# Package ‘emmeans’

May 25, 2020

**Type** Package  
**Title** Estimated Marginal Means, aka Least-Squares Means  
**Version** 1.4.7  
**Date** 2020-05-25  
**Depends** R (>= 3.2)  
**Imports** estimability (>= 1.3), graphics, methods, numDeriv, stats, utils, plyr, mvtnorm, xtable (>= 1.8-2)  
**Suggests** bayesplot, biglm, brms, car, coda (>= 0.17), ggplot2, lattice, mediation, mgcv, multcomp, multcompView, nlme, ordinal (>= 2014.11-12), pbkrtest (>= 0.4-1), lme4, lmerTest (>= 2.0.32), MASS, MuMIn, rsm, knitr, rmarkdown, scales, splines, testthat  
**Enhances** CARBayes, coxme, gee, geepack, MCMCglmm, MCMCpack, mice, nnet, pscl, rstanarm, sommer, survival  
**URL** [https://github.com/rvlenth/emmeans](https://github.com/rvlenth/emmeans)  
**BugReports** [https://github.com/rvlenth/emmeans/issues](https://github.com/rvlenth/emmeans/issues)  
**LazyData** yes  
**ByteCompile** yes  
**License** GPL-2 | GPL-3  
**Encoding** UTF-8  
**RoxygenNote** 7.0.1  
**VignetteBuilder** knitr  
**NeedsCompilation** no

emmeans-package

This package provides methods for obtaining estimated marginal means (EMMs, also known as least-squares means) for factor combinations in a variety of models. Supported models include [generalized linear] models, models for counts, multivariate, multinomial and ordinal responses, survival models, GEEs, and Bayesian models. For the latter, posterior samples of EMMs are provided. The package can compute contrasts or linear combinations of these marginal means with various multiplicity adjustments. One can also estimate and contrast slopes of trend lines. Some graphical displays of these results are provided.

Overview

Vignettes A number of vignettes are provided to help the user get acquainted with the emmeans package and see some examples.

Concept Estimated marginal means (see Searle et al. 1980) are popular for summarizing linear models that include factors. For balanced experimental designs, they are just the marginal means. For unbalanced data, they in essence estimate the marginal means you would have observed that the data arisen from a balanced experiment. Earlier developments regarding these techniques were developed in a least-squares context and are sometimes referred to as “least-squares means”. Since its early development, the concept has expanded far beyond least-squares settings.

Reference grids The implementation in emmeans relies on our own concept of a reference grid, which is an array of factor and predictor levels. Predictions are made on this grid, and estimated marginal means (or EMMs) are defined as averages of these predictions over zero or more dimensions of the grid. The function ref_grid explicitly creates a reference grid that can subsequently be used to obtain least-squares means. The object returned by ref_grid is of class "emmGrid", the same class as is used for estimated marginal means (see below).

Our reference-grid framework expands slightly upon Searle et al.’s definitions of EMMs, in that it is possible to include multiple levels of covariates in the grid.

Models supported As is mentioned in the package description, many types of models are supported by the package. See vignette("models", "emmeans") for full details. Some models may require other packages be installed in order to access all of the available features. For models not explicitly supported, it may still be possible to do basic post hoc analyses of them via the qdrg function.
add_grouping

Description

This function adds a grouping factor to an existing reference grid or other emmGrid object, such that the levels of an existing factor (call it the reference factor) are mapped to a smaller number of levels of the new grouping factor. The reference factor is then nested in the grouping factor. This facilitates obtaining marginal means of the grouping factor, and contrasts thereof.

Usage

add_grouping(object, newname, refname, newlevs)
as.list.emmGrid

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>An emmGrid object</td>
</tr>
<tr>
<td>newname</td>
<td>Character name of grouping factor to add (different from any existing factor in the grid)</td>
</tr>
<tr>
<td>refname</td>
<td>Character name of the reference factor</td>
</tr>
<tr>
<td>newlevs</td>
<td>Character vector or factor of the same length as that of the levels for refname. The grouping factor newname will have the unique values of newlevs as its levels.</td>
</tr>
</tbody>
</table>

Value

A revised emmGrid object having an additional factor named newname, and a new nesting structure refname %in% newname

Note

By default, the levels of newname will be ordered alphabetically. To dictate a different ordering of levels, supply newlevs as a factor having its levels in the required order.

Examples

```r
fiber.lm <- lm(strength ~ diameter + machine, data = fiber)
( frg <- ref_grid(fiber.lm) )

# Suppose the machines are two different brands
brands <- factor(c("FiberPro", "FiberPro", "Acme"), levels = c("FiberPro", "Acme"))
( gfrg <- add_grouping(frg, "brand", "machine", brands) )

emmeans(gfrg, "machine")
emmeans(gfrg, "brand")
```

as.list.emmGrid

Convert to and from emmGrid objects

Description

These are useful utility functions for creating a compact version of an emmGrid object that may be saved and later reconstructed, or for converting old ref.grid or lsmobj objects into emmGrid objects.

Usage

```r
## S3 method for class 'emmGrid'
as.list(x, ...)
as.emm_list(object, ...)
as.emmGrid(object, ...)
```
Arguments

**x**

An `emmGrid` object

**...**

In `as.emmGrid`, additional arguments passed to `update.emmGrid` before returning the object. This argument is ignored in `as.list.emmGrid`.

**object**

Object to be converted to class `emmGrid`. It may be a list returned by `as.list.emmGrid`, or a `ref.grid` or `lsmobj` object created by `emmeans`'s predecessor, the `lsmeans` package. An error is thrown if object cannot be converted.

Details

An `emmGrid` object is an S4 object, and as such cannot be saved in a text format or saved without a lot of overhead. By using `as.list`, the essential parts of the object are converted to a list format that can be easily and compactly saved for use, say, in another session or by another user. Providing this list as the arguments for `emmeans` allows the user to restore a working `emmGrid` object.

Value

`as.list.emmGrid` returns an object of class `list`.

`as.emm_list` returns an object of class `emm_list`.

`as.emmGrid` returns an object of class `emmGrid`. However, in fact, both `as.emmGrid` and `as.emm_list` check for an attribute in `object` to decide whether to return an `emmGrid` or `emm_list` object.

See Also

`emmeans`

Examples

```r
pigs.lm <- lm(log(conc) ~ source + factor(percent), data = pigs)
pigs.sav <- as.list(ref_grid(pigs.lm))
pigs.anew <- as.emmGrid(pigs.sav)
emmeans(pigs.anew, "source")
```

## Not run:

## Convert an entire workspace saved from an old **lsmeans** session
a.problem <- lsmeans::lsmeans(pigs.lm, "source")
#- Now global env contains at least two ref.grid and lsmobj objects,
#- and the "lsmeans" namespace is loaded
emmeans:::convert_workspace()
class(a.problem)
"lsmeans" %in% loadedNamespaces()
#- It’s all better now

## End(Not run)
Description

When a model is fitted using Markov chain Monte Carlo (MCMC) methods, its reference grid contains a post.beta slot. These functions transform those posterior samples to posterior samples of EMMs or related contrasts. They can then be summarized or plotted using, e.g., functions in the coda package.

Usage

```r
## S3 method for class 'emmGrid'
as.mcmc(x, names = TRUE, sep.chains = TRUE, likelihood,
        NE.include = FALSE, ...
)
```

```r
## S3 method for class 'emmGrid'
as.mcmc.list(x, names = TRUE, ...
)
```

Arguments

- **x**
  - An object of class emmGrid
- **names**
  - Logical scalar or vector specifying whether variable names are appended to levels in the column labels for the as.mcmc or as.mcmc.list result – e.g., column names of treat A and treat B versus just A and B. When there is more than one variable involved, the elements of names are used cyclically.
- **sep.chains**
  - Logical value. If TRUE, and there is more than one MCMC chain available, an mcmc.list object is returned by as.mcmc, with separate EMMs posteriors in each chain.
- **likelihood**
  - Character value or function. If given, simulations are made from the corresponding posterior predictive distribution. If not given, we obtain the posterior distribution of the parameters in object. See Prediction section below.
- **NE.include**
  - Logical value. If TRUE, non-estimable columns are kept but returned as columns of NA values (this may create errors or warnings in subsequent analyses using, say, coda). If FALSE, non-estimable columns are dropped, and a warning is issued. (If all are non-estimable, an error is thrown.)
- **...**
  - arguments passed to other methods

Value

An object of class mcmc or mcmc.list.
Details

When the object's post.beta slot is non-trivial, as.mcmc will return an mcmc or mcmc.list object that can be summarized or plotted using methods in the coda package. In these functions, post.beta is transformed by post-multiplying it by t(linfct), creating a sample from the posterior distribution of LS means. In as.mcmc, if sep.chains is TRUE and there is in fact more than one chain, an mcmc.list is returned with each chain's results. The as.mcmc.list method is guaranteed to return an mcmc.list, even if it comprises just one chain.

Prediction

When likelihood is specified, it is used to simulate values from the posterior predictive distribution corresponding to the given likelihood and the posterior distribution of parameter values. Denote the likelihood function as \( f(y|\theta, \phi) \), where \( y \) is a response, \( \theta \) is the parameter estimated in object, and \( \phi \) comprises zero or more additional parameters to be specified. If likelihood is a function, that function should take as its first argument a vector of \( \theta \) values (each corresponding to one row of object@grid). Any \( \phi \) values should be specified as additional named function arguments, and passed to likelihood via \( \ldots \). This function should simulate values of \( y \).

A few standard likelihoods are available by specifying likelihood as a character value. They are:
- "normal" The normal distribution with mean \( \theta \) and standard deviation specified by additional argument sigma
- "binomial" The binomial distribution with success probability theta, and number of trials specified by trials
- "poisson" The Poisson distribution with mean theta (no additional parameters)
- "gamma" The gamma distribution with scale parameter \( \theta \) and shape parameter specified by shape

Examples

```r
require("coda")

### A saved reference grid for a mixed logistic model (see lme4::cbpp)
cbpp.rg <- do.call(emmobj, 
  readRDS(system.file("extdata", "cbpplist", package = "emmeans")))
# Predictive distribution for herds of size 20
# (perhaps a bias adjustment should be applied; see "sophisticated" vignette)
pred.incidence <- as.mcmc(regrid(cbpp.rg), likelihood = "binomial", trials = 20)
```

Description

Three-factor experiment comparing pollution-filter noise for two filters, three sizes of cars, and two sides of the car.

Usage

auto.noise
Format

A data frame with 36 observations on the following 4 variables.

- **noise**: Noise level in decibels - a numeric vector.
- **size**: The size of the vehicle - an ordered factor with levels S, M, L.
- **type**: Type of anti-pollution filter - a factor with levels Std and Octel
- **side**: The side of the car where measurement was taken – a factor with levels L and R.

Details

The data are from a statement by Texaco, Inc., to the Air and Water Pollution Subcommittee of the Senate Public Works Committee on June 26, 1973. Mr. John McKinley, President of Texaco, cited an automobile filter developed by Associated Octel Company as effective in reducing pollution. However, questions had been raised about the effects of filters on vehicle performance, fuel consumption, exhaust gas back pressure, and silencing. On the last question, he referred to the data included here as evidence that the silencing properties of the Octel filter were at least equal to those of standard silencers.

Source

The dataset was obtained from the Data and Story Library (DASL) at Carnegie-Mellon University. Apparently it has since been removed. The original dataset was altered by assigning meaningful names to the factors and sorting the observations in random order as if this were the run order of the experiment.

Examples

```r
noise.lm <- lm(noise ~ size * type * side, data = auto.noise)

# Interaction plot of predictions
emmip(noise.lm, type ~ size | side)

# Confidence intervals
plot(emmeans(noise.lm, ~ size | side*type))
```

CLD  

Extract and display information on all pairwise comparisons of estimated marginal means.

Description

Extract and display information on all pairwise comparisons of estimated marginal means.
Usage

CLD(object, ...)

## S3 method for class 'emmGrid'
CLD(object, details = FALSE, sort = TRUE, by,
    alpha = 0.05, Letters = c("1234567890", LETTERS, letters),
    reversed = FALSE, ...)

cld.emmGrid(object, ...)

Arguments

object
  An object of class emmGrid

...  
  Arguments passed to contrast (for example, an adjust method)

This function uses the Piepho (2004) algorithm (as implemented in the multcompView package) to generate a compact letter display of all pairwise comparisons of estimated marginal means. The function obtains (possibly adjusted) P values for all pairwise comparisons of means, using the contrast function with method = "pairwise". When a P value exceeds alpha, then the two means have at least one letter in common.

details
  Logical value determining whether detailed information on tests of pairwise comparisons is displayed

sort
  Logical value determining whether the EMMs are sorted before the comparisons are produced. When TRUE, the results are displayed according to reversed.

by
  Character value giving the name or names of variables by which separate families of comparisons are tested. If NULL, all means are compared. If missing, the object's by.vars setting, if any, is used.

alpha
  Numeric value giving the significance level for the comparisons

Letters
  Character vector of letters to use in the display. Any strings of length greater than 1 are expanded into individual characters

reversed
  Logical value (passed to multcompView::multcompLetters.) If TRUE, the order of use of the letters is reversed. In addition, if both sort and reversed are TRUE, the sort order of results is reversed.

Value

When details == FALSE, an object of class summary.ref_grid (which inherits from data.frame) showing the summary of EMMs with an added column named .groups containing the CLD information. When details == TRUE, a list with the object just described, as well as the summary of the contrast results showing each comparison, its estimate, standard error, t ratio, and adjusted P value.

Deprecated

The CLD function and methods are deprecated. Compact-letter displays (CLDs) encourage a misleading interpretation of significance testing by visually grouping means whose comparisons have
$P > \alpha$ as though they are equal. However, failing to prove two means are different does not prove that they are the same. In addition, CLDs make a hard distinction between $P$ values nearly equal to $\alpha$ but on opposite sides.

Some users may find \texttt{pwpp} to be a useful alternative. It produces a plot showing all $P$ values for all pairwise comparisons (or other set of comparisons), and can also show one-sided $P$ values and tests of equivalence or noninferiority. Also, if you insist, \texttt{cld} is still available in the \texttt{multcomp} package, and \texttt{multcomp::cld(emm)} still works.

\begin{longtable}{ll}
\textbf{contrast} & \textit{Contrasts and linear functions of EMMs} \\
\hline
\end{longtable}

Description

These methods provide for follow-up analyses of \texttt{emmGrid} objects: Contrasts, pairwise comparisons, tests, and confidence intervals. They may also be used to compute arbitrary linear functions of predictions or EMMs.

Usage

\begin{verbatim}
contrast(object, ...) \\
## S3 method for class 'emmGrid'  
contrast(object, method = "eff", interaction = FALSE, by,  
  offset = NULL, scale = NULL, name = "contrast",  
  options = get_emm_option("contrast"), type, adjust, simple,  
  combine = FALSE, ratios = TRUE, ...)  \\
## S3 method for class 'emmGrid'  
pairs(x, reverse = FALSE, ...)  \\
## S3 method for class 'emmGrid'  
coef(object, ...) 
\end{verbatim}

Arguments

\begin{itemize}
  \item \textbf{object} An object of class \texttt{emmGrid}
  \item \textbf{...} Additional arguments passed to other methods
\end{itemize}
method Character value giving the root name of a contrast method (e.g., "pairwise" – see emmc-functions). Alternatively, a function of the same form, or a named list of coefficients (for a contrast or linear function) that must each conform to the number of results in each by group. In a multi-factor situation, the factor levels are combined and treated like a single factor.

interaction Character vector, logical value, or list. If this is specified, method is ignored. See the “Interaction contrasts” section below for details.

by Character names of variable(s) to be used for “by” groups. The contrasts or joint tests will be evaluated separately for each combination of these variables. If object was created with by groups, those are used unless overridden. Use by = NULL to use no by groups at all.

offset, scale Numeric vectors of the same length as each by group. The scale values, if supplied, multiply their respective linear estimates, and any offset values are added. Scalar values are also allowed. (These arguments are ignored when interaction is specified.)

name Character name to use to override the default label for contrasts used in table headings or subsequent contrasts of the returned object.

options If non-NULL, a named list of arguments to pass to update.emmGrid, just after the object is constructed.

type Character: prediction type (e.g., "response") – added to options

adjust Character: adjustment method (e.g., "bonferroni") – added to options

simple Character vector or list: Specify the factor(s) not in by, or a list thereof. See the section below on simple contrasts.

combine Logical value that determines what is returned when simple is a list. See the section on simple contrasts.

ratios Logical value determining how log and logit transforms are handled. These transformations are exceptional cases in that there is a valid way to back-transform contrasts: differences of logs are logs of ratios, and differences of logits are odds ratios. If ratios = TRUE and summarized with type = "response", contrast results are back-transformed to ratios whenever we have true contrasts (coefficients sum to zero). For other transformations, there is no natural way to back-transform contrasts, so even when summarized with type = "response", contrasts are computed and displayed on the linear-predictor scale. Similarly, if ratios = FALSE, log and logit transforms are treated in the same way as any other transformation.

x An emmGrid object

reverse Logical value - determines whether to use "pairwise" (if TRUE) or "revpairwise" (if FALSE).

