Package ‘finetune’

April 19, 2023

Title Additional Functions for Model Tuning

Version 1.1.0

Description The ability to tune models is important. 'finetune' enhances the 'tune' package by providing more specialized methods for finding reasonable values of model tuning parameters. Two racing methods described by Kuhn (2014) <arXiv:1405.6974> are included. An iterative search method using generalized simulated annealing (Bohachevsky, Johnson and Stein, 1986) <doi:10.1080/00401706.1986.10488128> is also included.

collect_predictions  Obtain and format results produced by racing functions

Description

Obtain and format results produced by racing functions

Usage

## S3 method for class 'tune_race'
collect_predictions(
x, 
summarize = FALSE,
parameters = NULL,
all_configs = FALSE,
...
)

## S3 method for class 'tune_race'
collect_metrics(x, summarize = TRUE, all_configs = FALSE, ...)

Arguments

x  The results of tune_grid(), tune_bayes(), fit_resamples(), or last_fit(). For collect_predictions(), the control option save_pred = TRUE should have been used.

summarize  A logical: should metrics be summarized over resamples (TRUE) or return the values for each individual resample. Note that, if x is created by last_fit(), summarize has no effect. For the other object types, the method of summarizing predictions is detailed below.

parameters  An optional tibble of tuning parameter values that can be used to filter the predicted values before processing. This tibble should only have columns for each tuning parameter identifier (e.g. "my_param" if tune("my_param") was used).

all_configs  A logical: should we return the complete set of model configurations or just those that made it to the end of the race (the default).

...  Not currently used.
Details

For `collect_metrics()` and `collect_predictions()`, when unsummarized, there are columns for each tuning parameter (using the id from `tune()`, if any). `collect_metrics()` also has columns `.metric` and `.estimator`. When the results are summarized, there are columns for `mean`, `n`, and `std_err`. When not summarized, the additional columns for the resampling identifier(s) and `.estimate`.

For `collect_predictions()`, there are additional columns for the resampling identifier(s), columns for the predicted values (e.g., `.pred`, `.pred_class`, etc.), and a column for the outcome(s) using the original column name(s) in the data.

`collect_predictions()` can summarize the various results over replicate out-of-sample predictions. For example, when using the bootstrap, each row in the original training set has multiple holdout predictions (across assessment sets). To convert these results to a format where every training set same has a single predicted value, the results are averaged over replicate predictions.

For regression cases, the numeric predictions are simply averaged. For classification models, the problem is more complex. When class probabilities are used, these are averaged and then renormalized to make sure that they add to one. If hard class predictions also exist in the data, then these are determined from the summarized probability estimates (so that they match). If only hard class predictions are in the results, then the mode is used to summarize.

For racing results, it is best to only collect model configurations that finished the race (i.e., were completely resampled). Comparing performance metrics for configurations averaged with different resamples is likely to lead to inappropriate results.

Value

A tibble. The column names depend on the results and the mode of the model.

