Package ‘directlabels’

October 13, 2022

Maintainer  Toby Dylan Hocking <toby.hocking@r-project.org>
Author       Toby Dylan Hocking
Version      2021.1.13

BugReports   https://github.com/tdhock/directlabels/issues
License      GPL-3
Title        Direct Labels for Multicolor Plots
Description  An extensible framework
              for automatically placing direct labels onto multicolor 'lattice' or
              'ggplot2' plots.
              Label positions are described using Positioning Methods
              which can be re-used across several different plots.
              There are heuristics for examining `trellis` and `ggplot` objects
              and inferring an appropriate Positioning Method.

ahull.grid

**Description**

Label the closest point on the alpha hull of the data.

**Usage**

```
"ahull.grid"
```

ahull.points

**Description**

Calculate the points on the ashape.

**Usage**

```
ahull.points(d, ..., 
ahull = default.ahull(d))
```
angled.boxes

Arguments

d

Author(s)

Toby Dylan Hocking

angled.boxes angled boxes

Description

Draw a box with the label inside, at the point furthest away from the plot border and any other curve.

Usage

"angled.boxes"

angled.endpoints angled endpoints

Description

Useful for labeling lines that all end at the top.

Usage

"angled.endpoints"
apply.method  
Apply a Positioning Method

Description
Run a Positioning Method list on a given data set. This function contains all the logic for parsing a Positioning Method and sequentially applying its elements to the input data to obtain the label positions.

Usage
apply.method(method,  
d, columns.to.check = c("x",  
"y", "groups",  
"label"), ...,  
debug = FALSE)

Arguments
method  
Direct labeling Positioning Method. Starting from the data frame of points to plot for the panel, the elements of the Positioning Method list are applied in sequence, and then each row of the resulting data frame is used to draw a direct label. The elements of a Positioning Method list can be
• a Positioning Function is any function(d,...) which takes a data.frame d with columns x,y,groups and returns another data.frame representing the positions of the desired direct labels. For a description of all the columns that are interpreted for drawing direct labels, see drawDetails.d1grob. For example, maxvar.points is a Positioning Function that returns a data.frame with columns x,y,groups,hjust,vjust.
• a character vector of length 1 is treated as the name of an R object. For example, specifying "maxvar.points" means to look up the variable called maxvar.points and use that. Using the name of a Positioning Function is preferable to specifying the Positioning Function itself, since then the name is visible in the Positioning Method list, which is more interpretable when debugging.
• a named list element is used to add or update variables in the data.frame of direct labels to plot. For example list("first.points",cex=1.5) means take only the first points of every group and then set the cex column to 1.5.
• an element of a Positioning Method list can be another Positioning Method list, in which case the elements of the inner list are applied.

d  
Data frame to which we apply the Positioning Method. The x and y columns should be in centimeters (cm), so that Positioning Methods can easily calculate the L2/Euclidean/visual distance between pairs of points.

columns.to.check  
After applying each Positioning Method list element, we check for the presence of these columns, and if not found we stop with an error.
Named arguments, passed to Positioning Functions.

If TRUE, print each Positioning Method list element and the direct label data.frame that results from its evaluation.

Value

The final data frame returned after applying all of the items in the Positioning Method list, with x and y in units of cm.

Author(s)

Toby Dylan Hocking
**Description**

Positioning Method for the bottom of a group of points.

**Usage**

```
bottom.points(d, ...)
```

**Arguments**

- `d`
- `...`

**Author(s)**

Toby Dylan Hocking

---

**Description**

Draw a speech polygon to the bottom point.

**Usage**

```
"bottom.polygons"
```

---

**Description**

Sequentially bump labels up, starting from the bottom, if they collide with the label underneath.

**Usage**

```
bumpup(d, ...)
```
**calc.borders**

**Arguments**

- `d`  
  ...

**Author(s)**

Toby Dylan Hocking

---

**calc.borders**  
*calc borders*

**Description**

Calculate bounding box based on newly calculated width and height.

**Usage**

```
calc.borders(d, ...)```  

**Arguments**

- `d`  
  Data frame of point labels, with new widths and heights in the w and h columns.  
- `...`  
  ignored.

**Author(s)**

Toby Dylan Hocking

---

**calc.boxes**  
*calc boxes*

**Description**

Calculate boxes around labels, for collision detection.

**Usage**

```
calc.boxes(d, debug = FALSE, ...)```  

**Arguments**

- `d`  
- `debug`  
  
- `...`
check for columns

Author(s)
Toby Dylan Hocking

Description
Stop if a data.frame does not have some columns.

Usage
check.for.columns(d, 
must.have)

Arguments
d         data.frame to check.
must.have column names to check.

Author(s)
Toby Dylan Hocking

chull.grid

chull grid

Description
Label the closest point on the convex hull of the data.

Usage
"chull.grid"
**chull.points**

**chull.points**

---

**Description**

Calculate the points on the convex hull.

**Usage**

\[ \text{chull.points}(d, \ldots) \]

**Arguments**

- \( d \)
- \( \ldots \)

**Author(s)**

Toby Dylan Hocking

---

**default.ahull**

**default ahull**

---

**Description**

Calculate the default alpha parameter for ashape based on the average size of label boxes.

**Usage**

\[ \text{default.ahull}(d, \ldots) \]

**Arguments**

- \( d \)
- \( \ldots \)

**Author(s)**

Toby Dylan Hocking
default_picker

**Description**

Look at options() for a user-defined default Positioning Method picker, and use that (or the hard-coded default picker), with the calling environment to figure out a good default.

**Usage**

```r
default_picker(f)
```

**Arguments**

- `f`: Object class to look for (trellis or ggplot).

**Author(s)**

Toby Dylan Hocking

---

defaultpf.ggplot

**Description**

Default method selection method for ggplot2 plots.

**Usage**

```r
defaultpf.ggplot(geom,
                   p, L, colvar, ...)
```

**Arguments**

- `geom`
- `p`
- `L`
- `colvar`
- `...`

**Author(s)**

Toby Dylan Hocking
**defaultpf.trellis**

Description

If no Positioning Method specified, choose a default using this function. The idea is that this is called with all the variables in the environment of `panel.superpose.dl`, and this can be user-customizable by setting the `directlabels.defaultpf.lattice` option to a function like this.

Usage

```r
defaultpf.trellis(lattice.fun.name, groups, type, ...)
```

Arguments

- `lattice.fun.name`
- `groups`
- `type`
- `...`

Author(s)

Toby Dylan Hocking

---

**direct.label**

Direct labels for color decoding

Description

Add direct labels to a plot, and hide the color legend. Modern plotting packages like lattice and ggplot2 show automatic legends based on the variable specified for color, but these legends can be confusing if there are too many colors. Direct labels are a useful and clear alternative to a confusing legend in many common plots.

Usage

```r
direct.label(p, method = NULL, debug = FALSE)
```
Arguments

- **p**: The "trellis" or "ggplot" object with things drawn in different colors.
- **method**: Positioning Method, which determines the positions of the direct labels as a function of the plotted data. If NULL, we examine the plot \( p \) and try to choose an appropriate default. See `apply.method` for more information about Positioning Methods.
- **debug**: Show debug output?