Value

contrast and pairs return an object of class emmGrid. Its grid will correspond to the levels of the contrasts and any by variables. The exception is that an emm_list object is returned if simple is a list and complete is FALSE.

c coef returns a data.frame containing the object’s grid, along with columns named c.1, c.2, ... containing the contrast coefficients. If
Pairs method

The call `pairs(object)` is equivalent to `contrast(object, method = "pairwise")`; and `pairs(object, reverse = TRUE)` is the same as `contrast(object, method = "revpairwise")`.

Interaction contrasts

When `interaction` is specified, interaction contrasts are computed. Specifically contrasts are generated for each factor separately, one at a time; and these contrasts are applied to the object (the first time around) or to the previous result (subsequently). (Any factors specified in by are skipped.) The final result comprises contrasts of contrasts, or, equivalently, products of contrasts for the factors involved. Any named elements of interaction are assigned to contrast methods; others are assigned in order of appearance in `object@levels`. The contrast factors in the resulting `emmGrid` object are ordered the same as in `interaction`.

`interaction` may be a character vector or list of valid contrast methods (as documented for the `method` argument). If the vector or list is shorter than the number needed, it is recycled. Alternatively, if the user specifies `contrast = TRUE`, the contrast specified in `method` is used for all factors involved.

Simple contrasts

`simple` is essentially the complement of `by`: When `simple` is a character vector, `by` is set to all the factors in the grid except those in `simple`. If `simple` is a list, each element is used in turn as `simple`, and assembled in an "emm_list". To generate all simple main effects, use `simple = "each"` (this works unless there actually is a factor named "each"). Note that a non-missing `simple` will cause `by` to be ignored.

Ordinarily, when `simple` is a list or "each", the return value is an `emm_list` object with each entry in correspondence with the entries of `simple`. However, with `combine = TRUE`, the elements are all combined into one family of contrasts in a single `emmGrid` object using `rbind.emmGrid`. In that case, the `adjust` argument sets the adjustment method for the combined set of contrasts.

Note

When `object` has a nesting structure (this can be seen via `str(object)`), then any grouping factors involved are forced into service as by variables, and the contrasts are thus computed separately in each nest. This in turn may lead to an irregular grid in the returned `emmGrid` object, which may not be valid for subsequent `emmeans` calls.

Examples

```r
warp.lm <- lm(breaks ~ wool*tension, data = warpbreaks)
warp.emm <- emmeans(warp.lm, ~ tension | wool)
contrast(warp.emm, "poly")  # inherits 'by = "wool"' from warp.emm
pairs(warp.emm)  # ditto
contrast(warp.emm, "eff", by = NULL)  # contrasts of the 6 factor combs
pairs(warp.emm, simple = "wool")  # same as pairs(warp.emm, by = "tension")

# Do all "simple" comparisions, combined into one family
pairs(warp.emm, simple = "each", combine = TRUE)
```
## Not run:

## Note that the following are NOT the same:

```r
contrast(warp.emm, simple = c("wool", "tension"))
contrast(warp.emm, simple = list("wool", "tension"))
```

## The first generates contrasts for combinations of wool and tension
## (same as by = NULL)
## The second generates contrasts for wool by tension, and for
## tension by wool, respectively.

## End(Not run)

# An interaction contrast for tension:wool

```r
tw.emm <- contrast(warp.emm, interaction = c(tension = "poly", wool = "consec"),
                  by = NULL)
tw.emm  # see the estimates
coeff(tw.emm)  # see the contrast coefficients
```

# Use of scale and offset
# an unusual use of the famous stack-loss data...

```r
mod <- lm(Water.Temp ~ poly(stack.loss, degree = 2), data = stackloss)
(emm <- emmeans(mod, "stack.loss", at = list(stack.loss = 10 * (1:4))))
```

# Convert results from Celsius to Fahrenheit:

```r
confint(contrast(emm, "identity", scale = 9/5, offset = 32))
```

---

**Description**

Functions with an extension of `.emmc` provide for named contrast families. One of the standard ones documented here may be used, or the user may write such a function.

**Usage**

```r
pairwise.emmc(levs, exclude = integer(0), include, ...)
revpairwise.emmc(levs, exclude = integer(0), include, ...)
tukey.emmc(levs, reverse = FALSE, ...)
poly.emmc(levs, max.degree = min(6, k - 1), ...)
trt.vs.ctrl.emmc(levs, ref = 1, reverse = FALSE, exclude = integer(0),
                include, ...)
trt.vs.ctrl1.emmc(levs, ref = 1, ...)
```
contrast-methods

trt.vs.ctrlk.emmc(levs, ref = length(levs), ...)

dunnett.emmc(levs, ref = 1, ...)

eff.emmc(levs, exclude = integer(0), include, ...)

del.eff.emmc(levs, exclude = integer(0), include, ...)

consec.emmc(levs, reverse = FALSE, exclude = integer(0), include, ...)

mean_chg.emmc(levs, reverse = FALSE, exclude = integer(0), include, ...)

identity.emmc(levs, exclude = integer(0), include, ...)

Arguments

levs Vector of factor levels
exclude integer vector of indices, or character vector of levels to exclude from consideration. These levels will receive weight 0 in all contrasts. Character levels must exactly match elements of levs.
include integer or character vector of levels to include (the complement of exclude). An error will result if the user specifies both exclude and include.
... Additional arguments, passed to related methods as appropriate
reverse Logical value to determine the direction of comparisons
max.degree Integer specifying the maximum degree of polynomial contrasts
ref Integer(s) or character(s) specifying which level(s) to use as the reference. Character values must exactly match elements of levs.

Details

Each standard contrast family has a default multiple-testing adjustment as noted below. These adjustments are often only approximate; for a more exacting adjustment, use the interfaces provided to glht in the multcomp package.

pairwise.emmc, revpairwise.emmc, and tukey.emmc generate contrasts for all pairwise comparisons among estimated marginal means at the levels in levs. The distinction is in which direction they are subtracted. For factor levels A, B, C, D, pairwise.emmc generates the comparisons A-B, A-C, A-D, B-C, B-D, and C-D, whereas revpairwise.emmc generates B-A, C-A, C-B, D-A, D-B, and D-C. tukey.emmc invokes pairwise.emmc or revpairwise.emmc depending on reverse. The default multiplicity adjustment method is "tukey", which is only approximate when the standard errors differ.

poly.emmc generates orthogonal polynomial contrasts, assuming equally-spaced factor levels. These are derived from the poly function, but an ad hoc algorithm is used to scale them to integer coefficients that are (usually) the same as in published tables of orthogonal polynomial contrasts. The default multiplicity adjustment method is "none".

trt.vs.ctrl.emmc and its relatives generate contrasts for comparing one level (or the average over specified levels) with each of the other levels. The argument ref should be the index(es)
contrast-methods

(not the labels) of the reference level(s). \texttt{trt.vs.ctrl1.emmc} is the same as \texttt{trt.vs.ctrl.emmc} with a reference value of 1, and \texttt{trt.vs.ctrlk.emmc} is the same as \texttt{trt.vs.ctrl} with a reference value of \texttt{length(levs)}. \texttt{dunnett.emmc} is the same as \texttt{trt.vs.ctrl}. The default multiplicity adjustment method is "dunnettx", a close approximation to the Dunnett adjustment. Note in all of these functions, it is illegal to have any overlap between the \texttt{ref} levels and the \texttt{exclude} levels. If any is found, an error is thrown.

\texttt{consec.emmc} and \texttt{mean_chg.emmc} are useful for contrasting treatments that occur in sequence. For a factor with levels A, B, C, D, E, \texttt{consec.emmc} generates the comparisons B-A, C-B, and D-C, while \texttt{mean_chg.emmc} generates the contrasts (B+C+D)/3 - A, (C+D)/2 - (A+B)/2, and D - (A+B+C)/3. With \texttt{reverse = TRUE}, these differences go in the opposite direction.

\texttt{eff.emmc} and \texttt{del.eff.emmc} generate contrasts that compare each level with the average over all levels (in \texttt{eff.emmc}) or over all other levels (in \texttt{del.eff.emmc}). These differ only in how they are scaled. For a set of \texttt{k} EMMs, \texttt{del.eff.emmc} gives weight 1 to one EMM and weight -1/(k-1) to the others, while \texttt{eff.emmc} gives weights (k-1)/k and -1/k respectively, as in subtracting the overall EMM from each EMM. The default multiplicity adjustment method is "fdr". This is a Bonferroni-based method and is slightly conservative; see \texttt{p.adjust}.

\texttt{identity.emmc} simply returns the identity matrix (as a data frame), minus any columns specified in \texttt{exclude}. It is potentially useful in cases where a contrast function must be specified, but none is desired.

**Value**

A data.frame, each column containing contrast coefficients for \texttt{levs}. The "desc" attribute is used to label the results in \texttt{emmeans}, and the "adjust" attribute gives the default adjustment method for multiplicity.

**Note**

Caution is needed in cases where the user alters the ordering of results (e.g., using the the "[...]" operator), because the contrasts generated depend on the order of the levels provided. For example, suppose \texttt{trt.vs.ctrl1} contrasts are applied to two by groups with levels ordered (Ctrl, T1, T2) and (T1, T2, Ctrl) respectively, then the contrasts generated will be for (T1 - Ctrl, T2 - Ctrl) in the first group and (T2 - T1, Ctrl - T1) in the second group, because the first level in each group is used as the reference level.

**Examples**

```r
warp.lm <- lm(breaks ~ wool*tension, data = warpbreaks)
warp.emm <- emmeans(warp.lm, ~ tension | wool)
contrast(warp.emm, "poly")
contrast(warp.emm, "trt.vs.ctrl1", ref = "M")

# Compare only low and high tensions
# Note pairs(emm, ...) calls contrast(emm, "pairwise", ...)
pairs(warp.emm, exclude = 2)
# (same results using exclude = "M" or include = c("L","H") or include = c(1,3))

### Setting up a custom contrast function
helmert.emmc <- function(levs, ...) {
```
eff_size <- as.data.frame(contr.helmert(levs))
names(M) <- paste(levs[-1], "vs earlier")
attr(M, "desc") <- "Helmert contrasts"
M

contrast(warp.emm, "helmert")
## Not run:
# See what is used for polynomial contrasts with 6 levels
eff_size(poly.emmc(1:6))
## End(Not run)

---

**eff_size**

*Calculate effect sizes and confidence bounds thereof*

**Description**

Standardized effect sizes are typically calculated using pairwise differences of estimates, divided by the SD of the population providing the context for those effects. This function calculates effect sizes from an `emmGrid` object, and confidence intervals for them, accounting for uncertainty in both the estimated effects and the population SD.

**Usage**

```r
eff_size(object, sigma, edf, method = "pairwise", ...)
```

**Arguments**

- **object**: an `emmGrid` object, typically one defining the EMMs to be contrasted. If instead, `class(object)` == "emm_list", such as is produced by `emmeans(model,pairwise ~ treatment)`, a message is displayed; the contrasts already therein are used; and method is replaced by "identity".
- **sigma**: numeric scalar, value of the population SD.
- **edf**: numeric scalar that specifies the equivalent degrees of freedom for the sigma. This is a way of specifying the uncertainty in sigma, in that we regard our estimate of sigma^2 as being proportional to a chi-square random variable with edf degrees of freedom. (edf should not be confused with the df argument that may be passed via ... to specify the degrees of freedom to use in t statistics and confidence intervals.)
- **method**: the contrast method to use to define the effects. This is passed to `contrast` after the elements of object are scaled.
- **...**: Additional arguments passed to `contrast`
Details

Any by variables specified in object will remain in force in the returned effects, unless overridden in the optional arguments.

For models having a single random effect, such as those fitted using `lm`; in that case, the `stats::sigma` and `stats::df.residual` functions may be useful for specifying sigma and edf. For models with more than one random effect, sigma may be based on some combination of the random-effect variances.

Specifying edf can be rather unintuitive but is also relatively uncritical; but the smaller the value, the wider the confidence intervals for effect size. The value of $\sqrt{2/\text{edf}}$ can be interpreted as the relative accuracy of sigma; for example, with edf = 50, $\sqrt{(2/50)} = 0.2$, meaning that sigma is accurate to plus or minus 20 percent. Note in an example below, we tried two different edf values as kind of a bracketing/sensitivity-analysis strategy. A value of Inf is allowable, in which case you are assuming that sigma is known exactly. Obviously, this narrows the confidence intervals for the effect sizes – unrealistically if in fact sigma is unknown.

Value

an `emmGrid` object containing the effect sizes

Computation

This function uses calls to `regrid` to put the estimated marginal means (EMMs) on the log scale. Then an extra element is added to this grid for the log of sigma and its standard error (where we assume that sigma is uncorrelated with the log EMMs). Then a call to `contrast` subtracts log(sigma) from each of the log EMMs, yielding values of log(EMM/sigma). Finally, the results are re-gridded back to the original scale and the desired contrasts are computed using method. In the log-scaling part, we actually rescale the absolute values and keep track of the signs.

Note

The effects are always computed on the scale of the linear-predictor; any response transformation or link function is completely ignored. If you wish to base the effect sizes on the response scale, it is not enough to replace object with `regrid(object)`, because this back-transformation changes the SD required to compute effect sizes.

Disclaimer: There is substantial disagreement among practitioners on what is the appropriate sigma to use in computing effect sizes; or, indeed, whether any effect-size measure is appropriate for some situations. The user is completely responsible for specifying appropriate parameters (or for failing to do so).

Examples

```r
fiber.lm <- lm(strength ~ diameter + machine, data = fiber)
emmm <- emmeans(fiber.lm, "machine")
eff_size(emmm, sigma = sigma(fiber.lm), edf = df.residual(fiber.lm))
# or equivalently:
eff_size(pairs(emmm), sigma(fiber.lm), df.residual(fiber.lm), method = "identity")
```
### Mixed model example:

```r
if (require(nlme)) {
  Oats.lme <- lme(yield ~ Variety + factor(nitro),
                  random = ~ 1 | Block / Variety,
                  data = Oats)

  # Combine variance estimates
  VarCorr(Oats.lme)
  totSD <- sqrt(214.4724 + 109.6931 + 162.5590)
  # I figure edf is somewhere between 5 (Blocks df) and 51 (Resid df)
  emmV <- emmeans(Oats.lme, ~ Variety)
  print(eff_size(emmV, sigma = totSD, edf = 5))
  print(eff_size(emmV, sigma = totSD, edf = 51))
}
```

# Multivariate model for the same data:

```r
MOats.lm <- lm(yield ~ Variety, data = MOats)
eff_size(emmeans(MOats.lm, "Variety"),
          sigma = sqrt(mean(sigma(MOats.lm)^2)), # RMS of sigma()
          edf = df.residual(MOats.lm))
```

# These results illustrate a sobering message that effect sizes are often
# not nearly as accurate as you may think.

---

### Support for multcomp::glht

**Description**

These functions and methods provide an interface between `emmeans` and the multcomp::glht function for simultaneous inference provided by the `multcomp` package.

**Usage**

```r
emm(...)
as.glht(object, ...)
```

# S3 method for class 'emmGrid'
as.glht(object, ...)

**Arguments**

...  

In `emm`, the `specs`, `by`, and `contra` arguments you would normally supply to `emmeans`. Only `specs` is required. Otherwise, arguments that are passed to other methods.
An object of class `emmGrid` or `emm_list`.

### Details

`emm` is meant to be called only from "glht" as its second (`linfct`) argument. It works similarly to `multcomp::mcp`, except with `specs` (and optionally `by` and `contr` arguments) provided as in a call to `emmeans`.

### Value

`emm` returns an object of an intermediate class for which there is a `multcomp::glht` method.

`as.glht` returns an object of class `glht` or `glht_list` according to whether `object` is of class `emmGrid` or `emm_list`. See Details below for more on `glht_list`.

### Details

A `glht_list` object is simply a list of `glht` objects. It is created as needed – for example, when there is a `by` variable. Appropriate convenience methods `coef`, `confint`, `plot`, `summary`, and `vcov` are provided, which simply apply the corresponding `glht` methods to each member.

### Note

The multivariate-t routines used by `glht` require that all estimates in the family have the same integer degrees of freedom. In cases where that is not true, a message is displayed that shows what `df` is used. The user may override this via the `df` argument.

### Examples

```r
if(require(multcomp)) {
  # --- multcomp must be installed
  warp.lm <- lm(breaks ~ wool*tension, data = warpbreaks)

  # Using 'emm'
  summary(glht(warp.lm, emm(pairwise ~ tension | wool)))

  # Same, but using an existing 'emmeans' result
  warp.emm <- emmeans(warp.lm, ~ tension | wool)
  summary(as.glht(pairs(warp.emm)))

  # Same contrasts, but treat as one family
  summary(as.glht(pairs(warp.emm), by = NULL))
}
```

# --- was tested only if multcomp is installed
emmeans

Estimated marginal means (Least-squares means)

Description

Compute estimated marginal means (EMMs) for specified factors or factor combinations in a linear model; and optionally, comparisons or contrasts among them. EMMs are also known as least-squares means.

