Package ‘flip’
February 19, 2015

Type Package
Title Multivariate Permutation Tests
Version 2.4.3
Date 2013-06-13
Author Livio Finos, with contributions by Dario Basso, Aldo Solari, Jelle Goeman and Marco Rinaldo. Special thanks are due to Ivan Marin-Franch and Fredrik Nilsson for the debugging and the good questions.
Maintainer Livio Finos <livio@stat.unipd.it>
Depends methods, e1071, someMTP, cherry
Imports Rcpp, RcppArmadillo
LinkingTo Rcpp, RcppArmadillo
Description It implements many univariate and multivariate permutation (and rotation) tests. Allowed tests: the one and two samples, ANOVA, linear models, Chi Squared test, rank tests (i.e. Wilcoxon, Mann-Whitney, Kruskal-Wallis), Sign test and McNemar. Test on Linear Models are performed also in presence of covariates (i.e. nuisance parameters). The permutation and the rotation methods to get the null distribution of the test statistics are available. It also implements methods for multiplicity control such as Westfall-Young minP procedure and Closed Testing (Marcus, 1976) and k-FWER. Moreover, it allows to test for fixed effects in mixed effects models.
License GPL (>= 2)
LazyLoad yes
NeedsCompilation yes

flipMix ............................................................ 9
npc ............................................................... 12
permutationSpace .................................................. 15
The library is devoted to permutation-based inferential methods.

Description

It implements many univariate and multivariate permutation (and rotation) tests.

The tests comprised are: the one and two samples, ANOVA, linear models, Chi Squared test, rank tests (i.e. Wilcoxon, Mann-Whitney, Kruskal-Wallis), Kolmogorov-Smirnov and Anderson-Darling.

Test on Linear Models are performed also in presence of covariates (i.e. nuisance parameters).

The permutation and the rotation method to get the null distribution of the test statistic(s) are available.

It also implements methods for multiplicity control such as Westfall-Young min-p procedure and Closed Testing (Marcus, 1976).

Maintainer: livio finos <livio@stat.unipd.it>

References

The structure of flip is widely borrowed from library globaltest by J. Goeman and J. Oosting in bioconductor.org.

Examples

```r
Y=data.frame(matrix(rnorm(50),10,5))
names(Y)=LETTERS[1:5]
```
The main function for univariate and multivariate testing under a permutation (and rotation) framework + some utilities.

Description

flip is the main function for permutation (or rotation) test.
It allows for multivariate one sample, C>=2 samples and any regression tests. Also the use of covariates (to be fitted in the model but) not under test is allowed.

Usage

```
flip(Y, X=NULL, Z=NULL, data=NULL, tail = 0, perms = 1000, statTest=NULL,
     Strata=NULL, flipReturn, testType=NULL, ...)  
```

```
    # c("t", "F", "ANOVA",
    # "Wilcoxon","Kruskal-Wallis", "kruskal", "rank", "Mann-Whitney",
    # "chisq","chisq.separated", "Fisher",
    # "McNemar", "Sign","sum","coeff","NA")

    orthoZ(Y, X=NULL, Z=NULL, data=NULL, returnGamma=FALSE)
```

Arguments

- **Y**
  The response vector of the regression model. May be supplied as a vector or as a *formula* object. In the latter case, the right hand side of Y is passed on to alternative if that argument is missing, or otherwise to null.

- **X**
  The part of the design matrix corresponding to the alternative hypothesis. The covariates of the null model do not have to be supplied again here. May be given as a half *formula* object (e.g. ~a+b). In that case the intercept is always suppressed.

- **Z**
  The part of the design matrix corresponding to the null hypothesis. May be given as a design matrix or as a half *formula* object (e.g. ~a+b). The default for Z is ~1, i.e. only an intercept. This intercept may be suppressed, if desired, with Z = ~0.
data
Only used when \( Y, X, \) or \( Z \) is given in formula form. An optional data frame, list or environment containing the variables used in the formula. If the variables in a formula are not found in data, the variables are taken from environment(formula), typically the environment from which gt is called.

tail
Vector of values -1, 0 or 1 indicating the tail to be used in the test for each column of \( Y \). \( tail=1 (-1) \) means that greater (smaller) values bring more evidence to the alternative hypothesis. \( tail=0 \) indicates a two sided alternative. If the length of tail is smaller than number of columns of \( Y \), the values are recycled.

perms
The number of permutations to use. The default is \( perms = 1000 \). Alternatively it can be a matrix (i.e. the permutation space) or a list with elements number and seed.

