Package ‘fiery’

February 5, 2024

Type Package
Title A Lightweight and Flexible Web Framework
Version 1.2.1
Maintainer Thomas Lin Pedersen <thomasp85@gmail.com>
Description A very flexible framework for building server side logic in
R. The framework is unopinionated when it comes to how HTTP requests
and WebSocket messages are handled and supports all levels of app
complexity; from serving static content to full-blown dynamic
web-apps. Fiery does not hold your hand as much as e.g. the shiny
package does, but instead sets you free to create your web app the way
you want.

Generate a New App Object

Description

The Fire generator creates a new Fire-object, which is the class containing all the app logic. The class is based on the R6 OO-system and is thus reference-based with methods and data attached to each object, in contrast to the more well known S3 and S4 systems. A fiery server is event driven, which means that it is build up and manipulated by adding event handlers and triggering events. To learn more about the fiery event model, read the event vignette. fiery servers can be modified directly or by attaching plugins. As with events, plugins has its own vignette.

Initialization:

A new 'Fire'-object is initialized using the new() method on the generator:

```r
app <- Fire$new(host = '127.0.0.1', port = 8080L)
```

Copying:

As Fire objects are using reference semantics new copies of an app cannot be made simply be assigning it to a new variable. If a true copy of a Fire object is desired, use the clone() method.

Active bindings

- **host** A string giving a valid IPv4 address owned by the server, or '0.0.0.0' to listen on all addresses. The default is '127.0.0.1'
- **port** An integer giving the port number the server should listen on (defaults to 8080L)
- **refresh_rate** The interval in seconds between run cycles when running a blocking server (defaults to 0.001)
- **refresh_rate_nb** The interval in seconds between run cycles when running a non-blocking server (defaults to 1)
- **trigger_dir** A valid folder where trigger files can be put when running a blocking server (defaults to NULL). See the The event cycle in fiery vignette for more information.
- **plugins** A named list of the already attached plugins. Read Only - can only be modified using the attach() method.
- **root** The location of the app. Setting this will remove the root value from requests (or decline them with 400 if the request does not match the root). E.g. the path of a request will be changed from /demo/test to /test if root == '/demo'
- **access_log_format** A glue string defining how requests will be logged. For standard formats see common_log_format and combined_log_format. Defaults to the Common Log Format
Methods

Public methods:

- Fire$new()
- Fire$format()
- Fire$ignite()
- Fire$start()
- Fire$reignite()
- Fire$response()
- Fire$extinguish()
- Fire$stop()
- Fire$on()
- Fire$off()
- Fire$trigger()
- Fire$send()
- Fire$close_ws_con()
- Fire$attach()
- Fire$has_plugin()
- Fire$header()
- Fire$set_data()
- Fire$get_data()
- Fire$remove_data()
- Fire$time()
- Fire$remove_time()
- Fire$delay()
- Fire$remove_delay()
- Fire$async()
- Fire$async()
- Fire$set_client_id_converter()
- Fire$set_logger()
- Fire$log()
- Fire$is_running()
- Fire$test_request()
- Fire$test_header()
- Fire$test_message()
- Fire$test_websocket()
- Fire$clone()

Method new(): Create a new Fire app

Usage:
Fire$new(host = "127.0.0.1", port = 8080)

Arguments:
host A string overriding the default host
port  An port number overriding the default port

Returns: A Fire object

Method format(): Human readable description of the app

Usage:
Fire$format(...)  
Arguments: ... ignored
Returns: A character vector

Method ignite(): Begin running the server. Will trigger the start event

Usage:
Fire$ignite(block = TRUE, showcase = FALSE, ..., silent = FALSE)
Arguments:  
block  Should the console be blocked while running (alternative is to run in the background)
showcase Should the default browser open up at the server address
... Arguments passed on to the start handler
silent  Should startup messaging by silenced

Method start(): Synonymous method to ignite()

Usage:
Fire$start(...)  
Arguments: ... passed on to ignite()

Method reignite(): Resume a session. This is equivalent to ignite() but will also trigger the resume event

Usage:
Fire$reignite(...)  
Arguments: ... passed on to ignite()

Method resume(): Synonymous method to reignite()

Usage:
Fire$resume(...)  
Arguments: ... passed on to ignite()

Method extinguish(): Stop the server. Will trigger the end event

Usage:
Fire$extinguish()

Method stop(): Synonymous method to extinguish()
Usage:
Fire$stop()

Method on(): Add a handler to an event. See the *The event cycle in fiery vignette* for more information.

