Package ‘fsdaR’

January 14, 2020

Title Robust Data Analysis Through Monitoring and Dynamic Visualization

Version 0.4-9

Date 2020-01-13

VersionNote Released 0.4-8 on 2020-01-13 on CRAN

Description Provides interface to the 'MATLAB' toolbox 'Flexible Statistical Data Analysis (FSDA)' which is a comprehensive and computationally efficient software package for robust statistics in regression, multivariate and categorical data analysis. The current R version implements tools for regression: (forward search, S- and MM-estimation, least trimmed squares (LTS) and least median of squares (LMS)), for multivariate analysis (forward search, S- and MM-estimation), for cluster analysis and cluster-wise regression. The distinctive feature of our package is the possibility of monitoring the statistics of interest as function of breakdown point, efficiency or subset size, depending on the estimator. This is accompanied by a rich set of graphical features, such as dynamic brushing, linking, particularly useful for exploratory data analysis.

Depends R (>= 3.5.0), rrcov

Imports rJava, methods, stats4, ggplot2

**Description**

Takes as input the output of function `tclustICsol` (that is a structure containing the best relevant solutions) and produces the car-bike plot. This plot provides a concise summary of the best relevant solutions. This plot shows on the horizontal axis the value of $c$ and on the vertical axis the value of $k$. For each solution we draw a rectangle for the interval of values for which the solution is best and stable and a horizontal line which departs from the rectangle for the values of $c$ in which the solution is only stable. Finally, for the best value of $c$ associated to the solution, we show a circle with two numbers, the first number indicates the ranked solution among those which are not spurious and the second one the ranked number including the spurious solutions. This plot has been baptized 'car-bike’, because the first best solutions (in general 2 or 3) are generally best and stable for a large number of values of $c$ and therefore will have large rectangles. In addition, these solutions are likely to be stable for additional values of $c$ and therefore are likely to have horizontal lines departing from the rectangles (from here the name ‘cars’). Finally, local minor solutions (which are associated with particular values of $c$ and $k$) do not generally present rectangles or lines and are shown with circles (from here the name ‘bikes’).

**Usage**

```r
carbikeplot(out, SpuriousSolutions = FALSE, trace = FALSE, ...)
```
Arguments

- `out`: An S3 object of class `tclusticsol.object`, (output of `tclustICsol`) containing the relevant solutions.

- `SpuriousSolutions`: Whether to include or not spurious solutions. By default spurious solutions are not included into the plot.

- `trace`: Whether to print intermediate results. Default is `trace=FALSE`.

- `...`: Potential further arguments passed to lower level functions.

References

Examples

```r
## Not run:
data(geyser2)
out <- tclustIC(geyser2, whichIC="MIXMIX", plot=FALSE, alpha=0.1)

## Plot first two best solutions using as Information criterion MIXMIX
print("Best solutions using MIXMIX")
outMIXMIX <- tclustICsol(out, whichIC="MIXMIX", plot=TRUE, NumberOfBestSolutions=2)
print(outMIXMIX$MIXMIXbs)
carbikeplot(outMIXMIXs)
## End(Not run)
```

Description

Provides a method for obtaining the maximum empirical efficiency (in case of MM estimates) or maximum empirical breakdown plot (in case of S estimates) or maximum subset size (in case of forward search), using various measures of correlation between the n Mahalanobis distances or residuals at adjacent values of efficiency, breakdown point or subset size.
Usage

corfwdplot(out, trace = FALSE, ...)

Arguments

out  An object of S3 class returned by one of the estimation functions with the monitoring option selected (monitoring=TRUE): fsreda.object, sregeda.object, mmregeda.object, fsmeda.object, smulteda.object or mmmulteda.object. This is a list containing the monitoring of minimum Mahalanobis distance in case of multivariate analysis or the monitoring of residuals in case of regression. The needed elements of out are

1. MAL: matrix containing the squared Mahalanobis distances monitored in each step of the forward search. Every row is associated with a unit (row of data matrix Y). This matrix can be created using one of the functions fsmult, smult or mmmult with the monitoring option selected, i.e. monitoring=TRUE.

2. RES: matrix containing the residuals monitored in each step of the forward search. Every row is associated with a unit (row of data matrix Y). This matrix can be created using the function fsreg with the monitoring option selected, i.e. monitoring=TRUE.

3. bdp: a vector containing breakdown point values that have been used, in case of S estimates.

4. eff: a vector containing efficiency values that have been used, in case of MM estimates.

trace   Whether to print intermediate results. Default is trace=FALSE.

...   potential further arguments passed to lower level functions.

Value

A ggplot plot object which can be printed on screen or to a file.

Author(s)

FSDA team, <valentin.todorov@chello.at>

Examples

## Not run:

data(hbk)
(out <- fsmult(hbk[,1:3], monitoring=TRUE))
corfwdplot(out)

(out <- fsmult(hbk[,1:3], monitoring=TRUE))
corfwdplot(out)

(out! <- smult(hbk, monitoring=TRUE, trace=TRUE))
corfwdplot(out!)
diabetes

## End(Not run)

### diabetes

**Diabetes data**

#### Description

The diabetes dataset, introduced by Reaven and Miller (1979), consists of 145 observations (patients). For each patient three measurements are reported: plasma glucose response to oral glucose, plasma insulin response to oral glucose, degree of insulin resistance.

#### Usage

```r
data("diabetes")
```

#### Format

A data frame with the following variables:

- **glucose** Area under plasma glucose curve after a three hour oral glucose tolerance test (OGTT).
- **insulin** Area under plasma insulin curve after a three hour oral glucose tolerance test (OGTT).
- **sspg** Steady state plasma glucose.
- **class** The type of diabetes: Normal, Overt, and Chemical.

#### Source

#### Examples

```r
data(diabetes)
head(diabetes)
plot(CovMcd(diabetes[, 1:3]), which="pairs", col=diabetes$class)
```
Demographic data from the 341 municipalities in Emilia Romagna (an Italian region).

Description

A data set containing 28 demographic variables for 341 municipalities in Emilia Romagna (an Italian region).

Usage

data(emilia2001)

Format

A data frame with 341 rows and 28 variables. The variables are as follows:

- less10: population aged less than 10
- more75: population aged more than 75
- single: single-member families
- divorced: divorced
- widows: widows and widowers
- graduates: population aged more than 25 who are graduates
- no_education: of those aged over 6 having no education
- employed: activity rate
- unemployed: unemployment rate
- increase_popul: standardised natural increase in population
- migration: standardised change in population due to migration
- birth_92_94: average birth rate over 1992-94
- fecundity: three-year average birth rate amongst women of child-bearing age
- houses: occupied houses built since 1982
- houses_2WCs: occupied houses with 2 or more WCs
- houses_heating: occupied houses with fixed heating system
- TV: TV licence holders
- cars: number of cars for 100 inhabitants
- luxury_cars: luxury cars
- hotels: working in hotels and restaurants
- banking: working in banking and finance
- income: average declared income amongst those filing income tax returns
- income_tax_returns: inhabitants filing income tax returns
• factories: residents employed in factories and public services
• factories_more10: employees employed in factories with more than 10 employees
• factories_more50: employees employed in factories with more than 50 employees
• artisanal: artisanal enterprises
• entrepreneurs: enterpreneurial and skilled self-employed among those of working age

### fsdalms.object

#### Description

An object of class `fsdalms.object` holds information about the result of a call to `fsreg`.

#### Value

The object itself is basically a `list` with the following components:

- **rew**: If `rew=TRUE` all subsequent output refers to reweighted else no reweighting is done.
- **beta**: p-by-1 vector containing the estimated regression parameters.
- **bs**: p x 1 vector containing the units forming subset associated with bLMS (bLTS).
- **residuals**: residuals.
- **scale**: scale estimate of the residuals.
- **weights**: Vector like y containing weights. The elements of this vector are 0 or 1. These weights identify the h observations which are used to compute the final LTS (LMS) estimate. sum(weights)=h if there is not a perfect fit otherwise sum(weights) can be greater than h
- **h**: The number of observations that have determined the LTS (LMS) estimator, i.e. the value of h.
- **outliers**: vector containing the list of the units declared as outliers using confidence level specified in input scalar `conflev`.
- **conflev**: confidence level which is used to declare outliers. Remark: `conflev` will be used to draw the horizontal lines (confidence bands) in the plots. Default value is 0.975
- **singsub**: Number of subsets without full rank. Notice that if this number is greater than 0.1*(number of subsamples) a warning is produced
- **X**: the data matrix X
- **y**: the response vector y

The object has class "fsdalms".
fsdalts.object

Examples

```r
## Not run:
(out <- fsreg(Y~., data=hbk, method="LMS"))
class(out)
summary(out)
```

## End(Not run)

---

**Description**

An object of class `fsdalts.object` holds information about the result of a call to `fsreg`.

**Value**

The object itself is basically a list with the following components:

- `rew` If rew=TRUE all subsequent output refers to reweighted else no reweighting is done.
- `beta` p-by-1 vector containing the estimated regression parameters.
- `bs` p x 1 vector containing the units forming subset associated with bLMS (bLTS).
- `residuals` residuals.
- `scale` scale estimate of the residuals.
- `weights` Vector like y containing weights. The elements of this vector are 0 or 1. These weights identify the h observations which are used to compute the final LTS (LMS) estimate. sum(weights)=h if there is not a perfect fit otherwise sum(weights) can be greater than h
- `h` The number of observations that have determined the LTS (LMS) estimator, i.e. the value of h.
- `outliers` vector containing the list of the units declared as outliers using confidence level specified in input scalar `confllev`.
- `confllev` confidence level which is used to declare outliers. Remark: `confllev` will be used to draw the horizontal lines (confidence bands) in the plots. Default value is 0.975
- `singsub` Number of subsets with out full rank. Notice that if this number is greater than 0.1*(number of subsamples) a warning is produced
- `X` the data matrix X
- `y` the response vector y

The object has class "fsdalts".
## Examples

```r
## Not run:
(out <- fsreg(Y~., data=hbk, method="LTS"))
class(out)
summ(out)
## End(Not run)
```

---

### fsmeda.object

**Description of fsmeda.object Objects**

An object of class `fsmeda.object` holds information about the result of a call to `fsmult` when called with parameter `monitoring=TRUE`.

### Value

The object itself is basically a `list` with the following components:

- **MAL**
  
  n x (n-init+1) matrix containing the monitoring of Each row represents the distance Mahalanobis distance for the corresponding unit.

- **BB**
  
  n x (n-init+1) matrix containing the information about the units belonging to the subset at each step of the forward search. The first column contains the indexes of the units forming subset in the initial step and each further column - the indexes of the units forming the corresponding step. The last column contains the units forming subset in the final step (all units).

- **md**
  
  n-by-1 vector containing the estimates of the robust Mahalanobis distances (in squared units). This vector contains the distances of each observation from the location of the data, relative to the scatter matrix cov.

- **mmd**
  
  (n-init) x 3 matrix. which contains the monitoring of minimum MD or (m+1)th ordered MD at each step of the forward search.
  
  - 1st column = fwd search index (from init to n-1)
  - 2nd column = minimum MD
  - 3rd column = (m+1)th-ordered MD

- **msr**
  
  (n-init+1) x 3 matrix which contains the monitoring of maximum MD or m-th ordered MD at each step of the forward search.
  
  - 1st column = fwd search index (from init to n)
  - 2nd column = maximum MD
  - 3rd column = mth-ordered MD

- **gap**
  
  (n-init+1) x 3 matrix which contains the monitoring of the gap (difference between minMD outside subset and max inside).
  
  - 1st column = fwd search index (from init to n)
  - 2nd column = min MD - max MD
• 3rd column = (m+1)th-ordered MD - mth ordered distance

Loc
(n-init+1) x (p+1) matrix which contains the monitoring of the estimated means at each step of the fwd search.

S2cov
(n-init+1) x (p*(p+1)/2+1) matrix which contains the monitoring of the of the elements of the covariance matrix in each step of the forward search.

- 1st column = fwd search index (from init to n)
- 2nd column = monitoring of $S[1,1]$
- 3rd column = monitoring of $S[1,2]$
- ...
- last column = monitoring of $S[p,p]$

detS
(n-init+1) x 2 matrix which contains the monitoring of the determinant of the covariance matrix in each step of the forward search.