Strata
A vector, which unique values identifies strata. This option is used only with testType="permutation"; parameter \( Z \) is not considered in this case. Also note that when only two levels with one observation per each level are present in each stratum, the problem becomes a paired two-samples problem and hence simplified to a one-sample test.

statTest
Choose from flip.statTest. See also Details section.

flipReturn
list of objects indicating what will be included in the output.
e.g. list(permp=TRUE,permT=TRUE,data=TRUE).

testType
by default testType="permutation". In alternative you can choose "rotation" resampling is performed through random linear combinations (i.e. a rotation test is performed). This option is useful when only few permutations are available, that is, minimum reachable significance is high. The old syntax rotationTest=TRUE is maintained for compatibility but is deprecated, use testType="rotation" instead.

returnGamma
logical. Should be the eigenvectors (with corresponding non-null eigenvalues) of the anti-projection matrix of \( Z \) (i.e. \( I - Z(Z'Z)^{-1} Z' \)) returned?

... Further parameters. The followings are still valid but deprecated:
permT.return = TRUE, permP.return = FALSE,
permSpace.return = FALSE, permY.return = FALSE. Use flipReturn instead.
dummyfy a named list of logical values (eg. list(X=TRUE,Y=TRUE))
rotationTest= TRUE. Deprecated, use testType='rotation' instead.

Details

statTest="t" is the t statistic derived from the correlation among the Xs and the Ys (i.e. a linear model for each couples of Xs and Ys). This is different from the fit of a multiple (multivariate) linear models, since the correlation does not consider the other covariates). The test \( t \) is valid only under the assumption that each variable in X is independent of each variable in Y. To get adequate test while adjusting for covariates, use \( Z \) (see example below) The test statistic "sum" is the sum of values (or frequencies) of the given sample centered on the expected (i.e. computed on the overall sample). "coeff" is the statistic based on the estimated coefficient of lm. It produce a test for every possible combination of (columns of) X and Y (p-values can be combined using npc).
"ANOVA" is synonyms of "F". Only valid for dependence tests (i.e. non constant X). "Mann-Whitney" is synonyms of "Wilcoxon". "rank" choose among "Wilcoxon" and "Kruskal-Wallis" depending if the samples are two or more (respectively).

The "Wilcoxon" statistic is based on the 'sum of ranks of second sample minus n1*(n+1)/2' instead of 'sum of ranks of smallest sample minus nSmallest*(n+1)/2'. Therefore the statistic is centered on 0 and allow for two sided alternatives. Despite the p-value are ok, it requires the X to be a two-levels factor in order to compute the right test statistic. When the X is not a two-levels factor, it measures the codeviance among X and ranks of Y.

For paired samples (see also the argument Strata and the example below) the Signed Rank test is performed. To perform the Sign Test use option Sign (i.e. same as Signed Rank but without using magnitude of ranks).

The "Fisher" test is allowed only with dichotomous Ys. The reported statistic is the bottom-right cell of the 2 by 2 frequencies table. The "chisq.separated" test perform cell-wise chi squared (see also Finos and Salmaso (2004) Communications in Statistics - Theory and methods).

The "McNemar" test is based on the signs of the differences, hence it can be used also with ordinal or continuous responses. Only valid for symmetry tests (i.e. X is constant or NULL). The reported statistic for "McNemar" test is the signed squared root of the McNemar statistic. Hence it allows for tailed alternatives.

For ordered X, a stochastic ordering test can be performed using "t", "Wilcoxon", "sum" and then combining the separated test using npc.

When statTest is a function, the first argument must be Y. This same function is ran to observed data Y and to a number of permuted rows of Y. The returned value must be a vector of test statistics. Please note that argument tail must be defined accordingly. The default way the rows of Y are rearranged is through permutation (without strata). More complex permutation strategies can be defined through proper definition of argument perm (see also permutationSpace).