control_race  Control aspects of the grid search racing process

Description

Control aspects of the grid search racing process

Usage

```r
control_race(
  verbose = FALSE,
  verbose_elim = FALSE,
  allow_par = TRUE,
  extract = NULL,
  save_pred = FALSE,
  burn_in = 3,
  num_ties = 10,
  alpha = 0.05,
  randomize = TRUE,
)```
Arguments

verbose  A logical for logging results (other than warnings and errors, which are always shown) as they are generated during training in a single R process. When using most parallel backends, this argument typically will not result in any logging. If using a dark IDE theme, some logging messages might be hard to see; try setting the tidymodels.dark option with options(tidymodels.dark = TRUE) to print lighter colors.

verbose_elim A logical for whether logging of the elimination of tuning parameter combinations should occur.

allow_par  A logical to allow parallel processing (if a parallel backend is registered).

event_level  A single string containing either "first" or "second". This argument is passed on to yardstick metric functions when any type of class prediction is made, and specifies which level of the outcome is considered the "event".

parallel_over A single string containing either "resamples" or "everything" describing how to use parallel processing. Alternatively, NULL is allowed, which chooses between "resamples" and "everything" automatically.
control_sim_anneal

If "resamples", then tuning will be performed in parallel over resamples alone. Within each resample, the preprocessor (i.e. recipe or formula) is processed once, and is then reused across all models that need to be fit.

If "everything", then tuning will be performed in parallel at two levels. An outer parallel loop will iterate over resamples. Additionally, an inner parallel loop will iterate over all unique combinations of preprocessor and model tuning parameters for that specific resample. This will result in the preprocessor being re-processed multiple times, but can be faster if that processing is extremely fast.

If NULL, chooses "resamples" if there are more than one resample, otherwise chooses "everything" to attempt to maximize core utilization.

Note that switching between parallel_over strategies is not guaranteed to use the same random number generation schemes. However, re-tuning a model using the same parallel_over strategy is guaranteed to be reproducible between runs.

backend_options

An object of class "tune_backend_options" as created by tune::new_backend_options(), used to pass arguments to specific tuning backend. Defaults to NULL for default backend options.

Value

An object of class control_race that echos the argument values.

Examples

  control_race()

control_sim_anneal  Control aspects of the simulated annealing search process

Description

Control aspects of the simulated annealing search process

Usage

control_sim_anneal(
  verbose = FALSE,
  verbose_iter = TRUE,
  no_improve = Inf,
  restart = 8L,
  radius = c(0.05, 0.15),
  flip = 3/4,
  cooling_coef = 0.02,
  extract = NULL,
  save_pred = FALSE,
  time_limit = NA,
control_sim_anneal

pkgs = NULL,
save_workflow = FALSE,
save_history = FALSE,
event_level = "first",
parallel_over = NULL,
allow_par = TRUE,
backend_options = NULL
)

Arguments

verbose A logical for logging results (other than warnings and errors, which are always shown) as they are generated during training in a single R process. When using most parallel backends, this argument typically will not result in any logging. If using a dark IDE theme, some logging messages might be hard to see; try setting the tidymodels.dark option with options(tidymodels.dark = TRUE) to print lighter colors.

verbose_iter A logical for logging results of the search process. Defaults to FALSE. If using a dark IDE theme, some logging messages might be hard to see; try setting the tidymodels.dark option with options(tidymodels.dark = TRUE) to print lighter colors.

no_improve The integer cutoff for the number of iterations without better results.

restart The number of iterations with no improvement before new tuning parameter candidates are generated from the last, overall best conditions.

radius Two real numbers on (0, 1) describing what a value "in the neighborhood" of the current result should be. If all numeric parameters were scaled to be on the [0, 1] scale, these values set the min. and max. of a radius of a circle used to generate new numeric parameter values.

flip A real number between [0, 1] for the probability of changing any non-numeric parameter values at each iteration.

cooling_coef A real, positive number to influence the cooling schedule. Larger values decrease the probability of accepting a sub-optimal parameter setting.

extract An optional function with at least one argument (or NULL) that can be used to retain arbitrary objects from the model fit object, recipe, or other elements of the workflow.

save_pred A logical for whether the out-of-sample predictions should be saved for each model evaluated.

time_limit A number for the minimum number of minutes (elapsed) that the function should execute. The elapsed time is evaluated at internal checkpoints and, if over time, the results at that time are returned (with a warning). This means that the time_limit is not an exact limit, but a minimum time limit.

pkgs An optional character string of R package names that should be loaded (by namespace) during parallel processing.

save_workflow A logical for whether the workflow should be appended to the output as an attribute.
save_history  A logical to save the iteration details of the search. These are saved to tempdir() named sa_history.RData. These results are deleted when the R session ends. This option is only useful for teaching purposes.

event_level  A single string containing either "first" or "second". This argument is passed on to yardstick metric functions when any type of class prediction is made, and specifies which level of the outcome is considered the "event".

parallel_over  A single string containing either "resamples" or "everything" describing how to use parallel processing. Alternatively, NULL is allowed, which chooses between "resamples" and "everything" automatically.