Un
(n-init)-by-11 matrix which contains the unit(s) included in the subset at each step of the fwd search. REMARK: in every step the new subset is compared with the old subset. Un contains the unit(s) present in the new subset but not in the old one. Un[end, 2] contains the units included in the final step of the search.

X
the data matrix X

The object has class "fsmeda".

Examples

### Not run:

```r
(out <- fsmult(hbk[,1:3], monitoring=TRUE))
class(out)
summary(out)
```

### End(Not run)

---

**fsmmmdrs**

*Performs random start monitoring of minimum Mahalanobis distance*

**Description**

The trajectories originate from many different random initial subsets and provide information on the presence of groups in the data. Groups are investigated by monitoring the minimum Mahalanobis distance outside the forward search subset.

**Usage**

```r
fsmmmdrs(x, plot = FALSE, init, bsbsteps, nsimul = 200,
nocheck = FALSE, numpool, cleanpool = FALSE, msg = FALSE,
trace = FALSE, ...)
```
Arguments

x
An n x p data matrix (n observations and p variables). Rows of x represent observations, and columns represent variables. Missing values (NA's) and infinite values (Inf's) are allowed, since observations (rows) with missing or infinite values will automatically be excluded from the computations.

plot
Plots the random starts minimum Mahalanobis distance with 1. If plot=FALSE (default) or plot=0 no plot is produced. The scale (ylim) for the y axis is defined as follows:

- ylim[2] is the maximum between the values of mmd in steps [n*0.2 n] and the final value of the 99 per cent envelope multiplied by 1.1.
- ylim[1] is the minimum between the values of mmd in steps [n*0.2 n] and the 1 per cent envelope multiplied by 0.9.

Remark: the plot which is produced is very simple. In order to control a series of options in this plot (including the y scale) and in order to connect it dynamically to the other forward plots it is necessary to use function mmdrsplot.

init
Point where to start monitoring required diagnostics. If init is not specified it will be set equal to (p+1).

bsbsteps
A vector which specifies for which steps of the forward search it is necessary to save the units forming subset for each random start. If bsbsteps = 0 for each random start we store the units forming subset in all steps. The default is store the units forming subset in all steps if n <= 500 else to store the units forming subset at step init and steps which are multiple of 100. For example, if n = 753 and init = 6, units forming subset are stored for m=init,100,200,300,400,500 and 600.

REMARK: The vector bsbsteps must contain numbers from init to n. If min(bsbsteps) < init a warning message will be issued.

nsimul
Number of random starts. Default value is nsimul=200.

nocheck
It controls whether to perform checks on matrix Y. If nocheck=TRUE, no check is performed.

numpool
If numpool > 1, the routine automatically checks if the Parallel Computing Toolbox is installed and distributes the random starts over numpool parallel processes. If numpool <= 1, the random starts are run sequentially. By default, numpool is set equal to the number of physical cores available in the CPU (this choice may be inconvenient if other applications are running concurrently). The same happens if the numpool value chosen by the user exceeds the available number of cores.

REMARK: up to R2013b, there was a limitation on the maximum number of cores that could be addressed by the parallel processing toolbox (8 and, more recently, 12). From R2014a, it is possible to run a local cluster of more than 12 workers.

REMARK: Unless you adjust the cluster profile, the default maximum number of workers is the same as the number of computational (physical) cores on the machine.
REMARK: In modern computers the number of logical cores is larger than the number of physical cores. By default, MATLAB is not using all logical cores because, normally, hyper-threading is enabled and some cores are reserved to this feature.

REMARK: It is because of Remarks 3 that we have chosen as default value for numpool the number of physical cores rather than the number of logical ones. The user can increase the number of parallel pool workers allocated to the multiple start monitoring by:

- setting the NumWorkers option in the local cluster profile settings to the number of logical cores (Remark 2). To do so go on the menu Home\Parallel\Manage Cluster Profile and set the desired "Number of workers to start on your local machine".
- setting numpool to the desired number of workers

Therefore, *if a parallel pool is not already open*, UserOption numpool (if set) overwrites the number of workers set in the local/current profile. Similarly, the number of workers in the local/current profile overwrites default value of numpool obtained as feature('numCores') (i.e. the number of physical cores).

**cleanpool**
Set cleanpool cleanpool=TRUE if the parallel pool has to be cleaned after the execution of the random starts. Otherwise (default) cleanpool=FALSE. Clearly this option has an effect just if previous option numpool > 1.

**msg**
Level of output to sidplay. It controls whether to display or not messages about random start progress. More precisely, if previous option numpool > 1, then a progress bar is displayed, on the other hand a message will be displayed on the screen when 10 REMARK: in order to create the progress bar when nparpool > 1 the program writes on a temporary .txt file in the folder where the user is working. Therefore it is necessary to work in a folder where the user has write permission. If this is not the case and the user (say) is working without write permission in folder C:/Program Files/MATLAB the following message will appear on the screen:

*Error using ProgressBar (line 57) Do you have write permissions for C:/Program Files/MATLAB?*

**trace**
Whether to print intermediate results. Default is trace=FALSE.

Potential further arguments passed to lower level functions.

**Value**

Returns an object of class `fsmmmdrs.object`.

**Author(s)**

FSDA team, <valentin.todorov@chello.at>

**References**

### Examples

```r
## Not run:
data(hbk)
out <- fsmmmdrs(hbk[,1:3])
class(out)
summary(out)
## End(Not run)
```

---

#### Description

An object of class `fsmmmdrs.object` holds information about the result of a call to `fsmmmdrs`.

#### Value

The object itself is basically a `list` with the following components:

- **mmdrs**
  Minimum Mahalanobis distance, (n-init) by (nsimul+1) matrix which contains the monitoring of minimum Mahalanobis distance at each step of the forward search.
  - 1st column = fwd search index (from init to n-1)
  - 2nd column = minimum Mahalanobis distance for random start 1
  - 3rd column...
  - nsimul+1 column=minimum Mahalanobis distance for random start nsimul

- **BBrs**
  Units belonging to the subset at the steps specified by input option bsbsteps. If bsbsteps=0 BBrs has size n-by-(n-init+1)-by-nsimul. In this case BBrs[,] with j=1, 2, ..., nsimul has the following structure:
  - 1st row = has number 1 in correspondence of the steps in which unit 1 is included inside subset and a missing value for the other steps
  - ...
  - (n-1)-th row= has number n-1 in correspondence of the steps in which unit n-1 is included inside subset and a missing value for the other steps
  - n-th row= has the number n in correspondence of the steps in which unit n is included inside subset and a missing value for the other steps
If, on the other hand, bsbsteps is a vector which specifies the steps of the search in which it is necessary to store subset, BBrs has size \( n \times \text{length(bsbsteps)} \times \text{nsimul} \). In other words, BBrs[:,j] with \( j=1,2,\ldots,\text{nsimul} \) has the same structure as before, but now contains just \( \text{length(bsbsteps)} \) columns.

\[ X \]
the data matrix \( X \)

The object has class "fsmmdrs".

**Examples**

```r
## Not run:
out <- fsmmmdrs(hbk[,1:3])
class(out)
summary(out)
## End(Not run)
```

---

**fsmult**  
*Gives an automatic outlier detection procedure in multivariate analysis*

**Description**

Gives an automatic outlier detection procedure in multivariate analysis and performs forward search in multivariate analysis with exploratory data.

**Usage**

```r
fsmult(x, bsb, monitoring = FALSE, crit = c("md", "biv", "uni"),
       rf = 0.95, init, plot = FALSE, bonflev, msg = TRUE,
       nocheck = FALSE, scaled = FALSE, trace = FALSE, ...)
```

**Arguments**

- **x**  
  An \( n \times p \) data matrix (\( n \) observations and \( p \) variables). Rows of \( x \) represent observations, and columns represent variables. Missing values (NA’s) and infinite values (Inf’s) are allowed, since observations (rows) with missing or infinite values will automatically be excluded from the computations.

- **bsb**  
  List of units forming the initial subset or size of the initial subset. If monitoring=FALSE the default is to start the search with \( p+1 \) units, containing those observations which are not outlying on any scatterplot, found as the intersection of all points lying within a robust contour containing a specified portion of the data (Riani and Zani 1997) and inside the univariate boxplot. Remark: if bsb is a vector, the option crit is ignored.
monitoring Whether to perform monitoring of Mahalanobis distances and other specific quantities

crit If specified, the criterion to be used to initialize the search.
  • If crit="md" the units which form initial subset are those which have the smallest m0 pseudo Mahalanobis distances computed using procedure unibiv() (bivariate robust ellipses).
  • If crit="biv" sorting is done first in terms of times units fell outside robust bivariate ellipses and then in terms of pseudoMD. In other words, the units forming initial subset are chosen first among the set of those which never fell outside robust bivariate ellipses then among those which fell only once outside bivariate ellipses ... up to reach m0.
  • If crit="uni" sorting is done first in terms of times units fell outside univariate boxplots and then in terms of pseudoMD. In other words, the units forming initial subset are chosen first among the set of those which never fell outside univariate boxplots then among those which fell only once outside univariate boxplots... up to reach m0.

Remark: as the user can see the starting point of the search is not going to affect at all the results of the analysis. The user can explore this point with his own datasets.

Remark: if crit="biv" the user can also supply in scalar rf (see below) the confidence level of the bivariate ellipses.

rf Confidence level for bivariate ellipses. The default is 0.95. This option is useful only if crit='biv'.

init Point where to start monitoring required diagnostics. Note that if a vector m0 is supplied, init >= length(m0). If init is not specified it will be set equal to floor(n*0.6).

plot Plots the minimum Mahalanobis distance. If plot=FALSE (default) or plot=0 no plot is produced. If plot=TRUE the plot of minimum MD with envelopes based on n observations and the scatterplot matrix with the outliers highlighted is produced. If plot=2 the additional plots of envelope resuperimposition are produced. If plot is a list it may contain the following fields:
  • ylim vector with two elements controlling minimum and maximum on the y axis. Default value is " (automatic scale)
  • xlim vector with two elements controlling minimum and maximum on the x axis. Default value is " (automatic scale)
  • resuper vector which specifies for which steps it is necessary to show the plots of resuperimposed envelopes if resuper is not supplied a plot of each step in which the envelope is resuperimposed is shown. Example: if resuper = c(85 87) plots of resuperimposed envelopes are shown at steps m=85 and m=87
  • ncoord If ncoord=1 plots are shown in normal coordinates else (default) plots are shown in traditional mmd coordinates
  • labeladd If labeladd=1, the outliers in the spm are labelled with the unit row index. The default value is labeladd="", i.e. no label is added
  • nameY character vector containing the labels of the variables. As default value, the labels which are added are Y1, ...Yp.
fsmult

- lwd controls line width of the curve which contains the monitoring of minimum Mahalanobis distance. Default is lwd=2.
- lwdenv Controls linewidth of the envelopes. Default is lwdenv=2.

bonflev Option that might be used to identify extreme outliers when the distribution of the data is strongly non normal. In these circumstances, the general signal detection rule based on consecutive exceedances cannot be used. In this case bonflev can be:

1. a scalar smaller than 1, which specifies the confidence level for a signal and a stopping rule based on the comparison of the minimum deletion residual with a Bonferroni bound. For example if bonflev=0.99 the procedure stops when the trajectory exceeds for the first time the 99 per cent bonferroni bound.

2. a scalar value greater than 1. In this case the procedure stops when the residual trajectory exceeds for the first time this value.

Default value is empty, which means to rely on general rules based on consecutive exceedances.

msg It controls whether to display or not messages on the screen. If msg=TRUE (default) messages about the progression of the search are displayed on the screen otherwise only error messages will be displayed.

nocheck It controls whether to perform checks on matrix Y. If nocheck=TRUE, no check is performed.

scaled Controls whether to monitor scaled Mahalanobis distances (only if monitoring=TRUE). If scaled=TRUE Mahalanobis distances monitored during the search are scaled using ratio of determinant. If scaled=2 Mahalanobis distances monitored during the search are scaled using asymptotic consistency factor. The default is scaled=FALSE, that is Mahalanobis distances are not scaled.

trace Whether to print intermediate results. Default is trace=FALSE.

... potential further arguments passed to lower level functions.