Value

An object of class flip.object. Several operations and plots can be made from this object. See also flip.object-class.

Examples

```r
Y = matrix(rnorm(50), 10, 5)
colnames(Y) = LETTERS[1:5]
Y[,1:2] = Y[,1:2] + 2
res = flip(Y)
res
plot(res)

X = rep(0:1,5)
Y = Y + matrix(X * 2, 10, 5)

data = data.frame(Y, X, Z = rnorm(10))
# testing dependence among Y's and X
(res = flip(Y, ~ X, data = data))
# same as:
# res = flip(A + B + C + D + E ~ X, data = data)

# testing dependence among Y's and X, also using covariates
(res = flip(Y, ~ X, ~ Z, data = data))
res
# Note that
# flip(Y, X = ~ X, Z = ~ 1, data = data)
# is different from
# flip(Y, ~ X, data = data)
# since the former is based on orthogonalized residuals of Y and X by Z.

## Not run:
# Rotation tests:
rot = flip(Y, X, Z = ~ 1, testType = "rotation")
# note the use Z = ~ 1.

## End (Not run)

# Using rank tests:
(res = flip(Y, ~ X, data = data, statTest = "wilcoxon"))
res

# testing symmetry of Y around 0
Y[,1:2] = Y[,1:2] + 2
res = flip(Y)
res
plot(res)

# use of strata (in this case equal to paired samples)
data$S = rep(1:5, rep(2, 5))
# paired t
flip(A + B + C + D + E ~ X, data = data, statTest = "t", Strata = ~ S)
# signed Rank test
flip(A + B + C + D + E ~ X, data = data, statTest = "wilcox", Strata = ~ S)
```
# tests for categorical data
data=data.frame(X=rep(0:2,10))
data=data.frame(X=factor(data$X),Y=factor(rbinom(30,2,.2*data$X)))
flip(~Y~X,data=data,statTest="chisq")
# separated chisq (Finos and Salmaso, 2004. Nonparametric multi-focus analysis
# for categorical variables. CommStat - T.M.)
(res.sep=flip(~Y~X,data=data,statTest="chisq.separated"))
npc(res.sep,"sumT2") # note that combined test statistic is the same as chisq

## Not run:
## User-defined test statistic:
my.fun <- function(Y){
    summary(lm(Y~X))$coeff[1,"Pr(>|t|)"
}
X<- matrix(rep(0:2,10))
Y <- matrix(rnorm(30))
flip(Y,Y,X,X,statTest=my.fun)

## End(Not run)

---

**flip.object-class**  
*Class "flip.object" (and related functions) for storing the result of the function flip and flipMix*

---

**Description**

The class `flip.object` is the output of a call to `flip`, `flipMix`, `npc` and `flip.adjust`. It stores the information needed for various diagnostic plots. Specific functions to deal with these objects are also documented here.

**Usage**

```r
getFlip(obj, element)
cFlip(...)
```

**Arguments**

- **obj**  
  Any `flip-object`

- **element**  
  Character string of either slot names of `obj` (i.e. "res", "call", "permP", "permT", "permSpace", "permY", "tail", "data", "call.env"), elements of slot `obj@data` (e.g. "Y", "X", "Z", "Strata") or columns of `obj@res` (usually "Test", "Stat", "tail", "p-value"). Specific uses: "Adjust:" returns all columns of adjusted p-values in `obj@res`. Any among "nperms", "perms", "B" return the number of permutation used.

- **...**  
  `flip-objects` to be concatenated.
Objects from the Class

Objects can be created by calls of the form `new("flip.object", ...)`.