Value

A plot with direct labels and no color legend.

Author(s)

Toby Dylan Hocking

Examples

```r
if(require(ggplot2)){
  ## Add direct labels to a ggplot2 scatterplot, making sure that each
  ## label is close to its point cloud, and doesn't overlap points or
  ## other labels.
  scatter <- qplot(jitter(hwy),jitter(cty),data=mpg,colour=class,
                   main="Fuel efficiency depends on car size")
  print(direct.label(scatter))
}

## direct labels for lineplots that do not overlap and do not go off
## the plot.
library(nlme)
library(lattice)
oldopt <- lattice.options(panel.error=NULL)
ratplot <-
  xyplot(weight~Time|Diet,BodyWeight,groups=Rat,type='l',layout=c(3,1))
  ## Using the default Positioning Method (maxvar.qp), the labels are
  ## placed on the side which is most spread out, so in multipanel
  ## plots they sometimes end up on different sides.
  print(direct.label(ratplot))
  ## To put them on the same side, just manually specify the
  ## Positioning Method.
  print(direct.label(ratplot,"last.qp"))

lattice.options(oldopt)
```
**direct.label.ggplot**  
*direct label ggplot*

**Description**  
Direct label a ggplot2 grouped plot.

**Usage**  
```r
## S3 method for class 'ggplot'
direct.label(p,  
    method = NULL, debug = FALSE)
```

**Arguments**  
- `p`  
The ggplot object.
- `method`  
Method for direct labeling as described in `apply.method`.
- `debug`  
Show debug output?

**Value**  
The ggplot object with direct labels added.

**Author(s)**  
Toby Dylan Hocking

---

**direct.label.trellis**  
*direct label trellis*

**Description**  
Add direct labels to a grouped lattice plot. This works by parsing the trellis object returned by the high level plot function, and returning it with a new panel function that will plot direct labels using the specified method.

**Usage**  
```r
## S3 method for class 'trellis'
direct.label(p,  
    method = NULL, debug = FALSE)
```
dl.combine

Arguments

- `p` The lattice plot (result of a call to a high-level lattice function).
- `method` Method for direct labeling as described in `apply.method`.
- `debug` Show debug output?

Value

The lattice plot.

Author(s)

Toby Dylan Hocking

---

dl.combine

Combine output of several methods

Description

Apply several Positioning methods to the original data frame.

Usage

dl.combine(...)

Arguments

... Several Positioning Methods.

Value

A Positioning Method that returns the combined data frame after applying each specified Positioning Method.

Author(s)

Toby Dylan Hocking

Examples

```r
## Simple example: label the start and endpoints
library(nlme)
library(lattice)
ratplot <- xyplot(
  weight~Time|Diet,BodyWeight,groups=Rat,type='l',layout=c(3,1))
both <- dl.combine("first.points","last.points")
rat.both <- direct.label(ratplot,"both")
print(rat.both)
```
## same as repeated call to direct.label:
rat.repeated <-
  direct.label(direct.label(ratplot,"last.points"),"first.points")
print(rat.repeated)

## same with ggplot2:
if(require(ggplot2)){
  rp2 <- qplot(
    Time,weight,data=BodyWeight,geom="line",facets=~Diet,colour=Rat)
  print(direct.label(direct.label(rp2,"last.points"),"first.points"))
  print(direct.label(rp2,"both"))
}

## more complex example: first here is a function for computing the
## lasso path.
mylars <- function
## Least angle regression algorithm for calculating lasso solutions.
(x,
## Matrix of predictor variables.
y,
## Vector of responses.
epsilon=1e-6
## If correlation < epsilon, we are done.
(){
  xscale <- scale(x) # need to work with standardized variables
  b <- rep(0,ncol(x))## coef vector starts at 0
  names(b) <- colnames(x)
  ycor <- apply(xscale,2,function(xj)sum(xj*y))
  j <- which.max(ycor) # variables in active set, starts with most correlated
  alpha.total <- 0
  out <- data.frame()
  while(1){## lar loop
    xak <- xscale[,j] # current variables
    r <- y-xscale%*%b # current residual
    # direction of parameter evolution
    delta <- solve(t(xak)%*%xak)%*%t(xak)%*%r
    # Current correlations (actually dot product)
    intercept <- apply(xscale,2,function(xk)sum(r*xk))
    # current rate of change of correlations
    z <- xak%*%delta
    slope <- apply(xscale,2,function(xk)-sum(z*xk))
    # store current values of parameters and correlation
    out <- rbind(out,data.frame(variable=colnames(x),
                              coef=b,
                              corr=abs(intercept),
                              alpha=alpha.total,
                              arclength=sum(abs(b)),
                              coef.unscaled=b/attr(xscale,"scaled:scale")))
    if(sum(abs(intercept)) < epsilon)#corr==0 so we are done
      return(transform(out,s=arclength/max(arclength)))
    ## If there are more variables we can enter into the regression,
    ## then see which one will cross the highest correlation line
## first, and record the alpha value of where the lines cross.
\[d\gets\text{data.frame(slope, intercept)}\]
\[\text{d[d$intercept<0,.]}\gets-1\]
\[\text{d0}\gets\text{data.frame(d[j[1]],.)}\]# highest correlation line
\[d2\gets\text{data.frame(rbind(d,-d),variable=names(slope))}\]# reflected lines
## Calculation of alpha for where lines cross for each variable
\[\text{d2$alpha}\gets(d0$intercept-d2$intercept)/(d2$slope-d0$slope)\]
\[\text{subd}\gets\text{d2[!d2$variable%in%colnames(x)[j]]&d2$alpha>epsilon,]}\]
\[\text{subd}\gets\text{subd[which.min(subd$alpha),]}\]
\[\text{nextvar}\gets\text{subd$variable}\]
\[\text{alpha}\gets\text{if(nrow(subd))subd$alpha else 1}\]
## If one of the coefficients would hit 0 at a smaller alpha
## value, take it out of the regression and continue.
\[\text{hit0}\gets\text{xor(b[j]>0,delta>0)&b[j]!=0}\]
\[\text{alpha0}\gets-b[j][hit0]/\text{delta[hit0]}\]
\[\text{takeout}\gets\text{length(alpha0)}\&\text{min(alpha0)}<\text{alpha}\]
\[\text{if(takeout)}\{
    \text{i}\gets\text{which.min(alpha0)}\]
    \[\text{alpha}\gets\text{alpha0[i]}\]
\}\]
\[\text{b[j]}\gets\text{b[j]+alpha*delta}\]# evolve parameters
\[\text{alpha.total}\gets\text{alpha.total}+\text{alpha}\]
## add or remove a variable from the active set
\[\text{j}\gets\text{if(takeout)[j]!}\text{which(names(i)==colnames(x))]}\]
\[\text{else}\text{c(j,which(nextvar==colnames(x))})\]
\}

## Calculate lasso path, plot labels at two points: (1) where the
## variable enters the path, and (2) at the end of the path.
\[\text{if(require(lars))}\{
    \text{data(diabetes,envir=environment())}\]
\[\text{dres}\gets\text{with(diabetes,mylars(x,y))}\]
\[\text{P}\gets\text{xyplot(coef-arclength,dres,groups=variable,type="l")}\]
\[\text{mylasso}\gets\text{dl.combine("lasso.labels", "last.qp")}\]
\[\text{plot(direct.label(P,"mylasso"))}\]
\}

---

### dl.env

**Description**

This environment holds an integer id that will be incremented to get a unique id for each `dlgrob`.