Usage

emmeans(object, specs, by = NULL, fac.reduce = function(coefs) apply(coefs, 2, mean), contr, options = get_emm_option("emmeans"), weights, offset, trend, ..., tran)

Arguments

object An object of class emmGrid; or a fitted model object that is supported, such as the result of a call to lm or lmer. Many fitted-model objects are supported; see vignette("models", "emmeans") for details.
specs A character vector specifying the names of the predictors over which EMMs are desired. specs may also be a formula or a list (optionally named) of valid specs. Use of formulas is described in the Overview section below.
by A character vector specifying the names of predictors to condition on.
fac.reduce A function that combines the rows of a matrix into a single vector. This implements the “marginal averaging” aspect of EMMs. The default is the mean of the rows. Typically if it is overridden, it would be some kind of weighted mean of the rows. If fac.reduce is nonlinear, bizarre results are likely, and EMMs will not be interpretable. NOTE: If the weights argument is non-missing, fac.reduce is ignored.
contr A character value or list specifying contrasts to be added. See contrast. NOTE: contr is ignored when specs is a formula.
options If non-NULL, a named list of arguments to pass to update.emmGrid, just after the object is constructed. (Options may also be included in ...)
weights Character value, numeric vector, or numeric matrix specifying weights to use in averaging predictions. See “Weights” section below.
offset Numeric vector or scalar. If specified, this adds an offset to the predictions, or overrides any offset in the model or its reference grid. If a vector of length differing from the number of rows in the result, it is subsetted or cyclically recycled.
trend This is now deprecated. Use emtrends instead.
... When object is not already a "emmGrid" object, these arguments are passed to ref_grid. Common examples are at, cov.reduce, data, codetype, transform, df, nesting, and vcov. Model-type-specific options (see vignette("models"),...
"emmeans"), commonly mode, may be used here as well. In addition, if the model formula contains references to variables that are not predictors, you must provide a params argument with a list of their names.

Arguments that could go in options may instead be included in . . . , typically, arguments such as type, infer, etc. that in essence are passed to summary.emmGrid. Arguments in both places are overridden by the ones in . . . .

There is a danger that . . . arguments could partially match those used by both ref_grid and update.emmGrid, creating a conflict. If these occur, usually they can be resolved by providing complete (or at least longer) argument names; or by isolating non-ref_grid arguments in options; or by calling ref_grid separately and passing the result as object. See a not-run example below.

**Details**

Users should also consult the documentation for ref_grid, because many important options for EMMs are implemented there, via the . . . argument.

**Value**

When specs is a character vector or one-sided formula, an object of class "emmGrid". A number of methods are provided for further analysis, including summary.emmGrid, confint.emmGrid, test.emmGrid, contrast.emmGrid, pairs.emmGrid, and CLD.emmGrid. When specs is a list or a formula having a left-hand side, the return value is an emm_list object, which is simply a list of emmGrid objects.

**Overview**

Estimated marginal means or EMMs (sometimes called least-squares means) are predictions from a linear model over a reference grid; or marginal averages thereof. The ref_grid function identifies/creates the reference grid upon which emmeans is based.

For those who prefer the terms “least-squares means” or “predicted marginal means”, functions lsmeans and pmmeans are provided as wrappers. See wrappers.

If specs is a formula, it should be of the form ~ specs, ~ specs | by, contr ~ specs, or contr ~ specs | by. The formula is parsed and the variables therein are used as the arguments specs, by, and contr as indicated. The left-hand side is optional, but if specified it should be the name of a contrast family (e.g., pairwise). Operators like * or : are needed in the formula to delineate names, but otherwise are ignored.

In the special case where the mean (or weighted mean) of all the predictions is desired, specify specs as ~ 1 or "1".

A number of standard contrast families are provided. They can be identified as functions having names ending in .emmc – see the documentation for emmc-functions for details – including how to write your own .emmc function for custom contrasts.
Weights

If `weights` is a vector, its length must equal the number of predictions to be averaged to obtain each EMM. If a matrix, each row of the matrix is used in turn, wrapping back to the first row as needed. When in doubt about what is being averaged (or how many), first call `emmeans` with `weights = "show.levels"`.

If `weights` is a string, it should partially match one of the following:

- "equal" Use an equally weighted average.
- "proportional" Weight in proportion to the frequencies (in the original data) of the factor combinations that are averaged over.
- "outer" Weight in proportion to each individual factor’s marginal frequencies. Thus, the weights for a combination of factors are the outer product of the one-factor margins.
- "cells" Weight according to the frequencies of the cells being averaged.
- "flat" Give equal weight to all cells with data, and ignore empty cells.
- "show.levels" This is a convenience feature for understanding what is being averaged over. Instead of a table of EMMs, this causes the function to return a table showing the levels that are averaged over, in the order that they appear.

Outer weights are like the 'expected' counts in a chi-square test of independence, and will yield the same results as those obtained by proportional averaging with one factor at a time. All except "cells" uses the same set of weights for each mean. In a model where the predicted values are the cell means, cell weights will yield the raw averages of the data for the factors involved. Using "flat" is similar to "cells", except nonempty cells are weighted equally and empty cells are ignored.

Offsets

Unlike in `ref_grid`, an offset need not be scalar. If not enough values are supplied, they are cyclically recycled. For a vector of offsets, it is important to understand that the ordering of results goes with the first name in `specs` varying fastest. If there are any by factors, those vary slower than all the primary ones, but the first by variable varies the fastest within that hierarchy. See the examples.

See Also

`ref_grid, contrast, vignette("models", "emmeans")`

Examples

```r
warp.lm <- lm(breaks ~ wool * tension, data = warpbreaks)
emmeans (warp.lm, ~ wool | tension)
  # or equivalently emmeans(warp.lm, "wool", by = "tension")
emmeans (warp.lm, poly ~ tension | wool)

## Not run:
### Offsets: Consider a silly example:
  emmeans(warp.lm, ~ tension | wool, offset = c(17, 23, 47)) @ grid
```
# note that offsets are recycled so that each level of tension receives
# the same offset for each wool.
# But using the same offsets with ~ wool | tension will probably not
# be what you want because the ordering of combinations is different.

### Conflicting arguments...
# This will error because 'tran' is passed to both ref_grid and update
emmeans(some.model, "treatment", tran = "log", type = "response")

# Use this if the response was a variable that is the log of some other variable
# (Keep 'tran' from being passed to ref_grid)
emmeans(some.model, "treatment", options = list(tran = "log"), type = "response")

# This will re-grid the result as if the response had been log-transformed
# ('transform' is passed only to ref_grid, not to update)
emmeans(some.model, "treatment", transform = "log", type = "response")

## End(Not run)

### Description

The emmGrid class encapsulates linear functions of regression parameters, defined over a grid of predictors. This includes reference grids and grids of marginal means thereof (aka estimated marginal means). Objects of class 'emmGrid' may be used independently of the underlying model object. Instances are created primarily by ref_grid and emmeans, and several related functions.

### Slots

- **model.info** list. Contains the elements call (the call that produced the model), terms (its terms object), and xlev (factor-level information).
- **roles** list. Contains at least the elements predictors, responses, and multresp. Each is a character vector of names of these variables.
- **grid** data.frame. Contains the combinations of the variables that define the reference grid. In addition, there is an auxiliary column named ".wgt." holding the observed frequencies or weights for each factor combination (excluding covariates). If the model has one or more offset() calls, there is an another auxiliary column named ".offset.". Auxiliary columns are not considered part of the reference grid. (However, any variables included in offset calls are in the reference grid.)
- **levels** list. Each entry is a character vector with the distinct levels of each variable in the reference grid. Note that grid is obtained by applying the function expand.grid to this list.
- **matlevs** list. Like levels but has the levels of any matrices in the original dataset. Matrix columns are always concatenated and treated as a single variable for purposes of the reference grid.
- **linfct** matrix. Each row consists of the linear function of the regression coefficients for predicting its corresponding element of the reference grid. The rows of this matrix go in one-to-one correspondence with the rows of grid, and the columns with elements of bhat.
bhat numeric. The regression coefficients. If there is a multivariate response, the matrix of coefficients is flattened to a single vector, and linfct and V redefined appropriately. Important: bhat must include any NA values produced as a result of collinearity in the predictors. These are taken care of later in the estimability check.

nbasis matrix. The basis for the non-estimable functions of the regression coefficients. Every EMM will correspond to a linear combination of rows of linfct, and that result must be orthogonal to all the columns of nbasis in order to be estimable. If everything is estimable, nbasis should be a 1 x 1 matrix of NA.

V matrix. The symmetric variance-covariance matrix of bhat
dffun function having two arguments. dffun(k, dfargs) should return the degrees of freedom for the linear function sum(k*bhat), or NA if unavailable
dfargs list. Used to hold any additional information needed by dffun.
misc list. Additional information used by methods. These include at least the following: estName (the label for the estimates of linear functions), and the default values of infer, level, and adjust to be used in the summary.emmGrid method. Elements in this slot may be modified if desired using the update.emmGrid method.

post.beta matrix. A sample from the posterior distribution of the regression coefficients, if MCMC methods were used; or a 1 x 1 matrix of NA otherwise. When it is non-trivial, the as.mcmc.emmGrid method returns post.beta %*% t(linfct), which is a sample from the posterior distribution of the EMMs.

Methods

All methods for these objects are S3 methods except for show. They include [.emmGrid, as.glht.emmGrid, as.mcmc.emmGrid, as.mcmc.list.emmGrid (see coda), cld.emmGrid (see multcomp), coef.emmGrid, confint.emmGrid, contrast.emmGrid, pairs.emmGrid, plot.emmGrid, predict.emmGrid, print.emmGrid, rbind.emmGrid, show.emmGrid, str.emmGrid, summary.emmGrid, test.emmGrid, update.emmGrid, vcov.emmGrid, and xtable.emmGrid

---

emnip

Interaction-style plots for estimated marginal means

description

Creates an interaction plot of EMMs based on a fitted model and a simple formula specification.

usage

emnip(object, formula, ...)
Arguments

object  An object of class emmGrid, or a fitted model of a class supported by the emmeans package.

formula  Formula of the form trace.factors ~ x.factors | by.factors. The EMMs are plotted against x.factor for each level of trace.factors. by.factors is optional, but if present, it determines separate panels. Each element of this formula may be a single factor in the model, or a combination of factors using the * operator.

Additional arguments passed to emmeans (when object is not already an emmGrid object), predict.emmGrid, ggplot, or xyplot.

type  As in predict.emmGrid, this determines whether we want to inverse-transform the predictions (type = "response") or not (any other choice). The default is "link", unless the "predict.type" option is in force; see emm_options.

CIs  Logical value. If TRUE, confidence intervals (or HPD intervals for Bayesian models) are added to the plot (works only with engine = "ggplot").

PIs  Logical value. If TRUE, prediction intervals are added to the plot (works only with engine = "ggplot"). If both CIs and CIs are TRUE, the prediction intervals will be somewhat longer, lighter, and thinner than the confidence intervals. Additional parameters to predict.emmGrid (e.g., sigma) may be passed via .... For Bayesian models, PIs require frequentist = TRUE and a value for sigma.

style  Optional character value. This has an effect only when the horizontal variable is a single numeric variable. If style is unspecified or "numeric", the horizontal scale will be numeric and curves are plotted using lines (and no symbols). With style = "factor", the horizontal variable is treated as the levels of a factor (equally spaced along the horizontal scale), and curves are plotted using lines and symbols. When the horizontal variable is character or factor, or a combination of more than one predictor, "factor" style is always used.

engine  Character value matching "ggplot" (default) or "lattice". The graphics engine to be used to produce the plot. These require, respectively, the ggplot2 or lattice package to be installed.

pch  The plotting characters to use for each group (i.e., levels of trace.factors). They are recycled as needed.

lty  The line types to use for each group. Recycled as needed.

col  The colors to use for each group, recycled as needed. If not specified, the default trellis colors are used.

plotit  Logical value. If TRUE, a graphical object is returned; if FALSE, a data.frame is returned containing all the values used to construct the plot.

nesting.order  Logical value. If TRUE, factors that are nested are presented in order according to their nesting factors, even if those nesting factors are not present in formula. If FALSE, only the variables in formula are used to order the variables.

Value

If plotit = FALSE, a data.frame (actually, a summary_emm object) with the table of EMMs that would be plotted. The variables plotted are named xvar and yvar, and the trace factor is named
This data frame has an added "labs" attribute containing the labels `xlab`, `ylab`, and `tlab` for these respective variables. The confidence limits are also included, renamed `LCL` and `UCL`.

If `plotit = TRUE`, the function returns an object of class "ggplot" or a "trellis", depending on engine.

### Details

If `object` is a fitted model, `emmeans` is called with an appropriate specification to obtain estimated marginal means for each combination of the factors present in `formula` (in addition, any arguments in `...` that match `at`, `trend`, `cov.reduce`, or `fac.reduce` are passed to `emmeans`). Otherwise, if `object` is an `emmGrid` object, its first element is used, and it must contain one estimate for each combination of the factors present in `formula`.

### Note

Conceptually, this function is equivalent to `interaction.plot` where the summarization function is thought to return the EMMs.

### See Also

`emmeans`, `interaction.plot`.

### Examples

```r
#--- Three-factor example
noise.lm = lm(noise ~ size * type * side, data = auto.noise)

# Separate interaction plots of size by type, for each side
emmip(noise.lm, type ~ size | side)

# One interaction plot, using combinations of size and side as the x factor
# ... with added confidence intervals
emmip(noise.lm, type ~ side * size, CIs = TRUE)

# One interaction plot using combinations of type and side as the trace factor
emmip(noise.lm, type * side ~ size)

# Individual traces in panels
emmip(noise.lm, ~ size | type * side)

# Example for the 'style' argument
fib.lm = lm(strength ~ machine * sqrt(diameter), data = fiber)
fib.rg = ref_grid(fib.lm, at = list(diameter = c(3.5, 4, 4.5, 5, 5.5, 6)^2))
emmip(fib.rg, machine ~ diameter)  # curves (because diameter is numeric)
emmip(fib.rg, machine ~ diameter, style = "factor")  # points and lines

# For an example using extra ggplot2 code, see 'vignette("messy-data")',
# in the section on nested models.
```

---

emnip

27
Construct an \texttt{emmGrid} object from scratch

**Description**

This allows the user to incorporate results obtained by some analysis into an \texttt{emmGrid} object, enabling the use of \texttt{emmGrid} methods to perform related follow-up analyses.

**Usage**

\begin{verbatim}
emmobj(bhat, V, levels, linfct, df = NA, dffun, dfargs = list(),
       post.beta = matrix(NA), ...)
\end{verbatim}

**Arguments**

- **bhat**: Numeric. Vector of regression coefficients
- **V**: Square matrix. Covariance matrix of \texttt{bhat}
- **levels**: Named list or vector. Levels of factor(s) that define the estimates defined by \texttt{linfct}. If not a list, we assume one factor named "level"
- **linfct**: Matrix. Linear functions of \texttt{bhat} for each combination of \texttt{levels}.
- **df**: Numeric value or function with arguments (\texttt{x,dfargs}). If a number, that is used for the degrees of freedom. If a function, it should return the degrees of freedom for \texttt{sum(x*bhat)}, with any additional parameters in \texttt{dfargs}.
- **dffun**: Overrides \texttt{df} if specified. This is a convenience to match the slot names of the returned object.
- **dfargs**: List containing arguments for \texttt{df}. This is ignored if \texttt{df} is numeric.
- **post.beta**: Matrix whose columns comprise a sample from the posterior distribution of the regression coefficients (so that typically, the column averages will be \texttt{bhat}). A 1 x 1 matrix of \texttt{NA} indicates that such a sample is unavailable.
- **...**: Arguments passed to \texttt{update.emmGrid}

**Details**

The arguments must be conformable. This includes that the length of \texttt{bhat}, the number of columns of \texttt{linfct}, and the number of columns of \texttt{post.beta} must all be equal. And that the product of lengths in \texttt{levels} must be equal to the number of rows of \texttt{linfct}. The grid slot of the returned object is generated by \texttt{expand.grid} using \texttt{levels} as its arguments. So the rows of \texttt{linfct} should be in corresponding order.

The functions \texttt{qdrg} and \texttt{emmobj} are close cousins, in that they both produce \texttt{emmGrid} objects. When starting with summary statistics for an existing grid, \texttt{emmobj} is more useful, while \texttt{qdrg} is more useful when starting from an unsupported fitted model.

**Value**

An \texttt{emmGrid} object
See Also

qdrg, an alternative that is useful when starting with a fitted model not supported in emmeans.

Examples

# Given summary statistics for 4 cells in a 2 x 2 layout, obtain
# marginal means and comparisons thereof. Assume heteroscedasticity
# and use the Satterthwaite method
levels <- list(trt = c("A", "B"), dose = c("high", "low"));
ybar <- c(57.6, 43.2, 88.9, 69.8);
s <- c(12.1, 19.5, 22.8, 43.2);
n <- c(44, 11, 37, 24);
se2 = s^2 / n;
Satt.df <- function(x, dfargs) {
  sum(x * dfargs$v)^2 / sum((x * dfargs$v)^2 / (dfargs$n - 1))
}
expt.rg <- emmobj(bhat = ybar, V = diag(se2),
  levels = levels, linfct = diag(c(1, 1, 1, 1)),
  df = Satt.df, dfargs = list(v = se2, n = n), estName = "mean")
plot(expt.rg)
(trt.emm <- emmeans(expt.rg, "trt") )
(dose.emm <- emmeans(expt.rg, "dose") )
rbind(pairs(trt.emm), pairs(dose.emm), adjust = "mvt")
**emmm_options**

Set or change emmeans options

**Description**

Use `emmm_options` to set or change various options that are used in the *emmeans* package. These options are set separately for different contexts in which `emmGrid` objects are created, in a named list of option lists.

