2 = rep(letters[3:5], 4),
               x3 = rep(letters[5:8], 3),
               y = rnorm(12))
DT = DT[sample(.N)]
DF = as.data.frame(DT)

# split consistency with data.frame: `x, f, drop`
all.equal(
  split(DT, list(DT$x1, DT$x2)),
  lapply(split(DF, list(DF$x1, DF$x2)), setDT)
)

# nested list using `flatten` arguments
split(DT, by=c("x1", "x2"), flatten=FALSE)

# dealing with factors
fdt = DT[, c(lapply(.SD, as.factor), list(y=y)), .SDcols=x1:x3]
fdf = as.data.frame(fdt)
sdf = split(fdf, list(fdf$x1, fdf$x2))
all.equal(
  split(fdt, by=c("x1", "x2"), sorted=TRUE),
  lapply(sdf[sort(names(sdf))], setDT)
)

# factors having unused levels, drop FALSE, TRUE
fdt = DT[, .(x1 = as.factor(c(as.character(x1), "c")[-13L]),
               x2 = as.factor(c("a", as.character(x2))[-1L],
               x3 = as.factor(c("a", as.character(x3), "z")[-1L,-14L]),
y = y)]
fdf = as.data.frame(fdt)
sdf = split(fdf, list(fdf$x1, fdf$x2))
all.equal(
  split(fdt, by=c("x1", "x2"), sorted=TRUE),
  lapply(sdf[sort(names(sdf))], setDT)
)
```

```r
sdf = split(fdf, list(fdf$x1, fdf$x2), drop=TRUE)
all.equal(
  split(fdt, by=c("x1", "x2"), sorted=TRUE, drop=TRUE),
  lapply(sdf[sort(names(sdf))], setDT)
)```
Description

Returns subsets of a data.table.

Usage

```r
## S3 method for class 'data.table'
subset(x, subset, select, ...)
```

Arguments

- `x` : data.table to subset.
- `subset` : logical expression indicating elements or rows to keep
- `select` : expression indicating columns to select from data.table
- `...` : further arguments to be passed to or from other methods

Details

The `subset` argument works on the rows and will be evaluated in the data.table so columns can be referred to (by name) as variables in the expression.

The data.table that is returned will maintain the original keys as long as they are not select-ed out.

Value

A data.table containing the subset of rows and columns that are selected.

See Also

- `subset`

Examples

```r
DT <- data.table(a=sample(c('a', 'b', 'c'), 20, replace=TRUE),
                 b=sample(c('a', 'b', 'c'), 20, replace=TRUE),
                 c=sample(20), key=c('a', 'b'))

sub <- subset(DT, a == 'a')
all.equal(key(sub), key(DT))
```
substitute2

Substitute expression

Description
Experimental, more robust, and more user-friendly version of base R substitute.

Usage
substitute2(expr, env)

Arguments
expr Unevaluated expression in which substitution has to take place.
env List, or an environment that will be coerced to list, from which variables will be taken to inject into expr.

Details
For convenience function will turn any character elements of env argument into symbols. In case if character is of length 2 or more, it will raise an error. It will also turn any list elements into list calls instead. Behaviour can be changed by wrapping env into I call. In such case any symbols must be explicitly created, for example using as.name function. Alternatively it is possible to wrap particular elements of env into I call, then only those elements will retain their original class.

Comparing to base R substitute, substitute2 function:
1. substitutes calls argument names as well
2. by default converts character elements of env argument to symbols
3. by default converts list elements of env argument to list calls
4. does not accept missing env argument
5. evaluates elements of env argument

Value
Quoted expression having variables and call argument names substituted.

Note
Conversion of character to symbol and list to list call works recursively for each list element in env list. If this behaviour is not desired for your use case, we would like to hear about that via our issue tracker. For the present moment there is an option to disable that: options(datatable.enlist=FALSE). This option is provided only for debugging and will be removed in future. Please do not write code that depends on it, but use I calls instead.