Value

Depending on the input parameter monitoring, one of the following objects will be returned:

1. fsmult.object
2. fsmeda.object

Control minimum and maximum on the x axis
(out1 <- fsmult(swissbanknotes[101:200,], plot=list(xlim=c(60,90))))

Monitor the exceedances of Minimum Mahalanobis Distance using normal coordinates for mmd.
(out1 <- fsmult(swissbanknotes[101:200,], plot=list(ncoord=1)))

End(Not run)

---

**Description of fsmult.object Objects**

**Description**

An object of class `fsmult.object` holds information about the result of a call to `fsmult`.

**Value**

The object itself is basically a list with the following components:

- **outliers**: kx1 vector containing the list of the k units declared as outliers or NULL if the sample is homogeneous.
- **loc**: p-by-1 vector containing location of the data.
- **cov**: p-by-p robust estimate of covariance matrix.
- **md**: n-by-1 vector containing the estimates of the robust Mahalanobis distances (in squared units). This vector contains the distances of each observation from the location of the data, relative to the scatter matrix `cov`.
- **mmd**: (n-init)-by-2 matrix. 1st col is the forward search index; 2nd col is the value of minimum Mahalanobis Distance in each step of the fwd search.
- **Un**: (n-init)-by-11 matrix which contains the unit(s) included in the subset at each step of the fwd search. REMARK: in every step the new subset is compared with the old subset. Un contains the unit(s) present in the new subset but not in the old one. Un[1,2] for example contains the unit included in step init+1. Un[end, 2] contains the units included in the final step of the search.
- **nout**: 2 x 5 matrix containing the number of times mdr went out of particular quantiles. First row contains quantiles 1 99 99.9 99.99 99.999. Second row contains the frequency distribution. It is NULL if bonflev threshold is used.
- **constr**: This output is produced only if the search found at a certain step is a non singular matrix X. In this case the search run in a constrained mode, that is including the units which produced a singular matrix in the last n-constr steps. out.constr is a vector which contains the list of units which produced a singular X matrix.
- **X**: the data matrix X

The object has class "fsmult".
Examples

```r
## Not run:
(out <- fsmult(hbk[,1:3]))
class(out)
summary(out)

## End(Not run)
```

## Description of fsr Object

An object of class `fsr.object` holds information about the result of a call to `fsreg`.

### Value

The object itself is basically a list with the following components:

- **beta**: p-by-1 vector containing the estimated regression parameters (in step n-k).
- **scale**: scalar containing the estimate of the scale (sigma).
- **residuals**: residuals.
- **fittedvalues**: fitted values.
- **outliers**: kx1 vector containing the list of the k units declared as outliers or NULL if the sample is homogeneous.
- **mdr**: (n-init) x 2 matrix 1st col = fwd search index, 2nd col = value of minimum deletion residual in each step of the fwd search.
- **Un**: (n-init) x 11 matrix which contains the unit(s) included in the subset at each step of the fwd search. REMARK: in every step the new subset is compared with the old subset. Un contains the unit(s) present in the new subset but not in the old one. Un(1,2) for example contains the unit included in step init+1. Un(end,2) contains the units included in the final step of the search.
- **nout**: 2 x 5 matrix containing the number of times mdr went out of particular quantiles. First row contains quantiles 1 99 99.9 99.99 99.999. Second row contains the frequency distribution.
- **constr**: This output is produced only if the search found at a certain step is a non singular matrix X. In this case the search run in a constrained mode, that is including the units which produced a singular matrix in the last n-constr steps. out.constr is a vector which contains the list of units which produced a singular X matrix.
- **X**: the data matrix X
- **y**: the response vector y

The object has class "fsr".
fsreda.object

Examples

## Not run:
(out <- fsreg(Y~., data=hbk, method="FS"))
class(out)
summary(out)

## End(Not run)

Description of fsreda Objects

Description

An object of class `fsreda.object` holds information about the result of a call to `fsreg`.

Value

The object itself is basically a list with the following components:

- **RES**: n x (n-init+1) matrix containing the monitoring of scaled residuals: the first row is the residual for the first unit, ..., n-th row is the residual for the n-th unit.
- **LEV**: (n+1) x (n-init+1) matrix containing the monitoring of leverage: the first row is the leverage for the first unit, ..., n-th row is the leverage for the n-th unit.
- **BB**: n x (n-init+1) matrix containing the information about the units belonging to the subset at each step of the forward search: first col contains indexes of the units forming subset in the initial step; ...; last column contains units forming subset in the final step (all units).
- **mdr**: n-init x 3 matrix which contains the monitoring of minimum deletion residual or (m+1)-ordered residual at each step of the forward search: first col is the fwd search index (from init to n-1); 2nd col = minimum deletion residual; 3rd col = (m+1)-ordered residual.
  Remark: these quantities are stored with sign, that is the min deletion residual is stored with negative sign if it corresponds to a negative residual.
- **msr**: n-init+1 x 3 matrix which contains the monitoring of maximum studentized residual or m-th ordered residual: first col is the fwd search index (from init to n); 2nd col = maximum studentized residual; 3rd col = (m)-ordered studentized residual.
- **nor**: (n-init+1) x 4 matrix containing the monitoring of normality test in each step of the forward search: first col = fwd search index (from init to n); 2nd col = Asymmetry test; 3rd col = Kurtosis test; 4th col = Normality test.
- **Bols**: (n-init+1) x (p+1) matrix containing the monitoring of estimated beta coefficients in each step of the forward search.
- **S2**: (n-init+1) x 4 matrix containing the monitoring of S2 or R2 in each step of the forward search.
1. 1st col = fwd search index (from init to n);
2. 2nd col = monitoring of S2;
3. 3rd col = monitoring of R2;
4. 4th col = monitoring of rescaled S2.
In this case the estimated of s2 at step m is divided by the consistency factor (to make the estimate asymptotically unbiased).

coo (n-init+1) x 3 matrix containing the monitoring of Cook or modified Cook distance in each step of the forward search:
1. 1st col = fwd search index (from init to n);
2. 2nd col = monitoring of Cook distance;
3. 3rd col = monitoring of modified Cook distance.

Tols (n-init+1) x (p+1) matrix containing the monitoring of estimated t-statistics (as specified in option input 'tstat') in each step of the forward search

Un (n-init) x 11 matrix which contains the unit(s) included in the subset at each step of the fwd search.
REMARK: in every step the new subset is compared with the old subset. Un contains the unit(s) present in the new subset but not in the old one Un(1,2) for example contains the unit included in step init+1 Un(end,2) contains the units included in the final step of the search.

betaINT Confidence intervals for the elements of β. betaINT is a (n-init+1)-by-2*length(confint)-by-p 3D array. Each third dimension refers to an element of beta:
1. betaINT[,,1] is associated with first element of beta;
2. ...;
3. betaINT[,,p] is associated with last element of beta.
The first two columns contain the lower and upper confidence limits associated with conflev(1). Columns three and four contain the lower and upper confidence limits associated with conflev(2); ...; The last two columns contain the lower and upper confidence limits associated with conflev(end). For example betaINT[,,3:4,5] contain the lower and upper confidence limits for the fifth element of beta using confidence level specified in the second element of input option conflev.

sigma2INT confidence interval for s2.
1. 1st col = fwd search index;
2. 2nd col = lower confidence limit based on conflev(1);
3. 3rd col = upper confidence limit based on conflev(1);
4. 4th col = lower confidence limit based on conflev(2);
5. 5th col = upper confidence limit based on conflev(2);
6. ...
7. penultimate col = lower confidence limit based on conflev(end);
8. last col = upper confidence limit based on conflev(end).

X the data matrix X
y the response vector y

The object has class "fsreda".
## Not run:
(out <- fsreg(Y~., data=hbk, method="FS", monitoring=TRUE))
class(out)
summary(out)
## End(Not run)

### Description

Creates an object of class `FSReda_control` to be used with the `fsreg()` function, containing various control parameters.

### Usage

```r
FSReda_control(intercept = TRUE, init, nocheck = FALSE,
tstat = c("trad", "scal"), conflev = c(0.95, 0.99))
```

### Arguments

- **intercept**
  - Indicator for constant term. Scalar. If intercept=TRUE, a model with constant term will be fitted (default), else, no constant term will be included.

- **init**
  - Search initialization, scalar. It specifies the initial subset size to start monitoring exceedances of minimum deletion residual, if init is not specified it set equal to: \( p+1 \), if the sample size is smaller than 40 or \( \min(3*p+1, \text{floor}(0.5*(n+p+1))) \), otherwise. For example, if init=100, the procedure starts monitoring from step \( m=100 \).

- **nocheck**
  - Check input arguments, scalar. If nocheck=TRUE no check is performed on matrix \( y \) and matrix \( X \). Notice that \( y \) and \( X \) are left unchanged. In other words the additional column of ones for the intercept is not added. As default nocheck=FALSE.

- **tstat**
  - The kind of t-statistics which have to be monitored. tstat="trad" implies monitoring of traditional t statistics (out$Tols). In this case the estimate of s2 at step m is based on s2m (notice that s2m=s2 when m/n is small) tstat="scal" (default) implies monitoring of rescaled t statistics. In this case the estimate of s2 at step m is based on s2m/vartruncnorm(m/n) where vartruncnorm(m/n) is the variance of the truncated normal distribution.

- **conflev**
  - Confidence level which is used to declare units as outliers. Usually conflev=0.95, 0.975, 0.99 (individual alpha) or conflev=1-0.05/n, 1-0.025/n, 1-0.01/n (simultaneous alpha). Default value is 0.975.

### Details

Creates an object of class `FSReda_control` to be used with the `fsreg()` function, containing various control parameters.
Value

An object of class "FSReda_control" which is basically a list with components the input arguments of the function mapped accordingly to the corresponding Matlab function.

## End(Not run)

fsreg

fsreg: an automatic outlier detection procedure in linear regression

Description

An automatic outlier detection procedure in linear regression

Usage

fsreg(x, ...)

## S3 method for class 'formula'
fsreg(formula, data, subset, weights, na.action, model = TRUE, x.ret = FALSE, y.ret = FALSE, contrasts = NULL, offset, ...)

## Default S3 method:
fsreg(x, y, bsb, intercept = TRUE, family = c("homo", "hetero", "bayes"), method = c("FS", "S", "MM", "LTS", "LMS"), monitoring = FALSE, control, ...)

fsreg
Arguments

formula: a formula of the form $y \sim x_1 + x_2 + \ldots$.

data: data frame from which variables specified in formula are to be taken.

subset: an optional vector specifying a subset of observations to be used in the fitting process.

weights: an optional vector of weights to be used in the fitting process. NOT USED YET.

na.action: a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The “factory-fresh” default is na.omit. Another possible value is NULL, no action. Value na.exclude can be useful.

model, x.ret, y.ret: logicals indicating if the model frame, the model matrix and the response are to be returned, respectively.

contrasts: an optional list. See the contrasts.arg of model.matrix.default.

offset: this can be used to specify an a priori known component to be included in the linear predictor during fitting. An offset term can be included in the formula instead or as well, and if both are specified their sum is used.

family: family of robust regression models, can be 'homo' for homoscedastic (same variance) regression model, 'hetero' for heteroskedastic regression model or 'bayes' Bayesian linear regression. The default is family=’homo’ for homoscedastic regression model.

method: robust regression estimation model, can be 'FS' for Forward search, 'S' for S regression, 'MM' for MM regression, 'LMS' or 'LTS'. The default is method=’FS’ for forward search estimation.

monitoring: whether to perform monitoring for several quantities in each step of the forward search or for series of values of the breakdown point in case of S estimates or for series of values of the efficiency in case of MM estimates. Default is monitoring=FALSE.

y: Response variable. Vector. Response variable, specified as a vector of length n, where n is the number of observations. Each entry in y is the response for the corresponding row of X. Missing values (NA’s) and infinite values (Inf’s) are allowed, since observations (rows) with missing or infinite values will automatically be excluded from the computations.

x: Predictor variables. Matrix. Matrix of explanatory variables (also called 'regressors’) of dimension n x (p-1) where p denotes the number of explanatory variables including the intercept. Rows of X represent observations, and columns represent variables. By default, there is a constant term in the model, unless you explicitly remove it using input option intercept=FALSE, so do not include a column of 1s in X. Missing values (NA’s) and infinite values (Inf’s) are allowed, since observations (rows) with missing or infinite values will automatically be excluded from the computations.

bsb: Initial subset - vector of indices. If bsb=0 (default) then the procedure starts with p units randomly chosen. If bsb is not 0 the search will start with m0=length(bsb).
intercept  Indicator for constant term. Scalar. If intercept=TRUE, a model with constant term will be fitted (default), else, no constant term will be included.

control  A control object (SS) containing estimation options. If the control object is supplied, the parameters from it will be used. If parameters are passed also in the invocation statement, they will override the corresponding elements of the control object.