**Usage**

```r
emmm_options(...)

get_emmm_option(x, default = emmm_defaults[[x]])

emmm_defaults
```

**Arguments**

- `...` Option names and values (see Details)
- `x` Character value - the name of an option to be queried
- `default` Value to return if `x` is not found

**Format**

An object of class `list` of length 17.

**Details**

Currently, the following main list entries are supported:

- `ref_grid` A named list of defaults for objects created by `ref_grid`. This could affect other objects as well. For example, if *emmeans* is called with a fitted model object, it calls `ref_grid` and this option will affect the resulting `emmGrid` object.

- `emmmmeans` A named list of defaults for objects created by *emmeans* or `emtrends`.

- `contrast` A named list of defaults for objects created by `contrast.emmGrid` or `pairs.emmGrid`.

- `summary` A named list of defaults used by the methods `summary.emmGrid`, `predict.emmGrid`, `test.emmGrid`, `confint.emmGrid`, and `emmip`. The only option that can affect the latter four is "predict.method".

- `cov.keep` The default value of `cov.keep` in `ref_grid`. Defaults to "2", i.e., two-level covariates are treated like factors.

- `graphics.engine` A character value matching c("ggplot","lattice"), setting the default engine to use in `emmip` and `plot.emmGrid`. Defaults to "ggplot".

- `msg.interaction` A logical value controlling whether or not a message is displayed when `emmeans` averages over a factor involved in an interaction. It is probably not appropriate to do this, unless the interaction is weak. Defaults to TRUE.
msg.nesting  A logical value controlling whether or not to display a message when a nesting structure is auto-detected. The existence of such a structure affects computations of EMMs. Sometimes, a nesting structure is falsely detected – namely when a user has omitted some main effects but included them in interactions. This does not change the model fit, but it produces a different parameterization that is picked up when the reference grid is constructed. Defaults to TRUE.

simplify.names  A logical value controlling whether to simplify (when possible) names in the model formula that refer to datasets – for example, should we simplify a predictor name like “data$trt” to just “trt”? Defaults to TRUE.

opt.digits  A logical value controlling the precision with which summaries are printed. If TRUE (default), the number of digits displayed is just enough to reasonably distinguish estimates from the ends of their confidence intervals; but always at least 3 digits. If FALSE, the system value getOption("digits") is used.

back.bias.adj  A logical value controlling whether we try to adjust bias when back-transforming. If FALSE, we use naive back transformation. If TRUE and sigma is available, a second-order adjustment is applied to estimate the mean on the response scale.

Some other options have more specific purposes:

estble.tol  Tolerance for determining estimability in rank-deficient cases. If absent, the value in emm_defaults$estble.tol is used.

save.ref_grid  Logical value of TRUE if you wish the latest reference grid created to be saved in .Last.ref_grid

Options for lme4::lmerMod models  Options lmer.df, disable.pbkrtest, pbkrtest.limit, disable.lmerTest, and lmerTest.limit options affect how degrees of freedom are computed for lmerMod objects produced by the lme4 package). See that section of the "models" vignette for details.

Value

emm_options returns the current options (same as the result of 'getOption("emmeans")') – invisibly, unless called with no arguments.

get_emm_option returns the currently stored option for x, or its default value if not found.

update.emmGrid

Examples

```r
## Not run:
emm_options(ref_grid = list(level = .90),
  contrast = list(infer = c(TRUE,FALSE)),
  estble.tol = 1e-6)
# Sets default confidence level to .90 for objects created by ref.grid
# AS WELL AS emmeans called with a model object (since it creates a
# reference grid). In addition, when we call 'contrast', 'pairs', etc.,
# confidence intervals rather than tests are displayed by default.

## End(Not run)
```
## Not run:
emtrends(disable.pbkrtest = TRUE)
# This forces use of asymptotic methods for lmerMod objects.
# Set to FALSE or NULL to re-enable using pbkrtest.

## End(Not run)

# See tolerance being used for determining estimability
get_emm_option("estble.tol")

### Description

The `emtrends` function is useful when a fitted model involves a numerical predictor `x` interacting with another predictor `a` (typically a factor). Such models specify that `x` has a different trend depending on `a`; thus, it may be of interest to estimate and compare those trends. Analogous to the `emmeans` setting, we construct a reference grid of these predicted trends, and then possibly average them over some of the predictors in the grid.

### Usage

```r
emtrends(object, specs, var, delta.var = 0.001 * rng, max.degree = 1, ...)
```

### Arguments

- **object**: A supported model object (*not* a reference grid)
- **specs**: Specifications for what marginal trends are desired – as in `emmeans`. If specs is missing or NULL, `emmeans` is not run and the reference grid for specified trends is returned.
- **var**: Character value giving the name of a variable with respect to which a difference quotient of the linear predictors is computed. In order for this to be useful, `var` should be a numeric predictor that interacts with at least one factor in specs. Then instead of computing EMMs, we compute and compare the slopes of the `var` trend over levels of the specified other predictor(s). As in EMMs, marginal averages are computed for the predictors in specs and by. See also the “Generalizations” section below.
- **delta.var**: The value of `h` to use in forming the difference quotient `(f(x + h) - f(x))/h`. Changing it (especially changing its sign) may be necessary to avoid numerical problems such as logs of negative numbers. The default value is 1/1000 of the range of `var` over the dataset.
- **max.degree**: Integer value. The maximum degree of trends to compute (this is capped at 5). If greater than 1, an additional factor degree is added to the grid, with corresponding numerical derivatives of orders 1, 2, ... `max.degree` as the estimates.
Additional arguments passed to `ref_grid` or `emmeans` as appropriate. See Details.

**Details**

The function works by constructing reference grids for `object` with various values of `var`, and then calculating difference quotients of predictions from those reference grids. Finally, `emmeans` is called with the given specs, thus computing marginal averages as needed of the difference quotients. Any ... arguments are passed to the `ref_grid` and `emmeans`; examples of such optional arguments include optional arguments (often `mode`) that apply to specific models; `ref_grid` options such as `data`, `at`, `cov.reduce`, `mult.names`, `nesting`, or `transform`; and `emmeans` options such as `weights` (but please avoid `trend` or `offset`.

**Value**

An `emmGrid` or `emm_list` object, according to specs. See `emmeans` for more details on when a list is returned.

**Generalizations**

Instead of a single predictor, the user may specify some monotone function of one variable, e.g., `var = "log(dose)"`. If so, the chain rule is applied. Note that, in this example, if `object` contains `log(dose)` as a predictor, we will be comparing the slopes estimated by that model, whereas specifying `var = "dose"` would perform a transformation of those slopes, making the predicted trends vary depending on `dose`.

**Note**

In earlier versions of `emtrends`, the first argument was named `model` rather than `object`. (The name was changed because of potential mis-matching with a `mode` argument, which is an option for several types of models.) For backward compatibility, `model` still works provided all arguments are named.

It is important to understand that trends computed by `emtrends` are not equivalent to polynomial contrasts in a parallel model where `var` is regarded as a factor. That is because the model object here is assumed to fit a smooth function of `var`, and the estimated trends reflect local behavior at particular value(s) of `var`; whereas when `var` is modeled as a factor and polynomial contrasts are computed, those contrasts represent the global pattern of changes over all levels of `var`.

See the `pigs.poly` and `pigs.fact` examples below for an illustration. The linear and quadratic trends depend on the value of `percent`, but the cubic trend is constant (because that is true of a cubic polynomial, which is the underlying model). The cubic contrast in the factorial model has the same P value as for the cubic trend, again because the cubic trend is the same everywhere.

`link(emmeans), ref_grid`
Examples

```r
fiber.lm <- lm(strength ~ diameter*machine, data=fiber)
# Obtain slopes for each machine ...
(fiber.emt <- emtrends(fiber.lm, "machine", var = "diameter") )
# ... and pairwise comparisons thereof
pairs(fiber.emt)

# Suppose we want trends relative to sqrt(diameter)...
emtrends(fiber.lm, - machine | diameter, var = "sqrt(diameter)",
        at = list(diameter = c(20, 30)))

# Obtaining a reference grid
mtcars.lm <- lm(mpg ~ poly(disp, degree = 2) * (factor(cyl) + factor(am)), data = mtcars)

# Center trends at mean disp for each no. of cylinders
mtcTrends.rg <- emtrends(mtcars.lm, var = "disp",
                          cov.reduce = disp ~ factor(cyl))
summary(mtcTrends.rg)  # estimated trends at grid nodes
emmeans(mtcTrends.rg, "am", weights = "prop")

### Higher-degree trends ...
pigs.poly <- lm(conc ~ poly(percent, degree = 3), data = pigs)
emt <- emtrends(pigs.poly, ~ degree | percent, "percent", max.degree = 3,
               at = list(percent = c(9, 13.5, 18))
        # note: 'degree' is an extra factor created by 'emtrends'
summary(emt, infer = c(TRUE, TRUE))

# Compare above results with poly contrasts when 'percent' is modeled as a factor ...
pigs.fact <- lm(conc ~ factor(percent), data = pigs)
emm <- emmeans(pigs.fact, "percent")
contrast(emm, "poly")
# Some P values are comparable, some aren't! See Note in documentation
```

---

**extending-emmeans**

**Support functions for model extensions**

**Description**

This documents the methods that `ref_grid` calls. A user or package developer may add `emmeans` support for a model class by writing `recover_data` and `emm_basis` methods for that class. (Users in need for a quick way to obtain results for a model that is not supported may be better served by the `qdrg` function.)
Usage

recover_data(object, ...)

## S3 method for class 'call'
recover_data(object, trms, na.action, data = NULL, params = "pi", ...)

emmeans(object, trms, xlev, grid, ...)

.emm_register(classes, pkgname)

Arguments

object 
An object of the same class as is supported by a new method.

... 
Additional parameters that may be supported by the method.

trms 
The terms component of object (typically with the response deleted, e.g. via delete.response)

na.action 
Integer vector of indices of observations to ignore; or NULL if none

data 
Data frame. Usually, this is NULL. However, if non-null, this is used in place of the reconstructed dataset. It must have all of the predictors used in the model, and any factor levels must match those used in fitting the model.

params 
Character vector giving the names of any variables in the model formula that are not predictors. For example, a spline model may involve a local variable knots that is not a predictor, but its value is needed to fit the model. Names of parameters not actually used are harmless, and the default value "pi" (the only numeric constant in base R) is provided in case the model involves it. An example involving splines may be found at https://github.com/rvlenth/emmeans/issues/180.

xlev 
Named list of factor levels (excluding ones coerced to factors in the model formula)

grid 
A data.frame (provided by ref_grid) containing the predictor settings needed in the reference grid

classes 
Character names of one or more classes to be registered. The package must contain the functions recover_data.foo and emm_basis.foo for each class foo listed in classes.

pkgname 
Character name of package providing the methods (usually should be the second argument of .onLoad)

Value

The recover_data method must return a data.frame containing all the variables that appear as predictors in the model, and attributes "call", "terms", "predictors", and "responses". (recover_data.call will provide these attributes.)
The `emm_basis` method should return a list with the following elements:

- **X** The matrix of linear functions over `grid`, having the same number of rows as `grid` and the number of columns equal to the length of `bhat`.
- **bhat** The vector of regression coefficients for fixed effects. This should include any NAs that result from rank deficiencies.
- **nbasis** A matrix whose columns form a basis for non-estimable functions of beta, or a 1x1 matrix of NA if there is no rank deficiency.
- **V** The estimated covariance matrix of `bhat`.
- **dffun** A function of \((k, dfargs)\) that returns the degrees of freedom associated with \(\text{sum}(k \times \text{bhat})\).
- **dfargs** A list containing additional arguments needed for `dffun`.

`.recover_data` and `.emm_basis` are hidden exported versions of `recover_data` and `emm_basis`, respectively. They run in `emmeans`'s namespace, thus providing access to all existing methods.

**Details**

To create a reference grid, the `ref_grid` function needs to reconstruct the data used in fitting the model, and then obtain a matrix of linear functions of the regression coefficients for a given grid of predictor values. These tasks are performed by calls to `recover_data` and `emm_basis` respectively. A vignette giving details and examples is available via `vignette("xtending","emmeans")`.

To extend `emmeans`'s support to additional model types, one need only write S3 methods for these two functions. The existing methods serve as helpful guidance for writing new ones. Most of the work for `recover_data` can be done by its method for class "call", providing the terms component and `na.action` data as additional arguments. Writing an `emm_basis` method is more involved, but the existing methods (e.g., `emmeans:::emm_basis.lm`) can serve as models. Certain `recover_data` and `emm_basis` methods are exported from `emmeans`. (To find out, do `methods("recover_data")`.) If your object is based on another model-fitting object, it may be that all that is needed is to call one of these exported methods and perhaps make modifications to the results. Contact the developer if you need others of these exported.

If the model has a multivariate response, `bhat` needs to be “flattened” into a single vector, and `X` and `V` must be constructed consistently.

In models where a non-full-rank result is possible (often, you can tell by seeing if there is a `singular.ok` argument in the model-fitting function), `summary.emmGrid` and its relatives check the estimability of each prediction, using the `nonest.basis` function in the `estimability` package.

The models already supported are detailed in the "models" vignette. Some packages may provide additional `emmeans` support for its object classes.

**Communication between methods**

If the `recover_data` method generates information needed by `emm_basis`, that information may be incorporated by creating a “misc” attribute in the returned recovered data. That information is then passed as the `misc` argument when `ref_grid` calls `emm_basis`.
Optional hooks

Some models may need something other than standard linear estimates and standard errors. If so, custom functions may be pointed to via the items misc$estHook, misc$vcovHook and misc$postGridHook. If just the name of the hook function is provided as a character string, then it is retrieved using get.

The estHook function should have arguments ‘(object, do.se, tol,...)’ where object is the emmGrid object, do.se is a logical flag for whether to return the standard error, and tol is the tolerance for assessing estimability. It should return a matrix with 3 columns: the estimates, standard errors (NA when do.se==FALSE), and degrees of freedom (NA for asymptotic). The number of rows should be the same as ‘object@linfct’. The vcovHook function should have arguments ‘(object, tol,...)’ as described. It should return the covariance matrix for the estimates. Finally, postGridHook, if present, is called at the very end of ref_grid; it takes one argument, the constructed object, and should return a suitably modified emmGrid object.

Registering S3 methods for a model class

The .emm_register function is provided as a convenience to conditionally register your S3 methods for a model class, recover_data.foo and emm_basis.foo, where foo is the class name. Your package should implement an .onLoad function and call .emm_register if emmeans is installed. See the example.

Note

Without an explicit data argument, recover_data returns the current version of the dataset. If the dataset has changed since the model was fitted, then this will not be the data used to fit the model. It is especially important to know this in simulation studies where the data are randomly generated or permuted, and in cases where several datasets are processed in one step (e.g., using dplyr). In those cases, users should be careful to provide the actual data used to fit the model in the data argument.

Vignette on extending emmeans

Examples

```r
## Not run:
#--- If your package provides recover_data and emm_grid methods for class 'mymod',
#--- put something like this in your package code -- say in zzz.R:
.onLoad = function(libname, pkname) {
  if (requireNamespace("emmeans", quietly = TRUE))
    emmeans::.emm_register("mymod", pkname)
}
## End(Not run)
```
**Description**

This is an unbalanced analysis-of-covariance example, where one covariate is affected by a factor. Feeder calves from various herds enter a feedlot, where they are fed one of three diets. The weight of the animal at entry is the covariate, and the weight at slaughter is the response.

**Usage**

```r
feedlot
```

**Format**

A data frame with 67 observations and 4 variables:

- `herd` a factor with levels 9 16 3 32 24 31 19 36 34 35 33, designating the herd that a feeder calf came from.
- `diet` a factor with levels Low Medium High: the energy level of the diet given the animal.
- `swt` a numeric vector: the weight of the animal at slaughter.
- `ewt` a numeric vector: the weight of the animal at entry to the feedlot.

**Details**

The data arise from a Western Regional Research Project conducted at New Mexico State University. Calves born in 1975 in commercial herds entered a feedlot as yearlings. Both diets and herds are of interest as factors. The covariate, ewt, is thought to be dependent on herd due to different genetic backgrounds, breeding history, etc. The levels of herd ordered to similarity of genetic background.

Note: There are some empty cells in the cross-classification of herd and diet.

**Source**

**Examples**

```r
feedlot.lm <- lm(swt ~ ewt + herd*diet, data = feedlot)
# Obtain EMMs with a separate reference value of ewt for each herd. This reproduces the last part of Table 2 in the reference
emmeans(feedlot.lm, ~ diet | herd, cov.reduce = ewt ~ herd)
```
Description

Fiber data from Montgomery Design (8th ed.), p.656 (Table 15.10). Useful as a simple analysis-of-covariance example.