**Usage**

"dl.env"
**dl.jitter**  

Description

Jitter the label positions.

Usage

dl.jitter(d, ...)

Arguments

d
...

Author(s)

Toby Dylan Hocking

---

**dl.move**  

Manually move a direct label

Description

Sometimes there is 1 label that is placed oddly by another Positioning Function. This function can be used to manually place that label in a good spot.

Usage

dl.move(group, x, y,  

...)

Arguments

group  

Group to change.

x  

Horizontal position of the new label.

y  

Vertical position of the new label. If missing(y) and !missing(x) then we will calculate a new y value using linear interpolation.

...  

Variables to change for the specified group

Value

A Positioning Function that moves a label into a good spot.
Author(s)

Toby Dylan Hocking

Examples

```r
if(require(ggplot2)){
  library(lattice)
  scatter <- xyplot(jitter(cty)-jitter(hwy),mpg,groups=class,aspect=1)
  dlcompare(list(scatter),
    list("extreme.grid",
      `+dl.move`=list(extreme.grid,dl.move("suv",15,15))))
  p <- qplot(log10(gamma),rate,data=svmtrain,group=data,colour=data,
    geom="line", facets=replicate~nu)
  adjust.kif <- dl.move("KIF11",-0.9,hjust=1,vjust=1)
  dlcompare(list(p+xlim(-8,7)),
    list("last.points",
      `+dl.move`=list(last.points,adjust.kif)))
}
```

---

**dl.summarize**

dl summarize

Description

summarize which preserves important columns for direct labels.

Usage

dl.summarize(OLD, ...)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OLD</td>
<td>data frame</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>

Author(s)

Toby Dylan Hocking
dl.trans  

*Direct label data transform*

**Description**

Make a function that transforms the data. This is for conveniently making a function that calls transform on the data frame, with the arguments provided. See examples.

**Usage**

dl.trans(...)

**Arguments**

...  

Arguments to pass to transform.

**Value**

A Positioning Function.

**Author(s)**

Toby Dylan Hocking

**Examples**

```r
complicated <- list(dl.trans(x=x+10),
                      gapply.fun(d[-2,]),
                      rot=c(30,180))
library(lattice)
direct.label(dotplot(VADeaths,type="o"),complicated,TRUE)
```

dlcompare  

*Direct label comparison plot*

**Description**

Compare several plots and/or label placement methods. This creates a custom grid graphics display based on lattice and/or ggplot2 output. Plots will be on the columns and positioning methods will be on the rows.

**Usage**

dlcompare(plots, pos.funs,
           rects = TRUE, row.items = "plots",
           debug = FALSE)
Arguments

plots List of ggplot2 or lattice plots. List names will be used to annotate the plot.
pos.funs List of label placement methods to apply to each plot. List names, or function names if specified as character strings, will be used to annotate the plot.
rects Draw rectangles around each plot, creating a grid?
row.items If "plots" then put plots on the rows and method on the columns. Otherwise, do the opposite.
debug Show debug output?

Author(s)

Toby Dylan Hocking

Examples

library(lattice)
oldopt <- lattice.options(panel.error=NULL)

## Compare two plots of the same data using lattice and ggplot2.
deads.by.sex <- list(male=mdeaths, female=fdeaths)
deads.list <- list()
for(sex in names(deads.by.sex)){
deads.ts <- deads.by.sex[[sex]]
deads.list[[sex]] <-
  data.frame(year=as.numeric(time(deaths.ts)),
             sex,
             deaths=as.integer(deaths.ts))
}
deads <- do.call(rbind, deaths.list)
dead.plot.list <-
  list(lattice=xyplot(deaths~year,deaths,groups=sex,type="l")
if(require(ggplot2)){
dead.plot.list$ggplot2 <-
  qplot(year,deaths,data=deaths,colour=sex,geom="line")
}

if(names(dev.cur())!="postscript"){
  ## to avoid error on pkg check.
  ## Use some exotic labeling options with different rotation, font
  ## face, family, and alpha transparency.
exotic <- list("last.points",
               rot=c(0,180),
               fontsize=c(10,20),
               fontface=c("bold","italic"),
               fontfamily=c("mono","serif"),
               alpha=c(0.25,1))
  dlcompare(death.plot.list, list(exotic))
}

lattice.options(oldopt)
## Compare a legend with direct labels on the same plot.
library(nlme)
if(require(ggplot2)){
  ggrat <- qplot(Time,weight,data=BodyWeight,
                 colour=Rat,geom="line",facets=-Diet)
  pfuns <- list("legend","direct labels"="last.qp")
  dcompare(list(ggrat),pfuns,rects=FALSE,row.items="posfuns")
}

---

**dl doc**

Make *directlabels* documentation

### Description

Positioning Methods for direct labels are supposed to work with only certain plot types. Each Positioning Method is defined in R/file.R and plot examples are found in tests/doc/file/*.R so that we can automatically assemble a database of example plots from the code.

### Usage

```
dl doc(pkgdir = "..")
```

### Arguments

- **pkgdir**: Package directory root.

### Value

Matrix of lists describing example plots and matching built-in Positioning Methods.

### Author(s)

Toby Dylan Hocking

---

**dl grob**

Make a grid grob that will draw direct labels.

### Usage

```
dl grob(data, method,
         debug = FALSE, axes2native = identity,
         ...
)```
Arguments

data           Data frame including points to plot in native coordinates.
method         Positioning Method.

draw.polygons  draw polygons

Description

Draw polygons around label positions.

Usage

draw.polygons(d, ...)

Arguments

d...

Author(s)

Toby Dylan Hocking

draw.rects    draw rects

Description

Positioning Function that draws boxes around label positions. Need to have previously called calc.boxes. Does not edit the data frame.

Usage

draw.rects(d, ...)
**Arguments**

d
...

**Author(s)**

Toby Dylan Hocking

---

**drawDetails.dlgrob**

**drawDetails dlgrob**

---

**Description**

Process data points using the Positioning Method and draw the resulting direct labels. This is called for every panel with direct labels, every time the plot window is resized.

**Usage**