Usage:
Fire$on(event, handler, pos = NULL)

Arguments:
- **event**: The name of the event that should trigger the handler
- **handler**: The handler function that should be triggered
- **pos**: The position in the handler stack to place it at. NULL will place it at the end.

Returns: A unique string identifying the handler

Method off(): Remove an event handler from the app.

Usage:
Fire$off(handlerId)

Arguments:
- **handlerId**: The unique id identifying the handler

Method trigger(): Trigger an event in the app. This will cause any handler attached to the event to be called. See the *The event cycle in fiery vignette* for more information.

Usage:
Fire$trigger(event, ...)

Arguments:
- **event**: The name of the event
- **...**: Arguments passed on to the handlers

Returns: A named list containing the return values of all handlers attached to the event

Method send(): Send a Websocket message to a client. Will trigger the send event.

Usage:
Fire$send(message, id)

Arguments:
- **message**: The message to send
- **id**: The id of the client to send to. If missing, the message will be send to all clients

Method close_ws_con(): Close a Websocket connection. Will trigger the websocket-closed event

Usage:
Fire$close_ws_con(id)

Arguments:
- **id**: The id of the client to close the websocket connection to
Method `attach()`: Attach a plugin to the app. See the *Creating and using fiery plugins vignette* for more information

Usage:
```
Fire$attach(plugin, ..., force = FALSE)
```

Arguments:
- `plugin` The plugin to attach
- `...` Arguments to pass into the plugins `on_attach()` method
- `force` If the plugin has already been attached an error is thrown, unless `force = TRUE` which tells the app to reattach it

Method `has_plugin()`: Check if the app has a plugin attached

Usage:
```
Fire$has_plugin(name)
```

Arguments:
- `name` The name of the plugin

Returns: A boolean indicating if the given plugin is already attached

Method `header()`: Add a global http header that will be applied to all responses

Usage:
```
Fire$header(name, value)
```

Arguments:
- `name` The name of the header
- `value` The value of the header. Use `NULL` to remove the global header

Method `set_data()`: Add data to the global data store

Usage:
```
Fire$set_data(name, value)
```

Arguments:
- `name` The name identifying the data
- `value` The data to add

Method `get_data()`: Retrieve data from the global data store

Usage:
```
Fire$get_data(name)
```

Arguments:
- `name` The name identifying the data

Returns: The data requested. Returns `NULL` if the store does not contain the requested data

Method `remove_data()`: Remove data from the global data store

Usage:
```
Fire$remove_data(name)
```

Arguments:
**Method** `time()`: Add a timed evaluation that will be evaluated after the given number of seconds. See the *Delaying code execution in Fiery vignette* for more information

*Usage:*

```r
Fire$time(expr, then, after, loop = FALSE)
```

*Arguments:*

- `expr` The expression to evaluate when the time has passed
- `then` A handler to call once `expr` has been evaluated
- `after` The time in second to wait before evaluating `expr`
- `loop` Should `expr` be called repeatedly with the interval given by `after`

*Returns:* A unique id identifying the handler

**Method** `remove_time()`: Remove a timed evaluation

*Usage:*

```r
Fire$remove_time(id)
```

*Arguments:*

- `id` The unique id identifying the handler

**Method** `delay()`: Add a delayed evaluation to be evaluated immediately at the end of the loop cycle. See the *Delaying code execution in Fiery vignette* for more information