See Also
substitute, I, call, name, eval
Examples

```r
## base R substitute vs substitute2
substitute(list(var1 = var2), list(var1 = "c1", var2 = 5L))
substitute2(list(var1 = var2), list(var1 = "c1", var2 = 5L)) ## works also on names

substitute(var1, list(var1 = "c1"))
substitute2(var1, list(var1 = I("c1"))) ## enforce character with I

substitute(var1, list(var1 = as.name("c1")))
substitute2(var1, list(var1 = "c1")) ## turn character into symbol, for convenience

## mix symbols and characters using 'I' function, both lines will yield same result
substitute2(list(var1 = var2), list(var1 = "c1", var2 = I("some_character")))

## list elements are enlist'ed into list calls
(cl1 = substitute(f(lst), list(lst = list(1L, 2L))))
(cl2 = substitute2(f(lst), I(list(lst = list(1L, 2L)))))
(cl3 = substitute2(f(lst), list(lst = quote(list(1L, 2L)))))
(cl4 = substitute2(f(lst), list(lst = list(1L, 2L))))
(cl5 = substitute2(f(lst), list(lst = list(1L, 2L))))

c11[[2L]] ## base R substitute with list element
c12[[2L]] ## same
c13[[2L]] ## same
c14[[2L]] ## desired
c15[[2L]] ## automatically

## character to name and list into list calls works recursively
(cl1 = substitute2(f(lst), list(lst = list(1L, list(2L)))))
(cl2 = substitute2(f(lst), I(list(lst = list(1L, list(2L)))))) ## unless I() used
last(c11[[2L]]) ## enlisted recursively
last(c12[[2L]]) ## AsIs

## using substitute2 from another function
f = function(expr, env) {
  eval(substitute(
    substitute2(.expr, env),
    list(.expr = substitute(expr))
  ))
}

f(list(var1 = var2), list(var1 = "c1", var2 = 5L))
```

### tables

Display `data.table` metadata

#### Description

Convenience function for concisely summarizing some metadata of all `data.tables` in memory (or an optionally specified environment).
tables

Usage

```
tables(mb=type_size, order.col="NAME", width=80,
   env=parent.frame(), silent=FALSE, index=FALSE)
```

Arguments

- **mb**: a function which accepts a data.table and returns its size in bytes. By default, `type_size` (same as `TRUE`) provides a fast lower bound by excluding the size of character strings in R’s global cache (which may be shared) and excluding the size of list column items (which also may be shared). A column "MB" is included in the output unless `FALSE` or `NULL`.

- **order.col**: Column name (character) by which to sort the output.

- **width**: integer; number of characters beyond which the output for each of the columns COLS, KEY, and INDICES are truncated.

- **env**: An environment, typically the `.GlobalEnv` by default, see Details.

- **silent**: logical; should the output be printed?

- **index**: logical; if `TRUE`, the column INDICES is added to indicate the indices assorted with each object, see `indices`.

Details

Usually `tables()` is executed at the prompt, where `parent.frame()` returns `.GlobalEnv`. `tables()` may also be useful inside functions where `parent.frame()` is the local scope of the function; in such a scenario, simply set it to `.GlobalEnv` to get the same behaviour as at prompt.

`mb = utils::object.size` provides a higher and more accurate estimate of size, but may take longer. Its default `units="b"` is appropriate.

Setting `silent=TRUE` prints nothing; the metadata is returned as a data.table invisibly whether `silent` is `TRUE` or `FALSE`.

Value

A data.table containing the information printed.

See Also

- `data.table`, `setkey`, `ls`, `objects`, `object.size`

Examples

```
DT = data.table(A=1:10, B=letters[1:10])
DT2 = data.table(A=1:10000, ColB=10000:1)
setkey(DT,B)
tables()
```
Description

An internal testing function used in data.table test scripts that are run by test.data.table.

Usage

```r
test(num, x, y = TRUE, error = NULL, warning = NULL, message = NULL, output = NULL, notOutput = NULL, ignore.warning = NULL)
```

Arguments

- **num**: A unique identifier for a test, helpful in identifying the source of failure when testing is not working. Currently, we use a manually-incremented system with tests formatted as n.m, where essentially n indexes an issue and m indexes aspects of that issue. For the most part, your new PR should only have one value of n (scroll to the end of inst/tests/tests.Rraw to see the next available ID) and then index the tests within your PR by increasing m. Note – n.m is interpreted as a number, so 123.4 and 123.40 are actually the same – please 0-pad as appropriate. Test identifiers are checked to be in increasing order at runtime to prevent duplicates being possible.

- **x**: An input expression to be evaluated.

- **y**: Pre-defined value to compare to x, by default TRUE.

- **error**: When you are testing behaviour of code that you expect to fail with an error, supply the expected error message to this argument. It is interpreted as a regular expression, so you can be abbreviated, but try to include the key portion of the error so as not to accidentally include a different error message.

