Package ‘dotwhisker’

June 27, 2018

Type Package
Title Dot-and-Whisker Plots of Regression Results
Version 0.5.0
Date 2018-06-27
Maintainer Frederick Solt <frederick-solt@uiowa.edu>
Description Quick and easy dot-and-whisker plots of regression results.
Encoding UTF-8

BugReports https://github.com/fsolt/dotwhisker/issues
Depends R (>= 3.2.0), ggplot2 (>= 2.2.1)
Imports grid, stats, broom, dplyr, stringr, ggstance, rlang, purrr, gtable
Suggests mfx, ordinal, tibble, gridExtra, knitr, rmarkdown
License MIT + file LICENSE
LazyData TRUE
VignetteBuilder knitr
RoxygenNote 6.0.1

add_brackets

Description

add_brackets draws brackets along the y-axis beyond the plotting area of a dot-and-whisker plot generated by dwplot, useful for labelling groups of predictors.

Usage

add_brackets(p, brackets, face = "italic")

Arguments

p A plot generated by dwplot. Any 'ggplot' customization should be done before passing the plot to add_brackets. To pass the finalized plot to add_brackets without creating an intermediate object, simply wrap the code that generates it in braces ('{ and '}).

brackets A list of brackets; each element of the list should be a character vector consisting of (1) a label for the bracket, (2) the name of the topmost variable to be enclosed by the bracket, and (3) the name of the bottommost variable to be enclosed by the bracket.

face A typeface for the bracket labels; options are "plain", "bold", "italic", "oblique", and "bold.italic".

Value

The function returns a ggplot object.

Examples

library(broom)
library(dplyr)
data(mtcars)
ml <- lm(mpg ~ wt + cyl + disp, data = mtcars)
two_brackets <- list(c("Engine", "Cylinder", "Displacement"),

add_brackets(two_brackets)
\end{verbatim}

by_2sd  
Rescale regression results by multiplying by 2 standard deviations

Description

by_2sd rescales regression results to facilitate making dot-and-whisker plots using \texttt{dwplot}.

Usage

\texttt{by_2sd(df, dataset)}

Arguments

\begin{itemize}
  \item \texttt{df} A data frame including the variables \texttt{term} (names of independent variables), \texttt{estimate} (corresponding coefficient estimates), \texttt{std.error} (corresponding standard errors), and optionally \texttt{model} (when multiple models are desired on a single plot) such as generated those by \texttt{tidy}.
  \item \texttt{dataset} The data analyzed in the models whose results are recorded in \texttt{df}, or (preferably) the \texttt{model matrix} used by the models in \texttt{df}; the information required for complex models can more easily be generated from the model matrix than from the original data set. In many cases the model matrix can be extracted from the original model via \texttt{model.matrix}.
\end{itemize}

Details

by_2sd multiplies the results from regression models saved as tidy data frames for predictors that are not binary by twice the standard deviation of these variables in the dataset analyzed. Standardizing in this way yields coefficients that are directly comparable to each other and to those for untransformed binary predictors (Gelman 2008) and so facilitates plotting using \texttt{dwplot}. Note that the current version of by_2sd does not subtract the mean (in contrast to Gelman's (2008) formula). However, all estimates and standard errors of the independent variables are the same as if the mean was subtracted. The only difference from Gelman (2008) is that for all variables in the model the intercept is shifted by the coefficient times the mean of the variable.

An alternative available in some circumstances is to pass a model object to \texttt{arm::standardize} before passing the results to \texttt{tidy} and then on to \texttt{dwplot}. The advantages of by_2sd are that...
(1) it takes a tidy data frame as its input and so is not restricted to only those model objects that standardize accepts and (2) it is much more efficient because it operates on the parameters rather than refitting the original model with scaled data.

Value

A tidy data frame

References

Examples

```r
library(broom)
library(dplyr)
data(mtcars)
ml <- lm(mpg ~ wt + cyl + disp, data = mtcars)
ml_df <- tidy(ml) %>% by_2sd(mtcars) # create data frame of rescaled regression results
```

---

dwplot  

**Dot-and-Whisker Plots of Regression Results**

Description

dwplot is a function for quickly and easily generating dot-and-whisker plots of regression models saved in tidy data frames.