If "resamples", then tuning will be performed in parallel over resamples alone. Within each resample, the preprocessor (i.e. recipe or formula) is processed once, and is then reused across all models that need to be fit.

If "everything", then tuning will be performed in parallel at two levels. An outer parallel loop will iterate over resamples. Additionally, an inner parallel loop will iterate over all unique combinations of preprocessor and model tuning parameters for that specific resample. This will result in the preprocessor being re-processed multiple times, but can be faster if that processing is extremely fast.

If NULL, chooses "resamples" if there are more than one resample, otherwise chooses "everything" to attempt to maximize core utilization.

Note that switching between parallel_over strategies is not guaranteed to use the same random number generation schemes. However, re-tuning a model using the same parallel_over strategy is guaranteed to be reproducible between runs.

allow_par  A logical to allow parallel processing (if a parallel backend is registered).

backend_options  An object of class "tune_backend_options" as created by tune::new_backend_options(), used to pass arguments to specific tuning backend. Defaults to NULL for default backend options.

Value

An object of class control_sim_anneal that echos the argument values.

Examples

control_sim_anneal()

plot_race  Plot racing results

Description

Plot the model results over stages of the racing results. A line is given for each submodel that was tested.
show_best.tune_race

Usage

plot_race(x)

Arguments

x
A object with class tune_results

Value

A ggplot object.

desc(p)

Description

show_best() displays the top sub-models and their performance estimates.

Usage

## S3 method for class 'tune_race'
show_best(x, metric = NULL, n = 5, ...)

Arguments

x
The results of tune_grid() or tune_bayes().

metric
A character value for the metric that will be used to sort the models. (See https://yardstick.tidymodels.org/articles/metric-types.html for more details). Not required if a single metric exists in x. If there are multiple metric and none are given, the first in the metric set is used (and a warning is issued).

n
An integer for the maximum number of top results/rows to return.

...
For select_by_one_std_err() and select_by_pct_loss(), this argument is passed directly to dplyr::arrange() so that the user can sort the models from most simple to most complex. That is, for a parameter p, pass the unquoted expression p if smaller values of p indicate a simpler model, or desc(p) if larger values indicate a simpler model. At least one term is required for these two functions. See the examples below.

Details

For racing results (from the finetune package), it is best to only report configurations that finished the race (i.e., were completely resampled). Comparing performance metrics for configurations averaged with different resamples is likely to lead to inappropriate results.
tune_race_anova

Efficient grid search via racing with ANOVA models

Description

tune_race_anova() computes a set of performance metrics (e.g. accuracy or RMSE) for a pre-defined set of tuning parameters that correspond to a model or recipe across one or more resamples of the data. After an initial number of resamples have been evaluated, the process eliminates tuning parameter combinations that are unlikely to be the best results using a repeated measure ANOVA model.

Usage

tune_race_anova(object, ...)

## S3 method for class 'model_spec'
tune_race_anova(
  object,
  preprocessor,
  resamples,
  ..., 
  param_info = NULL,
  grid = 10,
  metrics = NULL,
  control = control_race()
)

## S3 method for class 'workflow'
tune_race_anova(
  object,
  resamples,
  ..., 
  param_info = NULL,
  grid = 10,
  metrics = NULL,
  control = control_race()
)

Arguments

object A parsnip model specification or a workflows::workflow().

... Not currently used.

preprocessor A traditional model formula or a recipe created using recipes::recipe(). This is only required when object is not a workflow.

resamples An rset() object that has multiple resamples (i.e., is not a validation set).
param_info A `dials::parameters()` object or NULL. If none is given, a parameters set is derived from other arguments. Passing this argument can be useful when parameter ranges need to be customized.

grid A data frame of tuning combinations or a positive integer. The data frame should have columns for each parameter being tuned and rows for tuning parameter candidates. An integer denotes the number of candidate parameter sets to be created automatically.

metrics A `yardstick::metric_set()` or NULL.

control An object used to modify the tuning process. See `control_race()` for more details.

Details
The technical details of this method are described in Kuhn (2014).

Racing methods are efficient approaches to grid search. Initially, the function evaluates all tuning parameters on a small initial set of resamples. The `burn_in` argument of `control_race()` sets the number of initial resamples.

The performance statistics from these resamples are analyzed to determine which tuning parameters are not statistically different from the current best setting. If a parameter is statistically different, it is excluded from further resampling.

The next resample is used with the remaining parameter combinations and the statistical analysis is updated. More candidate parameters may be excluded with each new resample that is processed.

This function determines statistical significance using a repeated measures ANOVA model where the performance statistic (e.g., RMSE, accuracy, etc.) is the outcome data and the random effect is due to resamples. The `control_race()` function contains a parameter for the significance cutoff applied to the ANOVA results as well as other relevant arguments.

There is benefit to using racing methods in conjunction with parallel processing. The following section shows a benchmark of results for one dataset and model.

**Benchmarking results:**
To demonstrate, we use a SVM model with the kernlab package.