- **warning**: Same as error, in the case that you expect your code to issue a warning. Note that since the code evaluates successfully, you should still supply y.

- **message**: Same as warning but expects message exception.

- **output**: If you are testing the printing/console output behaviour; e.g. with `verbose=TRUE` or `options(datatable.verbose=TRUE)`. Again, regex-compatible and case sensitive.

- **notOutput**: Or if you are testing that a feature does not print particular console output. Case insensitive (unlike output) so that the test does not incorrectly pass just because the string is not found due to case.

- **ignore.warning**: A single character string. Any warnings emitted by x that contain this string are dropped. Remaining warnings are compared to the expected warning as normal.

Value

Logical TRUE when test passes, FALSE when test fails. Invisibly.
Note

NA_real_ and NaN are treated as equal, use identical if distinction is needed. See examples below.

If warning= is not supplied then you are automatically asserting no warning is expected; the test will fail if any warning does occur. Similarly for message=.

Multiple warnings are supported; supply a vector of strings to warning=. If x does not produce the correct number of warnings in the correct order, the test will fail.

Strings passed to notOutput= should be minimal; e.g. pick out single words from the output that you desire to check does not occur. The reason being so that the test does not incorrectly pass just because the output has slightly changed. For example notOutput="revised" is better than notOutput="revised flag to true". notOutput= is automatically case insensitive for this reason.

See Also

test.data.table

Examples

test = data.table:::test
test(1, x = sum(1:5), y = 15L)
test(2, log(-1), NaN, warning="NaNs")
test(3, sum("a"), error="invalid character")
# test failure example
stopifnot(
  test(4, TRUE, FALSE) == FALSE
)
# NA_real_ vs NaN
(test(5.01, NA_real_, NaN)
test(5.03, all.equal(NaN, NA_real_))
test(5.02, identical(NaN, NA_real_), FALSE)

---

test.data.table  Runs a set of tests.

Description

Runs a set of tests to check data.table is working correctly.

Usage

test.data.table(script = "tests.Rraw", verbose = FALSE, pkg = ".",
  silent = FALSE,
  showProgress = interactive() && !silent,
  memtest = Sys.getenv("TEST_DATA_TABLE_MEMTEST", 0),
  memtest.id = NULL)

**Arguments**

- **script**
  
  Run arbitrary R test script.

- **verbose**
  
  TRUE sets `options(datatable.verbose=TRUE)` for the duration of the tests. This tests there are no errors in the branches that produce the verbose output, and produces a lot of output. The output is normally used for tracing bugs or performance tuning. Tests which specifically test the verbose output is correct (typically looking for an expected substring) always run regardless of this option.

- **pkg**
  
  Root directory name under which all package content (ex: DESCRIPTION, src/, R/, inst/ etc..) resides. Used only in dev-mode.

- **silent**
  
  Controls what happens if a test fails. Like silent in `try`, TRUE causes the error message to be suppressed and FALSE to be returned, otherwise the error is returned.

- **showProgress**
  
  Output 'Running test <n> ...' at the start of each test?

- **memtest**
  
  Measure and report memory usage of tests (1:gc before ps, 2:gc after ps) rather than time taken (0) by default. Intended for and tested on Linux. See PR #5515 for more details.

- **memtest.id**
  
  An id for which to print memory usage for every sub id. May be a range of ids.

**Details**

Runs a series of tests. These can be used to see features and examples of usage, too. Running `test.data.table` will tell you the full location of the test file(s) to open.

Setting silent=TRUE sets showProgress=FALSE too, via the default of showProgress.

**Value**

If all tests were successful, TRUE is returned. Otherwise, see the silent argument above. silent=TRUE is intended for use at the start of production scripts; e.g. `stopifnot(test.data.table(silent=TRUE))` to check `data.table` is passing its own tests before proceeding.

**See Also**

- `data.table`, `test`

**Examples**

```r
## Not run:
test.data.table()
```

```r
## End(Not run)
```
timetaken

Pretty print of time taken

description

Pretty print of time taken since last started.at.

usage

```
timetaken(started.at)
```

Arguments

```
started.at  The result of proc.time() taken some time earlier.
```

value

A character vector of the form HH:MM:SS, or SS.MMMsec if under 60 seconds.