Slots

- **res**: Object of class `flip.object`
- **call**: Object of class "call"
- **permP**: A matrix p-values of size B x p (number of permutations x number of variables), first line representing the p-value computed on observed data.
- **permT**: A matrix test statistics of size B x p (number of permutations x number of variables), first line representing the test statistic computed on observed data.
- **permSpace**: A list that may contain `bLnLrotfunctLpermid`. `b` is the number of permutations/rotations, `n` number of observations (possibly after orthogonalization of the residuals), `rotfunct` is the function used to resample the elements. `permID` is a matrix permutation of size B x n (number of permutations x sampel size), first line representing the p-value computed on observed data. This matrix is usually generated by `make.permSpace` or `make.signSpace`
- **permY**: Not implemented yet
- **tail**: tail of the alternative. 1 means right tail, -1 left tail and 0 is bidirectional alternative

Methods

- `[`: Select tests from the `flip.object`. Tests can be selected by position of name. It also allow for grep-like selection.
- `[[`: Same as `[`
  - **hist**: Produces a histogram to visualize the permutation test statistics (same as `globaltest.gt.object`)
  - **length**: Number of tests
  - **names**: signature(x = "flip.object"): ...
  - **names<-.**: signature(x = "flip.object"): ...
  - **p.value**: Extracts p-values from the object.
  - **p.adjust**: Performs multiple testing correction and produces multiplicity-corrected p-values. See `flip.adjust` for details.
  - **plot**: signature(x = "flip.object", y = "missing"). It plots the permutation space and the observed test statistic. The plot is an histogram (see `hist.flip.object`) if there is only one test, while it is a biplot when there are more variables. In this case the arrows of the rotations are colored in red when the associated p-value(res)<=.05.
  - **result**: report table of results
  - **show**: report table of results
  - **size**: Returns the size of permT (i.e. number of permutations X number of tests)
  - **sort**: Sorts the tests to increasing p-values.
  - **summary**: Provides the call, the number of permutations. Option `star.signif`: =TRUE (default) set stars depending on the last column of p-values; =FALSE inhibits stars, ="p-value" or any other names indicates the column to which the stars refer.

Examples

showClass("flip.object")

y=matrix(rnorm(50),10,5)
colnames(y)=c("X1","X2","Y1","Y2","Y3")
res=flip(y)

## Sort by p-values
sort(res)

## Selecting tests
res[1:2]
#same as
res["X"]
#different from (it selects tests having "1" or "2" in the name)
res[c("1","2")]

## Concatenates two flip-objects
cFlip(res[1:2],res[5])

#plotting results
plot(flip(y))

#Get any slot of the flip-object. eg the permutation space:
head(getFlip(res,"permT"))
#Get any element of the list obj$data. eg Y:
getFlip(res,"Y")
#Get any columns of the results table: obj@res. eg Statistic (choose among colnames(obj@res) ):
getFlip(res,"Stat")

flipMix

The main function for testing mixed models under a permutation (and rotation) framework

Description

It allows to test fixed effect in mixed models. You can test within-unit effects, between-unit and interactions of the two. The response can be uni- or multi-variate. See also examples below.

Usage

flipMix(modelWithin, X = NULL, Z = NULL, units, perms = 1000, data = NULL, tail = NULL, statTest = NULL, flipReturn, testType = "permutation", Su = NULL, equal.se = FALSE, se = NA, replaceNA.coefWithin = "coeffMeans"
replaceNA.coeffWithin.se = replaceNA.coeffWithin, 

flipMixWithin(modelWithin, units, X = ~1, perms=1000, data=NULL, tail=NULL, 
statTest=NULL, flipReturn, 
Su=NULL, equal.se=FALSE, se=NA, replaceNA.coeffWithin=0, 
replaceNA.coeffWithin.se = Inf, 

obs2coeffWithin(modelWithin, units, X = NULL, Z = NULL, data = NULL, equal.se = FALSE, 
se = NA, replaceNA.coeffWithin = NA, replaceNA.coeffWithin.se = Inf, 

Arguments

modelWithin When it is a formula object, a (possibly multivariate) multiple linear model is fitted. Responses are on the left, while the right part contains ONLY within-unit variables. In this case data must be supplied. Alternatively, it can be a glm, a lm or vgam (library(VGAM)) (i.e. vglm) object. The modelWithin have to be performed using only variables within-unit, without using units indicator (in this case the argument data is not used). It can be also a list of models. It can be null if data is provided in the right format (see below).

X The part of the design matrix corresponding to the between-unit effect that are not null under the alternative hypothesis. If it is a matrix or a data.frame it must have a number of rows equal to the number of units or equal to the total number of observations (in the latest case all elements of the same units must have the same values since they are between-unit effects). The non-null between-unit covariates of null model are defined in Z (see argument below) and do not have to be supplied again here. See also the function flip.