```r
## S3 method for class 'dlgrob'
drawDetails(x,
            recording)
```

**Arguments**

- **x**
  The `dlgrob` list object. `x$method` should be a Positioning Method list and `x$data` should be a data.frame with the following variables:
  - `x,y` numeric horizontal and vertical positions of direct labels, in native units. These are converted to cm units before applying the Positioning Method.
  - `groups` factor that indices the different groups, and `colour` indicates the corresponding group colour.
  - `hjust` and `vjust` (optional) numeric values usually in [0,1] that control the justification of the text label relative to the `x,y` position.
  - `rot` (optional) numeric value in [0,360] that specifies the degrees which the text should be rotated.
  - `cex, alpha, fontface, fontfamily` (optional) passed to `gpar`.

Additionally, `x$debug` should be set to TRUE or FALSE, and `x$axestonative` should be a function that converts units shown on the axes to native units of `x$data[,c("x","y")].`

- **recording**

**Author(s)**

Toby Dylan Hocking
edges.to.outside

Description

Given a list of edges from the convex or alpha hull, and a list of cluster centers, calculate a point near to each cluster on the outside of the hull.

Usage

edges.to.outside(edges, centers, debug = FALSE, ...)

Arguments

edges
centers
depug
...

Author(s)

Toby Dylan Hocking

empty.grid

Description

Label placement method for scatterplots that ensures labels are placed in different places. A grid is drawn over the whole plot. Each cluster is considered in sequence and assigned to the point on this grid which is closest to the point given by the input data points. Makes use of attr(d,"orig.data").

Usage

empty.grid(d, debug = FALSE, ...

Arguments

d Data frame of target points on the scatterplot for each label.
d ebug Show debugging info on the plot?
... ignored.
\textit{enlarge.box}

\section*{Value}
Data frame with columns \texttt{groups x y}, 1 line for each group, giving the positions on the grid closest to each cluster.

\section*{Author(s)}
Toby Dylan Hocking

\section*{Description}
Make text bounding box larger by some amount.

\section*{Usage}
enlarge.box(d, \ldots )

\section*{Arguments}
d
\ldots 

\section*{Author(s)}
Toby Dylan Hocking

\section*{extract.plot}
\textit{Extract plot and definition for documentation}

\section*{Description}
Given an R code file, execute it, store the definition, and save the resulting plot in a variable.

\section*{Usage}
extract.plot(f)

\section*{Arguments}
f \hspace{1cm} R code file with plot example.

\section*{Author(s)}
Toby Dylan Hocking
extract.posfun

*Extract Positioning Method for documentation*

**Description**

Use inlinedocs to extract comments and definitions from code, then for each item found add the value and its name to the list.

**Usage**

```r
eextract.posfun(f)
```

**Arguments**

- `f`
  
  R code file, which should contain only Positioning Methods that can be used with examples defined in the doc/ subdirectory with the same name.

**Value**

List of lists, each of which describes one Positioning Method defined in `f`.

**Author(s)**

Toby Dylan Hocking

---

**extreme.grid**

*extreme grid*

**Description**

Label each point cloud near the extremities of the plot region.

**Usage**

```r
"extreme.grid"
```
**extreme.points**

**Description**
Label the points furthest from the middle for each group.

**Usage**
```
extreme.points(d, ...)
```

**Arguments**
- `d`
- `...`

**Author(s)**
Toby Dylan Hocking

---

**far.from.others.borders**

**Description**
Find the point on each curve which maximizes the distance to the plot border or to another curve.

**Usage**
```
far.from.others.borders(all.groups, ..., debug = FALSE)
```

**Arguments**
- `all.groups`
- `...`
- `debug`

**Author(s)**
Toby Dylan Hocking
**filltemplate**

**Description**

Fill in occurrences of OBJ$item in the file template with the value in R of L$item.

**Usage**

`filltemplate(L, template)`

**Arguments**

- `L`
- `template`

**Author(s)**

Toby Dylan Hocking

---

**first.bumpup**

**Description**

Label first points, bumping labels up if they collide.

**Usage**

`"first.bumpup"`

---

**first.points**

**Description**

Positioning Method for the first of a group of points.

**Usage**

`first.points(d, ...)`
first.polygons

Arguments

d
...

Author(s)

Toby Dylan Hocking

---

first.polygons  first polygons

Description

Draw a speech polygon to the first point.

Usage

"first.polygons"

---

first.qp  first qp

Description

Label first points from QP solver that ensures labels do not collide.

Usage

"first.qp"
Description
apply a Positioning Method to every group. works like ddply from plyr package, but the grouping column is always called groups, and the Positioning Method is not necessarily a function (but can be).

Usage
gapply(d, method, ..., 
groups = "groups")

Arguments
- d: data frame with column groups.
- method: Positioning Method to apply to every group separately.
- ...: additional arguments, passed to Positioning Methods.
- groups: can also be useful for piece column.

Value
data frame of results after applying FUN to each group in d.

Author(s)
Toby Dylan Hocking

Description
Makes a function you can use to specify the location of each group independently.

Usage
gapply.fun(expr)

Arguments
- expr: Expression that takes a subset of the d data frame, with data from only a single group, and returns the direct label position.
Value
A Positioning Function.

Author(s)
Toby Dylan Hocking

Examples
```r
complicated <- list(dl.trans(x=x+10),  
gapply.fun(d[-2,]),  
rot=c(30,180))
libiary(lattice)
direct.label(dotplot(VADeaths,type="o"),complicated,TRUE)
```

---

**GeomDl**

**Description**
ggproto object implementing direct labels.

**Usage**
```
"GeomDl"
```

---

**geom_dl**

**Description**
Geom that will plot direct labels.

**Usage**
```
geom_dl(mapping = NULL,  
data = NULL, ...,  
method = stop("must specify method= argument"),  
ddebug = FALSE, stat = "identity",  
position = "identity",  
inherit.aes = TRUE)
```
Arguments

- **mapping**: `aes(label=variable_that_will_be_used_as_groups_in_Positioning_Methods)`.
- **data**: data.frame to start with for direct label computation.
- **method**: Positioning Method for direct label placement, passed to `apply.method`.
- **debug**: Show directlabels debugging output?
- **stat**: passed to layer.
- **position**: passed to layer.
- **inherit.aes**: inherit aes from global ggplot definition?

Author(s)

Toby Dylan Hocking

Examples