```r
library(kernlab)
library(tidymodels)
library(finetune)
library(doParallel)

##----------------------------------------------------------------------------
data(cells, package = "modeldata")
cells <- cells %>% select(-case)

##----------------------------------------------------------------------------
set.seed(6376)
rs <- bootstraps(cells, times = 25)
```
We’ll only tune the model parameters (i.e., not recipe tuning):

```r
## ----------------------------------------------------------

svm_spec <-
  svm_rbf(cost = tune(), rbf_sigma = tune()) %>%
  set_engine("kernlab") %>%
  set_mode("classification")

svm_rec <-
  recipe(class ~ ., data = cells) %>%
  step_YeoJohnson(all_predictors()) %>%
  step_normalize(all_predictors())

svm_wflow <-
  workflow() %>%
  add_model(svm_spec) %>%
  add_recipe(svm_rec)

set.seed(1)
svm_grid <-
  svm_spec %>%
  parameters() %>%
  grid_latin_hypercube(size = 25)

We’ll get the times for grid search and ANOVA racing with and without parallel processing:

```r
## Regular grid search
system.time({
  set.seed(2)
  svm_wflow %>% tune_grid(resamples = rs, grid = svm_grid)
})
```

```r
## user  system elapsed
## 741.660 19.654 761.357
```

```r
## With racing
system.time({
  set.seed(2)
  svm_wflow %>% tune_race_anova(resamples = rs, grid = svm_grid)
})
```

```r
## user  system elapsed
## 133.143 3.675 136.822
```

Speed-up of 5.56-fold for racing.
## Parallel processing setup

```r
cores <- parallel::detectCores(logical = FALSE)
cores
```

```r
## [1] 10
c1 <- makePSOCKcluster(cores)
registerDoParallel(c1)
```

## Parallel grid search

```r
system.time({
  set.seed(2)
  svm_wflow %>% tune_grid(resamples = rs, grid = svm_grid)
})
```

```r
## user  system elapsed
## 1.112 0.190 126.650
```

Parallel processing with grid search was 6.01-fold faster than sequential grid search.

## Parallel racing

```r
system.time({
  set.seed(2)
  svm_wflow %>% tune_race_anova(resamples = rs, grid = svm_grid)
})
```

```r
## user  system elapsed
## 1.908 0.261 21.442
```

Parallel processing with racing was 35.51-fold faster than sequential grid search.

There is a compounding effect of racing and parallel processing but its magnitude depends on the type of model, number of resamples, number of tuning parameters, and so on.

### Value

An object with primary class `tune_race` in the same standard format as objects produced by `tune::tune_grid()`.

