Package ‘eatATA’

September 15, 2020

Type Package
Title Create Constraints for Small Test Assembly Problems
Version 0.7.0
Description Provides simple functions to create constraints for small test assembly problems (e.g. van der Linden (2005, ISBN: 978-0-387-29054-6)) using sparse matrices. Currently, only ‘Gurobi’ is supported as an optimizer.

**analyzeBlockExclusion**

Analyse block exclusiveness

**Description**

Use exclusion tuples information to determine which assembled test blocks are exclusive.

**Usage**

```r
analyzeBlockExclusion(processedObj, idCol, exclusionTuples)
```

**Arguments**

- **processedObj** Object created by gurobi solver and processed by `processGurobiOutput`. Must be a list.
- **idCol** Column name with item IDs in the `data.frames` in `processedObj`.
- **exclusionTuples** `data.frame` with two columns, containing tuples with item IDs which should be in test forms exclusively. Must be the same object as used in `itemExclusionConstraint`.

**Details**

If exclusion tuples have been used to assemble test forms (using the `itemExclusionConstraint` function), the resulting item blocks might also be exclusive. Using the initially used item exclusion tuples and the processed gurobi output (via `processGurobiOutput`) this function determines, which item blocks are exclusive and can not be together in an assembled test form.

**Value**

A `data.frame` of block exclusions.
Examples

```r
## Full workflow using itemExclusionTuples
# Example data.frame
items <- data.frame(ID = c("items1", "items2", "items3", "items4"),
                    exclusions = c("items2, items3", NA, NA, NA))

# Create tuples
exTuples2 <- itemExclusionTuples(items = items, idCol = "ID", exclusions = "exclusions",
                                  sepPattern = ",\s")

# Create constraints
exclusion_constraint <- itemExclusionConstraint(nForms = 2, exclusionTuples = exTuples2,
                                                itemIDs = items$ID)
depletion_constraint <- depletePoolConstraint(2, nItems = 4)
target_constraint <- itemTargetConstraint(nForms = 2, nItems = 4,
                                          itemValues = c(3, 1.5, 2, 4), targetValue = 1)

gurobi_model <- prepareConstraints(list(exclusion_constraint, target_constraint,
                                        depletion_constraint),
                                     nForms = 2, nItems = 4)

## Not run:
# Run gurobi (this can only be run with Gurobi and the gurobi package installed,
# for which a Gurobi license is required)
gurobi_out <- gurobi::gurobi(gurobi_model, params = list(TimeLimit = 30))
processedObj <- processGurobiOutput(gurobi_out, items = items, nForms = 2, output = "list")
analyzeBlockExclusion(processedObj, exTuples2)

## End(Not run)
```

autoItemValuesMinMax  Create single value constraints with minimum and maximum.

Description

`itemValuesDeviation` creates constraints related to an item parameter/value. `autoItemValuesMinMax` automatically determines the appropriate `targetValue` and then calls `itemValuesDeviation`. The function only works for (dichotomous) dummy indicators with values 0 and 1.

Usage

```r
autoItemValuesMinMax(
  nForms,  # Number of forms
  itemValues,  # Values of the items
  allowedDeviation = NULL,  # Allowed deviation
  relative = FALSE,  # Whether to use relative deviation
)
```
computeTargetValues

verbose = TRUE
)

Arguments

nForms Number of forms to be created.
itemValues Item parameter/values for which the sum per test form should be constrained.
allowedDeviation Numeric value of length 1. How much deviance is allowed from target values?
relative Is the allowedDeviation expressed as a proportion?
verbose Should calculated values be reported?

Details

Two scenarios are possible when automatically determining the target value: (a) Either items with
the selected property could be exactly distributed across test forms or (b) this is not possible. An
example would be 2 test forms and 4 multiple choice items (a) or 2 test forms and 5 multiple choice
items (b). If (a), the tolerance level works exactly as one would expect. If (b) the tolerance level
is adapted, meaning that if tolerance level is 0 in example (b), allowed values are 2 or 3 multiple
choice items per test form.