```r
if(require(ggplot2)){
  vad <- as.data.frame.table(VADeaths)
  names(vad) <- c("age","demographic","deaths")
  # color + legend
  leg <- ggplot(vad,aes(deaths,age,colour=demographic))+
    geom_line(aes(group=demographic))+
    xlim(8,80)
  print(direct.label(leg,list("last.points",rot=30)))
  # this is what direct.label is doing internally:
  labeled <- leg+
    geom_dl(aes(label=demographic), method=list("last.points",rot=30))+
    scale_colour_discrete(guide="none")
  print(labeled)
  # no color, just direct labels!
  p <- ggplot(vad,aes(deaths,age))+
    geom_line(aes(group=demographic))+
    geom_dl(aes(label=demographic),method="top.qp")
  print(p)
  # add color:
  p+aes(colour=demographic)+
    scale_colour_discrete(guide="none")
  # add linetype:
  p+aes(linetype=demographic)+
    scale_linetype(guide="none")
  # no color, just direct labels
  library(nlme)
  bwbase <- ggplot(BodyWeight,aes(Time,weight,label=Rat))+
    geom_line(aes(group=Rat))+
    facet_grid(.~Diet)
  bw <- bwbase+geom_dl(method="last.qp")
  print(bw)
  # add some more direct labels
  bw2 <- bw+geom_dl(method="first.qp")
}
```
get.means

print(bw2)
## add color
colored <- bw2+aes(colour=Rat)+
  scale_colour_discrete(guide="none")
print(colored)
## or just use direct.label if you use color:
direct.label(bwbase+aes(colour=Rat),dl.combine("first.qp","last.qp"))

## iris data example
giris <- ggplot(iris,aes(Petal.Length,Sepal.Length))+
  geom_point(aes(shape=Species))
giris.labeled <- giris+
  geom_dl(aes(label=Species),method="smart.grid")+
  scale_shape_manual(values=c(setosa=1,virginica=6,versicolor=3),
  guide="none")
##png("~/R/directlabels/www/scatter-bw-ggplot2.png",h=503,w=503)
print(giris.labeled)
##dev.off()
}

get.means

Description

Positioning Function for the mean of each cluster of points.

Usage

get.means(d, ...)

Arguments

d ... 

Author(s)

Toby Dylan Hocking
getLegendVariables

Description
get the aes which are variable in one legend.

Usage
getLegendVariables(mb)

Arguments
mb

Author(s)
Toby Dylan Hocking

ignore.na

Description
Remove rows for which either x or y is NA

Usage
ignore.na(d, ...)

Arguments
d
...

Author(s)
Toby Dylan Hocking
in1box

Description
Calculate how many points fall in a box.

Usage
\[
in1box(p, box)
\]

Arguments
p
box

Author(s)
Toby Dylan Hocking

in1which

Description
Calculate which points fall in a box.

Usage
\[
in1which(p, box)
\]

Arguments
p data frame of points with columns x and y and many rows.
box data frame of 1 row with columns left right top bottom.

Author(s)
Toby Dylan Hocking
inside

**Description**

Calculate for each box how many points are inside.

**Usage**

```r
inside(boxes, points)
```

**Arguments**

- `boxes` Data frame of box descriptions, each row is 1 box, need columns left right top bottom.
- `points` Data frame of points, each row is 1 point, need columns x y.

**Value**

Vector of point counts for each box.

**Author(s)**

Toby Dylan Hocking

---

iris.l1.cluster

*Clustering of the iris data with the l1 clusterpath*

**Description**

The l1 clustering algorithm from the clusterpath package was applied to the iris dataset and the breakpoints in the solution path are stored in this data frame.

**Usage**

```r
data(iris.l1.cluster)
```

**Format**

A data frame with 9643 observations on the following 8 variables.

- `row` a numeric vector: row of the original iris data matrix
- `Species` a factor with levels setosa versicolor virginica: Species from corresponding row
- `alpha` a numeric vector: the value of the optimal solution.
- `lambda` a numeric vector: the regularization parameter (ie point in the path).
col a factor with levels Sepal.Length Sepal.Width Petal.Length Petal.Width: column from the original iris data.
gamma a factor with levels 0: parameter from clustering.
norm a factor with levels 1 parameter from clustering.
solver a factor with levels path algorithm used for clustering.

Source

clusterpath package

References

clusterpath article

Examples

data(iris.l1.cluster,package="directlabels")
iris.l1.cluster$y <- iris.l1.cluster$alpha
if(require(ggplot2)){
  p <- ggplot(iris.l1.cluster,aes(lambda,y,group=row,colour=Species))+
    geom_line(alpha=1/4)+
    facet_grid(col~.)
  p2 <- p+xlim(-0.0025,max(iris.l1.cluster$lambda))
  print(direct.label(p2,list(first.points,get.means)))
}

label.endpoints label endpoints

Description

Make a Positioning Method that labels a certain x value.

Usage

label.endpoints(FUN,
    HJUST)

Arguments

FUN
    FUN(d$x) should return an index of which point to label. for example you can use which.min or which.max.

HJUST
    hjust of the labels.

Value

A Positioning Method like first.points or last.points.
Author(s)
Toby Dylan Hocking

label.pieces

Description
Make a Positioning Method that will, for every piece, select points and assign a vjust value.

Usage
label.pieces(FUN, VJUST)

Arguments
FUN
VJUST

Author(s)
Toby Dylan Hocking

lasso.labels

Description
Label points at the zero before the first nonzero y value.

Usage
"lasso.labels"

last.bumpup

Description
Label last points, bumping labels up if they collide.

Usage
"last.bumpup"
last.points

Description
Positioning Method for the last of a group of points.

Usage
last.points(d, ...)

Arguments
d
...

Author(s)
Toby Dylan Hocking

last.polygons

Description
Draw a speech polygon to the last point.

Usage
"last.polygons"

last.qp

Description
Label last points from QP solver that ensures labels do not collide.

Usage
"last.qp"
Description

Some lattice plot functions do some magic in the background to translate the data you give them into the data points that are plotted onscreen. We have to replicate this magic in native coordinate space before applying the Positioning Method in cm space. These functions accomplish this translation.

Usage

"lattice.translators"

left.points

Description

Positioning Method for the first of a group of points.

Usage

left.points(d, ...)

Arguments

d
...

Author(s)

Toby Dylan Hocking

left.polygons

Description

Draw a speech polygon to the first point.

Usage

"left.polygons"
Description

Extract guides to hide from a ggplot.

Usage

```r
legends2hide(p)
```

Arguments

- `p`

Value

NULL if no legends with colour or fill to hide.

Author(s)

Toby Dylan Hocking

Description

Positioning Method for 2 groups of longitudinal data. One curve is on top of the other (on average), so we label the top one at its maximal point, and the bottom one at its minimal point. Vertical justification is chosen to minimize collisions with the other line. This may not work so well for data with high variability, but then again lineplots may not be the best for these data either.

Usage