...  potential further arguments passed to lower level functions.

Value

Depending on the input parameters family and method, one of the following objects will be returned:

1. fsr.object
2. sreg.object
3. mmreg.object
4. fsdalms.object
5. fsdalts.object
6. fsreda.object
7. sregeda.object
8. mmregeda.object

Examples

```r
## Not run:
n <- 200
p <- 3

X <- matrix(data=rnorm(n*p), nrow=n, ncol=p)
y <- matrix(data=rnorm(n*1), nrow=n, ncol=1)
(out = fsreg(X, y))

## Now we use the formula interface:
(out1 = fsreg(y~X, control=FSR_control(plot=FALSE)))

## Or use the variables in a data frame
(out2 = fsreg(Y~., data=hbk, control=FSR_control(plot=FALSE)))
```
## let us compare to the LTS solution
(out3 = ltsReg(Y-. , data=hbk))

## Now compute the model without intercept
(out4 = fsreg(Y-. -1, data=hbk, control=FSR_control(plot=FALSE)))

## And compare again with the LTS solution
(out5 = ltsReg(Y-. -1, data=hbk))

## using default (optional arguments)
(out6 = fsreg(Y-. -1, data=hbk, control=FSR_control(plot=FALSE, nsamp=1500, h=50)))

## End(Not run)

---

**FSR_control**

*Creates an FSR_control object*

---

### Description

Creates an object of class `FSR_control` to be used with the `fsreg()` function, containing various control parameters.

### Usage

```r
FSR_control(intercept = TRUE, h, nsamp = 1000, lms = 1, init, nocheck = FALSE, 
bonflev = "", msg = TRUE, bsbmfullrank = 1, 
plot = FALSE, bivarfit = "", multivarfit = "", 
labeladd = "", nameX, namey, ylim, xlim)
```

### Arguments

- **intercept**: Indicator for constant term. Scalar. If `intercept=TRUE`, a model with constant term will be fitted (default), else, no constant term will be included.
- **h**: The number of observations that have determined the least trimmed squares estimator, scalar. `h` is an integer greater or equal than `p` but smaller then `n`. Generally if the purpose is outlier detection `h=[0.5*(n+p+1)]` (default value). `h` can be smaller than this threshold if the purpose is to find subgroups of homogeneous observations. In this function the LTS/LMS estimator is used just to initialize the search.
- **nsamp**: Number of subsamples which will be extracted to find the robust estimator, scalar. If `nsamp=0` all subsets will be extracted. They will be `n choose p`. If the number of all possible subset is <1000 the default is to extract all subsets otherwise just 1000.
- **lms**: Criterion to use to find the initial subset to initialize the search (LMS, LTS with concentration steps, LTS without concentration steps or subset supplied directly by the user). The default value is 1 (Least Median of Squares is computed to initialize the search). On the other hand, if the user wants to initialize the search...
FSR Control

with LTS with all the default options for concentration steps then lms=2. If the
user wants to use LTS without concentration steps, lms can be a scalar different
from 1 or 2. If lms is a list it is possible to control a series of options for
concentration steps (for more details see option lms inside LXS_control). If,
on the other hand, the user wants to initialize the search with a prespecified set
of units there are two possibilities:

1. lms can be a vector with length greater than 1 which contains the list of
   units forming the initial subset. For example, if the user wants to initialize
   the search with units 4, 6 and 10 then lms=c(4,6,10);
2. lms is a struct which contains a field named bsb which contains the list of
   units to initialize the search. For example, in the case of simple regression
   through the origin with just one explanatory variable, if the user wants to
   initialize the search with unit 3 then lms=list(bsb=3).

init

Search initialization, scalar. It specifies the initial subset size to start monitoring
exceedances of minimum deletion residual, if init is not specified it set equal to:
p+1, if the sample size is smaller than 40 or \min(3*p+1, \floor(0.5*(n+p+1)));
otherwise. For example, if \texttt{init}=100, the procedure starts monitoring from step
m=100.

nocheck

Check input arguments, scalar. If nocheck=TRUE no check is performed on ma-
trix \( y \) and matrix \( X \). Notice that \( y \) and \( X \) are left unchanged. In other words the ad-
ditional column of ones for the intercept is not added. As default \texttt{nocheck}=FALSE.

bonflev

Option to be used if the distribution of the data is strongly non normal and, thus,
the general signal detection rule based on consecutive exceedances cannot be
used. In this case bonflev can be:

1. a scalar smaller than 1 which specifies the confidence level for a signal
   and a stopping rule based on the comparison of the minimum MD with a
   Bonferroni bound. For example if bonflev=0.99 the procedure stops when
   the trajectory exceeds for the first time the 99% bonferroni bound.
2. A scalar value greater than 1. In this case the procedure stops when the
   residual trajectory exceeds for the first time this value.

Default value is ", which means to rely on general rules based on consecutive
exceedances.

msg

Controls whether to display or not messages on the screen If msg==1 (default)
messages are displayed on the screen about step in which signal took place else
no message is displayed on the screen.

bsbfullrank

How to behave in case subset at step \( m \) (say bsbm) produces a singular X. In
other words, this options controls what to do when \( \text{rank}(X[\text{bsbm},:]) \) is smaller
then number of explanatory variables. If bsbffullrank=1 (default) these units
(whose number is say mnofullrank) are constrained to enter the search in the
final n-mnofullrank steps else the search continues using as estimate of beta at
step \( m \) the estimate of beta found in the previous step.

plot

Plot on the screen. Scalar. If plots=TRUE the plot of minimum deletion resid-
ual with envelopes based on \( n \) observations and the scatterplot matrix with the
outliers highlighted is produced. If plots=2 the user can also monitor the inter-
mediate plots based on envelope superimposition. If plots=FALSE (default) no
plot is produced.
**bivarfit**

Whether to superimpose bivariate least square lines on the plot (if `plot=TRUE`). This option adds one or more least squares lines, based on SIMPLE REGRESSION of y on Xi, to the plots of yi|Xi. The default is `bivarfit=FALSE`: no line is fitted. If `bivarfit=1`, a single OLS line is fitted to all points of each bivariate plot in the scatter matrix yi|Xi. If `bivarfit=2`, two OLS lines are fitted: one to all points and another to the group of the genuine observations. The group of the potential outliers is not fitted. If `bivarfit=0` one OLS line is fitted to each group. This is useful for the purpose of fitting mixtures of regression lines. If `bivarfit='i1'` or `bivarfit='i2'`, etc. an OLS line is fitted to a specific group, the one with index ‘i’ equal to 1, 2, 3 etc. Again, useful in case of mixtures.

**multivarfit**

Whether to superimpose multivariate least square lines. This option adds one or more least square lines, based on MULTIVARIATE REGRESSION of y on X, to the plots of yi|Xi. The default is `multivarfit=FALSE`: no line is fitted. If `multivarfit=1`, a single OLS line is fitted to all points of each bivariate plot in the scatter matrix yi|Xi. The line added to the scatter plot yi|Xi is avconst + Ci*Xi, where Ci is the coefficient of Xi in the multivariate regression and avconst is the effect of all the other explanatory variables different from Xi evaluated at their centroid (that is overline(y)'C)). If `multivarfit=2`, same action as with `multivarfit=1` but this time we also add the line based on the group of unselected observations (i.e. the normal units).

**labeladd**

Add outlier labels in plot. If `labeladd=TRUE`, we label the outliers with the unit row index in matrices X and y. The default value is `labeladd=FALSE`, i.e. no label is added.

**nameX**

Add variable labels in plot. A vector of strings of length p containing the labels of the variables of the regression dataset. If it is empty (default) the sequence X1,...,Xp will be created automatically.

**namey**

Add response label. A string containing the label of the response.

**ylim**

Control y scale in plot. Vector with two elements controlling minimum and maximum on the y axis. Default is to use automatic scale.

**xlim**

Control x scale in plot. Vector with two elements controlling minimum and maximum on the x axis. Default is to use automatic scale.

**Details**

Creates an object of class `FSR_control` to be used with the `fsreg()` function, containing various control parameters.

**Value**

An object of class "FSR_control" which is basically a list with components the input arguments of the function mapped accordingly to the corresponding Matlab function.

**geyser2**  
*Old Faithful Geyser Data.*

Description

A bivariate data set obtained from the Old Faithful Geyser, containing the eruption length and the length of the previous eruption for 271 eruptions of this geyser in minutes.

Usage

data(geyser2)

Format

A data frame with 271 rows and 2 variables The variables are as follows:

- Eruption length: The eruption length in minutes.
- Previous eruption length: The length of the previous eruption in minutes.

References

levfwdplot

Plots the trajectories of the monitored scaled (squared) residuals

Description

Plots the trajectories of the monitored scaled (squared) residuals

Usage

levfwdplot(out, 
  xlim, ylim, xlab, ylab, main, lwd, lty, col, cex.lab, cex.axis, 
  xvalues, 
  fg.thresh, fg.unit, fg.labstep, fg.lwd, fg.lty, fg.col, fg.mark, fg.cex, 
  bg.thresh, bg.style, 
  xground=c("lev", "res"), tag, datatooltip, label, nameX, namey, msg, databrush, 
  standard, fground, bground, ...) 

Arguments

out An object containing monitoring of leverage, fsreda.object.  
The needed elements of out are
  1. LEV: matrix containing the leverage monitored in each step of the forward 
     search. Every row is associated with a unit. This matrix can be created 
     using function fsreg() with method="FS",monitoring=TRUE.
  2. Un: (for FSR only) - matrix containing the order of entry in the subset of 
     each unit (required only when datatooltip is true or databrush is not empty).
  3. y: a vector containing the response (required only when option databrush is 
     requested).
  4. X: a matrix containing the explanatory variables (required only when option 
     databrush is requested).
  5. Bols: (n-init+1) x (p+1) matrix containing the estimated beta coefficients 
     monitored in each step of the robust procedure (required only when option 
     databrush is requested and suboption multivarfit is requested).
ylim Control y scale in plot. Vector with two elements controlling minimum and 
     maximum on the y axis. Default is to use automatic scale.
xlim Control x scale in plot. Vector with two elements controlling minimum and 
     maximum on the x axis. Default is to use automatic scale.
xlab a title for the x axis
ylab a title for the y axis
main an overall title for the plot
lwd The line width, a positive number, defaulting to 1
lty The line type. Line types can either be specified as an integer (1=solid (default), 
     2=dashed, 3=dotted, 4=dotdash, 5=longdash, 6=twodash) or as one of the char- 
     acter strings "solid", "dashed", "dotted", "dotdash", "longdash", or "twodash". 
     The latter two are not supported by Matlab.
colors to be used for the highlighted units