Value

A sparse matrix.

Examples

autoItemValuesMinMax(2, itemValues = c(0, 1, 0, 1))
computeTargetValues

## Default S3 method:
computeTargetValues(
  itemValues,
  nForms,
  testLength = NULL,
  allowedDeviation = NULL,
  relative = FALSE
)

## S3 method for class 'factor'
computeTargetValues(
  itemValues,
  nForms,
  testLength = NULL,
  allowedDeviation = NULL,
  relative = FALSE
)

### Arguments

- **itemValues**: Item parameter/values for which the sum per test form should be constrained.
- **nForms**: Number of forms to be created.
- **testLength**: to be documented.
- **allowedDeviation**: Numeric value of length 1. How much deviance is allowed from target values?
- **relative**: Is the allowedDeviation expressed as a proportion?

### Details

Both for numerical and categorical item values, the target values are the item pool average scaled by the ratio of items in the forms and items in the item pool. The behavior of the function changes depending on the class of itemValues.

When itemValues is a numerical vector, an when allowedDeviation is NULL (the default), only one target value is computed. This value could be used in the targetConstraint-function. Otherwise (i.e., allowedDeviation is a numerical value), the target is computed, but a minimal and a maximal (target)value are returned, based on the allowed deviation. When relative == TRUE the allowed deviation should be expressed as a proportion. In that case the minimal and maximal values are computed proportionally.

When itemValues is a factor, it is assumed that the item values are item categories, and hence only whole valued frequencies are returned. To be more precise, a matrix with the minimal and maximal target frequencies for every level of the factor are returned. When allowedDeviation is NULL, the difference between the minimal and maximal value is one (or zero). As a consequence, dummy-item values are best specified as a factor (see examples).

### Value

A vector or a matrix with target values (see details)
Methods (by class)

- default: compute target values
- factor: compute target frequencies for item categories

Examples

```r
## Assume an item pool with 50 items with random item information values (iif) for a given ability value.
set.seed(50)
itemInformations <- runif(50, 0.5, 3)

## The target value for the test information value (i.e., sum of the item informations) when three test forms of 10 items are assembled is:
computeTargetValues(itemInformations, nForms = 3, testLength = 10)

## The minimum and maximum test iformation values for an allowed deviation of 10 percent are:
computeTargetValues(itemInformations, nForms = 3, allowedDeviation = .10, relative = TRUE, testLength = 10)

## items$MC is dummy variable indication which items in the pool are multiple choise
str(items$MC)

## when used as a numerical vector, the dummy is not treated as a categorical indicator, but rather as a numerical value.
computeTargetValues(items$MC, nForms = 14)
computeTargetValues(items$MC, nForms = 14, allowedDeviation = 1)

## Therefore, it is best to convert dummy variables into a factor, so that automatically frequencies are returned
MC_factor <- factor(items$MC, labels = c("not MC", "MC"))
computeTargetValues(MC_factor, nForms = 14)
computeTargetValues(MC_factor, nForms = 3)
```

---

depletePoolConstraint  Use complete item pool.

Description

Creates constraints that assure that every item in the item pool is used (at least) once. Essentially a wrapper around itemUsageConstraint.

Usage

depletePoolConstraint(nForms, nItems)
**dummiesToFactor**

**Arguments**
- `nForms` Number of forms to be created.
- `nItems` Number of items in the item pool.

**Value**
A sparse matrix.

**Examples**
```
depetePoolConstraint(2, 10)
```

---

**dummiesToFactor**  
*Convert dummy variables to factor.*

**Description**
Convert multiple dummy variables into a single factor variable.

**Usage**
```
dummiesToFactor(dat, dummies, facVar, nameEmptyCategory = "_none_")
```

**Arguments**
- `dat` A data.frame.
- `dummies` Character vector containing the names of the dummy variables in the data.frame.
- `facVar` Name of the factor variable, that should be created.
- `nameEmptyCategory` a character of length 1 that defines the name of cases for which no dummy is equal to one.