Examples

```
started.at=proc.time()
Sys.sleep(1)
cat("Finished in",timetaken(started.at),"\n")
```

transpose

Efficient transpose of list

description

transpose is an efficient way to transpose lists, data frames or data tables.

usage

```
transpose(l, fill=NA, ignore.empty=FALSE, keep.names=NULL, make.names=NULL)
```

arguments

```
l  A list, data.frame or data.table.
fill  Default is NA. It is used to fill shorter list elements so as to return each element of the transposed result of equal lengths.
ignore.empty  Default is FALSE. TRUE will ignore length-0 list elements.
keep.names  The name of the first column in the result containing the names of the input; e.g. keep.names="rn". By default NULL and the names of the input are discarded.
make.names  The name or number of a column in the input to use as names of the output; e.g. make.names="rn". By default NULL and default names are given to the output columns.
```
Details

The list elements (or columns of data.frame/data.table) should be all atomic. If list elements are of unequal lengths, the value provided in fill will be used so that the resulting list always has all elements of identical lengths. The class of input object is also preserved in the transposed result. The ignore.empty argument can be used to skip or include length-0 elements. This is particularly useful in tasks that require splitting a character column and assigning each part to a separate column. This operation is quite common enough that a function tstrsplit is exported. factor columns are converted to character type. Attributes are not preserved at the moment. This may change in the future.

Value

A transposed list, data.frame or data.table.

See Also

data.table, tstrsplit

Examples

ll = list(1:5, 6:8)
transpose(ll)

DT = data.table(x=1:5, y=6:10)
transpose(DT)

Description

These functions are experimental and somewhat advanced. By experimental we mean their names might change and perhaps the syntax, argument names and types. So if you write a lot of code using them, you have been warned! They should work and be stable, though, so please report problems with them. alloc.col is just an alias to setalloccol. We recommend to use setalloccol (though alloc.col will continue to be supported) because the set* prefix in setalloccol makes it clear that its input argument is modified in-place.

Usage

truelength(x)
setalloccol(DT,
  n = getOption("datatable.alloccol"), # default: 1024L
  verbose = getOption("datatable.verbose")) # default: FALSE
alloc.col(DT,
  n = getOption("datatable.alloccol"), # default: 1024L
  verbose = getOption("datatable.verbose")) # default: FALSE
Arguments

x Any type of vector, including data.table which is a list vector of column pointers.

DT A data.table.

n The number of spare column pointer slots to ensure are available. If DT is a 1,000 column data.table with 24 spare slots remaining, n=1024L means grow the 24 spare slots to be 1024. truelength(DT) will then be 2024 in this example.

verbose Output status and information.

Details

When adding columns by reference using :=, we could simply create a new column list vector (one longer) and memcpy over the old vector, with no copy of the column vectors themselves. That requires negligible use of space and time, and is what v1.7.2 did. However, that copy of the list vector of column pointers only (but not the columns themselves), a shallow copy, resulted in inconsistent behaviour in some circumstances. So, as from v1.7.3 data.table over allocates the list vector of column pointers so that columns can be added fully by reference, consistently.

When the allocated column pointer slots are used up, to add a new column data.table must reallocate that vector. If two or more variables are bound to the same data.table this shallow copy may or may not be desirable, but we don’t think this will be a problem very often (more discussion may be required on data.table issue tracker). Setting options(datatable.verbose=TRUE) includes messages if and when a shallow copy is taken. To avoid shallow copies there are several options: use copy to make a deep copy first, use setalloccol to reallocate in advance, or, change the default allocation rule (perhaps in your .Rprofile); e.g., options(datatable.alloccol=10000L).

Please note: over allocation of the column pointer vector is not for efficiency per se; it is so that := can add columns by reference without a shallow copy.

Value

truelength(x) returns the length of the vector allocated in memory. length(x) of those items are in use. Currently, it is just the list vector of column pointers that is over-allocated (i.e. truelength(DT)), not the column vectors themselves, which would in future allow fast row insert(). For tables loaded from disk however, truelength is 0 in R 2.14.0+ (and random in R <= 2.13.2), which is perhaps unexpected. data.table detects this state and over-alllocates the loaded data.table when the next column addition occurs. All other operations on data.table (such as fast grouping and joins) do not need truelength.

setalloccol reallocates DT by reference. This may be useful for efficiency if you know you are about to going to add a lot of columns in a loop. It also returns the new DT, for convenience in compound queries.

See Also

copy
tstrsplit

strsplit and transpose the resulting list efficiently

Description

This is equivalent to transpose(strsplit(...)). This is a convenient wrapper function to split a column using strsplit and assign the transposed result to individual columns. See examples.