NOTE: When called from flipMixWithin, W is used only if statTest="TBTWest".

Z The part of the design matrix corresponding to the non-null between-unit covariates of the model under the null hypothesis. May be given as a design matrix or as a half formula object (e.g. ~a+b). See also the function flip. If it is a matrix or a data.frame it must have a number of rows equal to the number of units or equal to the total number of observations (in the latest case all elements of the same units must have the same values since they are between-unit effects).

units Vector of units IDs. May be given as a vector or as a half formula object (e.g. ~subj).

perms The number of permutations to use. The default is perms = 1000. Alternatively it can be a matrix (i.e. the permutation space) or a list with elements number and seed. See also the function flip.

data Same as in the function flip. If can also be the results of obs2coeffWithin.

tail Same as in the function flip.

statTest For function flipMix choose among "t" and "F" (very similar to statTest in function flip. For function flipMixWithin choose among "Tnaive" (i.e. no estimate of the variance), "TH0est" (Default, i.e. estimate of the variance under H0), "TH1est" (i.e. estimate of the variance under H1 for each permutation. Slower but some time more powerful) and "TBTWest" (i.e. estimate of the variance using ILS algorithm at each permutation; it allows for Z different from a
constant term. This is the same algorithm used for flipMix. MUCH slower but some time even more powerful).
Both functions allow for vector arguments.

**flipReturn**
Same as in the function flip.

**testType**
See also the function flip. Note that this option used only with function flipMix.

**Su**
Usually NULL. It is the covariance matrix of the random effects. If not supplied, it is estimated by iterative least square algorithm.

**equal.se**
Logical. If TRUE it force the unit to have the same variance of errors (like it is usually assumed in the lmer methods).

**se**
Usually NULL. It is a matrix of unit-specific standard errors. If not supplied it is estimated by the algorithm.

**replaceNA.coeffWithin**
deafult is NA i.e. no replacement. You can provide a specific value (or a vector of values). You can also choose among "coeffMeans" and "unitMeans" (i.e. mean along columns or along rows of Y).

**replaceNA.coeffWithin.se**
deafult is Inf. Use the same options of replaceNA.coeffWithin (but means are over the variances and then rooted).

... Further parameters. test.coeffWithin Vector of names or IDs of within-unit variables that have to be tested (and reported). Note that variables not in the list are used in the model (i.e. the they play the role of nuisance parameters). fastSumCombination,onlyMANOVA and linComb are used in flipMix to deal with combination of variables/coefficents.

See also the function flip for other parameters.

**Value**
flipMix and flipMixWithin return an object of class flip.object. Several operations and plots can be made from this object. See also flip.object-class.

Note that function flipMix with statTest="t" or "F" provides tests for each effect between (and interaction) and also provides the overall test PC1 and sum (i.e. all effects ar null, same as npc does). Use npc with any comb.funct=c("data.sum","data.linComb","data.pc","data.trace") to combine results.

obs2coeffWithin return a list of objects that can be used as argument of data in the function flipMix and flipMixWithin.

flip.npc

Examples

N=10
toyData= data.frame(subj=rep(1:N,rep(4,N)), Within=rep(1:2,N*2),
 XBetween= rep(1:2,rep(N/2+4,2)), ZBetween= rep(rnorm(N/2),rep(8,N/2)))
toyData= cbind(Y1=rnorm(n=N*4,mean=toyData$subj+toyData$ZBetween+toyData$XBetween),
 Y2=rnorm(n=N*4,mean=toyData$subj+toyData$ZBetween+toyData$Within+2),toyData)

(test)

### Testing Between-unit effects
(res=flipMix(modelWithin=as.matrix(toyData[,c("Y1","Y2")])~Within, data=toyData,
 X=-XBetween, Z=-ZBetween, units=-subj, perms=1000, testType="permutation", statTest="t")

# same as:
modelWithin <- lm(as.matrix(toyData[,c("Y1","Y2")])~Within, data=toyData)

(res=flipMix(modelWithin=modelWithin, data=toyData, X=-XBetween, Z=-ZBetween, units=-subj,
 perms=1000, testType="permutation", statTest="t")

### Note that this is different from:
modelWithin <- list(Y1=lm(Y1~Within, data=toyData),Y2=lm(Y2~Within, data=toyData))

(res=flipMix(modelWithin=modelWithin, data=toyData, X=-XBetween, Z=-ZBetween, units=-subj,
 perms=1000, testType="permutation", statTest="t")

### Combining results

(npc(res,"data.pc"))

(npc(res,"data.trace"))

### Testing Within-unit effects

# The resulting test is approximated. The estimate of the variance within units
# takes into account the presence of effects between units.