### References

`tune::tune_grid()`, `control_race()`, `tune_race_win_loss()`
Examples

```r
library(parsnip)
library(rsample)
library(dials)

if (rlang::is_installed(c("discrim", "lme4", "modeldata"))) {
  library(discrim)
  data(two_class_dat, package = "modeldata")

  set.seed(6376)
  rs <- bootstraps(two_class_dat, times = 10)

  rda_spec <-
    discrim_regularized(frac_common_cov = tune(), frac_identity = tune()) %>%
    set_engine("klaR")

  ctrl <- control_race(verbose_elim = TRUE)
  set.seed(11)
  grid_anova <-
    rda_spec %>%
    tune_race_anova(Class ~ ., resamples = rs, grid = 10, control = ctrl)

  # Shows only the fully resampled parameters
  show_best(grid_anova, metric = "roc_auc", n = 2)

  plot_race(grid_anova)
}
```

tune_race_win_loss

**Efficient grid search via racing with win/loss statistics**

description

tune_race_win_loss() computes a set of performance metrics (e.g. accuracy or RMSE) for a pre-defined set of tuning parameters that correspond to a model or recipe across one or more resamples of the data. After an initial number of resamples have been evaluated, the process eliminates tuning parameter combinations that are unlikely to be the best results using a statistical model. For each pairwise combinations of tuning parameters, win/loss statistics are calculated and a logistic regression model is used to measure how likely each combination is to win overall.
Usage

tune_race_win_loss(object, ...)

## S3 method for class 'model_spec'
tune_race_win_loss(
  object,
  preprocessor,
  resamples,
  ...,
  param_info = NULL,
  grid = 10,
  metrics = NULL,
  control = control_race()
)

## S3 method for class 'workflow'
tune_race_win_loss(
  object,
  resamples,
  ...,
  param_info = NULL,
  grid = 10,
  metrics = NULL,
  control = control_race()
)

Arguments

object  A parsnip model specification or a workflows::workflow().
...

Not currently used. The technical details of this method are described in Kuhn (2014).

Racing methods are efficient approaches to grid search. Initially, the function evaluates all tuning parameters on a small initial set of resamples. The burn_in argument of control_race() sets the number of initial resamples.

The performance statistics from the current set of resamples are converted to win/loss/tie results. For example, for two parameters (j and k) in a classification model that have each been resampled three times:

<table>
<thead>
<tr>
<th>area under the ROC curve</th>
</tr>
</thead>
<tbody>
<tr>
<td>resample</td>
</tr>
<tr>
<td>---------------------------------------------</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
</tbody>
</table>

After the third resample, parameter k has a 2:1 win/loss ratio versus j. Parameters with equal results are treated as a half-win for each setting. These
statistics are determined for all pairwise combinations of the parameters and a
Bradley-Terry model is used to model these win/loss/tie statistics. This model
can compute the ability of a parameter combination to win overall. A confidence
interval for the winning ability is computed and any settings whose interval in-
cludes zero are retained for future resamples (since it is not statistically different
form the best results).
The next resample is used with the remaining parameter combinations and the
statistical analysis is updated. More candidate parameters may be excluded with
each new resample that is processed.
The control_race() function contains are parameter for the significance cutoff
applied to the Bradley-Terry model results as well as other relevant arguments.

preprocessor A traditional model formula or a recipe created using recipes::recipe().
resamples An rset() object that has multiple resamples (i.e., is not a validation set).
param_info A dials::parameters() object or NULL. If none is given, a parameters set
is derived from other arguments. Passing this argument can be useful when
parameter ranges need to be customized.
grid A data frame of tuning combinations or a positive integer. The data frame should
have columns for each parameter being tuned and rows for tuning parameter
candidates. An integer denotes the number of candidate parameter sets to be
created automatically.
metrics A yardstick::metric_set() or NULL.
control An object used to modify the tuning process.

Value
An object with primary class tune_race in the same standard format as objects produced by
tune::tune_grid().

tune_sim_anneal

**Optimization of model parameters via simulated annealing**

**Description**

tune_sim_anneal() uses an iterative search procedure to generate new candidate tuning parameter combinations based on previous results. It uses the generalized simulated annealing method of Bohachevsky, Johnson, and Stein (1986).

**Usage**

tune_sim_anneal(object, ...)