**Details**
The content of a single factor variable can alternatively be stored in multiple dichotomous dummy variables coded with 0/1 or NA/1. 1 always has to refer to "this category applies". The function requires factor levels to be exclusive (i.e. only one factor level applies per row.).

**Value**
A data.frame containing the newly created factor.
itemCategoryConstraint

Examples

# Example data set
tdat <- data.frame(ID = 1:3, d1 = c(1, 0, 0), d2 = c(0, 1, 0), d3 = c(0, 0, 1))
dummiesToFactor(tdat, dummies = c("d1", "d2", "d3"), facVar = "newFac")

gurobiExample  
Example Gurobi output.

Description

An example Gurobi output containing the optimal solution for the example in the vignette.

Usage

gurobiExample

Format

A list.

itemCategoryConstraint

Create item category constraints.

Description

Create constraints related to item categories/groupings (as represented by itemCategories). That is, the created constraints assure that the number of items of each category per test form is either (a) smaller or equal than (operator = "<="), (b) equal to (operator = "="), or (c) greater than or equal to (operator = ">=") the corresponding targetValues.

Usage

itemCategoryConstraint(
  nForms,
  nItems,
  itemCategories,
  operator = c("<=", "=" , ">="),
  targetValues
)

itemCategoryRange

Arguments

nForms Number of forms to be created.
nItems Number of items in the item pool.
itemCategories a factor representing the categories/grouping of the items
operator a character indicating which operator should be used in the constraints, with three possible values: "<=", "=" or ">=". See details for more information.
targetValues an integer vector representing the target number per category. The order of the target values should correspond with the order of the levels of the factor in itemCategory.

Value

A sparse matrix.

Examples

### constraints to make sure that there are at least 3 items of each item type in each test form
nItems <- 30
item_type <- factor(sample(1:3, size = nItems, replace = TRUE))
itemCategoryConstraint(2, nItems, item_type, ">=", targetValues = c(3, 3, 3))
allowedDeviation,  
relative = FALSE  
)

Arguments

nForms  Number of forms to be created.
nItems  Number of items in the item pool.
itemCategories  a factor representing the categories/grouping of the items
range  a matrix with two columns representing the the minimal and the maximum frequency of the items from each level/category itemCategories
min  the minimal sum of the itemValues per test form
max  the minimal sum of the itemValues per test form
targetValues  an integer vector representing the target number per category. The order of the target values should correspond with the order of the levels of the factor in itemCategory.
allowedDeviation  the maximum allowed deviation from the targetValue
relative  a logical expressing whether or not the allowedDeviation should be interpreted as a proportion of the targetValue

Details

itemCategoriesDeviation also constrains the minimal and the maximal value of the number of items of each category per test form, but based on chosen targetValues, and maximal allowed deviations (i.e., allowedDeviation) from those targetValues.

Value

A sparse matrix.

Functions

- itemCategoryMin: constrain minimum value
- itemCategoryMax: constrain maximum value
- itemCategoryDeviation: constrain the distance from the targetValues

Examples

## constraints to make sure that there are at least 2 and maximally 4
## items of each item type in each test form
nItems <- 30
item_type <- factor(sample(1:3, size = nItems, replace = TRUE))
itemCategoryRange(2, nItems, item_type, range = cbind(min = rep(2, 3), range = rep(4, 3)))

## or alternatively
itemCategoryDeviation(2, nItems, item_type, targetValues = rep(3, 3), allowedDeviation = rep(4, 3))
**itemExclusionConstraint**

Create item exclusion constraints.

**Description**

Create constraints that prohibit that item pairs occur in the same test forms.

**Usage**

`itemExclusionConstraint(nForms, exclusionTuples, itemIDs)`

**Arguments**

- `nForms` Number of forms to be created.
- `exclusionTuples` data.frame with two columns, containing tuples with item IDs which should be in test forms exclusively.
- `itemIDs` Character vector of item IDs in correct ordering.

**Details**

Item exclusion pairs can, for example, be created by the function `itemExclusionTuples`.

