Package ‘desplot’

April 4, 2019

Title Plotting Field Plans for Agricultural Experiments
Version 1.5
Date 2019-04-02
Type Package
Description A function for plotting maps of agricultural field experiments that are laid out in grids.
Imports ggplot2, grid, lattice, reshape2,
Suggests agridat, knitr, testthat
License GPL-3
LazyData yes
URL https://github.com/kwstat/desplot
BugReports https://github.com/kwstat/desplot/issues
VignetteBuilder knitr
RoxygenNote 6.1.1
NeedsCompilation no
Author Kevin Wright [aut, cre] (<https://orcid.org/0000-0002-0617-8673>)

desplot

Plot the layout/data of a field experiment.

Description

Use this function to plot the layout of a rectangular lattice field experiment and also the observed data values.

Usage

\[
\text{desplot}(\text{form} = \text{formula(} \text{null} \sim x \times y | \text{location}\), \text{data}, \text{num} = \text{NULL}, \\
\text{num.string} = \text{NULL}, \text{col} = \text{NULL}, \text{col.string} = \text{NULL}, \text{text} = \text{NULL}, \\
\text{text.string} = \text{NULL}, \text{out1} = \text{NULL}, \text{out1.string} = \text{NULL}, \text{out2} = \text{NULL}, \\
\text{out2.string} = \text{NULL}, \text{col.regions} = \text{RedGrayBlue}, \text{col.text} = \text{NULL}, \\
\text{text.levels} = \text{NULL}, \text{out1.gpar} = \text{list(} \text{col} = \text{"black"}, \text{lwd} = 3\), \\
\text{out2.gpar} = \text{list(} \text{col} = \text{"yellow"}, \text{lwd} = 1, \text{lty} = 1\), \text{at}, \\
\text{midpoint} = \text{"median"}, \text{ticks} = \text{FALSE}, \text{flip} = \text{FALSE}, \text{main} = \text{NULL}, \\
\text{xlab}, \text{ylab}, \text{shorten} = \text{"abb"}, \text{show.key} = \text{TRUE}, \text{key.cex}, \text{cex} = 0.4, \\
\text{strip.cex} = 0.75, \text{subset} = \text{TRUE}, \text{gg} = \text{FALSE}, \ldots)
\]

\[
\text{ggdesplot}(\text{form} = \text{formula(} \text{null} \sim x \times y\), \text{data}, \text{num} = \text{NULL}, \\
\text{num.string} = \text{NULL}, \text{col} = \text{NULL}, \text{col.string} = \text{NULL}, \text{text} = \text{NULL}, \\
\text{text.string} = \text{NULL}, \text{out1} = \text{NULL}, \text{out1.string} = \text{NULL}, \text{out2} = \text{NULL}, \\
\text{out2.string} = \text{NULL}, \text{col.regions} = \text{RedGrayBlue}, \text{col.text} = \text{NULL}, \\
\text{text.levels} = \text{NULL}, \text{out1.gpar} = \text{list(} \text{col} = \text{"black"}, \text{lwd} = 3\), \\
\text{out2.gpar} = \text{list(} \text{col} = \text{"yellow"}, \text{lwd} = 1, \text{lty} = 1\), \text{at}, \\
\text{midpoint} = \text{"median"}, \text{ticks} = \text{FALSE}, \text{flip} = \text{FALSE}, \text{main} = \text{NULL}, \\
\text{xlab}, \text{ylab}, \text{shorten} = \text{"abb"}, \text{show.key} = \text{TRUE}, \text{key.cex}, \text{cex} = 0.4, \\
\text{strip.cex} = 0.75, \text{subset} = \text{TRUE}, \text{gg} = \text{FALSE}, \ldots)
\]

Arguments

- **form**: A formula like `yield~x*y|location`. Note x,y are numeric.
- **data**: A data frame.
- **num**: Bare name (no quotes) of the column of the data to use as a factor for number-coding the text in each cell.
- **num.string**: String name of the column of the data to use as a factor for number-coding the text in each cell.
- **col**: Bare name (no quotes) of the column of the data to use for color-coding the text shown in each cell.
- **col.string**: String name of the column of the data to use for color-coding the text shown in each cell.
- **text**: Bare name (no quotes) of the column of the data to use for the actual text shown in each cell.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>

<td>An expression that evaluates to logical index vector for subsetting the data.</td>
</tr>
<tr>
<td>gg</td>
<td>If TRUE, desplot() switches to ggdesplot().</td>
</tr>
<tr>
<td>...</td>
<td>Other.</td>
</tr>
</tbody>
</table>

**Details**

To create the plot using lattice graphics: 1. desplot(...).

To create the plot using ggplot2 graphics, use one of the following: 1. ggdesplot(...). 2. desplot(..., gg=TRUE). 3. options(desplot.gg=TRUE); desplot(...). Method 3 is useful to modify all results from existing scripts.
The lattice version is complete, mature, and robust. The ggplot2 version is incomplete. The legend can only show colors, and some function arguments are ignored. In general, lattice graphics are about 4-5 times faster than ggplot2 graphics. Not all lattice parameters are passed down to `xyplot`, but it is possible to make almost any change to the plot by assigning the desplot object to a variable and then edit the object by hand or use `update` to modify the object. Then print it manually. See the first example below.

Use `col.regions` to specify fill colors. This can either be a vector of colors or a function that produces a vector of colors. If the response variable is a factor and `col.regions` is a function, it will be ignored and the cells are filled with default light-colored backgrounds and a key is placed on the left. If the response variable is numeric, the cells are colored according to `col.regions`, and a ribbon key is placed on the right.