*Usage:*

```r
Fire$delay(expr, then)
```

*Arguments:*

- `expr` The expression to evaluate at the end of the cycle
- `then` A handler to call once `expr` has been evaluated

*Returns:* A unique id identifying the handler

**Method** `remove_delay()`: Remove a delayed evaluation

*Usage:*

```r
Fire$remove_delay(id)
```

*Arguments:*

- `id` The unique id identifying the handler

**Method** `async()`: Add an asynchronous evaluation to be evaluated in another process without blocking the server. See the *Delaying code execution in Fiery vignette* for more information

*Usage:*

```r
Fire$async(expr, then)
```

*Arguments:*

- `expr` The expression to evaluate at the end of the cycle
- `then` A handler to call once `expr` has been evaluated

*Returns:* A unique id identifying the handler
Method `remove_async()`: Remove an async evaluation

*Usage:*
Fire$remove_async(id)

*Arguments:*
id The unique id identifying the handler

Method `set_client_id_converter()`: Sets the function that converts an HTTP request into a specific client id

*Usage:*
Fire$set_client_id_converter(converter)

*Arguments:*
converter A function with the argument request

Method `set_logger()`: Sets the logging function to use

*Usage:*
Fire$set_logger(logger)

*Arguments:*
logger A function with the arguments event, message, request, and ...

Method `log()`: Log a message with the logger attached to the app. See loggers for build in functionality

*Usage:*
Fire$log(event, message, request = NULL, ...)

*Arguments:*
event The event associated with the message
message The message to log
request The Request object associated with the message, if any.
... Additional arguments passed on to the logger.

Method `is_running()`: Test if an app is running

*Usage:*
Fire$is_running()

Method `test_request()`: Send a request directly to the request logic of a non-running app. Only intended for testing the request logic

*Usage:*
Fire$test_request(request)

*Arguments:*
request The request to send

Method `test_header()`: Send a request directly to the header logic of a non-running app. Only intended for testing the request logic

*Usage:*

Fire\$test\_header(request)

\textbf{Arguments:}
request The request to send

\textbf{Method test\_message():} Send a message directly \textbf{to} the message logic of a non-running app. Only intended for testing the websocket logic

\textbf{Usage:}
Fire\$test\_message(request, binary, message, withClose = TRUE)

\textbf{Arguments:}
request The request to use to establish the connection
binary Is the message send in binary or character format
message The message to send. If binary = FALSE a character vector, if binary = TRUE a raw vector
withClose Should the websocket connection be closed at the end by the client

\textbf{Method test\_websocket():} Send a message directly \textbf{from} a non-running app. Only intended for testing the websocket logic

\textbf{Usage:}
Fire\$test\_websocket(request, message, close = TRUE)

\textbf{Arguments:}
request The request to use to establish the connection
message The message to send from the app
close Should the websocket connection be closed at the end by the server

\textbf{Method clone():} The objects of this class are cloneable with this method.

\textbf{Usage:}
Fire\$clone(deep = FALSE)

\textbf{Arguments:}
deep Whether to make a deep clone.

\section*{Examples}

\# Create a New App
app <- Fire\$new(port = 4689)

\# Setup the data every time it starts
app\$on('start', function(server, ...) {
    server\$set\_data('visits', 0)
    server\$set\_data('cycles', 0)
})

\# Count the number of cycles
app\$on('cycle\_start', function(server, ...) {
    server\$set\_data('cycles', server\$get\_data('cycles') + 1)
})
# Count the number of requests
app$on('before-request', function(server, ...) {
    server$set_data('visits', server$get_data('visits') + 1)
})

# Handle requests
app$on('request', function(server, ...) {
    list(
        status = 200L,
        headers = list('Content-Type' = 'text/html'),
        body = paste('This is indeed a test. You are number', server$get_data('visits'))
    )
})

# Show number of requests in the console
app$on('after-request', function(server, ...) {
    message(server$get_data('visits'))
    flush.console()
})