(res=flipMix(modelWithin=as.matrix(toyData[,c("Y1","Y2")])~Within, data=toyData,
 units=-subj, perms=1000, testType="permutation", statTest="t")

### The resulting tests are exact. If effects between are presents,
### statTest="Tukey" or "TBMWest" are more suitable:

(res=flipMixWithin(modelWithin=as.matrix(toyData[,c("Y1","Y2")])~Within, data=toyData,
 units=-subj, perms=1000, statTest=c("TH1est"))

npc(res)

npc

Functions for multiplicity corrections

Description

npc provides overall tests (i.e. weak FWER control), while flip.adjust provides adjusted p-values (i.e. strong FWER control).
Usage

npc(permTP, comb.funct = c(flip.npc.methods, p.adjust.methods),
    subsets=NULL, weights=NULL, stdSpace=FALSE, ...)
flip.adjust(permTP, method = flip.npc.methods, maxalpha = 1,
    weights = NULL, stdSpace=FALSE, ...)

flip.npc.methods
  # "minP", "maxT", "maxTstd", "sumT", "Direct", "sumTstd", "sumT2", "kwer",
  # "data.sum", "data.linComb", "data.pc", "data.trace")
  # use methods in the last row only for outputs of function flipMix()

Arguments

permTP A permutation space (B times m matrix) or an flip.object as produced by
          flip. Alternatively it can be a flip.object-class resulting, for example from
          a call of function flip.
comb.funct A combining function flip.npc.methods (all but "kfwer"): "Fisher", "Liptak",
            "MahalanobisT", "MahalanobisP" (i.e. related to Hotelling T2), "minP" (i.e.
            Tippel), "maxT", "sumT" (i.e. direct), "sumT2" (sum of T^2). "Fisher"
            combining function is the default. See also the section Details.
method A method among flip.npc.methods or p.adjust.methods. By default "maxT"
        is used. See also the section Details.
maxalpha Adjusted p-values greater than maxalpha are forced to 1. It saves computational
         time when there are many hypotheses under test.
weights Optional argument that can be used to give certain variables greater weight in
         the combined test. Can be a vector or a list of vectors. In the latter case, a
         separate test will be performed for each weight vector. If both subsets and
         weights are specified as a list, they must have the same length. In that case,
         weights vectors may have either the same length as the number of covariates in
         alternative, or the same length as the corresponding subset vector. Weights
         can be negative; the sign has no effect unless directional is TRUE. It works for
         npc and flip.adjust with method = "maxT", "maxTstd" or "minP"
subsets Optional argument that can be used to test one or more subsets of variables. Can
         be a vector of column names or indices of a flip.object-class (names(flipObject)),
         or a list of such vectors. In the latter case, a separate test will be performed for
         each subset. Only for comb.funct
stdSpace Ask if the permutation distribution of the test statistic should be standardized or
          not. The default is FALSE. The option is applied only if comb. funct or method
          is equal to "maxT" or "sumT", it becomes useful when test statistics are of different
          nature (e.g. chisquare and t-test).
... further arguments. Among them, tail can be used to set the tail of the alterna-
          tive for the permTP (see also flip). The arguments statTest, fastSumCombination
          and linComb are used in objects flipMix and comb.funct= "data.sum", "data.linComb", "data.pc"
          or "data.trace".
Details

npc combines the p-values using the combining functions (and the method) described in Pesarin (2001). It makes use of the join space of the permutations. This is usually derived from a call of flip function or flipMixWithin.