Use `shorten='abb'` (this is default) to shorten the cell text using the `abbreviate` function. Use `shorten='sub'` to use a 3-character substring. Use `shorten='no'` or `shorten=FALSE` for no shortening.

Note that two sub-plots with identical levels of the split-plot factor can be adjacent to each other by virtue of appearing in different whole-plots. To correctly outline the split-plot factor, simply concatenate the whole-plot factor and sub-plot factor together.

To get a map of a field with a true aspect ratio (lattice version only), include ‘aspect=ylen/xlen’ in the call, where ‘ylen’ is the vertical length of the field and ‘xlen’ is the horizontal length of the field.

To call this function inside another function, you can hack like this: `vr <- "yield"`; `vx <- "x"`; `vy <- "y"`; `eval(parse(text=paste("desplot("", vr, " ~ \", vx, " \", vy, ", data=yates.oats")))`)

### Value

A lattice or ggplot2 object

### Author(s)

Kevin Wright

### References

### Examples

```r
if(require(agridat)){

  # Show how to customize any feature. Here: make the strips bigger.
  data(besag.met)
  d1 <- desplot(yield ~ col*row|county, besag.met, main="besag.met",
    out1=rep, out2=block, out2.gpar=list(col="white"), strip.cex=2)
  d1 <- update(d1, par.settings = list(layout.heights=list(strip=2)))
  print(d1)

  # Show experiment layout
  data(yates.oats)
  desplot(yield ~ col+row, yates.oats, out1=block, out2=gen)
}
```
### Description

'geom_tileborder' draws a border between tiles of different classes. The required aesthetics are 'aes(x,y,grp)', where 'grp' is the grouping classification that separates tiles.

### Usage

```r
desplot(block = col+row, yates.oats, col=nitro, text=gen, cex=1, out1=block, 
        out2=gen, out2.gpar=list(col = "gray50", lwd = 1, lty = 1))
```

### Arguments

- `mapping`: Set of aesthetic mappings created by `aes()` or `aes()`. If specified and `inherit.aes = TRUE` (the default), it is combined with the default mapping at the top level of the plot. You must supply `mapping` if there is no plot mapping.

- `data`: The data to be displayed in this layer. There are three options:
  - If `NULL`, the default, the data is inherited from the plot data as specified in the call to `ggplot()`. A `data.frame`, or other object, will override the plot data. All objects will be fortified to produce a data frame. See `fortify()` for which variables will be created.
  - A function will be called with a single argument, the plot data. The return value must be a `data.frame`, and will be used as the layer data.

- `geom`: The geometric object to use display the data

- `position`: Position adjustment, either as a string, or the result of a call to a position adjustment function.

- `na.rm`: If `FALSE`, the default, missing values are removed with a warning. If `TRUE`, missing values are silently removed.

- `show.legend`: logical. Should this layer be included in the legends? `NA`, the default, includes if any aesthetics are mapped. `FALSE` never includes, and `TRUE` always includes. It can also be a named logical vector to finely select the aesthetics to display.

- `inherit.aes`: If `FALSE`, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. `borders()`.

- `...`: Other arguments passed on to `layer()`. These are often aesthetics, used to set an aesthetic to a fixed value, like `colour = "red"` or `size = 3`. They may also be parameters to the paired geom/stat.
Details

Note, we cannot use ‘aes(group)” because it groups the interaction of ALL discrete variables including 
facets. Since we do not want to draw a border between facets, we had to define a new aesthetic. 
See: # http://ggplot2.tidyverse.org/reference/aes_group_order.html
Also, we do not want to split the data into separate groups for each level of ‘grp’, so we need to 
include ‘aes(group=1)”.

Examples

dd <- data.frameH
  x=c(1,2,1,2,3,1,2),
  y=c(2,1,2,1,1,1,1),
  loc=factor(c(1,2,1,2,2,1,1,1,2,2,2)),
  rep=factor(c(2,1,2,3,1,1,1,2,3)))
library(ggplot2)
ggplot(dd, aes(x=x, y=y)) +
  facet_wrap( ~ loc) +
  geom_tile(aes(fill=rep)) +
  geom_tileborder(aes(group=1, grp=rep), lwd=1.5)
# Compare to lattice version of desplot.
# desplot::desplot(rep ~ x+y|loc, data=dd, out1=rep)

panel.outlinelevelplot

Panel Function for desplot

Description

This is a panel function for desplot which fills cells with a background color and adds outlines 
around blocks of cells.

Usage

panel.outlinelevelplot(x, y, z, subscripts, at, ..., alpha.regions = 1,
  out1f, out1g, out2f, out2g)

Arguments

  x          Coordinates
  y          Coordinates
  z          Value for filling each cell.
  subscripts For compatibility.
  at          Breakpoints for the colors.
  ...        Other
  alpha.regions Transparency for fill colors. Not well tested.
RedGrayBlue

out1f  Factors to use for outlining.
out1g  Factors to use for outlining.
out2f  Graphics parameters to use for outlining.
out2g  Graphics parameters to use for outlining.

Details
It does not add the text labels, numbers, or colors.
The rule for determining where to draw outlines is to compare the levels of the factor used for outlining. If bordering cells have different levels of the factor, then a border is drawn. 'NA' values are ignored (otherwise, too many lines would be drawn).
The code works, but is probably overkill and has not been streamlined.

References
Derived from lattice::panel.levelplot

---

RedGrayBlue  *Function to create a Red-Gray-Blue palette*

Description
A function to create a Red-Gray-Blue palette.

Usage
RedGrayBlue(n)

Arguments
n  Number of colors to create

Details
Using gray instead of white allows missing values to appear as white (actually, transparent).

Value
A vector of n colors.