Usage

fiber

Format

A data frame with 15 observations and 3 variables:

- machine a factor with levels A B C. This is the primary factor of interest.
- strength a numeric vector. The response variable.
- diameter a numeric vector. A covariate.

Details

The goal of the experiment is to compare the mean breaking strength of fibers produced by the three machines. When testing this, the technician also measured the diameter of each fiber, and this measurement may be used as a concomitant variable to improve precision of the estimates.

Source

Examples

```r
fiber.lm <- lm(strength ~ diameter + machine, data=fiber)
ref_grid(fiber.lm)
```

# Covariate-adjusted means and comparisons
```
emmeans(fiber.lm, pairwise ~ machine)
```
hpd.summary

Summarize an emmGrid from a Bayesian model

Description

This function computes point estimates and HPD intervals for each factor combination in object@emmGrid. While this function may be called independently, it is called automatically by the S3 method summary.emmGrid when the object is based on a Bayesian model. (Note: the level argument, or its default, is passed as prob).

Usage

hpd.summary(object, prob, by, type, point.est = median, bias.adjust = get_emm_option("back.bias.adj"), sigma, ...)

Arguments

object an emmGrid object having a non-missing post.beta slot
prob numeric probability content for HPD intervals (note: when not specified, the current level option is used; see emm_options)
by factors to use as by variables
type prediction type as in summary.emmGrid
point.est function to use to compute the point estimates from the posterior sample for each grid point
bias.adjust Logical value for whether to adjust for bias in back-transforming (type = "response"). This requires a value of sigma to exist in the object or be specified.
sigma Error SD assumed for bias correction (when type = "response"). If not specified, object@misc$sigma is used, and an error is thrown if it is not found. Note: sigma may be a vector, as long as it conforms to the number of observations in the posterior sample.
...
required but not used

Value

an object of class summary_emm

See Also

summary.emmGrid
**Examples**

```r
if(require("coda")) {
  # Create an emmGrid object from a system file
  cbpp.rg <- do.call(emmobj,
                     readRDS(system.file("extdata", "cbpplist", package = "emmeans")))
  hpd.summary(emmeans(cbpp.rg, "period"))
}
```

**Description**

This function produces an analysis-of-variance-like table based on linear functions of predictors in a model or emmGrid object. Specifically, the function constructs, for each combination of factors (or covariates reduced to two or more levels), a set of (interaction) contrasts via `contrast`, and then tests them using `test` with `joint = TRUE`. Optionally, one or more of the predictors may be used as by variable(s), so that separate tables of tests are produced for each combination of them.

**Usage**

```r
joint_tests(object, by = NULL, show0df = FALSE, ...)
```

**Arguments**

- `object`: a fitted model or an emmGrid. If a fitted model, it is replaced by `ref_grid(object, cov.reduce = range,...)`
- `by`: character names of by variables. Separate sets of tests are run for each combination of these.
- `show0df`: logical value; if TRUE, results with zero numerator degrees of freedom are displayed, if FALSE they are skipped
- `...`: additional arguments passed to `ref_grid` and `emmeans`

**Details**

In models with only factors, no covariates, we believe these tests correspond to “type III” tests a la SAS, as long as equal-weighted averaging is used and there are no estimability issues. When covariates are present and interact with factors, the results depend on how the covariate is handled in constructing the reference grid. See the example at the end of this documentation. The point that one must always remember is that `joint_tests` always tests contrasts among EMMs, in the context of the reference grid, whereas type III tests are tests of model coefficients – which may or may not have anything to do with EMMs or contrasts.

**Value**

a summary_emm object (same as is produced by `summary.emmGrid`). All effects for which there are no estimable contrasts are omitted from the results.

```

---

**lsmeans**

Wrappers for alternative naming of EMMs

Description

These are wrappers for `emmeans` and related functions to provide backward compatibility, or for users who may prefer to use other terminology than "estimated marginal means" – namely "least-squares means" or "predicted marginal means".
lsmeans

Usage

lsmeans(...)
pmmeans(...)
lstrends(...)
pmtrends(...)
lsmip(...)
pmmip(...)
lsm(...)
pmm(...)
lsmobj(...)
pmmobj(...)
lsm.options(...)
get.lsm.option(x, default = emm_defaults[[x]])

Arguments

... Arguments passed to the corresponding emxxxx function
x Character name of desired option
default default value to return if x not found

Details

For each function with lsxxxx or pmxxxx in its name, the same function named emxxxx is called. Any estimator names or list items beginning with “em” are replaced with “ls” or “pm” before the results are returned

Value

The result of the call to emxxxx, suitably modified.

get.lsm.option and lsm.options remap options from and to corresponding options in the lsmeans options system.

See Also

emmeans, emtrends, emmip, emm, emmobj, emm_options, get_emm_option
**Examples**
```
pigs.lm <- lm(log(conc) ~ source + factor(percent), data = pigs)
lsmeans(pigs.lm, "source")
```

---

**make.tran**  
Response-transformation extensions

**Description**
The `make.tran` function creates the needed information to perform transformations of the response variable, including inverting the transformation and estimating variances of back-transformed predictions via the delta method. `make.tran` is similar to `make.link`, but it covers additional transformations. The result can be used as an environment in which the model is fitted, or as the tran argument in `update.emmGrid` (when the given transformation was already applied in an existing model).

**Usage**
```
make.tran(type = c("genlog", "power", "boxcox", "sympower", "asin.sqrt", "bcnPower"), param = 1)
```

**Arguments**
- `type`  
  The name of the transformation. See Details.
- `param`  
  Numeric parameter needed for the transformation. Optionally, it may be a vector of two numeric values; the second element specifies an alternative base or origin for certain transformations. See Details.

**Details**
The functions `emmeans`, `ref.grid`, and related ones automatically detect response transformations that are recognized by examining the model formula. These are `log`, `log2`, `log10`, `sqrt`, `logit`, `probit`, `cauchit`, `cloglog`; as well as (for a response variable `y`) `asin(sqrt(y))`, `asinh(sqrt(y))`, and `sqrt(y) + sqrt(y+1)`. In addition, any constant multiple of these (e.g., `2*sqrt(y)`) is auto-detected and appropriately scaled (see also the `tran.mult` argument in `update.emmGrid`).

A few additional character strings may be supplied as the tran argument in `update.emmGrid`: "identity", "1/mu^2", "inverse", "reciprocal", "asin.sqrt", and "asinh.sqrt".

More general transformations may be provided as a list of functions and supplied as the tran argument as documented in `update.emmGrid`. The `make.tran` function returns a suitable list of functions for several popular transformations. Besides being usable with `update`, the user may use this list as an enclosing environment in fitting the model itself, in which case the transformation is auto-detected when the special name `linkfun` (the transformation itself) is used as the response transformation in the call. See the examples below.

Most of the transformations available in "make.tran" require a parameter, specified in `param`; in the following discussion, we use `p` to denote this parameter, and `y` to denote the response variable. The type argument specifies the following transformations:
"genlog" Generalized logarithmic transformation: \( \log(y + p) \), where \( y > -p \)
"power" Power transformation: \( y^p \), where \( y > 0 \). When \( p = 0 \), "log" is used instead
"boxcox" The Box-Cox transformation (unscaled by the geometric mean): \( (y^p - 1)/p \), where \( y > 0 \). When \( p = 0 \), \( \log(y) \) is used.
"sympower" A symmetrized power transformation on the whole real line: \( \text{abs}(y)^p \times \text{sign}(y) \). There are no restrictions on \( y \), but we require \( p > 0 \) in order for the transformation to be monotone and continuous.
"asin.sqrt" Arcsin-square-root transformation: \( \sin^{-1}\left(\frac{y}{p}\right)^{1/2} \). Typically, the parameter \( p \) is equal to 1 for a fraction, or 100 for a percentage.
"bcnPower" Box-Cox with negatives allowed, as described for the bcnPower function in the car package. It is defined as the Box-Cox transformation \( (z^p - 1)/p \) of the variable \( z = y + (y^2 + g^2)^{1/2} \). This requires \( \text{param} \) to have two elements: the power \( p \) and the offset \( g > 0 \).

The user may include a second element in \( \text{param} \) to specify an alternative origin (other than zero) for the "power", "boxcox", or "sympower" transformations. For example, "type = "power", param = c(1.5,4)" specifies the transformation \( (y - 4)^{1.5} \). In the "genpower" transformation, a second \( \text{param} \) element may be used to specify a base other than the default natural logarithm. For example, ‘type = "genlog", param = c(.5,10)’ specifies the \( \log_{10}(y + .5) \) transformation. In the "bcnPower" transformation, the second element is required and must be positive.

For purposes of back-transformation, the \( \sqrt{y} + \sqrt{y+1} \) transformation is treated exactly the same way as \( 2\sqrt{y} \), because both are regarded as estimates of \( \sqrt{\mu} \).

Value
A list having at least the same elements as those returned by \text{make.link}. The \text{linkfun} component is the transformation itself.

Note
The genlog transformation is technically unneeded, because a response transformation of the form \( \log(y + c) \) is now auto-detected by \text{ref_grid}.

We modify certain \text{make.link} results in transformations where there is a restriction on valid prediction values, so that reasonable inverse predictions are obtained, no matter what. For example, if a sqrt transformation was used but a predicted value is negative, the inverse transformation is zero rather than the square of the prediction. A side effect of this is that it is possible for one or both confidence limits, or even a standard error, to be zero.

Examples
# Fit a model using an oddball transformation:
bctrans <- \text{make.tran}("boxcox", 0.368)
warp.bc <- with(bctrans, \text{lm(linkfun(breaks) ~ wool * tension, data = warpbreaks)})
# Obtain back-transformed LS means:
\text{emmeans}(warp.bc, ~ tension | wool, type = "response")

## Not run:
# An existing model 'mod' was fitted with a y^2/3 transformation...
mod.rg <- update(ref_grid(mod), tran = make.tran("power", 2/3))
emmeans(mod.rg, "treatment")

## End(Not run)

MOats                      Oats data in multivariate form

Description
This is the Oats dataset provided in the nlme package, but it is rearranged as one multivariate observation per plot.

Usage
MOats

Format
A data frame with 18 observations and 3 variables

Variety  a factor with levels Golden Rain, Marvellous, Victory
Block    an ordered factor with levels VI < V < III < IV < II < I
yield    a matrix with 4 columns, giving the yields with nitrogen concentrations of 0, .2, .4, and .6.

Details
These data arise from a split-plot experiment reported by Yates (1935) and used as an example in Pinheiro and Bates (2000) and other texts. Six blocks were divided into three whole plots, randomly assigned to the three varieties of oats. The whole plots were each divided into 4 split plots and randomized to the four concentrations of nitrogen.

Source
The dataset Oats in the nlme package.

References

Examples
MOats.lm <- lm (yield ~ Block + Variety, data = MOats)
MOats.rg <- ref_grid (MOats.lm, mult.name = "nitro")
emmeans(MOats.rg, ~ nitro | Variety)
Models supported in \texttt{emmeans}

\section*{Description}

Documentation for models has been moved to a vignette. To access it, use \texttt{vignette("models", "emmeans")}.

\section*{neuralgia \hspace{1cm} Neuralgia data}

\subsection*{Description}

These data arise from a study of analgesic effects of treatments of elderly patients who have neuralgia. Two treatments and a placebo are compared. The response variable is whether the patient reported pain or not. Researchers recorded the age and gender of 60 patients along with the duration of complaint before the treatment began.

\subsection*{Usage}

\texttt{neuralgia}

\subsection*{Format}

A data frame with 60 observations and 5 variables:

- \texttt{Treatment} Factor with 3 levels A, B, and P. The latter is placebo
- \texttt{Sex} Factor with two levels F and M
- \texttt{Age} Numeric covariate – patient's age in years
- \texttt{Duration} Numeric covariate – duration of the condition before beginning treatment
- \texttt{Pain} Binary response factor with levels \texttt{No} and \texttt{Yes}

\subsection*{Source}

\subsection*{Examples}

\begin{verbatim}
# Model and analysis shown in the SAS report:
neuralgia.glm <- glm(Pain ~ Treatment * Sex + Age, family = binomial(),
data = neuralgia)
pairs(emmeans(neuralgia.glm, ~ Treatment, at = list(Sex = "F"),
reverse = TRUE, type = "response", adjust = "bonferroni")
\end{verbatim}
**Description**

This observational dataset involves three factors, but where several factor combinations are missing. It is used as a case study in Milliken and Johnson, Chapter 17, p.202. (You may also find it in the second edition, p.278.)

**Usage**

`nutrition`

**Format**

A data frame with 107 observations and 4 variables:

- **age**: a factor with levels 1, 2, 3, 4. Mother’s age group.
- **group**: a factor with levels FoodStamps, NoAid. Whether or not the family receives food stamp assistance.
- **race**: a factor with levels Black, Hispanic, White. Mother’s race.
- **gain**: a numeric vector (the response variable). Gain score (posttest minus pretest) on knowledge of nutrition.

**Details**

A survey was conducted by home economists “to study how much lower-socioeconomic-level mothers knew about nutrition and to judge the effect of a training program designed to increase their knowledge of nutrition.” This is a messy dataset with several empty cells.

**Source**

**Examples**

```r
nutr.aov <- aov(gain ~ (group + age + race)^2, data = nutrition)
# Summarize predictions for age group 3
nutr.emm <- emmeans(nutr.aov, ~ race * group, at = list(age="3"))
emmpair(nutr.emm, race ~ group)

# Hispanics seem exceptional; but this doesn’t test out due to very sparse data
CLD(nutr.emm, by = "group")
CLD(nutr.emm, by = "race")
```
Description

This example dataset on sales of oranges has two factors, two covariates, and two responses. There is one observation per factor combination.

Usage

oranges

Format

A data frame with 36 observations and 6 variables:

store a factor with levels 1 2 3 4 5 6. The store that was observed.

day a factor with levels 1 2 3 4 5 6. The day the observation was taken (same for each store).

price1 a numeric vector. Price of variety 1.

price2 a numeric vector. Price of variety 2.

sales1 a numeric vector. Sales (per customer) of variety 1.

sales2 a numeric vector. Sales (per customer) of variety 2.

Source

References

Examples

# Example on p.244 of Littell et al.
oranges.lm <- lm(sales1 ~ price1*day, data = oranges)
emmeans(oranges.lm, "day")

# Example on p.246 of Littell et al.
emmeans(oranges.lm, "day", at = list(price1 = 0))

# A more sensible model to consider, IMHO (see vignette("interactions"))
org.mlm <- lm(cbind(sales1, sales2) ~ price1 * price2 + day + store,
data = oranges)
Effects of dietary protein on free plasma leucine concentration in pigs

Description

A two-factor experiment with some observations lost

Usage

pigs

Format

A data frame with 29 observations and 3 variables:

- **source**: Source of protein in the diet (factor with 3 levels: fish meal, soybean meal, dried skim milk)
- **percent**: Protein percentage in the diet (numeric with 4 values: 9, 12, 15, and 18)
- **conc**: Concentration of free plasma leucine, in mcg/ml

Source

Examples

```r
pigs.lm <- lm(log(conc) ~ source + factor(percent), data = pigs)
emmeans(pigs.lm, "source")
```

Description

Methods are provided to plot EMMs as side-by-side CIs, and optionally to display “comparison arrows” for displaying pairwise comparisons.
**plot.emmGrid**

### Usage

#### S3 method for class 'emmGrid'

```r
plot(x, y, type, CIs = TRUE, PIs = FALSE, comparisons = FALSE, colors = c("black", "blue", "blue", "red"), alpha = 0.05, adjust = "tukey", int.adjust = "none", intervals, frequentist, ...)
```

#### S3 method for class 'summary_emm'