**Value**

A sparse matrix.

**Examples**

```r
## item-IDs
IDs <- c("item1", "item2", "item3", "item4")

## tuples: Item 1 can not be in the test form as item 2 and 3
exTuples <- data.frame(v1 = c("item1", "item1"), v2 = c("item2", "item3"), stringsAsFactors = FALSE)

## Create constraints
itemExclusionConstraint(nForms = 2, exclusionTuples = exTuples, itemIDs = IDs)

########
## Full workflow using itemExclusionTuples
# Example data.frame
items <- data.frame(ID = c("items1", "items2", "items3", "items4"),
                     exclusions = c("items2, items3", NA, NA, NA))

# Create tuples
exTuples2 <- itemExclusionTuples(items = items, idCol = "ID", exclusions = "exclusions",
```
sepPattern = ",,\)"

# Create constraints
itemExclusionConstraint(nForms = 2, exclusionTuples = exTuples2, itemIDs = IDs)

---

itemExclusionTuples  Create item exclusion tuples.

---

Description

If item exclusions are stored as a character vector, `itemExclusionTuples` separates this vector and creates item pairs ('tuples').

Usage

`itemExclusionTuples(items, idCol = "ID", exclusions, sepPattern = ",,\)"

Arguments

- `items`: A data.frame with information on an item pool.
- `idCol`: Name of the item ID column.
- `exclusions`: Name of the exclusion column.
- `sepPattern`: String which should be used for separating item IDs in the exclusions column.

Details

Exclusion tuples can be used by `itemExclusionConstraint` to set up exclusion constraints.

Value

A data.frame with two columns.

Examples

```r
# Example data.frame
items <- data.frame(ID = c("items1", "items2", "items3", "items4"),
                    exclusions = c("items2, items3", NA, NA, NA))

# Create tuples
itemExclusionTuples(items = items, idCol = "ID", exclusions = "exclusions",
                    sepPattern = ",,\)
```
**items**  
*Small artificial item pool example.*

**Description**

A data.frame containing 80 items with different categorical and metric properties.

**Usage**

`items`

**Format**

A data.frame.

- **Item_ID**: Item identifier.
- **exclusions**: Items which can not be in the same test form.
- **RT_in_min**: Average response times in minutes. 2.5 equals 2 minutes and 30 seconds, for example.
- **subitems**: Number of sub items.
- **MC, CMC, short_answer, open**: Answer formats.
- **diff_1, diff_2, diff_3, diff_4, diff_5**: Difficulty categories.

**itemsPerFormConstraint**

*Create number of items per test form constraints.*

**Description**

Creates constraints related to the number of items in each test form.

**Usage**

```r
itemsPerFormConstraint(
  nForms,
  nItems,
  operator = c("<=", ",", ">="),
  targetValue
)
```
Arguments

- **nForms**: Number of forms to be created.
- **nItems**: Number of items in the item pool.
- **operator**: A character indicating which operator should be used in the constraints, with three possible values: "\(<\)"", "\(=\)"", or "\(\geq\)". See details for more information.
- **targetValue**: The target value to be used in the constraints. That is, the number of items per form.

Details

The number of items per test form is constrained to be either (a) smaller or equal than (operator = "\(<\)"), (b) equal to (operator = "\(=\)"), or (c) greater or equal than (operator = "\(\geq\)") the chosen value.

Value

A sparse matrix.

Examples

```r
## Constrain the test forms to have exactly five items
itemsPerFormConstraint(3, 20, operator = "=", targetValue = 5)
```

Description

Create constraints that define the optimization goal of an automated test assembly problem.

Usage

```
itemTargetConstraint(nForms, nItems, itemValues, targetValue)
```

Arguments

- **nForms**: Number of forms to be created.
- **nItems**: Number of items in the item pool.
- **itemValues**: Item parameter/values for which the sum per test form should be constrained.
- **targetValue**: The target value to be used in the constraints.