Usage

dwplot(x, dodge_size = 0.4, order_vars = NULL, show_intercept = FALSE, model_name = "model", style = c("dotwhisker", "distribution"), by_2sd = TRUE, vline = NULL, dot_args = list(size = 1.2), whisker_args = list(size = 0.5), dist_args = list(alpha = 0.5), line_args = list(alpha = 0.75, size = 1), ...)

dw_plot(x, dodge_size = 0.4, order_vars = NULL, show_intercept = FALSE, model_name = "model", style = c("dotwhisker", "distribution"), by_2sd = TRUE, vline = NULL, dot_args = list(size = 1.2), whisker_args = list(size = 0.5), dist_args = list(alpha = 0.5), line_args = list(alpha = 0.75, size = 1), ...)
Arguments

x Either a model object to be tidied with tidy, or a list of such model objects, or a tidy data frame of regression results (see 'Details').
dodge_size A number indicating how much vertical separation should be between different models' coefficients when multiple models are graphed in a single plot. Lower values tend to look better when the number of independent variables is small, while a higher value may be helpful when many models appear on the same plot; the default is 0.4.
order_vars A vector of variable names that specifies the order in which the variables are to appear along the y-axis of the plot.
show_intercept A logical constant indicating whether the coefficient of the intercept term should be plotted.
model_name The name of a variable that distinguishes separate models within a tidy data frame.
style Either "dotwhisker" or "distribution". "dotwhisker", the default, shows the regression coefficients' point estimates as dots with confidence interval whiskers. "distribution" shows the normal distribution with mean equal to the point estimate and standard deviation equal to the standard error, underscored with a confidence interval whisker.
by_2sd When x is model object or list of model objects, should the coefficients for predictors that are not binary be rescaled by twice the standard deviation of these variables in the dataset analyzed, per Gelman (2008)? Defaults to TRUE. Note that when x is a tidy data frame, one can use by_2sd to rescale similarly.
vline A geom_vline() object, typically with xintercept = 0, to be drawn behind the coefficients.
dot_args When style is "dotwhisker", a list of arguments specifying the appearance of the dots representing mean estimates. For supported arguments, see geom_point.
whisker_args When style is "dotwhisker", a list of arguments specifying the appearance of the whiskers representing the confidence intervals. For supported arguments, see geom_linerangeh.
dist_args When style is "distribution", a list of arguments specifying the appearance of normally distributed regression estimates. For supported arguments, see geom_polygon.
line_args When style is "distribution", a list of arguments specifying the appearance of the line marking the confidence interval beneath the normal distribution. For supported arguments, see geom_linerangeh.
... Extra arguments to pass to tidy.

Details
dwplot visualizes regression model objects or regression results saved in tidy data frames by, e.g., tidy as dot-and-whisker plots generated by ggplot.

Tidy data frames to be plotted should include the variables term (names of predictors), estimate (corresponding estimates of coefficients or other quantities of interest), std.error (corresponding standard errors), and optionally model (when multiple models are desired on a single plot;
different name for this last variable may be specified using the model_name argument). In place of std.error one may substitute conf.low (the lower bounds of the confidence intervals of each estimate) and conf.high (the corresponding upper bounds).

For convenience, dwplot also accepts as input those model objects that can be tidied by tidy, or a list of such model objects.

By default, the plot will display 95-percent confidence intervals. To display a different interval when passing a model object or objects, specify a conf.level argument to pass to tidy. When passing a data frame of results, include the variables conf.low and conf.high describing the bounds of the desired interval.

Because the function can take a data frame as input, it is easily employed for a wide range of models, including those not supported by tidy. And because the output is a ggplot object, it can easily be further customized with any additional arguments and layers supported by ggplot2. Together, these two features make dwplot extremely flexible.

Value

The function returns a ggplot object.

split(.sam) %>%
purrr::map(~ lm(mpg ~ wt + cyl + disp, data = .x)) %>%
dwplot() %>%
relabel_predictors(c(wt = "Weight", cyl = "Cylinders", disp = "Displacement"); theme_bw() + xlab("Coefficient") + ylab("") +
geom_vline(xintercept = 0, colour = "grey60", linetype = 2) +
ggtitle("Predicting Gas Mileage, OLS Estimates") +
relabel_predictors

Relabel the Predictors in a Tidy Data Frame of Regression Results

Description

relabel_predictors is a convenience function for relabeling the predictors in a tidy data frame to be passed to dwplot or a plot generated by dwplot.

Usage

relabel_predictors(x, ...)

Arguments

x

Either a tidy data frame to be passed to dwplot or a plot generated by dwplot.

...

Named replacements, as in recode. The argument names should be the current values to be replaced, and the argument values should be the new (replacement) values. For backwards compatibility, a named character vector, with new values as values, and old values as names may also be used. The order of the named replacements will be preserved, so this function also serves the purpose of re-ordering variables.

Value

The function returns an object of the same type as it is passed: a tidy data frame or a plot generated by dwplot.