The magnification to be used for x and y labels relative to the current setting of cex
The magnification to be used for axis annotation relative to the current setting of cex
values for the x axis. Numeric vector of ncol(RES) controlling the x axis coordinates. The default value of xvalues is (nrow(RES) - ncol(RES) + 1):nrow(RES)
(alternative to fg.unit) numeric vector of length 1 or 2 which specifies the highlighted trajectories. If length(fg.thresh) == 1 the highlighted trajectories are those of units that throughout the search had at least once a residual greater (in absolute value) than thresh. The default value is fg.thresh=2.5. If length(fg.thresh) == 2 the highlighted trajectories are those of units that throughout the search had a residual at least once bigger than fg.thresh[2] or smaller than fg.thresh[1].
(alternative to fg.thresh), vector containing the list of the units to be highlighted. If fg.unit is supplied, fg.thresh is ignored.
numeric vector which specifies the steps of the search where to put labels for the highlighted trajectories (units). The default is to put the labels at the initial and final steps of the search. flabstep=’’ means no label.
The line width for the highlighted trajectories (units). Default is 1.
The line type for the highlighted trajectories (units). Line types can either be specified as an integer (1=solid (default), 2=dashed, 3=dotted, 4=dotdash, 5=longdash, 6=twodash) or as one of the character strings "solid", "dashed", "dotted", "dotdash", "longdash", or "twodash". The latter two are not supported by Matlab.
colors to be used for the highlighted units.
Controls whether to plot highlighted trajectories as symbols. if fg.mark=TRUE each line is plotted using a different symbol else no marker is used (default).
controls the font size of the labels of the trajectories in foreground.
numeric vector of length 1 or 2 which specifies how to define the unimportant trajectories. Unimportant trajectories will be plotted using a colormap, in greyish or will be hidden. If length(thresh) == 1 the irrelevant units are those which always had a residual smaller (in absolute value) than thresh. If length(bthresh) == 2 the irrelevant units are those which always had a residual greater than bthresh(1) and smaller than bthresh(2). The default is: bg.thresh=2.5 if n > 100 and bg.thresh=-Inf if n <= 100 i.e. to treat all trajectories as important if n <= 100 and, if n > 100, to reduce emphasis only to trajectories having in all steps of the search a value of scaled residual smaller than 2.5.
specifies how to plot the unimportant trajectories as defined in option bthresh.
1. bg.style="faint": unimportant trajectories are plotted using a colormap.
2. bg.style="hide": unimportant trajectories are hidden.
3. bg.style="greyish": unimportant trajectories are displayed in a faint grey.
When n>100 the default option is bg.style=’faint’. When n <= 100 and bg.thresh == -Inf option bstyle is ignored. Remark: bground=’’ is equivalent to -Inf that is all trajectories are considered relevant.
levfwdplot

Plot handle. String which identifies the handle of the plot which is about to be created. The default is to use tag 'pl_resfwd'. Notice that if the program finds a plot which has a tag equal to the one specified by the user, then the output of the new plot overwrites the existing one in the same window else a new window is created.

xground

trajectories to highlight in connection with resfwdplot. If xground="lev" (default), the levfwdplot trajectories are put in foreground or in background depending on the leverage values. If xground="res", the levfwdplot trajectories are put in foreground or in background depending on the residual values. See options bg.thresh and fg.thresh.

datatoltip

Interactive clicking. It is inactive if this parameter is missing or empty. The default is datatoltip=TRUE, i.e. the user can select with the mouse an individual residual trajectory in order to have information about the corresponding unit. The information displayed depends on the estimator in use.

For example for class fsreda.object the information concerns the label and the step of the search in which the unit enters the subset. If datatoltip is a list it may contain the following fields:

1. DisplayStyle determines how the data cursor displays. Possible values are 'datatip' and 'window' (default). 'datatip' displays data cursor information in a small yellow text box attached to a black square marker at a data point you interactively select. 'window' displays data cursor information for the data point you interactively select in a floating window within the figure.

2. SnapToDataVertex: specifies whether the data cursor snaps to the nearest data value or is located at the actual pointer position. Possible values are SnapToDataVertex='on' (default) and SnapToDataVertex='off'.

3. LineColor: controls the color of the trajectory selected with the mouse. It can be an RGB triplet of values between 0 and 1, or character vector indicating a color name. Note that a RGB vector can be conveniently chosen with our MATLAB class FSColor, see documentation.

4. SubsetLinesColor: enables to control the color of the trajectories of the units that are in the subset at a given step of the search (if levfwdplot() is applied to an object of class fsreda.object) or have a weight greater than 0.9 (if levfwdplot() is applied to an object of class sregeda.object or mmregeda.object). This can be done (repeatedly) with a left mouse click in proximity of the step of interest. A right mouse click will terminate the selection by marking with a up-arrow the step corresponding to the highlighted lines. The highlighted lines by default are in red, but a different color can be specified as RGB triplet or character of color name. Note that a RGB vector can be conveniently chosen with our MATLAB class FSColor, see documentation. By default SubsetLinesColor="", i.e. the modality is not active. Any initialization for SubsetLinesColor which cannot be interpreted as RGB vector will be converted to blue, i.e. SubsetLinesColor will be forced to be [0 0 1]. If SubsetLinesColor is not empty the previous option LineColor is ignored.

label

Character vector containing the labels of the units (optional argument used when datatoltip=TRUE. If this field is not present labels row1, ..., rown will be
automatically created and included in the pop up datatooltip window).

**nameX**
Add variable labels in plot. A vector of strings of length p containing the labels of the variables of the regression dataset. If it is empty (default) the sequence X1,...,Xp will be created automatically.

**namey**
Add response label. A string containing the label of the response.

**msg**
Controls whether to display or not messages on the screen. If msg==1 (default) messages are displayed on the screen about step in which signal took place else no message is displayed on the screen.

**databrush**
Interactive mouse brushing. If databrush is missing or empty (default), no brushing is done. The activation of this option (databrush is a scalar or a list) enables the user to select a set of trajectories in the current plot and to see them highlighted in the y|X plot, i.e. a matrix of scatter plots of y against each column of X, grouped according to the selection(s) done by brushing. If the plot y|X does not exist it is automatically created. In addition, brushed units are automatically highlighted in the minimum deletion residual plot if it is already open. The extension to the following plots will be available in future versions of the toolbox:

1. monitoring leverage plot;
2. maximum studentized residual;
3. s^2 and R^2;
4. Cook distance and modified Cook distance;
5. deletion t statistics.

Note that the window style of the other figures is set equal to that which contains the monitoring residual plot. In other words, if the monitoring residual plot is docked all the other figures will be docked too.

If databrush=TRUE the default selection tool is a rectangular brush and it is possible to brush only once (that is persist="").

If databrush=list(...), it is possible to use all optional arguments of function selectdataFS() and the following optional argument:

1. persist. Persist is an empty value or a character containing 'on' or 'off'. The default value is persist="", that is brushing is allowed only once. If persist="on" or persist="off" brushing can be done as many times as the user requires. If persist='on' then the unit(s) currently brushed are added to those previously brushed. It is possible, every time a new brushing is done, to use a different color for the brushed units. If persist='off' every time a new brush is performed units previously brushed are removed.

2. bivarfit. This option adds one or more least square lines based on SIMPLE REGRESSION to the plots of y|X, depending on the selected groups.

3. bivarfitWether to superimpose bivariate least square lines on the plot (if plot=TRUE). This option adds one or more least squares lines, based on SIMPLE REGRESSION of y on Xi, to the plots of y|Xi. The default is bivarfit=FALSE: no line is fitted. If bivarfit=1, a single OLS line is fitted to all points of each bivariate plot in the scatter matrix y|X. If bivarfit=2, two OLS lines are fitted: one to all points and another to the group of the genuine observations. The group of the potential outliers is not
fitted. If bivarfit=0 one OLS line is fitted to each group. This is useful for the purpose of fitting mixtures of regression lines. If bivarfit='i1' or bivarfit='i2', etc. an OLS line is fitted to a specific group, the one with index 'i' equal to 1, 2, 3 etc. Again, useful in case of mixtures.

4. multivarfitWhether to superimpose multivariate least square lines. This option adds one or more least square lines, based on MULTIVARIATE REGRESSION of y on X, to the plots of y|Xi. The default is multivarfit=FALSE: no line is fitted. If bivarfit=1, a single OLS line is fitted to all points of each bivariate plot in the scatter matrix y|X. The line added to the scatter plot y|Xi is avconst + Ci*Xi, where Ci is the coefficient of Xi in the multivariate regression and avconst is the effect of all the other explanatory variables different from Xi evaluated at their centroid (that is overline(y)'C)). If multivarfit=2, same action as with multivarfit=1 but this time we also add the line based on the group of unselected observations (i.e. the normal units).

5. labeladdAdd outlier labels in plot. If labeladd=TRUE, we label the outliers with the unit row index in matrices X and y. The default value is labeladd=FALSE, i.e. no label is added.

standard (MATLAB-style arguments) appearance of the plot in terms of xlim, ylim, axes labels and their font size style, color of the lines, etc.

fground MATLAB-style arguments for the fground trajectories in foregroud.

bground MATLAB-style arguments for the fground trajectories in backgroud.

... potential further arguments passed to lower level functions.

Examples

## Not run:

n <- 100  
y <- rnorm(n)  
X <- matrix(rnorm(n*4), nrow=n)  
out <- fsreg(y~X, method="LTS")  
out <- fsreg(y~X, method="FS", bsb=out$bs, monitoring=TRUE)  
levfwdplot(out)
Description

The loyalty data consist of 509 observations on the behaviour of customers with loyalty cards from a supermarket chain in Northern Italy. The response y is the amount in euros spent at the shop over six months and the explanatory variables are: X1, the number of visits to the supermarket in the six month period; X2, the age of the customer; X3, the number of members of the customers' family. To find out more about this data set please see Atkinson and Riani (2006), JCGS.

Usage

```r
data("loyalty")
```

Format

A data frame with 509 observations on the following 4 variables.

- `visits`: the number of visits to the supermarket in the six month period
- `age`: the age of the customer
- `family`: the number of members of the customers' family
- `amount_spent`: the amount in euros spent at the shop over six months

Details

To find out more about this data set please see Atkinson and Riani (2006), JCGS.

Source

The data are themselves a random sample from a larger database. The sample of 509 observations is available at [http://www.riani.it/trimmed](http://www.riani.it/trimmed).

Examples

```r
data(loyalty)
```
LXS_control

**Description**

Creates an object of class LXS_control to be used with the fsreg() function, containing various control parameters.

**Usage**

```r
LXS_control(intercept = TRUE, lms, h, bdp, nsamp, rew = FALSE, conflev = 0, 
             msg = TRUE, nocheck = FALSE, nomes = FALSE, plot = FALSE)
```

**Arguments**

- `intercept`  
  Indicator for constant term. Scalar. If intercept=TRUE, a model with constant term will be fitted (default), else, no constant term will be included.

- `lms`  
  Criterion to use to find the initial subset to initialize the search (LMS, LTS with concentration steps, LTS without concentration steps or subset supplied directly by the user). The default value is 1 (Least Median of Squares is computed to initialize the search). On the other hand, if the user wants to initialize the search with LTS with all the default options for concentration steps then lms=2. If the user wants to use LTS without concentration steps, lms can be a scalar different from 1 or 2. If lms is a list it is possible to control a series of options for concentration steps (for more details see option lms inside LXS_control). If, on the other hand, the user wants to initialize the search with a prespecified set of units there are two possibilities:

  1. `lms` can be a vector with length greater than 1 which contains the list of units forming the initial subset. For example, if the user wants to initialize the search with units 4, 6 and 10 then `lms=c(4,6,10)`;

  2. `lms` is a struct which contains a field named bsb which contains the list of units to initialize the search. For example, in the case of simple regression through the origin with just one explanatory variable, if the user wants to initialize the search with unit 3 then `lms=list(bsb=3)`.

- `h`  
  The number of observations that have determined the least trimmed squares estimator, scalar. h is an integer greater or equal than p but smaller than n. Generally if the purpose is outlier detection h=[0.5*(n+p+1)] (default value). h can be smaller than this threshold if the purpose is to find subgroups of homogeneous observations. In this function the LTS/LMS estimator is used just to initialize the search.

- `bdp`  
  Breakdown point. It measures the fraction of outliers the algorithm should resist. In this case any value greater than 0 but smaller or equal than 0.5 will do fine. If on the other hand the purpose is subgroups detection then bdp can be greater than 0.5. In any case however n*(1-bdp) must be greater than p. If this condition is not fulfilled an error will be given. Please specify h or bdp not both.
nsamp
Number of subsamples which will be extracted to find the robust estimator, scalar. If nsamp=0 all subsets will be extracted. They will be \( \binom{n}{p} \). If the number of all possible subset is <1000 the default is to extract all subsets otherwise just 1000.

rew
LXS reweighted - if rew=1 the reweighted version of LTS (LMS) is used and the output quantities refer to the reweighted version else no reweighting is performed (default).

conflev
Confidence level which is used to declare units as outliers, usually conflev=0.95, 0.975, 0.99 (individual alpha) or 1-0.05/n, 1-0.025/n, 1-0.01/n (simultaneous alpha). Default value is 0.975.

msg
Controls whether to display or not messages on the screen If msg==1 (default) messages are displayed on the screen about step in which signal took place else no message is displayed on the screen.

nocheck
Check input arguments, scalar. If nocheck=TRUE no check is performed on matrix y and matrix X. Notice that y and X are left unchanged. In other words the additional column of ones for the intercept is not added. As default nocheck=FALSE.

nomes
It controls whether to display or not on the screen messages about estimated time to compute LMS (LTS). If nomes is equal to 1 no message about estimated time to compute LMS (LTS) is displayed, else if nomes is equal to 0 (default), a message about estimated time is displayed.

plot
Plot on the screen. Scalar. If plots=TRUE the plot of minimum deletion residual with envelopes based on n observations and the scatterplot matrix with the outliers highlighted is produced. If plots=2 the user can also monitor the intermediate plots based on envelope superimposition. If plots=FALSE (default) no plot is produced.