Very shortly:
"Fisher" = \(-\sum \log(p\text{-values})\)
"Liptak" = \(\sum \text{qnorm}(p\text{-values})\)
"Mahalanobis T" = Mahalanobis distance of centered matrix \(\text{permTP} \) (or \(\text{permTP} \oplus \text{permTP} \))
"Mahalanobis P" = same as above, but using scores defined by \(\text{qnorm}(p\text{-values})\) (tails are forced to be one-sided)
"minP" = \(\text{Tippett} = \min(p\text{-values})\)
"maxT" = \(\max(\text{test statistics})\)
"maxTstd" = \(\max(\text{standardized test statistics})\)
"sumT" = \(\sum(\text{test statistics})\)
"sumTstd" = \(\sum(\text{standardized test statistics})\)
"sumT2" = \(\sum(\text{test statistics})^2\)

The followings have to be used carefully and only with objects from function flipMix(): "data.sum" = sum of all columns of \(Y\)
"data.lincomb" = sum of all columns of \(Y\) (include a vector or matrix \(\text{linComb}\) among the arguments)
"data.pc" = extract the first principal component from the covariance matrix (you may also include a vector \(\text{which}PCs\) indicating which PCs you want to consider)
"data.trace" = Extends the Pillai Trace, use parametric bootstrap to assess the significance.
"kfwer" = can be only used with \(\text{flip.adjust}\) (not in \(\text{npc}\)). It requires an extra parameter \(k\) (\(k=11\) by default).

\(\text{flip.adjust}\) adjusts the p-value for multiplicity (Family Wise Error Rate -FWER- and kFWER). When method is equal to "maxT", "maxTstd" (i.e. \(\max T\) on \(\text{scale(permTP)}\)) or "minP" (i.e. Tippett) it performs the step-down method of Westfall and Young (1993). For any other element of \(\text{flip.npc.methods}\) (i.e. "Fisher", "Liptak", "sumT" (i.e. direct) or "sumT2" (sum of \(T^2\)) a call to \(\text{npc}\) together with a closing testing procedure is used (it make use of \text{cherry:closed}).

When method is any among \(\text{p.adjust.methods}\) the function \(\text{stats:p.adjust or -if weights are provided- someMT:p.adjust.w}\) is used. To perform control of the kFWER use \(\text{flip.adjust with method="kfwer" and extra parameter k}\).

Value

The function returns an object of class \text{flip.object-class} (and the use of \text{getFlip(obj,"Adjust")}).

References

Examples

```r
Y=data.frame(matrix(rnorm(50),10,5))
names(Y)=LETTERS[1:5]
Y[,1:2]=Y[,1:2]+1.5
res = flip(Y,perms=10000)
```

#######npc
permutationSpace

These functions handle the orbit of permutation/rotation tests (i.e. permutation/rotation space).

Description

make.permSpace computes the perms x n matrix of ids used for test of dependence. make.signSpace computes the perms x n vector of +1 and -1 used for symmetry test.

rom computes a Random Orthogonal Matrix of size nXn.

t2p computes the (possibly multivariate) space of p-values from the space of test statistic.

Usage

make.permSpace(IDs, perms, return.permIDs=FALSE, testType="permutation", Strata=NULL)
make.signSpace(N, perms)
allpermutations(Y)
npermutations(Y)
rom(N)
t2p(T, obs.only = TRUE, tail)

Arguments

IDs vector of IDs to be permuted. If IDs is a scalar, it is replaced with 1:IDs.
return.permIDs logical. If TRUE, the matrix of permuted IDs is stored and returned. Only used with testType="permutation"
N number of elements of the sample. It is also the dimension of the random orthogonal matrix in rom.
permutationSpace

Y a vector of data. It can also be a vector 1:N referring to the IDs of observations.
perms number of random permutations. If it is a list, it has two elements number (the number of random permutation requested) and seed (the seed to be set when start generating. it is useful for reproducibility) If perms > number of all possible flips, then compute the complete space.
T the (possibly multivariate) permutation space as returned, for example by flip
obs.only logical. If TRUE only the p-value for observed test statistic is returned, otherwise the whole space is computed
tail Tail of the distribution being significant for H1. See also argument tail in flip
testType See argument testType in flip
strata See argument testType in flip

Details

rom implements the algorithm of Stewart (1980). The function is compiled in C++.