Value

A sparse matrix.
itemUsageConstraint

Examples

itemTargetConstraint(nForms = 2, nItems = 4, c(1, 0.5, 1.5, 2), targetValue = 1)

Description

Creates constraints related to item usage. That is, the number of times an item is selected is con-
strained to be either (a) smaller or equal than (operator = "<="), (b) equal to (operator = "="), or
(c) greater or equal than (operator = ">=") the chosen value.

Usage

itemUsageConstraint(
  nForms,
  nItems,
  operator = c("<=", "=" , ">="),
  targetValue = 1
)

Arguments

nForms Number of forms to be created.
nItems Number of items in the item pool.
operator a character indicating which operator should be used in the constraints, with
three possible values: "<=", ",=" or ">=". See details for more information.
targetValue The value to be used in the constraints

Details

When operator = "<=" and value = 1 (the default), each item can be selected maximally once,
which corresponds with assuring that there is no item overlap between the forms. When operator
= "=" and value = 1, each item is used exactly once, which corresponds to no item-overlap and
complete item pool depletion.

Value

A sparse matrix.

Examples

## create no-item overlap constraints with item pool depletion
## for 2 test forms with an item pool of 20 items
itemUsageConstraint(2, 20, operator = ",=" , targetValue = 1)
**itemValuesConstraint**  
*Create single value constraints.*

**Description**
Create constraints related to an item parameter/value. That is, the created constraints assure that the sum of the item values (itemValues) per test form is either (a) smaller than or equal to (operator = "\(\leq\)"), (b) equal to (operator = "\(=\)"), or (c) greater than or equal to (operator = "\(\geq\)") the chosen targetValue.

**Usage**

```
itemValuesConstraint(
  nForms,  
  nItems,  
  itemValues,  
  operator = c("\(\leq\)", "\(=\)", "\(\geq\)"),  
  targetValue  
)
```

**Arguments**
- **nForms**  
  Number of forms to be created.
- **nItems**  
  Number of items in the item pool.
- **itemValues**  
  Item parameter/values for which the sum per test form should be constrained.
- **operator**  
  A character indicating which operator should be used in the constraints, with three possible values: "\(\leq\)", "\(=\)", or "\(\geq\)". See details for more information.
- **targetValue**  
  The target test form value

**Value**
A sparse matrix.

**Examples**
```
## constraints to make sure that the sum of the item values (1:10) is between
## 4 and 6
rbind(
  itemValuesConstraint(2, 10, 1:10, operator = "\(\geq\)", targetValue = 4),
  itemValuesConstraint(2, 10, 1:10, operator = "\(\leq\)", targetValue = 6))
```
**itemValuesRange**  
Create single value constraints with minimum and maximum.

**Description**

`itemValuesRange`, `itemValuesMin`, and `itemValuesMax` create constraints related to an item parameter/value. That is, the created constraints assure that the sum of the `itemValues` is smaller than or equal to `max`, greater than or equal to `min`, or both range.

**Usage**

```r
itemValuesRange(nForms, nItems, itemValues, range)
itemValuesMin(nForms, nItems, itemValues, min)
itemValuesMax(nForms, nItems, itemValues, max)
itemValuesDeviation(
  nForms,
  nItems,
  itemValues,
  targetValue,
  allowedDeviation,
  relative = FALSE
)
```

**Arguments**

- `nForms` Number of forms to be created.
- `nItems` Number of items in the item pool.
- `itemValues` Item parameter/values for which the sum per test form should be constrained.
- `range` a vector with two values, the the minimal and the maximum sum of the `itemValues` per test form, respectively
- `min` the minimal sum of the `itemValues` per test form
- `max` the minimal sum of the `itemValues` per test form
- `targetValue` the target test form value
- `allowedDeviation` the maximum allowed deviation from the targetValue
- `relative` a logical expressing whether or not the `allowedDeviation` should be interpreted as a proportion of the `targetValue`

**Details**

`itemValuesDeviation` also constrains the minimal and the maximal value of the sum of the `itemValues`, but based on a chosen and a maximal allowed deviation (i.e., `allowedDeviation`) from that `targetValue`. 
matrixExclusionTuples

Value
A sparse matrix.