Details
Creates an object of class FSR_control to be used with the fsreg() function, containing various control parameters.

Value
An object of class "LXS_control" which is basically a list with components the input arguments of the function mapped accordingly to the corresponding Matlab function.

(out <- fsreg(Y~., data=hbk, method="LMS", control=LXS_control(h=56, nsamp=500, lms=2)))
## End(Not run)
```

M5data

Mixture M5 Data.

Description

A bivariate data set obtained from three normal bivariate distributions with different scales and proportions 1:2:2. One of the components is strongly overlapping with another one. A 10 noise is added uniformly distributed in a rectangle containing the three normal components and not strongly overlapping with the three mixture components. A precise description of the M5 data set can be found in Garcia-Escudero et al. (2008).

Usage

```r
data(M5data)
```

Format

A data frame with 2000 rows and 3 variables. The first two columns are the two variables. The last column is the true classification vector where symbol "0" stands for the contaminating data points.

Source

malfwdplot

Plots the trajectories of scaled Mahalanobis distances along the search

Description

Plots the trajectories of scaled Mahalanobis distances along the forward search

Usage

```r
malfwdplot(out, xlim, ylim, xlab, ylab, main, lwd, lty, col, cex.lab, cex.axis, subsize, fg.thresh, fg.unit, fg.labstep, fg.lwd, fg.lty, fg.col, fg.mark, fg.cex, bg.thresh, bg.style, standard, fground, bground, tag, datatooltip, label, nameX, databrush, conflev, trace = FALSE, ...)
```
Arguments

out: An object of S3 class `fsmeda.object` returned by `fsmult` with `monitoring=TRUE` - a list containing the monitoring of minimum Mahalanobis distance.

The needed elements of `out` are:

1. MAL: matrix containing the squared Mahalanobis distances monitored in each step of the forward search. Every row is associated with a unit (row of data matrix Y). This matrix can be created using function FSMeda (mandatory argument)
2. Un: matrix containing the order of entry of each unit (necessary if datatooltip or databrush is selected).
3. X: The data matrix.

xlim: Controls the x scale in the plot. `xlim` is a vector with two elements controlling minimum and maximum on the x-axis. Default is to use automatic scale.

ylim: Controls the y scale in the plot. `ylim` is a vector with two elements controlling minimum and maximum on the y-axis. Default is to use automatic scale.

xlab: A title for the x axis

ylab: A title for the y axis

main: An overall title for the plot

lwd: The line width, a positive number, defaulting to 1

lty: The line type. Line types can either be specified as an integer (1=solid (default), 2=dashed, 3=dotted, 4=dotdash, 5=longdash, 6=twodash) or as one of the character strings "solid", "dashed", "dotted", "dotdash", "longdash", or "twodash". The latter two are not supported by Matlab.

col: Colors to be used for the highlighted units

cex.lab: The magnification to be used for x and y labels relative to the current setting of `cex`

cex.axis: The magnification to be used for axis annotation relative to the current setting of `cex`

subsize: Numeric vector containing the subset size with length equal to the number of columns of matrix of mahalanobis distances. The default value of `subsize` is `nrow(MAL) - ncol(MAL) + 1`: `nrow(MAL)`

fg.thresh: (alternative to `fg.unit`) numeric vector of length 1 or 2 which specifies the highlighted trajectories. If `length(fg.thresh) == 1` the highlighted trajectories are those of units that throughout the search had at least once a mahalanobis distance greater than `fg.thresh`. The default value is `fg.thresh=2.5`. If `length(fg.thresh) == 2` the highlighted trajectories are those of units that throughout the search had a mahalanobis distance at least once bigger than `fg.thresh[2]` or smaller than `fg.thresh[1]`.

fg.unit: (alternative to `fg.thresh`), vector containing the list of the units to be highlighted. If `fg.unit` is supplied, `fg.thresh` is ignored.

fg.labstep: numeric vector which specifies the steps of the search where to put labels for the highlighted trajectories (units). The default is to put the labels at the initial and final steps of the search. `fg.labstep=``' '`` means no label.
fg.lwd  The line width for the highlighted trajectories (units). Default is 1.

fg.lty  The line type for the highlighted trajectories (units). Line types can either be specified as an integer (1=solid (default), 2=dashed, 3=dotted, 4=dotdash, 5=longdash, 6=twodash) or as one of the character strings "solid", "dashed", "dotted", "dotdash", "longdash", or "twodash". The latter two are not supported by Matlab.

fg.col  colors to be used for the highlighted units.

fg.mark  Controls whether to plot highlighted trajectories as symbols. If fg.mark==TRUE each line is plotted using a different symbol else no marker is used (default).

fg.cex  Controls the font size of the labels of the trajectories in foreground. If fg.cex=0 no labels will be shown - equivalent to fg.labstop="".

bg.thresh  Numeric vector of length 1 or 2 which specifies how to define the unimportant trajectories. Unimportant trajectories will be plotted using a colormap, in greyish or will be hidden. If length(bg.thresh) == 1 the irrelevant units are those which always had a mahalanobis distance smaller than bg.thresh. If length(bg.thresh) == 2 the irrelevant units are those which always had a mahalanobis distance greater than bg.thresh[1] and smaller than bg.thresh[2]. The default is bg.thresh=2.5 if n > 100 and bg.thresh=-Inf if n <= 100 i.e. to treat all trajectories as important if n <= 100 and, if n > 100, to reduce emphasis only to trajectories having in all steps of the search a value of mahalanobis distance smaller than 2.5.

bg.style  Specifies how to plot the unimportant trajectories as defined in option bg.thresh.

   1. bg.style="faint": unimportant trajectories are plotted using a colormap.
   2. bg.style="hide": unimportant trajectories are hidden.
   3. bg.style="greyish": unimportant trajectories are displayed in a faint grey.

When n > 100 the default option is bg.style='faint'. When n <= 100 and bg.thresh == -Inf option bg.style is ignored. Remark: bground=" is equivalent to -Inf that is all trajectories are considered relevant.

standard  MATLAB-style arguments - appearance of the plot in terms of xlim, ylim, axes labels and their font size style, color of the lines, etc.

fground  MATLAB-style arguments - for the trajectories in foreground.

bground  MATLAB-style arguments - for the trajectories in background.

tag  Plot handle. String which identifies the handle of the plot which is about to be created. The default is to use tag 'pl_resfwd'. Notice that if the program finds a plot which has a tag equal to the one specified by the user, then the output of the new plot overwrites the existing one in the same window else a new window is created.

datatooltip  Interactive clicking. It is inactive if this parameter is set to FALSE. The default is datatooltip=TRUE, the user can select with the mouse an individual mahalanobis distance trajectory in order to have information about the corresponding unit, the associated label and the step of the search in which the unit enters the subset. If datatooltip is a list it may contain the following fields:
1. **DisplayStyle** determines how the data cursor displays. Possible values are 'datatip' and 'window' (default). 'datatip' displays data cursor information in a small yellow text box attached to a black square marker at a data point you interactively select. 'window' displays data cursor information for the data point you interactively select in a floating window within the figure.

2. **SnapToDataVertex**: specifies whether the data cursor snaps to the nearest data value or is located at the actual pointer position. Possible values are `SnapToDataVertex='on'` (default) and `SnapToDataVertex='off'`.

3. **LineColor**: controls the color of the trajectory selected with the mouse. It can be an RGB triplet of values between 0 and 1, or character vector indicating a color name. Note that a RGB vector can be conveniently chosen with our MATLAB class FSColor, see documentation.

4. **SubsetLinesColor**: enables to control the color of the trajectories of the units that are in the subset at a given step of the search (if `resfwdplot()` is applied to an object of class `fsreda.object`) or have a weight greater than 0.9 (if `resfwdplot()` is applied to an object of class `sregeda.object` or `mmregeda.object`). This can be done (repeatedly) with a left mouse click in proximity of the step of interest. A right mouse click will terminate the selection by marking with a up-arrow the step corresponding to the highlighted lines. The highlighted lines by default are in red, but a different color can be specified as RGB triplet or character of color name. Note that a RGB vector can be conveniently chosen with our MATLAB class FSColor, see documentation. By default `SubsetLinesColor=''`, i.e. the modality is not active. Any initialization for `SubsetLinesColor` which cannot be interpreted as RGB vector will be converted to blue, i.e. `SubsetLinesColor` will be forced to be `[0 0 1]`. If `SubsetLinesColor` is not empty the previous option `LineColor` is ignored.

```
label
Character vector containing the labels of the units (optional argument used when `datatooltip=TRUE`. If this field is not present labels row1, ..., rown will be automatically created and included in the pop up datatooltip window).
```

```
nameX
Add variable labels in plot. A vector of strings of length `p` containing the labels of the variables in the dataset. If it is empty (default) the sequence `X1,...,Xp` will be created automatically
```

```
databrush
Interactive mouse brushing. If databrush is missing or empty (default), no brushing is done. The activation of this option (databrush is `TRUE` or a list) enables the user to select a set of trajectories in the current plot and to see them highlighted in the scatterplot matrix. If the scatterplot matrix does not exist it is automatically created. In addition, brushed units can be highlighted in the monitoring mahalanobis distance plot. Note that the window style of the other figures is set equal to that which contains the monitoring mahalanobis distance plot. In other words, if the monitoring mahalanobis distance plot is docked all the other figures will be docked too.

If `databrush=TRUE` the default selection tool is a rectangular brush and it is possible to brush only once (that is persist="").

If `databrush=list(...)`, it is possible to use all optional arguments of the MATLAB function `selectdataFS()` and the following optional arguments:
malfwdplot

• persist. Persist is an empty value or a character containing 'on' or 'off'. The default value is persist="", that is brushing is allowed only once. If persist="on" or persist="off" brushing can be done as many times as the user requires. If persist='on' then the unit(s) currently brushed are added to those previously brushed. It is possible, every time a new brushing is done, to use a different color for the brushed units. If persist='off' every time a new brush is performed units previously brushed are removed.

• label: add labels of brushed units in the monitoring plot.

• labeladd: add labels of brushed units in the scatterplot matrix. If this option is '1', we label the units of the last selected group with the unit row index in the matrix X. The default value is labeladd="", i.e. no label is added.

conflев confidence interval for the horizontal bands. It can be a vector of different confidence level values, e.g. c(0.95, 0.99, 0.999). The confidence interval is based on the $\chi^2$ distribution.

trace Whether to print intermediate results. Default is trace=FALSE.

... potential further arguments passed to lower level functions.

Value

none

Examples

```r
# Not run:
# Produce monitoring MD plot with all the default options.
# Generate input structure for malfwdplot
n <- 100
p <- 4
Y <- matrix(rnorm(n*p), ncol=p)
Y[1:10,] <- Y[1:10,] + 4
out <- fsmult(Y, monitoring=TRUE, init=30)

# Produce monitoring MD plot with all the default options
malfwdplot(out)

# End(Not run)
```
malindexplot  

*Plots the trajectory of minimum Mahalanobis distance (mmd)*

### Description

Plots the trajectory of minimum Mahalanobis distance (mmd)

### Usage

```r
malindexplot(out, p, xlab, ylab, main, nameX, conflev, trace = FALSE, ...)
```

### Arguments

- `out`  
  a numeric vector or an object of S3 class (one of `fsmult.object`, `smult.object` or `mmmult.object`) returned by one of the functions `fsmult` or `smult` or `mmmult` - a list containing the monitoring of minimum Mahalanobis distance

- `p`  
  If `out` is a vector, `p` is its length (i.e. number of variables).

- `xlab`  
  A title for the x axis

- `ylab`  
  A title for the y axis

- `main`  
  An overall title for the plot

- `nameX`  
  Add variable labels in the plot. A vector of strings of length `p` containing the labels of the variables of the original data matrix `X`. If it is empty (default) the sequence `X1,...,Xp` will be created automatically

- `conflev`  
  confidence interval for the horizontal bands. It can be a vector of different confidence level values, e.g. c(0.95, 0.99, 0.999). The confidence interval is based on the chi^2 distribution.