```r
plot(x, y, horizontal = TRUE, CIs = TRUE, xlab, ylab, layout, colors = c("black", "blue", "blue", "red"), intervals, plotit = TRUE, ...)
```

### Arguments

- **x**: Object of class `emmGrid` or `summary_emm`
- **y**: (Required but ignored)
- **type**: Character value specifying the type of prediction desired (matching "linear.predictor", "link", or "response"). See details under `summary.emmGrid`.
- **CIs**: Logical value. If `TRUE`, confidence intervals are plotted for each estimate.
- **PIs**: Logical value. If `TRUE`, prediction intervals are plotted for each estimate. If `object` is a Bayesian model, this requires `frequentist = TRUE` and `sigma = (some value)`. Note that the PIs option is not available with `summary_emm` objects – only for `emmGrid` objects. Also, prediction intervals are not available with `engine = "lattice"`.
- **comparisons**: Logical value. If `TRUE`, “comparison arrows” are added to the plot, in such a way that the degree to which arrows overlap reflects as much as possible the significance of the comparison of the two estimates. (A warning is issued if this can’t be done.)
- **colors**: Character vector of color names to use for estimates, CIs, PIs, and comparison arrows, respectively. CIs and PIs are rendered with some transparency, and colors are recycled if the length is less than four; so all plot elements are visible even if a single color is specified.
- **alpha**: The significance level to use in constructing comparison arrows
- **adjust**: Character value: Multiplicity adjustment method for comparison arrows only.
- **int.adjust**: Character value: Multiplicity adjustment method for the plotted confidence intervals only.
- **intervals**: If specified, it is used to set CIs. This is the previous name of CIs and is provided for backward compatibility.
- **frequentist**: Logical value. If there is a posterior MCMC sample and `frequentist` is non-missing and `TRUE`, a frequentist summary is used for obtaining the plot data, rather than the posterior point estimate and HPD intervals. This argument is ignored when it is not a Bayesian model.
- **...**: Additional arguments passed to `update.emmGrid`, `predict.emmGrid`, or `dotplot`
- **horizontal**: Logical value specifying whether the intervals should be plotted horizontally or vertically.
xlab
Character label for horizontal axis

ylab
Character label for vertical axis

layout
Numeric value passed to dotplot

plotit
Logical value. If TRUE, a graphical object is returned; if FALSE, a data.frame is returned containing all the values used to construct the plot.

Value

If plotit = TRUE, a graphical object is returned.

If plotit = FALSE, a data.frame with the table of EMMs that would be plotted. In the latter case, the estimate being plotted is named the.emmean, and any factors involved have the same names as in the object. Confidence limits are named lower.CL and upper.CL, prediction limits are named lpl and upl, and comparison-arrow limits are named lcmpl and ucmpl. There is also a variable named pri.fac which contains the factor combinations that are not among the by variables.

Details

If any by variables are in force, the plot is divided into separate panels. These functions use the dotplot function, and thus require that the lattice package be installed. For "summary_emm" objects, the ... arguments in plot are passed only to dotplot, whereas for "emmGrid" objects, the object is updated using ... before summarizing and plotting.

In plots with comparisons = TRUE, the resulting arrows are only approximate, and in some cases may fail to accurately reflect the pairwise comparisons of the estimates – especially when estimates having large and small standard errors are intermingled in just the wrong way. Note that the maximum and minimum estimates have arrows only in one direction, since there is no need to compare them with anything higher or lower, respectively. See the vignette("xplanations", "emmeans") for details on how these are derived.

If adjust or int.adjust are not supplied, they default to the internal adjust setting saved in pairs(x) and x respectively (see update.emmGrid).

Examples

warp.lm <- lm(breaks ~ wool * tension, data = warpbreaks)
warp.emm <- emmeans(warp.lm, ~ tension | wool)
plot(warp.emm)
plot(warp.emm, by = NULL, comparisons = TRUE, adjust = "mvt",
     horizontal = FALSE, colors = "darkgreen")
**pwpm**

**Description**

This function presents results from emmeans and pairwise comparisons thereof in a compact way. It displays a matrix (or matrices) of estimates, pairwise differences, and P values. The user may opt to exclude any of these via arguments `means`, `diffs`, and `pvals`, respectively. To control the direction of the pairwise differences, use `reverse`; and to control what appears in the upper and lower triangle(s), use `flip`. Optional arguments are passed to `contrast.emmGrid` and/or `summary.emmGrid`, making it possible to control what estimates and tests are displayed.

**Usage**

```r
pwpm(emm, by, reverse = FALSE, pvals = TRUE, means = TRUE, diffs = TRUE,
     flip = FALSE, digits, ...)
```

**Arguments**

- `emm` An `emmGrid` object
- `by` Character vector of variable(s) in the grid to condition on. These will create different matrices, one for each level or level-combination. If missing, `by` is set to `emm@misc$by.vars`. Grid factors not in `by` are the primary factors: whose levels or level combinations are compared pairwise.
- `reverse` Logical value passed to `pairs.emmGrid`. Thus, `FALSE` specifies "pairwise" comparisons (earlier vs. later), and `TRUE` specifies "revpairwise" comparisons (later vs. earlier).
- `pvals` Logical value. If `TRUE`, the pairwise differences of the EMMs are included in each matrix according to `flip`.
- `means` Logical value. If `TRUE`, the estimated marginal means (EMMs) from `emm` are included in the matrix diagonal(s).
- `diffs` Logical value. If `TRUE`, the pairwise differences of the EMMs are included in each matrix according to `flip`.
- `flip` Logical value that determines where P values and differences are placed. `FALSE` places the P values in the upper triangle and differences in the lower, and `TRUE` does just the opposite.
- `digits` Integer. Number of digits to display. If missing, an optimal number of digits is determined.
- `...` Additional arguments passed to `contrast.emmGrid` and `summary.emmGrid`. You should *not* include `method` here, because pairwise comparisons are always used.

**Value**

A matrix or 'list' of matrices, one for each 'by' level.

**See Also**

A graphical display of essentially the same results is available from `pwpp`
Examples

```r
warp.lm <- lm(breaks ~ wool * tension, data = warpbreaks)
warp.emm <- emmeans(warp.lm, ~ tension | wool)
pwpm(warp.emm)

# use dot options to specify noninferiority tests
pwpm(warp.emm, by = NULL, side = ">", delta = 5, adjust = "none")
```

---

**pwpp**

*Pairwise P-value plot*

**Description**

Constructs a plot of P values associated with pairwise comparisons of estimated marginal means.

**Usage**

```r
pwpp(emm, method = "pairwise", by, sort = TRUE, values = TRUE,
     rows = ".", xlab, ylab, xsub = ",", plim = numeric(0), add.space = 0,
     ...)```

**Arguments**

- **emm**: An `emmGrid` object
- **method**: Character or list. Passed to `contrast`, and defines the contrasts to be displayed. Any contrast method may be used, provided that each contrast includes one coefficient of 1, one coefficient of -1, and the rest 0. That is, calling `contrast(object, method)` produces a set of comparisons, each with one estimate minus another estimate.
- **by**: Character vector of variable(s) in the grid to condition on. These will create different panels, one for each level or level-combination. Grid factors not in by are the primary factors: whose levels or level combinations are compared pairwise.
- **sort**: Logical value. If TRUE, levels of the factor combinations are ordered by their marginal means. If FALSE, they appear in order based on the existing ordering of the factor levels involved. Note that the levels are ordered the same way in all panels, and in many cases this implies that the means in any particular panel will not be ordered even when sort = TRUE.
- **values**: Logical value. If TRUE, the values of the EMMs are included in the plot. When there are several side-by-side panels due to by variable(s), the labels showing values start stealing a lot of space from the plotting area; in those cases, it may be desirable to specify FALSE or use rows so that some panels are vertically stacked.
Character vector of which by variable(s) are used to define rows of the panel layout. Those variables in by not included in rows define columns in the array of panels. A "." indicates that only one row is used, so all panels are stacked side-by-side.

Character label to use in place of the default for the P-value axis.

Character label to use in place of the default for the primary-factor axis.

Character label used as caption at the lower right of the plot.

Numeric vector of value(s) between 0 and 1. These are included among the observed p values so that the range of tick marks includes at least the range of plim. Choosing plim = c(0,1) will ensure the widest possible range.

Numeric value to adjust amount of space used for value labels. Positioning of value labels is tricky, and depends on how many panels and the physical size of the plotting region. This parameter allows the user to adjust the position. Changing it by one unit should shift the position by about one character width (right if positive, left if negative).

Additional arguments passed to contrast and summary.emmGrid

Details

Factor levels (or combinations thereof) are plotted on the vertical scale, and P values are plotted on the horizontal scale. Each P value is plotted twice – at vertical positions corresponding to the levels being compared – and connected by a line segment. Thus, it is easy to visualize which P values are small and large, and which levels are compared. In addition, factor levels are color-coded, and the points and half-line segments appear in the color of the other level. The P-value scale is nonlinear, so as to stretch-out smaller P values and compress larger ones. P values smaller than 0.0004 are altered and plotted in a way that makes them more distinguishable from one another.

If xlab, ylab, and xsub are not provided, reasonable labels are created. xsub is used to note special features; e.g., equivalence thresholds or one-sided tests.

Note

The ggplot2 and scales packages must be installed in order for pwpp to work.

See Also

A numerical display of essentially the same results is available from pwpm

Examples

```r
pigs.lm <- lm(log(conc) ~ source * factor(percent), data = pigs)
emm = emmeans(pigs.lm, ~ percent | source)
pwpp(emm)
pwpp(emm, method = "trt.vs.ctrl1", type = "response", side = ">")
```
**qdrg**

*Quick and dirty reference grid*

**Description**

This function may make it possible to compute a reference grid for a model object that is otherwise not supported.

**Usage**

qdrg(formula, data, coef, mcmc, vcov, object, df, subset, weights, contrasts, link, qr, ...)

**Arguments**

- `formula`: Formula for the fixed effects
- `data`: Dataset containing the variables in the model
- `coef`: Fixed-effect regression coefficients (must conform to formula)
- `mcmc`: Posterior sample of fixed-effect coefficients
- `vcov`: Variance-covariance matrix of the fixed effects
- `object`: Optional model object. If provided, it is used to set certain other arguments, if not specified. See Details.
- `df`: Error degrees of freedom
- `subset`: Subset of data used in fitting the model
- `weights`: Weights used in fitting the model
- `contrasts`: List of contrasts specified in fitting the model
- `link`: Link function (character or list) used, if a generalized linear model. (Note: response transformations are auto-detected from formula)
- `qr`: QR decomposition of the model matrix; needed only if there are NAs in coef.
- `...`: Optional arguments passed to ref_grid

**Details**

If object is specified, it is used to try to obtain certain other arguments, as detailed below. The user should ensure that these defaults will work. The default values for the arguments are as follows:

- `formula`: Required unless obtainable via formula(object)
- `data`: Required if variables are not in parent.frame() or obtainable via object$data
- `coef`: coef(object)
- `mcmc`: object$sample
- `vcov`: vcov(object)
- `df`: Set to Inf if not available in object$df.residual
rbind.emmGrid

- subset: NULL (so that all observations in data are used)
- contrasts: NULL (so that getOption("contrasts") is used)

The functions qdrg and emmobj are close cousins, in that they both produce emmGrid objects. When starting with summary statistics for an existing grid, emmobj is more useful, while qdrg is more useful when starting from a fitted model.

Value

An emmGrid object constructed from the arguments

See Also

emmobj for an alternative way to construct an emmGrid.

Examples

```r
if (require(biglm)) {
  # Post hoc analysis of a "biglm" object -- not supported by emmeans
  bigmod <- biglm(log(conc) ~ source + factor(percent), data = pigs)

  rg2 <- qdrg(object = bigmod, data = pigs)
  summary(emmeans(rg2, "source"), type = "response")
}
if(require(coda) && require(lme4)) {
  # Use a stored example having a posterior sample
  # Model is based on the data in lme4::cbpp

  post <- readRDS(system.file("extdata", "cbpplist", package = "emmeans"))$post.beta
  rg1 <- qdrg(~ size + period, data = lme4::cbpp, mcmc = post, link = "logit")
  summary(rg1, type = "response")
}
```

rbind.emmGrid

**Combine or subset emmGrid objects**

Description

These functions provide methods for `rbind` and `[` that may be used to combine emmGrid objects together, or to extract a subset of cases. The primary reason for doing this would be to obtain multiplicity-adjusted results for smaller or larger families of tests or confidence intervals.

Usage

```r
## S3 method for class 'emmGrid'
rbind(..., deparse.level = 1, adjust = "bonferroni")
```

## S3 method for class 'emmGrid'
e1 + e2

## S3 method for class 'emmGrid'
x[i, adjust, drop.levels = TRUE, ...]

### Arguments

... In `rbind`, object(s) of class `emmGrid`. In "[", it is ignored.
deparse.level (required but not used)
adjust Character value passed to `update.emmGrid`
e1 An `emmGrid` object
e2 Another `emmGrid` object
x An `emmGrid` object to be subsetted
i Integer vector of indexes
drop.levels Logical value. If TRUE, the "levels" slot in the returned object is updated to hold only the predictor levels that actually occur

### Value

A revised object of class `emmGrid`
The result of `e1 + e2` is the same as `rbind(e1, e2)`

### Note

`rbind` throws an error if there are incompatibilities in the objects’ coefficients, covariance structures, etc. But they are allowed to have different factors; a missing level `.` is added to factors as needed.

### Examples

```r
warp.lm <- lm(breaks ~ wool * tension, data = warpbreaks)
warp.rg <- ref_grid(warp.lm)
# Show only 3 of the 6 cases
summary(warp.rg[c(2,4,5)])

# Do all pairwise comparisons within rows or within columns, # all considered as one family of tests:
w.t <- pairs(emmeans(warp.rg, ~ wool | tension))
t.w <- pairs(emmeans(warp.rg, ~ tension | wool))
rbind(w.t, t.w, adjust = "mvt")
update(w.t + t.w, adjust = "fdr")  ## same as above except for adjustment
```
ref_grid

Create a reference grid from a fitted model

Description

Using a fitted model object, determine a reference grid for which estimated marginal means are
defined. The resulting ref_grid object encapsulates all the information needed to calculate EMMs
and make inferences on them.

Usage

ref_grid(object, at, cov.reduce = mean,
         cov.keep = get_emm_option("cov.keep"), mult.names, mult.levs,
         options = get_emm_option("ref_grid"), data, df, type, transform, nesting,
         offset, sigma, ...)

Arguments

object
An object produced by a supported model-fitting function, such as lm. Many
models are supported. See vignette("models", "emmeans").

at
Optional named list of levels for the corresponding variables

cov.reduce
A function, logical value, or formula; or a named list of these. Each covariate
not specified in cov.keep or at is reduced according to these specifications. See
the section below on “Using cov.reduce and cov.keep”.

cov.keep
Character vector: names of covariates that are not to be reduced; these are
treated as factors and used in weighting calculations. cov.keep may also in-
clude integer value(s), and if so, the maximum of these is used to set a threshold
such that any covariate having no more than that many unique values is auto-
matically included in cov.keep.

mult.names
Character value: the name(s) to give to the pseudo-factor(s) whose levels delin-
eate the elements of a multivariate response. If this is provided, it overrides the
default name(s) used for class(object) when it has a multivariate response
(e.g., the default is "rep.meas" for "mlm" objects).

mult.levs
A named list of levels for the dimensions of a multivariate response. If there
is more than one element, the combinations of levels are used, in expand.grid
order. The (total) number of levels must match the number of dimensions. If
mult.name is specified, this argument is ignored.

options
If non-NULL, a named list of arguments to pass to update.emmGrid, just after
the object is constructed.

data
A data.frame to use to obtain information about the predictors (e.g. factor
levels). If missing, then recover_data is used to attempt to reconstruct the
data. See the note with recover_data for an important precaution.

df
Numeric value. This is equivalent to specifying options(df = df). See update.emmGrid.

type
Character value. If provided, this is saved as the "predict.type" setting. See
update.emmGrid and the section below on prediction types and transformations.
transform Character, logical, or list. If non-missing, the reference grid is reconstructed via `regrid` with the given `transform` argument. See the section below on prediction types and transformations.

nesting If the model has nested fixed effects, this may be specified here via a character vector or named list specifying the nesting structure. Specifying `nesting` overrides any nesting structure that is automatically detected. See the section below on Recovering or Overriding Model Information.

offset Numeric scalar value (if a vector, only the first element is used). This may be used to add an offset, or override offsets based on the model. A common usage would be to specify offset = 0 for a Poisson regression model, so that predictions from the reference grid become rates relative to the offset that had been specified in the model.

sigma Numeric value to use for subsequent predictions or back-transformation bias adjustments. If not specified, we use `sigma(object)`, if available, and NULL otherwise.

... Optional arguments passed to `summary.emmGrid`, `emm_basis`, and `recover_data`, such as `params`, `vcov` (see Covariance matrix below), or options such as `mode` for specific model types (see vignette("models", "emmeans").

Details

To users, the `ref_grid` function itself is important because most of its arguments are in effect arguments of `emmeans` and related functions, in that those functions pass their ... arguments to `ref_grid`.

The reference grid consists of combinations of independent variables over which predictions are made. Estimated marginal means are defined as these predictions, or marginal averages thereof. The grid is determined by first reconstructing the data used in fitting the model (see `recover_data`), or by using the `data.frame` provided in `data`. The default reference grid is determined by the observed levels of any factors, the ordered unique values of character-valued predictors, and the results of `cov.reduce` for numeric predictors. These may be overridden using `at`. See also the section below on recovering/overriding model information.

Value

An object of the S4 class "emmGrid" (see `emmGrid-class`). These objects encapsulate everything needed to do calculations and inferences for estimated marginal means, and contain nothing that depends on the model-fitting procedure.

Using `cov.reduce` and `cov.keep`

The `cov.keep` argument was not available in `emmeans` versions 1.4.1 and earlier. Any covariates named in this list are treated as if they are factors: all the unique levels are kept in the reference grid. The user may also specify an integer value, in which case any covariate having no more than that number of unique values is implicitly included in `cov.keep`. The default for `cov.keep` is set and retrieved via the `emm_options` framework, and the system default is "2", meaning that covariates having only two unique values are automatically treated as two-level factors. See also the Note below on backward compatibility.
There is a subtle distinction between including a covariate in `cov.keep` and specifying its values manually in `at`: Covariates included in `cov.keep` are treated as factors for purposes of weighting, while specifying levels in `at` will not include the covariate in weighting. See the `mtcars.lm` example below for an illustration.