Usage

tstrsplit(x, ..., fill=NA, type.convert=FALSE, keep, names=FALSE)

Arguments

x The vector to split (and transpose).
... All the arguments to be passed to strsplit.
fill Default is NA. It is used to fill shorter list elements so as to return each element of the transposed result of equal lengths.
type.convert TRUE calls type.convert with as.is=TRUE on the columns. May also be a function, list of functions, or named list of functions to apply to each part; see examples.
keep Specify indices corresponding to just those list elements to retain in the transposed result. Default is to return all.
names TRUE auto names the list with V1, V2 etc. Default (FALSE) is to return an un-named list.

Details

It internally calls strsplit first, and then transpose on the result.

names argument can be used to return an auto named list, although this argument does not have any effect when used with :=, which requires names to be provided explicitly. It might be useful in other scenarios.

Value

A transposed list after splitting by the pattern provided.
update_dev_pkg

Perform update of development version of a package

Description

Downloads and installs latest development version, only when a new commit is available. Defaults are set to update data.table, other packages can be used as well. Repository of a package has to include git commit SHA information in PACKAGES file.

See Also
data.table, transpose, type.convert

Examples

```r
x = c("abcde", "ghij", "klmnopq")
strsplit(x, "", fixed=TRUE)
tstrsplit(x, "", fixed=TRUE, fill="<NA>")

# using keep to return just 1,3,5
tstrsplit(x, "", fixed=TRUE, keep=c(1,3,5))

# names argument
tstrsplit(x, "", fixed=TRUE, keep=c(1,3,5), names=LETTERS[1:3])

DT = data.table(x=c("A/B", "A", "B"), y=1:3)
DT[, c("c1") := tstrsplit(x, "/", fixed=TRUE, keep=1L)]

# type.convert argument
DT = data.table(
  w = c("Yes/F", "No/M"),
  x = c("Yes 2000-03-01 A/T", "No 2000-04-01 E/R"),
  y = c("1/1/2", "2/5/2.5"),
  z = c("Yes/1/2", "No/5/3.5"),
  v = c("Yes 10 30.5 2000-03-01 A/T", "No 20 10.2 2000-04-01 E/R")
)

# convert each element in the transpose list to type factor
DT[, tstrsplit(w, "/", type.convert=as.factor)]

# convert part and leave any others
DT[, tstrsplit(z, "/", type.convert=list(as.numeric=2:3))]}

# convert part with one function and any others with another
DT[, tstrsplit(z, "/", type.convert=list(as.factor=1L, as.numeric))]}

# convert the remaining using 'type.convert(x, as.is=TRUE)' (i.e. what type.convert=TRUE does)
DT[, tstrsplit(v, " ", type.convert=list(as.IDate=4L, function(x) type.convert(x, as.is=TRUE)))]
```
Usage

update_dev_pkg(pkg="data.table",
    repo="https://Rdatatable.gitlab.io/data.table",
    field="Revision", type=getOption("pkgType"), lib=NULL, ...)

Arguments

pkg character scalar, package name.
repo character scalar, url of package devel repository.
field character scalar, metadata field to use in PACKAGES file and DESCRIPTION file, default "Revision".
type character scalar, default getOption("pkgType"), used to define if package has to be installed from sources, binaries or both.
lib character scalar, library location where package is meant to be upgraded.
... passed to install.packages.

Details

In case if a devel repository does not provide binaries user will need development tools installed for package compilation, like Rtools on Windows, or alternatively eventually set type="source".

Value

Invisibly TRUE if package was updated, otherwise FALSE.

data.table repositories

By default the function uses our GitLab-hosted R repository at https://Rdatatable.gitlab.io/data.table. This repository is updated nightly. It runs multiple test jobs (on top of GitHub tests jobs run up-stream) and publish the package (sources and binaries), even if GitLab test jobs are failing. Status of GitLab test jobs can be checked at Package Check Results. We also publish bleeding edge version of the package on GitHub-hosted R repository at https://Rdatatable.gitlab.io/data (just minor change in url from lab to hub). GitHub version should be considered less stable than GitLab one. It publishes only package sources. There are also other repositories maintained by R community, for example https://rdatatable.r-universe.dev. Those can be used as well, but as they are unlikely to provide git commit SHA, the function will install the package even if latest version is already installed.

Note

Package namespace is unloaded before attempting to install newer version.