```r
lines2(d, offset = 0.3, 
    ...)
```

Arguments

- `d` The data.
- `offset` Offset from 0 or 1 for the vjust values.
- `...` ignored.

Author(s)

Toby Dylan Hocking
Description

For the LOPART paper we computed ROC curves for predictions of changepoint detection algorithms.

Usage

data("LOPART.ROC")

Format

A named list of two data frames: points has one row per model/algorithm, roc has one row per point on the ROC curve.

Source

Figure/paper describing LOPART algorithm and R package, https://github.com/tdhock/LOPART-paper/blob/master/figure-cv-BIC.R

Description

Results of running LOPART algorithm (for changepoint detection in partially labeled data sequence) on a simulated data set of size 100.

Usage

data("LOPART100")

Format

Named list of data frames: signal has one row per data point, labels has one row per label, segments has one row per segment, cost has one row per feasible last changepoint for model up to t=100 data.

Source

Figure/paper describing LOPART algorithm and R package, https://github.com/tdhock/LOPART-paper/blob/master/figure-candidates.R
\textit{make.tiebreaker}  

\textbf{Description}  
Make a tiebreaker function that can be used with \textit{qp.labels}.

\textbf{Usage}  
\begin{verbatim}  
make.tiebreaker(x.var,  
tiebreak.var)  
\end{verbatim}

\textbf{Arguments}  
x.var  
tiebreak.var

\textbf{Author(s)}  
Toby Dylan Hocking

\textit{maxvar.points}  

\textbf{Description}  
Do first or last, whichever has points most spread out.

\textbf{Usage}  
\begin{verbatim}  
maxvar.points(d, ...)  
\end{verbatim}

\textbf{Arguments}  
d  
\ldots

\textbf{Author(s)}  
Toby Dylan Hocking
**Description**

Label first or last points, whichever are more spread out, and use a QP solver to make sure the labels do not collide.

**Usage**

```
"maxvar qp"
```

**Description**

Copied from reshape.

**Usage**

```
merge_recurse(dfs, ...)
```

**Arguments**

- `dfs`
- `...`

**Author(s)**

Toby Dylan Hocking
**midrange**

**Description**
Point halfway between the min and max

**Usage**
```
midrange(x)
```

**Arguments**
- `x`<br>

**Author(s)**
Toby Dylan Hocking

---

**normal.l2.cluster**

**Clustering of some normal data in 2d with the l2 clusterpath**

**Description**
The `l2` clustering algorithm from the clusterpath package was applied to some randomly generated data in 2 dimensions, and the solutions found using the descent algorithm are stored in this data frame.

**Usage**
```
data(normal.l2.cluster)
```

**Format**
The format is: List of 2 $ pts :'data.frame': 320 obs. of 3 variables: ..$ class: Factor w/ 8 levels "1","2","3","4",...: 1 1 1 1 1 1 1 1 ... ..$ x : num [1:320] -2.73 -3.63 -2.13 -1.27 -2.98 ... ..$ y : num [1:320] -3.89 -3.43 -3.42 -3.17 -2.75 ... ..$ path:Classes 'l2', 'clusterpath' and 'data.frame': 21760 obs. of 7 variables: ..$ x : num [1:21760] -2.73 -3.63 -2.13 -1.27 -2.98 ... ..$ y : num [1:21760] -3.89 -3.43 -3.42 -3.17 -2.75 ... ..$ lambda: num [1:21760] 0 0 0 0 0 0 0 0 0 0 ... ..$ row : Factor w/ 320 levels "1","2","3","4",...: 1 2 3 4 5 6 7 8 9 10 ... ..$ gamma : Factor w/ 1 level "0.1": 1 1 1 1 1 1 1 1 1 1 ... ..$ norm : Factor w/ 1 level "2": 1 1 1 1 1 1 1 1 1 ... ..$ solver: Factor w/ 1 level "descent.nocheck": 1 1 1 1 1 1 1 1 1 1 ... attr(*, "data")= num [1:320, 1:2] -2.73 -3.63 -2.13 -1.27 -2.98 ... .. attr(*, "dimnames")=List of 2 .. ..$ : NULL .. ..$ : chr [1:2] "x" "y" ..- attr(*, "alphacolnames")= chr [1:2] "x" "y" ..- attr(*, "dimnames")=List of 2 .. ..$ : NULL .. ..$ : chr [1:2] "x" "y"

odd_timings

Odd timings

Description

These timings data made strange output labels with the "right.polygons" method.

Usage

data("odd_timings")

Format

A data frame with 116 observations on the following 4 variables. Plot median.seconds versus N.col using a different line for each fun and a different panel for each captures.

N.col a numeric vector
fun a character vector
captures a numeric vector
median.seconds a numeric vector

Source

https://github.com/tdhock/nc-article
only.unique.vals

Description
Create a 1-row data.frame consisting of only the columns for which there is only 1 unique value.

Usage
only.unique.vals(d, ...)

Arguments
d
...

Author(s)
Toby Dylan Hocking

outside.ahull

Description
Calculate closest point on the alpha hull with size of the boxes, and put it outside that point.

Usage
outside.ahull(d, ...)

Arguments
d
...

Author(s)
Toby Dylan Hocking
outside.chull

Description
Calculate closest point on the convex hull and put it outside that point. Assume d is the center for each point cloud and then use orig.data to calculate hull.

Usage
outside.chull(d, ...)

Arguments
d
...

Author(s)
Toby Dylan Hocking

panel.superpose.dl

Description
Call panel.superpose for the data points and then for the direct labels. This is a proper lattice panel function that behaves much like panel.superpose.

Usage
panel.superpose.dl(x,
    y = NULL, subscripts,
    groups, panel.groups,
    method = NULL, .panel.superpose = lattice::panel.superpose,
    type = "p", debug = FALSE,
    ...
)

Arguments
x Vector of x values.
y Vector of y values.
subscripts Subscripts of x,y.groups.
groups Vector of group ids.
panel.superpose.dl

panel.groups To be parsed for default labeling method, and passed to panel.superpose.
method Positioning Method for direct labeling. NULL indicates to choose a Positioning Method based on the panel.groups function.
.panel.superpose The panel function to use for drawing data points.
type Plot type, used for default method dispatch.
debug passed to dlgrob.
... passed to real panel function, and to translator.

Author(s)
Toby Dylan Hocking

Examples

loci <- data.frame(ppp=c(rbeta(800,10,10),rbeta(100,0.15,1),rbeta(100,1,0.15)),
type=factor(c(rep("NEU",800),rep("POS",100),rep("BAL",100))))
## 3 equivalent ways to make the same plot:
library(lattice)
print(direct.label( ## most user-friendly
densityplot(~ppp,loci,groups=type,n=500)
))
print(direct.label( ## exactly the same as above but with specific panel fns
densityplot(~ppp,loci,groups=type,n=500,
panel=lattice::panel.superpose,
panel.groups="panel.densityplot")
))
## using panel.superpose.dl as the panel function automatically adds
## direct labels
print(densityplot(~ppp,loci,groups=type,n=500,
panel=panel.superpose.dl,panel.groups="panel.densityplot"))

## Exploring custom panel and panel.groups functions
library(nlme)
## Say we want to use a simple linear model to explain rat body weight:
fit <- lm(weight~Time+Diet+Rat,BodyWeight)
bw <- BodyWeight
bw$.fitted <- predict(fit,BodyWeight)
## lots of examples to come, all with these arguments:
ratxy <- function(...){
 xyplot(weight~Time|Diet,bw,groups=Rat,type="l",layout=c(3,1),...)
}
## No custom panel functions:
##regular <- ratxy(par.settings=simpleTheme(col=c("red","black")))
regular <- ratxy()
print(regular) ## normal lattice plot
print(direct.label(regular)) ## with direct labels

## The direct label panel function panel.superpose.dl can be used to
## display direct labels as well:
print(ratxy(panel=panel.superpose.dl,panel.groups="panel.xyplot"))
print(ratxy(panel=function(...)  
    panel.superpose.dl(panel.groups="panel.xyplot",...)))

## Not very user-friendly, since default label placement is  
## impossible, but these should work:  
print(ratxy(panel=panel.superpose.dl,panel.groups=panel.xyplot,  
    method=first.points))
print(ratxy(panel=function(...)  
    panel.superpose.dl(panel.groups=panel.xyplot,...),  
    method=first.points))

## Custom panel.groups functions:  
## This panel.groups function will display the model fits:  
panel.model <- function(x,subscripts,col.line,...){  
    panel.xyplot(x=x,subscripts=subscripts,col.line=col.line,...)  
    llines(x,bw[subscripts,".fitted"],col=col.line,lty=2)  
}
pg <- ratxy(panel=lattice::panel.superpose,panel.groups=panel.model)
print(pg)
## If you use panel.superpose.dl with a custom panel.groups function,  
## you need to manually specify the Positioning Method, since the  
## name of panel.groups is used to infer a default:  
print(direct.label(pg,method="first.qp"))
print(ratxy(panel=panel.superpose.dl,panel.groups="panel.model",  
    method="first.qp"))

## Custom panel function that draws a box around values:  
panel.line1 <- function(ps=lattice::panel.superpose){  
    function(y,...){  
        panel.abline(h=range(y))  
        ps(y=y,...)  
    }  
}
custom <- ratxy(panel=panel.line1())
print(custom)
print(direct.label(custom))
## Alternate method, producing the same results, but using  
## panel.superpose.dl in the panel function. This is useful for direct  
## label plots where you use several datasets.  
print(ratxy(panel=panel.line1(panel.superpose.dl),panel.groups="panel.xyplot"))

## Lattice plot with custom panel and panel.groups functions:  
both <- ratxy(panel=panel.line1(),panel.groups="panel.model")
print(both)
print(direct.label(both,method="first.qp"))
print(ratxy(panel=panel.line1(panel.superpose.dl),  
    panel.groups=panel.model,method="first.qp"))
polygon.method

Description

draw.polygons

Author(s)

Toby Dylan Hocking
positioning.functions  

Built-in Positioning Methods for direct label placement

Description

When adding direct labels to a grouped plot, label placement can be specified using a Positioning Method (or a list of them), of the form function(d,...), where d is a data frame of the points to plot, with columns x y groups. The job of the Positioning Method(s) is to return the position of each direct label you want to plot as a data frame, with 1 row for each label. Thus normally a Positioning Method will return 1 row for each group. Several built-in Positioning Methods are discussed below, but you can also create your own, either from scratch or by using dl.indep and dl.trans.

## End(Not run)
```