- `trace`  
  Whether to print intermediate results. Default is `trace=FALSE`.

- `...`  
  potential further arguments passed to lower level functions.

### Value

none

## Not run:
## Mahalanobis distance plot of 100 random numbers.
## Numbers are from from the chisq with 5 degrees of freedom
malindexplot(rchisq(100, 5), 5)
## End(Not run)
```

### mdrplot

Plots the trajectory of minimum deletion residual (mdr).

#### Description

Plots the trajectory of minimum deletion residual (mdr).

#### Usage

```r
mdrplot(out, quant = c(0.01, 0.5, 0.99), sign = TRUE,
mplus1 = FALSE, envm, xlim, ylim, xlab, ylab, main,
lwdenv, lwd, cex.lab, cex.axis, tag, datatooltip, label, nameX, namey, databrush,
...)```

#### Arguments

- **out**: An object returned by FSReda() (see `FSReda_control`). The needed elements of out are
  1. `mdr`: Minimum deletion residual. A matrix containing the monitoring of minimum deletion residual in each step of the forward search. The first column of mdr must contain the fwd search index.
  2. `Un`: (for FSR only) - matrix containing the order of entry in the subset of each unit (required only when datatooltip is true or databrush is not empty).
  3. `y`: a vector containing the response (required only when option databrush is requested).
  4. `X`: a matrix containing the explanatory variables (required only when option databrush is requested).
  5. `Bols`: (n-init+1) x (p+1) matrix containing the estimated beta coefficients monitored in each step of the robust procedure (required only when option databrush is requested and suboption multivarfit is requested).
- **quant**: Quantiles for which envelopes have to be computed. The default is to produce 1%, 50% and 99% envelopes. In other words the default is `quant = c(0.01, 0.5, 0.99).`
mdrplot

sign: Whether to use MDR with sign: if sign=TRUE (default) we distinguish steps for which minimum deletion residual was associated with positive or negative value of the residual. Steps associated with positive values of mdr are plotted in black, while other steps are plotted in red.

mplusr: Whether to plot the (m+1)-th order statistic. Specifies if it is necessary to plot the curve associated with (m+1)-th order statistic.

eenvm: Sample size for drawing enevlopes. Specifies the size of the sample which is used to superimpose the envelope. The default is to add an envelope based on all the observations (size n envelope).

ylim: Control y scale in plot. Vector with two elements controlling minimum and maximum on the y axis. Default is to use automatic scale.

xlim: Control x scale in plot. Vector with two elements controlling minimum and maximum on the x axis. Default is to use automatic scale.

xlab: a title for the x axis

ylab: a title for the y axis

main: an overall title for the plot

lwdenv: Controls the width of the lines associated with the envelopes, default is lwdenv=1.

lwd: Controls the linewidth of the curve which contains the monitoring of minimum deletion residual.

cex.lab: The magnification to be used for x and y labels relative to the current setting of cex

cex.axis: The magnification to be used for axis annotation relative to the current setting of cex

tag: Plot handle. String which identifies the handle of the plot which is about to be created. The default is to use tag 'pl_mdr'. Notice that if the program finds a plot which has a tag equal to the one specified by the user, then the output of the new plot overwrites the existing one in the same window else a new window is created.

datatooltip: If datatooltip is not empty the user can use the mouse in order to have information about the unit selected, the step in which the unit enters the search and the associated label. If datatooltip is a list, it is possible to control the aspect of the data cursor (see MATLAB function datacursormode() for more details or see the examples below). The default options are DisplayStyle="Window" and SnapToDataVertex="on".

label: Character vector containing the labels of the units (optional argument used when datatooltip=TRUE. If this field is not present labels row1, ..., rown will be automatically created and included in the pop up datatooltip window).

nameX: Add variable labels in plot. A vector of strings of length p containing the labels of the variables of the regression dataset. If it is empty (default) the sequence X1,...,Xp will be created automatically

namey: Add response label. A string containing the label of the response

databrush: interactive mouse brushing. If databrush is missing or empty (default), no brushing is done. The activation of this option (databrush is a scalar or a list) enables
the user to select a set of trajectories in the current plot and to see them highlighted in the \( y \mid X \) plot, i.e. a matrix of scatter plots of \( y \) against each column of \( X \), grouped according to the selection(s) done by brushing. If the plot \( y \mid X \) does not exist it is automatically created. In addition, brushed units are automatically highlighted in the minimum deletion residual plot if it is already open.

The extension to the following plots will be available in future versions of the toolbox:

1. monitoring leverage plot;
2. maximum studentized residual;
3. \( s^2 \) and \( R^2 \);
4. Cook distance and modified Cook distance;
5. deletion \( t \) statistics.

Note that the window style of the other figures is set equal to that which contains the monitoring residual plot. In other words, if the monitoring residual plot is docked all the other figures will be docked too.

If `databrush=TRUE` the default selection tool is a rectangular brush and it is possible to brush only once (that is `persist="`).

If `databrush=list(...)`, it is possible to use all optional arguments of function `selectdataFS()` and the following optional argument:

1. persist. Persist is an empty value or a character containing 'on' or 'off'. The default value is `persist="",` that is brushing is allowed only once. If `persist="on"` or `persist="off"` brushing can be done as many times as the user requires. If `persist='on'` then the unit(s) currently brushed are added to those previously brushed. It is possible, every time a new brushing is done, to use a different color for the brushed units. If `persist='off'` every time a new brush is performed units previously brushed are removed.

2. `bivarfit` Whether to superimpose bivariate least square lines on the plot (if `plot=TRUE`). This option adds one or more least squares lines, based on SIMPLE REGRESSION of \( y \) on \( X_i \), to the plots of \( y \mid X_i \). The default is `bivarfit=False`: no line is fitted. If `bivarfit=1`, a single OLS line is fitted to all points of each bivariate plot in the scatter matrix \( y \mid X \). If `bivarfit=2`, two OLS lines are fitted: one to all points and another to the group of the genuine observations. The group of the potential outliers is not fitted. If `bivarfit=0` one OLS line is fitted to each group. This is useful for the purpose of fitting mixtures of regression lines. If `bivarfit='i1'` or `bivarfit='i2', etc. an OLS line is fitted to a specific group, the one with index 'i' equal to 1, 2, 3 etc. Again, useful in case of mixtures.

3. `multivarfit` Whether to superimpose multivariate least square lines. This option adds one or more least square lines, based on MULTIVARIATE REGRESSION of \( y \) on \( X \), to the plots of \( y \mid X_i \). The default is `multivarfit=False`: no line is fitted. If `multivarfit=1`, a single OLS line is fitted to all points of each bivariate plot in the scatter matrix \( y \mid X \). The line added to the scatter plot \( y \mid X_i \) is \( a \text{const} + C_i X_i \), where \( C_i \) is the coefficient of \( X_i \) in the multivariate regression and \( a \text{const} \) is the effect of all the other explanatory variables different from \( X_i \) evaluated at their centroid (that is \( \overline{y}' C \)). If `multivarfit=2`, same action as with `multivarfit=1` but this time we also
add the line based on the group of unselected observations (i.e. the normal
units).
4. labeladdAdd outlier labels in plot. If labeladd=TRUE, we label the out-
liers with the unit row index in matrices X and y. The default value is
labeladd=FALSE, i.e. no label is added.

## Not run:

n <- 100
y <- rnorm(n)
X <- matrix(rnorm(n*4), nrow=n)

out <- fsreg(y~X, method="LTS")
out <- fsreg(y~X, method="FS", bsb=out$bs, monitoring=TRUE)
mdrplot(out)

## End(Not run)
Arguments

out
An object of S3 class \texttt{fsmeda.object} returned by \texttt{fsmult} with \texttt{monitoring=TRUE} - a list containing the monitoring of minimum Mahalanobis distance

quant
Quantiles for which envelopes have to be computed. The default is to produce 1%, 50% and 99% envelopes. In other words the default is \texttt{quant=c(0.01, 0.5, 0.99)}.

\texttt{mplus1}
Whether to plot the \((m+1)\)-th order statistic.

\texttt{envm}
Sample size for drawing envelopes. Specifies the size of the sample which is used to superimpose the envelope. The default is to add an envelope based on all the observations (size \(n\) envelope).

\texttt{lwd}
Controls the line width of the curve which contains the monitoring of minimum deletion residual.

\texttt{lwdenv}
Controls the width of the lines associated with the envelopes. Default is \texttt{lwdenv=1}

\texttt{xlim}
Control the x scale in plot. Vector with two elements controlling minimum and maximum on the x axis. Default is to use automatic scale.

\texttt{ylim}
Control the y scale in plot. Vector with two elements controlling minimum and maximum on the y axis. Default is to use automatic scale.

\texttt{tag}
Plot handle. String which identifies the handle of the plot which is about to be created. The default is \texttt{tag=\"/\textasciitilde\textasciitilde.Var.pl_mmd/\textasciitilde\textasciitilde\"}. Notice that if the program finds a plot which has a tag equal to the one specified by the user, then the output of the new plot overwrites the existing one in the same window else a new window is created.

\texttt{datatooltip}
If datatooltip is not empty the user can use the mouse in order to have information about the unit selected, the step in which the unit enters the search and the associated label. If datatooltip is a list, it is possible to control the aspect of the data cursor (see MATLAB function \texttt{datacursormode()} for more details or see the examples below). The default options are \texttt{DisplayStyle=\"Window\"} and \texttt{SnapToDataVertex=\"on\"}.

\texttt{label}
Row labels. Character vector containing the labels of the units (optional argument used when \texttt{datatooltip=TRUE}. If this field is not present labels row1, ..., row\(n\) will be automatically created and included in the pop up datatooltip window).

\texttt{xlab}
A title for the x axis

\texttt{ylab}
A title for the y axis

\texttt{main}
An overall title for the plot

\texttt{nameX}
Add variable labels in the plot. A vector of strings of length \(p\) containing the labels of the variables of the original data matrix \(X\). If it is empty (default) the sequence \(X_1, \ldots, X_p\) will be created automatically

\texttt{cex.lab}
The magnification to be used for \(x\) and \(y\) labels relative to the current setting of \texttt{cex}

\texttt{cex.axis}
The magnification to be used for axis annotation relative to the current setting of \texttt{cex}
Interactive mouse brushing. If databrush is missing or empty (default), no brushing is done. The activation of this option (databrush is TRUE or a list) enables the user to select a set of trajectories in the current plot and to see them highlighted in the scatterplot matrix. If the scatterplot matrix does not exist it is automatically created. In addition, brushed units can be highlighted in the monitoring MD plot. Note that the window style of the other figures is set equal to that which contains the monitoring residual plot. In other words, if the monitoring residual plot is docked all the other figures will be docked too.