`cov.reduce` may be a function, logical value, formula, or a named list of these. If a single function, it is applied to each covariate. If logical and `TRUE`, `mean` is used. If logical and `FALSE`, it is equivalent to including all covariates in `cov.keep`. Use of `cov.reduce = FALSE` is inadvisable because it can result in a huge reference grid; it is far better to use `cov.keep`. If a formula (which must be two-sided), then a model is fitted to that formula using `lm`; then in the reference grid, its response variable is set to the results of `predict` for that model, with the reference grid as `newdata`. (This is done after the reference grid is determined.) A formula is appropriate here when you think experimental conditions affect the covariate as well as the response.

If `cov.reduce` is a named list, then the above criteria are used to determine what to do with covariates named in the list. (However, formula elements do not need to be named, as those names are determined from the formulas’ left-hand sides.) Any unresolved covariates are reduced using "mean".

Any `cov.reduce` of `cov.keep` specification for a covariate also named in `at` is ignored.

**Interdependent covariates**

Care must be taken when covariate values depend on one another. For example, when a polynomial model was fitted using predictors `x`, `x^2` (equal to `x*x`), and `x^3` (equal to `x*x*x`), the reference grid will by default set `x^2` and `x^3` to their means, which is inconsistent. The user should instead use the `at` argument to set these to the square and cube of `mean(x)`. Better yet, fit the model using a formula involving `poly(x, 3)` or `I(x^2)` and `I(x^3)`; then there is only `x` appearing as a covariate; it will be set to its mean, and the model matrix will have the correct corresponding quadratic and cubic terms.

**Matrix covariates**

Support for covariates that appear in the dataset as matrices is very limited. If the matrix has but one column, it is treated like an ordinary covariate. Otherwise, with more than one column, each column is reduced to a single reference value – the result of applying `cov.reduce` to each column (averaged together if that produces more than one value); you may not specify values in `at`; and they are not treated as variables in the reference grid, except for purposes of obtaining predictions.

**Recovering or overriding model information**

Ability to support a particular class of object depends on the existence of `recover_data` and `emm_basis` methods – see extending-emmeans for details. The call `methods("recover_data")` will help identify these.

**Data.** In certain models, (e.g., results of `glmer.nb`), it is not possible to identify the original dataset. In such cases, we can work around this by setting `data` equal to the dataset used in fitting the model, or a suitable subset. Only the complete cases in `data` are used, so it may be necessary to exclude some unused variables. Using `data` can also help save computing, especially when the dataset is large. In any case, `data` must represent all factor levels used in fitting the model. `It cannot` be used as an alternative to `at`. (Note: If there is a pattern of `NAs` that caused one or more factor levels to be excluded when fitting the model, then `data` should also exclude those levels.)
Covariance matrix. By default, the variance-covariance matrix for the fixed effects is obtained from `object`, usually via its `vcov` method. However, the user may override this via a `vcov.` argument, specifying a matrix or a function. If a matrix, it must be square and of the same dimension and parameter order of the fixed effects. If a function, must return a suitable matrix when it is called with `object` as its only argument.

Nested factors. Having a nesting structure affects marginal averaging in `emmeans` in that it is done separately for each level (or combination thereof) of the grouping factors. `ref_grid` tries to discern which factors are nested in other factors, but it is not always obvious, and if it misses some, the user must specify this structure via `nesting`; or later using `update.emmGrid`. The nesting argument may be a character vector, a named list, or `NULL`. If a list, each name should be the name of a single factor in the grid, and its entry a character vector of the name(s) of its grouping factor(s). Nested may also be a character value of the form "factor1 %in% (factor2*factor3)" (the parentheses are optional). If there is more than one such specification, they may be appended separated by commas, or as separate elements of a character vector. For example, these specifications are equivalent: `nesting = list(state = "country",city = c("state","country"), nesting = "state %in% country,city %in% (state*country)", and nesting = c("state %in% country","city %in% state*country")`.

Predictors with subscripts and data-set references

When the fitted model contains subscripts or explicit references to data sets, the reference grid may optionally be post-processed to simplify the variable names, depending on the `simplify.names` option (see `emm_options`), which by default is `TRUE`. For example, if the model formula is `data1$resp ~ data1$trt + data2[[3]] + data2["cov"`, the simplified predictor names (for use, e.g., in the specs for `emmeans`) will be `trt`, `data2[[3]]`, and `cov`. Numerical subscripts are not simplified; nor are variables having simplified names that coincide, such as if `data2$trt` were also in the model.

Please note that this simplification is performed after the reference grid is constructed. Thus, non-simplified names must be used in the `at` argument (e.g., `at = list("data2["cov"]" = 2:4)`. If you don’t want names simplified, use `emm_options(simplify.names = FALSE)`.

Prediction types and transformations

Transformations can exist because of a link function in a generalized linear model, or as a response transformation, or even both. In many cases, they are auto-detected, for example a model formula of the form `sqrt(y) ~ ...`. Even transformations containing multiplicative or additive constants, such as `2*sqrt(y + pi) ~ ...`, are auto-detected. A response transformation of `y + 1 ~ ...` is not auto-detected, but `I(y + 1) ~ ...` is interpreted as `identity(y + 1) ~ ...`. A warning is issued if it gets too complicated. Complex transformations like the Box-Cox transformation are not auto-detected; but see the help page for `make.tran` for information on some advanced methods.

There is a subtle difference between specifying `‘type = "response"’` and `‘transform = "response"’`. While the summary statistics for the grid itself are the same, subsequent use in `emmeans` will yield different results if there is a response transformation or link function. With `‘type = "response"’`, EMMs are computed by averaging together predictions on the linear-predictor scale and then back-transforming to the response scale; while with `‘transform = "response"’`, the predictions are already on the response scale so that the EMMs will be the arithmetic means of those response-scale predictions. To add further to the possibilities, `geometric` means of the response-scale predictions are obtainable via `‘transform = "log"`, `type = "response"’`. See also the help page for `regrid`. 
Side effect

The most recent result of `ref_grid`, whether called directly or indirectly via `emmeans`, `emtrends`, or some other function that calls one of these, is saved in the user’s environment as `.Last.ref_grid`. This facilitates checking what reference grid was used, or reusing the same reference grid for further calculations. This automatic saving is enabled by default, but may be disabled via ‘`emm_options(save.ref_grid = FALSE)`’, and re-enabled by specifying `TRUE`.

Note

The system default for `cov.keep` causes models containing indicator variables to be handled differently than in `emmeans` version 1.4.1 or earlier. To replicate older analyses, change the default via ‘`emm_options(cov.keep = character(0))`’.

Some earlier versions of `emmeans` offer a `covnest` argument. This is now obsolete; if `covnest` is specified, it is harmlessly ignored. Cases where it was needed are now handled appropriately via the code associated with `cov.keep`.

See Also

Reference grids are of class `emmGrid`, and several methods exist for them – for example `summary.emmGrid`. Reference grids are fundamental to `emmeans`. Supported models are detailed in `vignette("models", "emmeans")`. See `update.emmGrid` for details of arguments that can be in `options` (or in `...`).

Examples

```r
fiber.lm <- lm(strength ~ machine*diameter, data = fiber)
ref_grid(fiber.lm)
summary(.Last.ref_grid)

ref_grid(fiber.lm, at = list(diameter = c(15, 25)))

## Not run:  # We could substitute the sandwich estimator vcovHAC(fiber.lm)
# as follows:
# summary(ref_grid(fiber.lm, vcov. = sandwich::vcovHAC))
## End(Not run)

# If we thought that the machines affect the diameters
# (admittedly not plausible in this example), then we should use:
ref_grid(fiber.lm, cov.reduce = diameter ~ machine)

### Model with indicator variables as predictors:
mtcars.lm <- lm(mpg ~ disp + wt + vs * am, data = mtcars)
(rg.default <- ref_grid(mtcars.lm))
(rg.nokeep <- ref_grid(mtcars.lm, cov.keep = character(0)))
(rg.at <- ref_grid(mtcars.lm, at = list(vs = 0:1, am = 0:1)))

# Two of these have the same grid but different weights:
rg.default@grid
rg.at@grid
```
# Multivariate example

```r
MOats.lm = lm(yield ~ Block + Variety, data = MOats)
ref_grid(MOats.lm, mult.names = "nitro")
```

# Silly illustration of how to use 'mult.levs' to make comb's of two factors

```r
ref_grid(MOats.lm, mult.levs = list(T=LETTERS[1:2], U=letters[1:2]))
```

# Using 'params'

```r
require("splines")
my.knots = c(2.5, 3, 3.5)
mod = lm(Sepal.Length ~ Species * ns(Sepal.Width, knots = my.knots), data = iris)
## my.knots is not a predictor, so need to name it in 'params'
ref_grid(mod, params = "my.knots")
```

---

regrid **Reconstruct a reference grid with a new transformation or posterior sample**

### Description

The typical use of this function is to cause EMMs to be computed on a different scale, e.g., the back-transformed scale rather than the linear-predictor scale. In other words, if you want back-transformed results, do you want to average and then back-transform, or back-transform and then average?

### Usage

```r
regrid(object, transform = c("response", "mu", "unlink", "none", "pass", links), inv.link.lbl = "response", predict.type, bias.adjust = get_emm_option("back.bias.adj"), sigma, N.sim, sim = mvtnorm::rmvnorm, ...)
```

### Arguments

- **object**: An object of class `emmGrid`
- **transform**: A character, list, or logical value. If "response", "mu", or TRUE, the inverse transformation is applied to the estimates in the grid (but if there is both a link function and a response transformation, "mu" back-transforms only the link part); if "none" or FALSE, object is re-gridded so that its `bhat` slot contains `predict(object)` and its `linfct` slot is the identity. Any internal transformation information is preserved. If transform = "pass", the object is not re-gridded in any way (this may be useful in conjunction with N.sim).

If transform is a character value in `links` (which is the set of valid arguments for the `make.link` function, excepting "identity"), or if transform is a list of the same form as returned by make.links or `make.tran`, the results are formulated as if the response had been transformed with that link function.
**regrid**

inv.link.lbl  Character value. This applies only when transform is in links, and is used to label the predictions if subsequently summarized with type = "response".

predict.type  Character value. If provided, the returned object is updated with the given type to use by default by summary.emmGrid (see update.emmGrid). This may be useful if, for example, when one specifies transform = "log" but desires summaries to be produced by default on the response scale.

bias.adjust  Logical value for whether to adjust for bias in back-transforming (transform = "response"). This requires a value of sigma to exist in the object or be specified.

sigma  Error SD assumed for bias correction (when transform = "response" and a transformation is in effect). If not specified, object@misc$sigma is used, and an error is thrown if it is not found.

N.sim  Integer value. If specified and object is based on a frequentist model (i.e., does not have a posterior sample), then a fake posterior sample is generated using the function sim.

sim  A function of three arguments (no names are assumed). If N.sim is supplied with a frequentist model, this function is called with respective arguments N.sim, object@bhat, and object@V. The default is the multivariate normal distribution.

...  Ignored.

**Details**

The regrid function reparameterizes an existing ref.grid so that its linfct slot is the identity matrix and its bhat slot consists of the estimates at the grid points. If transform is TRUE, the inverse transform is applied to the estimates. Outwardly, when transform = "response", the result of summary.emmGrid after applying regrid is identical to the summary of the original object using 'type="response"'. But subsequent EMMs or contrasts will be conducted on the new scale – which is the reason this function exists.

This function may also be used to convert a reference grid for a frequentist model to one for a Bayesian model. To do so, specify a value for N.sim and a posterior sample is simulated using the function sim. The grid may be further processed in accordance with the other arguments; or if transform = "pass", it is simply returned with the only change being the addition of the posterior sample.

**Value**

An emmGrid object with the requested changes

**Degrees of freedom**

In cases where the degrees of freedom depended on the linear function being estimated (e.g., Satterthwaite method), the d.f. from the reference grid are saved, and a kind of “containment” method is substituted in the returned object, whereby the calculated d.f. for a new linear function will be the minimum d.f. among those having nonzero coefficients. This is kind of an ad hoc method, and it can over-estimate the degrees of freedom in some cases. An annotation is displayed below any subsequent summary results stating that the degrees-of-freedom method is inherited from the previous method at the time of re-gridding.
Note

Another way to use regrid is to supply a transform argument to ref_grid (either directly or indirectly via emmeans). This is often a simpler approach if the reference grid has not already been constructed.

Examples

```r
pigs.lm <- lm(log(conc) ~ source + factor(percent), data = pigs)
rg <- ref_grid(pigs.lm)

# This will yield EMMs as GEOMETRIC means of concentrations:
(emm1 <- emmeans(rg, "source", type = "response"))
pairs(emm1) ## We obtain RATIOS

# This will yield EMMs as ARITHMETIC means of concentrations:
(emm2 <- emmeans(regrid(rg, transform = "response"), "source"))
pairs(emm2) ## We obtain DIFFERENCES
# Same result, useful if we hadn't already created 'rg'
# emm2 <- emmeans(pigs.lm, "source", transform = "response")

# Simulate a posterior sample
set.seed(2.71828)
rgb <- regrid(rg, N.sim = 200, transform = "pass")
emmeans(rgb, "source", type = "response") ## similar to emm1
```

---

### str.emmGrid

**Miscellaneous methods for emmGrid objects**

**Description**

Miscellaneous methods for emmGrid objects

**Usage**

```r
## S3 method for class 'emmGrid'
str(object, ...)

## S3 method for class 'emmGrid'
print(x, ...)

## S3 method for class 'emmGrid'
vcov(object, ...)
```

**Arguments**

- `object`: An emmGrid object
- `...`: (required but not used)
- `x`: An emmGrid object
Value

The vcov method returns a symmetric matrix of variances and covariances for predict.emmGrid(object,type = "lp")

Description

These are the primary methods for obtaining numerical or tabular results from an emmGrid object. summary.emmGrid is the general function for summarizing emmGrid objects. It also serves as the print method for these objects; so for convenience, summary() arguments may be included in calls to functions such as emmeans and contrast that construct emmGrid objects. Note that by default, summaries for Bayesian models are diverted to hpd.summary.

Usage

## S3 method for class 'emmGrid'
summary(object, infer, level, adjust, by, type, df, calc,
null, delta, side, frequentist,
bias.adjust = get_emm_option("back.bias.adj"), sigma, ...)

## S3 method for class 'emmGrid'
predict(object, type, interval = c("none", "confidence", 
"prediction"), level = 0.95,
bias.adjust = get_emm_option("back.bias.adj"), sigma, ...)

## S3 method for class 'emmGrid'
as.data.frame(x, row.names = NULL, optional = FALSE, ...)

## S3 method for class 'summary.emm'
x[...], as.df = TRUE]

## S3 method for class 'emmGrid'
confint(object, parm, level = 0.95, ...)

test(object, null, ...)

## S3 method for class 'emmGrid'
test(object, null = 0, joint = FALSE, verbose = FALSE,
rows, by, status = FALSE, ...)

Arguments

object An object of class "emmGrid" (see emmGrid-class)
infer
A vector of one or two logical values. The first determines whether confidence intervals are displayed, and the second determines whether *t* tests and *P* values are displayed. If only one value is provided, it is used for both.

level
Numerical value between 0 and 1. Confidence level for confidence intervals, if \( \text{infer}[1] \) is TRUE.

adjust
Character value naming the method used to adjust *p* values or confidence limits; or to adjust comparison arrows in plot. See the P-value adjustments section below.

by
Character name(s) of variables to use for grouping into separate tables. This affects the family of tests considered in adjusted *P* values.

type
Character: type of prediction desired. This only has an effect if there is a known transformation or link function. "response" specifies that the inverse transformation be applied. "mu" (or equivalently, "unlink") is usually the same as "response", but in the case where the model has both a link function and a response transformation, only the link part is back-transformed. Other valid values are "link", "lp", and "linear.predictor"; these are equivalent, and request that results be shown for the linear predictor, with no back-transformation. The default is "link", unless the "predict.type" option is in force; see \texttt{emm_options}, and also the section below on transformations and links.

df
Numeric. If non-missing, a constant number of degrees of freedom to use in constructing confidence intervals and *P* values (NA specifies asymptotic results).

calc
Named list of character value(s) or formula(s). The expressions in char are evaluated and appended to the summary, just after the df column. The expression may include any names up through df in the summary, any additional names in object@grid (such as \texttt{.wgt.} or \texttt{.offset.}), or any earlier elements of calc.

null
Numeric. Null hypothesis value(s), on the linear-predictor scale, against which estimates are tested. May be a single value used for all, or a numeric vector of length equal to the number of tests in each family (i.e., by group in the displayed table).

delta
Numeric value (on the linear-predictor scale). If zero, ordinary tests of significance are performed. If positive, this specifies a threshold for testing equivalence (using the TOST or two-one-sided-test method), non-inferiority, or non-superiority, depending on side. See Details for how the test statistics are defined.

side
Numeric or character value specifying whether the test is left-tailed (~1, ~", code="<", "left", or "nonsuperiority"); right-tailed (1, "+", ">", "right", or "noninferiority"); or two-sided (0, 2, ~"=", "two-sided", "both", "equivalence", or ~"="). See the special section below for more details.

frequentist
Ignored except if a Bayesian model was fitted. If missing or FALSE, the object is passed to \texttt{hpd.summary}. Otherwise, a logical value of TRUE will have it return a frequentist summary.

bias.adjust
Logical value for whether to adjust for bias in back-transforming (type = "response"). This requires a value of sigma to exist in the object or be specified.
sigma  Error SD assumed for bias correction (when type = "response" and a transformation is in effect), or for constructing prediction intervals. If not specified, object@misc$sigma is used, and an error is thrown if it is not found. Note: sigma may be a vector, as long as it conforms to the number of rows of the reference grid.

interval  Type of interval desired (partial matching is allowed): "none" for no intervals, otherwise confidence or prediction intervals with given arguments, via confint.emmGrid.

x  object of the given class

row.names  passed to as.data.frame

optional  passed to as.data.frame

as.df  Logical value. With x[, ., as.df = TRUE], the result is object is coerced to an ordinary data.frame; otherwise, it is left as a summary_emm object.

parm  (Required argument for confint methods, but not used)

joint  Logical value. If FALSE, the arguments are passed to summary.emmGrid with infer=c(FALSE,TRUE). If joint = TRUE, a joint test of the hypothesis L beta = null is performed, where L is object@linfct and beta is the vector of fixed effects estimated by object@betahat. This will be either an F test or a chi-square (Wald) test depending on whether degrees of freedom are available. See also joint_tests.

verbose  Logical value. If TRUE and joint = TRUE, a table of the effects being tested is printed.

rows  Integer values. The rows of L to be tested in the joint test. If missing, all rows of L are used. If not missing, by variables are ignored.

status  logical. If TRUE, a note column showing status flags (for rank deficiencies and estimability issues) is displayed even when empty. If FALSE, the column is included only if there are such issues.