Examples

library(broom)
library(dplyr)

data(mtcars)
ml <- lm(mpg ~ wt + cyl + disp, data = mtcars)
ml_df <- broom::tidy(ml) %>%
  relabel_predictors("(Intercept)" = "Intercept",
  wt = "Weight",
  disp = "Displacement",
cyl = "Cylinder")
dwplot(m1_df)

dwplot(m1, show_intercept = TRUE) %>%
  relabel_predictors("(Intercept)" = "Intercept",
  wt = "Weight",
  disp = "Displacement",
  cyl = "Cylinder")

---

**relabel_y_axis**  
*Relabel the Y-Axis of a Dot-Whisker Plot*

**Description**

relabel_y_axis DEPRECATED. A convenience function for relabeling the predictors on the y-axis of a dot-whisker plot created by dwplot. It is deprecated; use relabel_predictors instead.

**Usage**

```r
relabel_y_axis(x)
```

**Arguments**

- **x**  
  A vector of labels for predictors, listed from top to bottom

**See Also**

relabel_predictors to relabel predictors on the y-axis of a dot-whisker plot or in a tidy data.frame

---

**secret_weapon**  
*Generate a ‘Secret Weapon’ Plot of Regression Results from Multiple Models*

**Description**

secret_weapon is a function for plotting regression results of multiple models as a ‘secret weapon’ plot

**Usage**

```r
secret_weapon(x, var = NULL, ...)
```
small_multiple

Arguments

x                Either a tidy data frame including results from multiple models (see `Details`) or a list of model objects that can be tidied with tidy

var              The predictor whose results are to be shown in the `secret weapon` plot

...              Arguments to pass to dWplot.

Details

Andrew Gelman has coined the term “the secret weapon” for dot-and-whisker plots that compare the estimated coefficients for a single predictor across many models or datasets. secret_weapon takes a tidy data frame of regression results or a list of model objects and generates a dot-and-whisker plot of the results of a single variable across the multiple models.

Tidy data frames to be plotted should include the variables term (names of predictors), estimate (corresponding estimates of coefficients or other quantities of interest), std.error (corresponding standard errors), and model (identifying the corresponding model). In place of std.error one may substitute lb (the lower bounds of the confidence intervals of each estimate) and ub (the corresponding upper bounds).

Alternately, secret_weapon accepts as input a list of model objects that can be tidied by tidy.

Value

The function returns a ggplot object.

Examples

library(broom)
library(dplyr)

# Estimate models across many samples, put results in a tidy data frame
by_clarity <- diamonds %>% group_by(clarity) %>%
do(broom::tidy(lm(price ~ carat + cut + color, data = .))) %>%
ungroup %>% rename(model = clarity)

# Generate a 'secret weapon' plot of the results of diamond size
secret_weapon(by_clarity, "carat")

small_multiple Generate a ‘Small Multiple’ Plot of Regression Results

Description

small_multiple is a function for plotting regression results of multiple models as a 'small multiple' plot
small_multiple

Usage

```r
small_multiple(x, dodge_size = 0.4, show_intercept = FALSE, by_2sd = TRUE,
              dot_args = list(size = 0.3), ...)
```

Arguments

- **x**: Either a tidy data frame including results from multiple models (see 'Details') or a list of model objects that can be tidied with `tidy`
- **dodge_size**: A number (typically between 0 and 0.3; the default is .06) indicating how much horizontal separation should appear between different submodels' coefficients when multiple submodels are graphed in a single plot. Lower values tend to look better when the number of models is small, while a higher value may be helpful when many submodels appear on the same plot.
- **show_intercept**: A logical constant indicating whether the coefficient of the intercept term should be plotted
- **by_2sd**: When x is model object or list of model objects, should the coefficients for predictors that are not binary be rescaled by twice the standard deviation of these variables in the dataset analyzed, per Gelman (2008)? Defaults to TRUE. Note that when x is a tidy data frame, one can use `by_2sd` to rescale similarly.
- **dot_args**: A list of arguments specifying the appearance of the dots representing mean estimates. For supported arguments, see `geom_pointrangeh`.
- **...**: Extra arguments to pass to `tidy`.

Details

`small_multiple`, following [https://doi.org/10.1017/S1537592707072209](https://doi.org/10.1017/S1537592707072209), provides a compact means of representing numerous regression models in a single plot.

Tidy data frames to be plotted should include the variables `term` (names of predictors), `estimate` (corresponding estimates of coefficients or other quantities of interest), `std.error` (corresponding standard errors), and `model` (identifying the corresponding model). In place of `std.error` one may substitute `conf.low` (the lower bounds of the confidence intervals of each estimate) and `conf.high` (the corresponding upper bounds).

Alternately, `small_multiple` accepts as input a list of model objects that can be tidied by `tidy`.

Optionally, more than one set of results can be clustered to facilitate comparison within each model; one example of when this may be desirable is to compare results across samples. In that case, the data frame should also include a variable `submodel` identifying the submodel of the results.

Value

The function returns a `ggplot` object.