Given a point and a set of line segments representing a convex or alpha hull, calculate the closest point on the segments.
Usage

```r
project.onto.segments(m, h, debug = FALSE, ...)
```

Arguments

- `m` is 1 row, a center of a point cloud, we need to find the distance to the closest point on each segment of the convex hull.
- `h` Data frame describing the line segments of the convex or alpha hull.
- `debug` ignored
- `...`

Author(s)

Toby Dylan Hocking

---

projectionSeconds  Timings of projection algorithms

Description

Timings of seconds for 3 projection algorithms.

Usage

```r
data(projectionSeconds)
```

Format

A data frame with 603 observations on the following 6 variables.

- `vector.length` a numeric vector
- `method` a factor with levels Heap Random Sort
- `mean` a numeric vector
- `sd` a numeric vector
- `min` a numeric vector
- `max` a numeric vector

Source

Mark Schmidt’s prettyPlot code for MATLAB http://www.di.ens.fr/~mschmidt/Software/prettyPlot.html
Make a Positioning Method for non-overlapping lineplot labels

**Description**

Use a QP solver to find the best places to put the points on a line, subject to the constraint that they should not overlap.

**Usage**

```r
qp.labels(target.var, 
lower.var, upper.var, 
order.labels = function(d) order(d[, 
  target.var]), 
limits = NULL)
```

**Arguments**

- `target.var`: Variable name of the label target.
- `lower.var`: Variable name of the lower limit of each label bounding box.
- `upper.var`: Variable name of the upper limit of each label bounding box.
- `order.labels`: Function that takes the data.frame of labels and returns an ordering, like from the order function. That ordering will be used to reorder the rows. This is useful to e.g. break ties when two groups have exactly the same value at the endpoint near the label.
- `limits`: Function that takes the data.frame of labels an returns a numeric vector of length 2. If finite, these values will be used to add constraints to the QP: limits[1] is the lower limit for the first label’s lower.var, and limits[2] is the upper limit for the last labels’s upper.var. Or NULL for no limits.

**Value**

Positioning Method that adjusts target.var so there is no overlap of the label bounding boxes, as specified by upper.var and lower.var.

**Author(s)**

Toby Dylan Hocking

**Examples**

```r
SegCost$error <- factor(SegCost$error,c("FP","FN","E","I"))
if(require(ggplot2)){
  fp.fn.colors <- c(FP="skyblue",FN="#E41A1C",I="black",E="black")
  fp.fn.sizes <- c(FP=2.5,FN=2.5,I=1,E=1)
  fp.fn.linetypes <- c(FP="solid",FN="solid",I="dashed",E="solid")
  err.df <- subset(SegCost,type!="Signal")
}
kplot <- ggplot(err.df,aes(segments,cost))+
  geom_line(aes(colour=error,size=error,linetype=error))+
  facet_grid(type~bases.per.probe)+
  scale_linetype_manual(values=fp.fn.linetypes)+
  scale_colour_manual(values=fp.fn.colors)+
  scale_size_manual(values=fp.fn.sizes)+
  scale_x_continuous(limits=c(0,20),breaks=c(1,7,20),minor_breaks=NULL)+
  theme_bw()+theme(panel.margin=grid::unit(0,"lines"))

## The usual ggplot without direct labels.
print(kplot)

## Get rid of legend for direct labels.
no.leg <- kplot+guides(colour="none",linetype="none",size="none")

## Default direct labels.
direct.label(no.leg)

## Explore several options for tiebreaking and limits. First let's
## make a qp.labels Positioning Method that does not tiebreak.
no.tiebreak <- list("first.points",
  "calc.boxes",
  qp.labels("y","bottom","top"))
direct.label(no.leg, no.tiebreak)

## Look at the weird labels in the upper left panel. The E curve is
## above the FN curve, but the labels are the opposite! This is
## because they have the same y value on the first points, which are
## the targets for qp.labels. We need to tiebreak.
qp.break <- qp.labels("y","bottom","top",make.tiebreaker("x","y"))
tiebreak <- list("first.points",
  "calc.boxes",
  "qp.break")
direct.label(no.leg, tiebreak)

## Enlarge the text size and spacing.
tiebreak.big <- list("first.points",
  cex=2,
  "calc.boxes",
  dl.trans(h=1.25*h),
  "calc.borders",
  "qp.break")
direct.label(no.leg, tiebreak.big)

## Even on my big monitor, the FP runs off the bottom of the screen
## in the top panels. To avoid that you can specify a limits
## function.

## Below, the ylimits function uses the limits of each panel, so
## labels appear inside the plot region. Also, if you resize your
## window so that it is small, you can see that the text size of the
## labels is decreased until they all fit in the plotting region.
reduce.cex