Details

default.emmGrid is equivalent to summary.emmGrid with infer = c(TRUE,FALSE). When called with joint = FALSE, test.emmGrid is equivalent to summary.emmGrid with infer = c(FALSE,TRUE).

With joint = TRUE, test.emmGrid calculates the Wald test of the hypothesis linfct %*% bhat = null, where linfct and bhat refer to slots in object (possibly subsetted according to by or rows). An error is thrown if any row of linfct is non-estimable. It is permissible for the rows of linfct to be linearly dependent, as long as null == 0, in which case a reduced set of contrasts is tested. Linear dependence and nonzero null cause an error.

Value

summary.emmGrid, confint.emmGrid, and test.emmGrid return an object of class "summary_emm", which is an extension of data.frame but with a special print method that displays it with custom
formatting. For models fitted using MCMC methods, the call is diverted to `hpd.summary` (with `prob` set to `level`, if specified); one may alternatively use general MCMC summarization tools with the results of `as.mcmc`.

`predict` returns a vector of predictions for each row of `object@grid`.

The `as.data.frame` method returns a plain data frame, equivalent to `as.data.frame(summary(.))`.

### Defaults

The `misc` slot in `object` may contain default values for `by`, `calc`, `infer`, `level`, `adjust`, `type`, `null`, `side`, and `delta`. These defaults vary depending on the code that created the object. The `update` method may be used to change these defaults. In addition, any options set using `emm_options(summary = ...)` will trump those stored in the object’s `misc` slot.

### Transformations and links

With `type = "response"`, the transformation assumed can be found in `object@misc$tran`, and its label, for the summary is in `object@misc$inv.lbl`. Any t or z tests are still performed on the scale of the linear predictor, not the inverse-transformed one. Similarly, confidence intervals are computed on the linear-predictor scale, then inverse-transformed.

When `bias.adjust` is `TRUE`, then back-transformed estimates are adjusted by adding $0.5h''(u)\sigma^2$, where $h$ is the inverse transformation and $u$ is the linear predictor. This is based on a second-order Taylor expansion. There are better or exact adjustments for certain specific cases, and these may be incorporated in future updates.

### P-value adjustments

The `adjust` argument specifies a multiplicity adjustment for tests or confidence intervals. This adjustment always is applied separately to each table or sub-table that you see in the printed output (see `rbind.emmGrid` for how to combine tables).

The valid values of `adjust` are as follows:

- **"tukey"** Uses the Studentized range distribution with the number of means in the family. (Available for two-sided cases only.)
- **"scheffe"** Computes $p$ values from the $F$ distribution, according to the Scheffe critical value of $\sqrt{r}F(\alpha; r, d)$, where $d$ is the error degrees of freedom and $r$ is the rank of the set of linear functions under consideration. By default, the value of $r$ is computed from `object@linfct` for each by group; however, if the user specifies an argument matching `scheffe.rank`, its value will be used instead. Ordinarily, if there are $k$ means involved, then $r = k - 1$ for a full set of contrasts involving all $k$ means, and $r = k$ for the means themselves. (The Scheffe adjustment is available for two-sided cases only.)
- **"sidak"** Makes adjustments as if the estimates were independent (a conservative adjustment in many cases).
- **"bonferroni"** Multiplies $p$ values, or divides significance levels by the number of estimates. This is a conservative adjustment.
- **"dunnetttx"** Uses our own ad hoc approximation to the Dunnett distribution for a family of estimates having pairwise correlations of 0.5 (as is true when comparing treatments with a control with equal sample sizes). The accuracy of the approximation improves with the number of simultaneous estimates, and is much faster than "mvt". (Available for two-sided cases only.)
"mvt" Uses the multivariate t distribution to assess the probability or critical value for the maximum of \( k \) estimates. This method produces the same \( p \) values and intervals as the default summary or confint methods to the results of \texttt{as.glht}. In the context of pairwise comparisons or comparisons with a control, this produces “exact” Tukey or Dunnett adjustments, respectively. However, the algorithm (from the \texttt{mvtnorm} package) uses a Monte Carlo method, so results are not exactly repeatable unless the same random-number seed is used (see \texttt{set.seed}). As the family size increases, the required computation time will become noticeable or even intolerable, making the "tukey", "dunnettx", or others more attractive.

"none" Makes no adjustments to the \( p \) values.

For tests, not confidence intervals, the Bonferroni-inequality-based adjustment methods in \texttt{p.adjust} are also available (currently, these include "holm", "hochberg", "hommel", "bonferroni", "BH", "BY", "fdr", and "none"). If a \texttt{p.adjust.methods} method other than "bonferroni" or "none" is specified for confidence limits, the straight Bonferroni adjustment is used instead. Also, if an adjustment method is not appropriate (e.g., using "tukey" with one-sided tests, or with results that are not pairwise comparisons), a more appropriate method (usually "sidak") is substituted.

In some cases, confidence and \( p \)-value adjustments are only approximate – especially when the degrees of freedom or standard errors vary greatly within the family of tests. The "mvt" method is always the correct one-step adjustment, but it can be very slow. One may use \texttt{as.glht} with methods in the \texttt{multcomp} package to obtain non-conservative multi-step adjustments to tests.

Testing nonsuperiority, noninferiority, or equivalence

When \( \text{delta} = 0 \), test statistics are of the usual form \((\text{estimate} - \text{null})/SE\), or notationally, \( t = (Q - \theta_0)/SE \) where \( Q \) is our estimate of \( \theta \); then left, right, or two-sided \( p \) values are produced.

When \( \text{delta} \) is positive, the test statistic depends on \texttt{side} as follows.

**Left-sided (nonsuperiority)** \( H_0 : \theta \geq \theta_0 + \delta \) versus \( H_1 : \theta < \theta_0 + \delta \)
\[ t = (Q - \theta_0 - \delta)/SE \]
The \( p \) value is the lower-tail probability.

**Right-sided (noninferiority)** \( H_0 : \theta \leq \theta_0 - \delta \) versus \( H_1 : \theta > \theta_0 - \delta \)
\[ t = (Q - \theta_0 + \delta)/SE \]
The \( p \) value is the upper-tail probability.

**Two-sided (equivalence)** \( H_0 : |\theta - \theta_0| \geq \delta \) versus \( H_1 : |\theta - \theta_0| < \delta \)
\[ t = (|Q - \theta_0| - \delta)/SE \]
The \( p \) value is the lower-tail probability.

Non-estimable cases

When the model is rank-deficient, each row \( x \) of object’s \texttt{linfct} slot is checked for estimability. If \( \text{sum}(x*bhat) \) is found to be non-estimable, then the string \texttt{NonEst} is displayed for the estimate, and associated statistics are set to \texttt{NA}. The estimability check is performed using the orthonormal basis \( N \) in the \texttt{nbasis} slot for the null space of the rows of the model matrix. Estimability fails when \(||Nx||^2/||x||^2\) exceeds \texttt{tol}, which by default is \(1e^{-8}\). You may change it via \texttt{emm_options} by setting \texttt{estble.tol} to the desired value.
Warning about potential misuse of P values

A growing consensus in the statistical and scientific community is that the term “statistical significance” should be completely abandoned, and that criteria such as “p < 0.05” never be used to assess the importance of an effect. These practices are just too misleading and prone to abuse. See the “basics” vignette for more discussion.

Note

In doing testing and a transformation and/or link is in force, any null and/or delta values specified must always be on the scale of the linear predictor, regardless of the setting for ‘type’. If type = “response”, the null value displayed in the summary table will be back-transformed from the value supplied by the user. But the displayed delta will not be changed, because there (usually) is not a natural way to back-transform it.

The default show method for emmGrid objects (with the exception of newly created reference grids) is print(summary()). Thus, with ordinary usage of emmeans and such, it is unnecessary to call summary unless there is a need to specify other than its default options.

link{hpd.summary}

Examples

```r
warp.lm <- lm(breaks ~ wool * tension, data = warpbreaks)
warp.emm <- emmeans(warp.lm, ~ tension | wool)
warp.emm  # implicitly runs 'summary'

# Consider as some of many possible contrasts among the six cell means
summary(con, infer = c(TRUE, TRUE), adjust = "scheffe", scheffe.rank = 5)
```
Description

Objects of class `emmGrid` contain several settings that affect such things as what arguments to pass to `summary.emmGrid`. The update method allows safer management of these settings than by direct modification of its slots.

Usage

```r
## S3 method for class 'emmGrid'
update(object, ..., silent = FALSE)
```

Arguments

- `object`: An `emmGrid` object
- `...`: Options to be set. These must match a list of known options (see Details)
- `silent`: Logical value. If `FALSE` (the default), a message is displayed if any options are not matched. If `TRUE`, no messages are shown.

Value

- an updated `emmGrid` object.

Details

The names in `...` are partially matched against those that are valid, and if a match is found, it adds or replaces the current setting. The valid names are

- `tran`, `tran2` (list or character) specifies the transformation which, when inverted, determines the results displayed by `summary.emmGrid`, `predict.emmGrid`, or `emmip` when `type="response"`. The value may be the name of a standard transformation from `make.link` or additional ones supported by name, such as `"log2"`; or, for a custom transformation, a list containing at least the functions `linkinv` (the inverse of the transformation) and `mu.eta` (the derivative thereof). The `make.tran` function returns such lists for a number of popular transformations. See the help page of `make.tran` for details as well as information on the additional named transformations that are supported. `tran2` is just like `tran` except it is a second transformation (i.e., a response transformation in a generalized linear model).

- `tran.mult`: Multiple for `tran`. For example, for the response transformation `2*sqrt(y)` (or `sqrt(y) + sqrt(y + 1)`), for that matter), we should have `tran = "sqrt"` and `tran.mult = 2`. If absent, a multiple of 1 is assumed.

- `tran.offset`: Additive constant before a transformation is applied. For example, a response transformation of `log(y + pi)` has `tran.offset = pi`. If no value is present, an offset of 0 is assumed.

- `estName` (character) is the column label used for displaying predictions or EMMs.
inv.lbl (character) is the column label to use for predictions or EMMs when type="response". by.vars (character) vector or NULL the variables used for grouping in the summary, and also for defining subfamilies in a call to contrast.

pri.vars (character vector) are the names of the grid variables that are not in by.vars. Thus, the combinations of their levels are used as columns in each table produced by summary.emmGrid.

alpha (numeric) is the default significance level for tests, in summary.emmGrid as well as plot.emmGrid when ‘CIs = TRUE’. Be cautious that methods that depend on specifying alpha are prone to abuse. See the discussion in vignette("basics", "emmeans").

adjust (character) is the default for the adjust argument in summary.emmGrid.

famSize (integer) is the number of means involved in a family of inferences; used in Tukey adjustment

infer (logical vector of length 2) is the default value of infer in summary.emmGrid.

level (numeric) is the default confidence level, level, in summary.emmGrid. Note: You must specify all five letters of ‘level’ to distinguish it from the slot name ‘levels’.

df (numeric) overrides the default degrees of freedom with a specified single value.

calc (list) additional calculated columns. See summary.emmGrid.

null (numeric) null hypothesis for summary or test (taken to be zero if missing).

side (numeric or character) side specification for for summary or test (taken to be zero if missing).

sigma (numeric) Error SD to use in predictions and for bias-adjusted back-transformations
delta (numeric) delta specification for summary or test (taken to be zero if missing).

predict.type or type (character) sets the default method of displaying predictions in summary.emmGrid, predict.emmGrid, and emmip. Valid values are "link" (with synonyms "lp" and "linear"), or "response".

bias.adjust, frequentist (character) These are used by summary if the value of these arguments are not specified.

estType (character) is used internally to determine what adjust methods are appropriate. It should match one of c("prediction", "contrast", "pairs"). As an example of why this is needed, the Tukey adjustment should only be used for pairwise comparisons (estType = "pairs"); if estType is some other string, Tukey adjustments are not allowed.

avgd.over (character) vector are the names of the variables whose levels are averaged over in obtaining marginal averages of predictions, i.e., estimated marginal means. Changing this might produce a misleading printout, but setting it to character(0) will suppress the “averaged over” message in the summary.

initMesg (character) is a string that is added to the beginning of any annotations that appear below the summary.emmGrid display.

methDesc (character) is a string that may be used for creating names for a list of emmGrid objects.

nesting (Character or named list) specifies the nesting structure. See “Recovering or overriding model information” in the documentation for ref_grid. The current nesting structure is displayed by str.emmGrid.
levels named list of new levels for the elements of the current emmGrid. The list name(s) are used as new variable names, and if needed, the list is expanded using expand.grid. These results replace current variable names and levels. This specification changes the levels, grid, roles, and misc slots in the updated emmGrid, and resets pri.vars, by.vars, adjust, famSize, avgd.over, and nesting. Note: All six letters of levels is needed in order to distinguish it from level.

(any other slot name) If the name matches an element of slotNames(object) other than levels, that slot is replaced by the supplied value, if it is of the required class (otherwise an error occurs).

The user must be very careful in replacing slots because they are interrelated; for example, the lengths and dimensions of grid, linfct, bhat, and V must conform.

Note

When it makes sense, an option set by update will persist into future results based on that object. But some options are disabled as well. For example, a calc option will be nulled-out if contrast is called, because it probably will not make sense to do the same calculations on the contrast results, and in fact the variable(s) needed may not even still exist.

Examples

# Using an already-transformed response:
mypigs <- transform(pigs, logconc = log(pigs$conc))
mypigs.lm <- lm(logconc ~ source + factor(percent), data = mypigs)

# Reference grid that knows about the transformation
# and asks to include the sample size in any summaries:
mypigs.rg <- update(ref_grid(mypigs.lm), tran = "log",
                  predict.type = "response",
                  calc = c(n = ~.wgt.))
emmeans(mypigs.rg, "source")

xtable.emmGrid    Using xtable for EMMs

Description

These methods provide support for the xtable package, enabling polished presentations of tabular output from emmeans and other functions.
Usage

```r
## S3 method for class 'emmGrid'
xtable(x, caption = NULL, label = NULL, align = NULL,
       digits = 4, display = NULL, auto = FALSE, ...)

## S3 method for class 'summary_emm'
xtable(x, caption = NULL, label = NULL,
       align = NULL, digits = 4, display = NULL, auto = FALSE, ...)

## S3 method for class 'xtable_emm'
print(x, type = getOption("xtable.type", "latex"),
      include.rownames = FALSE, sanitize.message.function = footnotesize, ...)
```

Arguments

- `x`: Object of class `emmGrid`
- `caption`: Passed to `xtableList`
- `label`: Passed to `xtableList`
- `align`: Passed to `xtableList`
- `digits`: Passed to `xtableList`
- `display`: Passed to `xtableList`
- `auto`: Passed to `xtableList`
- `type`: Passed to `print.xtable`
- `include.rownames`: Passed to `print.xtable`
- `sanitize.message.function`: Passed to `print.xtable`

Details

The methods actually use `xtableList`, because of its ability to display messages such as those for P-value adjustments. These methods return an object of class "xtable_emm" – an extension of "xtableList". Unlike other `xtable` methods, the number of digits defaults to 4; and degrees of freedom and t ratios are always formatted independently of digits. The `print` method uses `print.xtableList`, and any ... arguments are passed there.

Value

The `xtable` methods return an `xtable_emm` object, for which its print method is `print.xtable_emm`.

Examples

```r
pigsint.lm <- lm(log(conc) ~ source * factor(percent), data = pigs)
pigsint.emm <- emmeans(pigsint.lm, ~ percent | source)
xtable::xtable(pigsint.emm, type = "response")
```