# Terminate the server after 300 cycles
app$on('cycle-end', function(server, ...) {
    if (server$get_data('cycles') > 300) {
        message('Ending...')
        flush.console()
        server$extinguish()
    }
})

# Be polite
app$on('end', function(server) {
    message('Goodbye')
    flush.console()
})

### Not run:
app$ignite(showcase = TRUE)

### End(Not run)

---

### loggers

#### App Logging

**Description**

fiery has a build in logging mechanism that lets you capture event information however you like. Every user-injected warnings and errors are automatically captured by the logger along with most system errors as well. fiery tries very hard not to break due to faulty app logic. This means that any event handler error will be converted to an error log without fiery stopping. In the case of request handlers a 500L response will be send back if any error is encountered.
loggers

Usage

logger_null()

logger_console(format = "{time} - {event}: {message}"

logger_file(file, format = "{time} - {event}: {message}"

logger_switch(..., default = logger_null())

custom_log_format

combined_log_format

Arguments

format A glue string specifying the format of the log entry
file A file or connection to write to
... A named list of loggers to use for different events. The same semantics as switch
is used so it is possible to let events fall through e.g. logger_switch(error =,
warning = logger_file("errors.log"))

default A catch-all logger for use with events not defined in ...

Format

An object of class character of length 1.
An object of class character of length 1.

Setting a logger

By default, fiery uses logger_null() which forwards warning and error messages to stderr() and ignores any other logging events. To change this behavior, set a different logger using the set_logger() method:

app$set_logger(logger)

where logger is a function taking at least the following arguments: event, message, request, time, and ....

fiery comes with some additional loggers, which either writes all logs to a file or to the console. A new instance of the file logger can be created with logger_file(file):

app$set_logger(logger_file('fiery_log.log'))

A new instance of the console logger can be create with logger_console():

app$set_logger(logger_console())
Both functions take a format a argument that lets you customise how the log is written. Furthermore the console logger will style the logs with colour coding depending on the content if the console supports it.

As a last possibility it is possible to use different loggers dependent on the event by using the switch logger:

```r
app$set_logger(logger_switch(warning =,
    error = logger_file('errors.log),
    default = logger_file('info.log')))"
```

**Automatic logs**

fiery logs a number of different information by itself describing its operations during run. The following events are send to the log:

- **start** Will be send when the server starts up
- **resume** Will be send when the server is resumed
- **stop** Will be send when the server stops
- **request** Will be send when a request has been handled. The message will contain information about how long time it took to handle the request or if it was denied.
- **websocket** Will be send every time a WebSocket connection is established or closed as well as when a message is received or send
- **message** Will be send every time a message is emitted by an event handler or delayed execution handler
- **warning** Will be send everytime a warning is emitted by an event handler or delayed execution handler
- **error** Will be send everytime an error is signaled by an event handler or delayed execution handler. In addition some internal functions will also emit error event when exceptions are encountered

By default only **message**, **warning** and **error** events will be logged by sending them to the error stream as a `message()`.

**Access Logs**

Of particular interest are logs that detail requests made to the server. These are the request events detailed above. There are different standards for how requests are logged. fiery uses the **Common Log Format** by default, but this can be modified by setting the `access_log_format` field to a glue expression that has access to the following variables:

- **start_time** The time the request was recieved
- **end_time** The time the response was send back
- **request** The Request object
- **response** The Response object
- **id** The client id

To change the format:

```r
app$access_log_format <- combined_log_format
```
Custom logs

Apart from the standard logs described above it is also possible to send messages to the log as you please, e.g. inside event handlers. This is done through the log() method where you at the very least specify an event and a message. In general it is better to send messages through log() rather than with warning() and stop() even though the latters will eventually be caught, as it gives you more control over the logging and what should happen in the case of an exception.

An example of using log() in a handler could be:

```javascript
app$on('header', function(server, id, request) {
    server$log('info', paste0('request from ', id, ' received'), request)
})
```

Which would log the timepoint the headers of a request has been received.