## S3 method for class 'model_spec'
tune_sim_anneal(
  object,
  preprocessor,
  resamples,
  ...,
  iter = 10,
  param_info = NULL,
)
tune_sim_anneal

metrics = NULL,
initial = 1,
control = control_sim_anneal()
)

## S3 method for class 'workflow'
tune_sim_anneal(
  object,
  resamples,
  ..., 
  iter = 10,
  param_info = NULL,
  metrics = NULL,
  initial = 1,
  control = control_sim_anneal()
)

Arguments

- **object**: A `parsnip` model specification or a `workflows::workflow()`.
- **...**: Not currently used.
- **preprocessor**: A traditional model formula or a recipe created using `recipes::recipe()`. This is only required when `object` is not a workflow.
- **resamples**: An `rset()` object.
- **iter**: The maximum number of search iterations.
- **param_info**: A `dials::parameters()` object or NULL. If none is given, a parameter set is derived from other arguments. Passing this argument can be useful when parameter ranges need to be customized.
- **metrics**: A `yardstick::metric_set()` object containing information on how models will be evaluated for performance. The first metric in `metrics` is the one that will be optimized.
- **initial**: An initial set of results in a tidy format (as would the result of `tune_grid()`, `tune_bayes()`, `tune_race_win_loss()`, or `tune_race_anova()`) or a positive integer. If the initial object was a sequential search method, the simulated annealing iterations start after the last iteration of the initial results.
- **control**: The results of `control_sim_anneal()`.

Details

Simulated annealing is a global optimization method. For model tuning, it can be used to iteratively search the parameter space for optimal tuning parameter combinations. At each iteration, a new parameter combination is created by perturbing the current parameters in some small way so that they are within a small neighborhood. This new parameter combination is used to fit a model and that model’s performance is measured using resampling (or a simple validation set).

If the new settings have better results than the current settings, they are accepted and the process continues.
If the new settings has worse performance, a probability threshold is computed for accepting these sub-optimal values. The probability is a function of how sub-optimal the results are as well as how many iterations have elapsed. This is referred to as the “cooling schedule” for the algorithm. If the sub-optimal results are accepted, the next iterations settings are based on these inferior results. Otherwise, new parameter values are generated from the previous iteration’s settings.

This process continues for a pre-defined number of iterations and the overall best settings are recommended for use. The `control_sim_anneal()` function can specify the number of iterations without improvement for early stopping. Also, that function can be used to specify a restart threshold; if no globally best results have not be discovered within a certain number if iterations, the process can restart using the last known settings that globally best.

**Creating new settings:**
For each numeric parameter, the range of possible values is known as well as any transformations. The current values are transformed and scaled to have values between zero and one (based on the possible range of values). A candidate set of values that are on a sphere with random radii between \(r_{\text{min}}\) and \(r_{\text{max}}\) are generated. Infeasible values are removed and one value is chosen at random. This value is back transformed to the original units and scale and are used as the new settings. The argument radius of `control_sim_anneal()` controls the range neighborhood sizes.

For categorical and integer parameters, each is changes with a pre-defined probability. The `flip` argument of `control_sim_anneal()` can be used to specify this probability. For integer parameters, a nearby integer value is used.

Simulated annealing search may not be the preferred method when many of the parameters are non-numeric or integers with few unique values. In these cases, it is likely that the same candidate set may be tested more than once.

**Cooling schedule:**
To determine the probability of accepting a new value, the percent difference in performance is calculated. If the performance metric is to be maximized, this would be \(d = (\text{new} - \text{old}) / \text{old} \times 100\). The probability is calculated as \(p = \exp(d \times \text{coef} \times \text{iter})\) were \(\text{coef}\) is a user-defined constant that can be used to increase or decrease the probabilities.

The cooling_coef of `control_sim_anneal()` can be used for this purpose.

**Termination criterion:**
The restart counter is reset when a new global best results is found.
The termination counter resets when a new global best is located or when a suboptimal result is improved.

**Parallelism:**
The `tune` and `finetune` packages currently parallelize over resamples. Specifying a parallel back-end will improve the generation of the initial set of sub-models (if any). Each iteration of the search are also run in parallel if a parallel backend is registered.

**Value**
A tibble of results that mirror those generated by `tune_grid()`. However, these results contain an `.iter` column and replicate the `rset` object multiple times over iterations (at limited additional memory costs).
tune_sim_anneal