Functions

- `itemValuesMin`: constrain minimum value
- `itemValuesMax`: constrain maximum value
- `itemValuesDeviation`: constrain the distance from the `targetValue`

Examples

```r
## constraints to make sure that the sum of the item values (1:10) is between
## 4 and 6
itemValuesRange (2, 10, 1:10, range(min = 4, max = 6))

## or alternatively
itemValuesDeviation (2, 10, 1:10, targetValue = 5, allowedDeviation = 1)
```

matrixExclusionTuples **Create item exclusion tuples from matrix.**

Description

If item exclusions are stored as a matrix, `matrixExclusionTuples` transforms this format into item pairs ('tuples'). Information on exclusions has to be coded as 1 (items are exclusive) and 0 (items are not exclusive).

Usage

`matrixExclusionTuples(exclMatrix)`

Arguments

- `exclMatrix` A `data.frame` or `matrix` with information on item exclusiveness.

Details

Exclusion tuples can be used by `itemExclusionConstraint` to set up exclusion constraints.

Value

A `data.frame` with two columns.
prepareConstraints

Examples

# Example data.frame
exclDF <- data.frame(c(0, 1, 0, 0),
                     c(1, 0, 0, 1),
                     c(0, 0, 0, 0),
                     c(0, 1, 0, 0))
rownames(exclDF) <- colnames(exclDF) <- paste0("item", 1:4)

# Create tuples
matrixExclusionTuples(exclDF)

prepareConstraints Prepare a list of constraints for Gurobi

Description

Transform a list of constraints set up via eatATA as input to the gurobi function.

Usage

prepareConstraints(allConstraints, nForms, nItems)

Arguments

allConstraints List of constraints.
nForms Number of forms to be created.
nItems Number of items in the item pool.

Value

A gurobi model list.

Examples

## setup some example constraints
usage <- itemUsageConstraint(nForms = 2, nItems = 10, operator = ", targetValue = 1)
perform <- itemsPerFormConstraint(nForms = 2, nItems = 10, operator = "=", targetValue = 5)
target <- itemTargetConstraint(nForms = 2, nItems = 10, itemValues = 1:10, targetValue = 5)

## Prepare Constraints
prepareConstraints(list(usage, perform, target), nForms = 2, nItems = 10)
processGurobiOutput  

Description

Process a gurobi output of a successfully solved optimization problem so it becomes humanly readable.

Usage

processGurobiOutput(gurobiObj, items, nForms, output = "data.frame")

Arguments

gurobiObj  
Object created by gurobi solver.

items  
Original data.frame containing information on item level.

nForms  
Number of forms that have been created.

output  
Should the output be returned as a data.frame or a list?

Details

The output can either be transformed to a data.frame (optimal for writing to disk and re-importing into other programs) or to a list (optimal for quick visual inspection.)

Value

a data.frame or a list.

Examples

## using existing gurobi example
processGurobiOutput(gurobiExample, items = items, nForms = 2, output = "list")
processGurobiOutput(gurobiExample, items = items, nForms = 2, output = "data.frame")

## Full workflow
items <- data.frame(paste0("item", 1:10), stringsAsFactors = FALSE)
items$RTs <- c(5, 3, 4, 1, 2.5, 8.5, 6, 5, 4, 6.5)

# setup constraints
constraint1 <- depletePoolConstraint(2, nItems = 10)
constraint2 <- itemTargetConstraint(2, nItems = 10, itemValues = items$RTs, targetValue = 20)
gurobi_model <- prepareConstraints(list(constraint1, constraint2),
nForms = 2, nItems = 10)

## Not run:
# Run gurobi (this can only be run with Gurobi and the gurobi package installed,
gurobi_out <- gurobi::gurobi(gurobi_model, params = list(TimeLimit = 30))

processGurobiOutput(gurobi_out, items = items, nForms = 2, output = "list")

## End(Not run)