```r
qp.limited <- qp.labels("y","bottom","top",make.tiebreaker("x","y"),ylimits)
tiebreak.lim <- list("first.points",
  cex=2,
  "calc.boxed",
  dl.trans(h=1.25*h),
  "calc.borders",
  "qp.limited")
direct.label(no.leg, tiebreak.lim)
}
```

### Description

If edges of the text are going out of the plotting region, then decrease cex until it fits. We call `calc.boxed` inside, so you should set cex before using this.

### Usage

```r
reduce.cex(sides)
```

### Arguments

- `sides` string: lr (left and right) or tb (top and bottom).

### Author(s)

Toby Dylan Hocking

### Examples

```r
if(require(lars) && require(ggplot2)){
  data(diabetes,package="lars",envir=environment())
  X <- diabetes$x
  colnames(X) <- paste(colnames(X), colnames(X))
  fit <- lars(X,diabetes$y,type="lasso")
  beta <- scale(coef(fit),FALSE,1/fit$normx)
  arclength <- rowSums(abs(beta))
  path.list <- list()
  for(variable in colnames(beta)){
    standardized.coef <- beta[, variable]
    path.list[[variable]] <-
      data.frame(step=seq_along(standardized.coef),
                 arclength,
                 variable,
                 standardized.coef)
  }
  path <- do.call(rbind, path.list)
}```
p <- ggplot(path,aes(arclength,standardized.coef,colour=variable))+
  geom_line(aes(group=variable))
## the legend isn’t very helpful.
print(p)
## add direct labels at the end of the lines.
direct.label(p, "last.points")
## on my screen, some of the labels go off the end, so we can use
## this Positioning Method to reduce the text size until the labels
## are on the plot.
direct.label(p, list("last.points",reduce.cex("lr")))
## the default direct labels for lineplots are similar.
direct.label(p)

reduce.cex.lr
reduce cex lr

Description
If edges of the text are going left or right out of the plotting region, then decrease cex until it fits.

Usage
reduce.cex.lr(d, ...)

Arguments
d
...

Author(s)
Toby Dylan Hocking

reduce.cex.tb
reduce cex tb

Description
If edges of the text are going over the top or bottom of the plotting region, then decrease cex until it fits.

Usage
reduce.cex.tb(d, ...)
Arguments
d
...

Author(s)
Toby Dylan Hocking

Description
for standards compliance we should escape <>&

Usage
rhtmlescape(code)

Arguments
code R code to be displayed on a HTML page between pre tags.

Value
Standards compliant HTML to display.

Author(s)
Toby Dylan Hocking

Description
Positioning Method for the last of a group of points.

Usage
right.points(d, ...)

Arguments
d
...

Description
rhtmlescape rhtmlescape

rhtmlescape rhtmlescape

Value
Standards compliant HTML to display.

Author(s)
Toby Dylan Hocking

Description
right.points right points

right.points right points

Value
Positioning Method for the last of a group of points.

Usage
right.points(d, ...)

Arguments
d
...
**Author(s)**
Toby Dylan Hocking

---

**right.polygons**

**Description**
Draw a speech polygon to the last point.

**Usage**
"right.polygons"

---

**SegCost**

**Description**
20 segmentation models were fit to 2 simulated signals, and several different error measures were used to quantify the model fit.

**Usage**
data(SegCost)

**Format**
A data frame with 560 observations on the following 5 variables.

- **bases.per.probe** a factor with levels 374 7: the sampling density of the signal.
- **segments** numeric: the model complexity measured using number of segments.
- **cost** numeric: the cost value.
- **error** a factor with levels E FP FN I: what kind of error? FP = False Positive, FN = False Negative, I = Imprecision, E = Error (sum of the other terms).

**Source**
Description

Search the plot region for a label position near the center of each point cloud.

Usage

"smart.grid"

Arguments

x
y
groups
...

Author(s)

Toby Dylan Hocking
**svmtrain**

False positive rates from several 1-SVM models

**Description**

Support Vector Machine density estimation (1-SVM) was applied to a set of negative control samples, and then used to test on a positive control.

**Usage**

data(svmtrain)

**Format**

A data frame with 378 observations on the following 5 variables.

- **replicate**: a factor with levels 1 2 3, the experimental replicate. We fit 1-SVM models to each replicate separately.
- **rate**: a numeric vector, the percent of observations that were outside the trained model.
- **data**: a factor with levels KIF11 test train, which set of observations did we measure. test and train are each 50% random splits of the negative controls in the experiment, and KIF11 is the positive control in the experiment.
- **gamma**: a numeric vector, the tuning parameter of the radial basis function kernel.
- **nu**: a numeric vector, the regularization parameter of the 1-SVM.

---

**top.bumptwice**

**Description**

Label the tops, bump labels up to avoid other labels, then to the side to avoid collisions with points.

**Usage**

top.bumptwice(d, debug = FALSE, 
...)

**Arguments**

- **d**
- **debug**
- ...  

**Author(s)**

Toby Dylan Hocking
**top.points**

**Description**

Positioning Method for the top of a group of points.

**Usage**

`top.points(d, ...)`

**Arguments**

- `d`
- `...`

**Author(s)**

Toby Dylan Hocking
Arguments
d
...

Author(s)
Toby Dylan Hocking

Description
Draw a speech polygon to the top point.

Usage
"top.polygons"

Description
Label points at the top, making sure they don’t collide.

Usage
"top.qp"
Description

Show the ggplot2 legend, for comparison.

Usage

uselegend.ggplot(p, ...)

Arguments

p The ggplot object.
...
Ignored.

Author(s)

Toby Dylan Hocking

Description

Add a legend to a trellis plot, for comparison.

Usage

uselegend.trellis(p, ...)

Arguments

p The trellis object.
...
Ignored.

Author(s)

Toby Dylan Hocking
**vertical.qp**

---

**Description**

Make a Positioning Function from a set of points on a vertical line that will be spaced out using `qp.labels`.

**Usage**

`vertical.qp(M)`

**Arguments**

- `M`

**Author(s)**

Toby Dylan Hocking

---

**visualcenter**

---

**Description**

Point in the middle of the min and max for each group.

**Usage**

`visualcenter(d, ...)`

**Arguments**

- `d`
  - `...`

**Author(s)**

Toby Dylan Hocking
Description

Return the positions of the plot horizontal limits in cm, for use as the limit argument to \texttt{qp.labels}.

Usage

\texttt{xlimits(...)}

Arguments

... 

Author(s)

Toby Dylan Hocking

Description

Return the positions of the plot vertical limits in cm, for use as the limit argument to \texttt{qp.labels}.

Usage