If databrush=TRUE the default selection tool is a rectangular brush and it is possible to brush only once (that is persist="").

mmdplot(out)

## End(Not run)
```

**mmdrsplot**  
Plots the trajectories of minimum Mahalanobis distances from different starting points

**Description**  
Plots the trajectories of minimum Mahalanobis distances from different starting points

**Usage**  
mmdrsplot(out, quant = c(0.01, 0.5, 0.99), envm, lwd, lwdenv, xlim, ylim, tag, datatooltip, label, xlab, ylab, envlab = TRUE, main, nameX, cex.lab, cex.axis, databrush, scaled = FALSE, trace = FALSE, ...)

**Arguments**
- **out** An object of S3 class `fsmmmdrs.object` returned by `fsmmmdrs` - a list containing the following elements:
  - `mmdrs` = a matrix of size (n-ninit)-(nsimul+1) containing the monitoring of minimum Mahalanobis distance in each step of the forward search for each of the nsimul random starts. The first column of mmdrs must contain the forward search index. This matrix can be created using function `fsmmmdrs`.
  - `BBrs` = 3D array of size n-by-n-(init)-by-nsimul containing units forming subset for each random start. This field is necessary if datatooltip is true or databrush is not empty.
  - `X` = n-by-v matrix containing the original data matrix. This field is necessary if datatooltip is true or databrush is not empty.
- **quant** Quantiles for which envelopes have to be computed. The default is to produce 1%, 50% and 99% envelopes. In other words the default is `quant=c(0.01, 0.5, 0.99)`.
- **envm** Sample size for drawing envelopes. Specifies the size of the sample which is used to superimpose the envelope. The default is to add an envelope based on all the observations (size n envelope).
- **lwd** Controls the linewidth of the curve which contains the monitoring of minimum deletion residual.
- **lwdenv** line width: a scalar which controls the width of the lines associated with the envelopes. Default is `lwdenv=1`
- **xlim** Control the x scale in plot. Vector with two elements controlling minimum and maximum on the x axis. Default is to use automatic scale.
ylim
Control the y scale in plot. Vector with two elements controlling minimum and maximum on the y axis. Default is to use automatic scale.

tag
Plot handle. String which identifies the handle of the plot which is about to be created. The default is tag='pl_mmd'. Notice that if the program finds a plot which has a tag equal to the one specified by the user, then the output of the new plot overwrites the existing one in the same window else a new window is created.

datatooltip
If datatooltip is not empty the user can use the mouse in order to have information about the unit selected, the step in which the unit enters the search and the associated label. If datatooltip is a list, it is possible to control the aspect of the data cursor (see MATLAB function datacursormode() for more details or see the examples below). The default options are DisplayStyle="Window" and SnapToDataVertex="on".

label
Row labels. Character vector containing the labels of the units (optional argument used when datatooltip=TRUE. If this field is not present labels row1, ..., rown will be automatically created and included in the pop up datatooltip window).

xlab
A title for the x axis

ylab
A title for the y axis

envlab
Whether to label the envelopes. If envlab is true (default) labels of the confidence envelopes which are used are added on the y axis.

main
An overall title for the plot

nameX
Add variable labels in the plot. A vector of strings of length p containing the labels of the variables of the original data matrix X. If it is empty (default) the sequence X1,...,Xp will be created automatically

cex.lab
The magnification to be used for x and y labels relative to the current setting of cex

cex.axis
The magnification to be used for axis annotation relative to the current setting of cex

databrush
Interactive mouse brushing. If databrush is missing or empty (default), no brushing is done. The activation of this option (databrush is TRUE or a list) enables the user to select a set of trajectories in the current plot and to see them highlighted in the scatterplot matrix. If the scatterplot matrix does not exist it is automatically created. In addition, brushed units can be highlighted in the monitoring MD plot. Note that the window style of the other figures is set equal to that which contains the monitoring residual plot. In other words, if the monitoring residual plot is docked all the other figures will be docked too.

If databrush=TRUE the default selection tool is a rectangular brush and it is possible to brush only once (that is persist="").

Note that the window style of the other figures is set equal to that which contains the monitoring residual plot. In other words, if the monitoring residual plot is docked all the other figures will be docked too

If databrush=TRUE the default selection tool is a rectangular brush and it is possible to brush only once (that is persist="").

If databrush=list(...), it is possible to use all optional arguments of the MATLAB function selectdataFS() and the following optional arguments:
1. persist. Persist is an empty value or a character containing 'on' or 'off'. The default value is persist="", that is brushing is allowed only once. If persist="on" or persist="off" brushing can be done as many times as the user requires. If persist='on' then the unit(s) currently brushed are added to those previously brushed. It is possible, every time a new brushing is done, to use a different color for the brushed units. If persist='off' every time a new brush is performed units previously brushed are removed.

**scaled**

Whether to use scaled or unscaled envelopes. If scaled=TRUE the envelopes are produced for scaled Mahalanobis distances (no consistency factor is applied) else the traditional consistency factor is applied. Default is scaled=FALSE.

**trace**

Whether to print intermediate results. Default is trace=FALSE.

... potential further arguments passed to lower level functions.

**Value**

none

**References**

**Examples**

```r
## Not run:
data(hbk)
out <- fsmmmmdrs(hbk[,1:3])
mmmdrsplot(out)

## End(Not run)
```

---

**Description**

Computes MM estimators in multivariate analysis with auxiliary S-scale

**Usage**

```r
mmmult(x, monitoring = FALSE, plot = FALSE, eff, conflev = 0.975, nocheck = FALSE, trace = FALSE, ...)
```
Arguments

x  An n x p data matrix (n observations and p variables). Rows of x represent observations, and columns represent variables.

monitoring  Whether to perform monitoring of Mahalanobis distances and other specific quantities

plot  Plots the Mahalanobis distances against index number. If plot=FALSE (default) or plot=0 no plot is produced. The confidence level used to draw the confidence bands for the MD is given by the input option conflev. If conflev is not specified a nominal 0.975 confidence interval will be used. If plot=2 a scatter plot matrix with the outliers highlighted is produced. If plot is a list it may contain the following fields:

  • labeladd If labeladd=1, the outliers in the spm are labelled with the unit row index. The default value is labeladd="", i.e. no label is added
  • nameY character vector containing the labels of the variables. As default value, the labels which are added are Y1, ...Yp.

eff  Defining the nominal efficiency (i.e. a number between 0.5 and 0.99). The default value is eff=0.95.

conflev  confidence interval for the horizontal bands. It can be a vector of different confidence level values, e.g. c(0.95, 0.99, 0.999). The confidence interval is based on the chi^2 distribution.

nocheck  It controls whether to perform checks on matrix Y. If nocheck=TRUE, no check is performed.

trace  Whether to print intermediate results. Default is trace=FALSE.

Value

Depending on the input parameter monitoring, one of the following objects will be returned:

1. mmmult.object
2. mmmulteda.object

Details

This function follows the lines of MATLAB/R code developed during the years by many authors. For more details see http://www.econ.kuleuven.be/public/NDBAE06/programs/ and the R package CovMMest The core of these routines, e.g. the resampling approach, however, has been completely redesigned, with considerable increase of the computational performance.

## End(Not run)
```
Description

An object of class `mmmult.object` holds information about the result of a call to `mmmult`.

Value

The object itself is basically a list with the following components:

- **loc**: p-by-1 vector containing MM estimate of location.
- **shape**: p-by-p matrix with MM estimate of the shape matrix.
- **cov**: matrix with MM estimate of the covariance matrix. Remark: covariance = auxscale^2 * shape.
- **weights**: A vector containing the estimates of the weights.
- **outliers**: A vector containing the list of the units declared as outliers using confidence level specified in input scalar `conflev`.
- **Sloc**: A vector with S estimate of location.
- **Sshape**: A matrix with S estimate of the shape matrix.
- **Scov**: A matrix with S estimate of the covariance matrix.
- **auxscale**: S estimate of the scale.
- **md**: n-by-1 vector containing the estimates of the robust Mahalanobis distances (in squared units).
- **conflev**: Confidence level that was used to declare outliers.
- **X**: the data matrix X

The object has class "mmmult".

Examples

```r
## Not run:
data(hbk)
(out <- mmmult(hbk[,1:3]))
class(out)
summary(out)
## End(Not run)
```
Description

An object of class \texttt{mmulteda.object} holds information about the result of a call to \texttt{mmult} with \texttt{monitoring=TRUE}.

Value

The object itself is basically a \texttt{list} with the following components:

- **Loc**: \texttt{length(eff)-by-p} matrix containing MM estimate of location for each value of \texttt{eff}.
- **Shape**: \texttt{p-by-p-by-length(eff)} 3D array containing robust estimate of the shape for each value of \texttt{eff}. Remark: \texttt{det(shape)=1}.
- **Scale**: \texttt{length(eff)} vector containing robust estimate of the scale for each value of \texttt{eff}.
- **Cov**: \texttt{p-by-p-by-length(eff)} 3D array containing robust estimate of covariance matrix for each value of \texttt{eff}. Note that \texttt{scale(i)^2 * shape[,i]} = robust estimate of covariance matrix.
- **Bs**: \texttt{(p+1)-by-length(eff)} matrix containing the units forming best subset for each value of \texttt{eff}.
- **MAL**: \texttt{n-by-length(eff)} matrix containing the estimates of the robust Mahalanobis distances (in squared units) for each value of \texttt{eff}.
- **Outliers**: \texttt{n-by-length(eff)} matrix containing flags for the outliers. Boolean matrix containing the list of the units declared as outliers for each value of \texttt{eff} using confidence level specified in input scalar \texttt{conflev}.
- **Weights**: \texttt{n x length(eff)} matrix containing the weights for each value of \texttt{eff}.
- **conflev**: Confidence level that was used to declare outliers.
- **singsub**: Number of subsets without full rank. Notice that \texttt{singsub > 0.1*(number of subsamples)} produces a warning.
- **eff**: Vector which contains the values of \texttt{eff} which have been used.
- **X**: The data matrix \texttt{X}.

The object has class "\texttt{mmulteda}".

Examples

```r
## Not run:
data(hbk)
(out <- mmmult(hbk[,1:3], monitoring=TRUE))
class(out)
summary(out)

## End(Not run)
```
mmreg.object

Description of mmreg Objects

Description

An object of class mmreg.object holds information about the result of a call to fsreg with method="MM".

Value

The object itself is basically a list with the following components:

- **beta**: p-by-1 vector containing the MM estimate of regression coefficients.
- **auxscale**: scalar, S estimate of the scale (or supplied external estimate of scale, if option InitialEst is not empty).
- **residuals**: residuals.
- **fittedvalues**: fitted values.
- **weights**: n x 1 vector. Weights assigned to each observation.
- **Sbeta**: p x 1 vector containing S estimate of regression coefficients (or supplied initial external estimate of regression coefficients, if option InitialEst is not empty)
- **Ssingsub**: Number of subsets without full rank in the S preliminary part. Notice that out.singsub > 0.1*(number of subsamples) produces a warning.
- **outliers**: k x 1 vector containing the list of the k units declared as outliers or NULL if the sample is homogeneous.
- **conflev**: Confidence level which is used to declare units as outliers. Usually conflev=0.95, 0.975, 0.99 (individual alpha) or conflev=1-0.05/n, 1-0.025/n, 1-0.01/n (simultaneous alpha). Default value is 0.975
- **rhofunc**: Specifies the rho function which has been used to weight the residuals. If a different rho function is specified for S and MM loop then insted of rhofunc we will have rhofuncS and rhofuncMM.
- **rhofuncparam**: Vector which contains the additional parameters for the specified rho function which has been used. For hyperbolic rho function the value of k = sup CVC. For Hampel rho function the parameters a, b and c. If a different rho function is specified for S and MM loop then insted of rhofuncparam we will have rhofuncparamS and rhofuncparamMM.
- **X**: the data matrix X
- **y**: the response vector y

The object has class "mmreg".
**mmregeda.object**

**Examples**
```r
## Not run:
(out <- fsreg(Y~., data=hbk, method="MM"))
class(out)
summary(out)
## End(Not run)
```

---

**Description**

An object of class `mmregeda.object` holds information about the result of a call to `fsreg` when `method="MM"` and `monitoring=TRUE`.

**Value**

The object itself is basically a `list` with the following components:

- **auxscale**: scalar, $S$ estimate of the scale (or supplied external estimate of scale, if option `InitialEst` is not empty).
- **Beta**: $p \times \text{length}(\text{eff})$ matrix containing MM estimate of regression coefficients for each value of `eff`.
- **RES**: $n \times \text{length}(\text{eff})$ matrix containing the monitoring of scaled residuals for each value of `eff`.
- **Weights**: $n \times \text{length}(\text{eff})$ matrix containing the estimates of the weights for each value of `eff`.
- **Outliers**: Boolean matrix containing the list of the units declared as outliers for each value of `eff` using confidence level specified in input scalar `conflev`.
- **conflev**: Confidence level which is used to declare units as outliers. Remark: `conflev` will be used to draw the horizontal line (confidence band) in the plot.
- **Singsub**: Number of subsets without full rank. Notice that `singsub > 0.1*(number of subsamples)` produces a warning.
- **rhofunc**: string identifying the rho function which has been used.
- **rhofuncparam**: vector which contains the additional parameters for the specified rho function which have been used. For hyperbolic rho function the value of $k = \sup \text{CVC}$. For Hampel rho function the parameters $a$, $b$ and $c$.
- **eff**: vector containing the value of `eff` which have been used.
- **X**: the data matrix $X$.
- **y**: the response vector $y$.

The object has class "mmregeda".
MMregeda_control

Assigns an object of class MMregeda_control to be used with the fsreg() function, containing various control parameters.

Usage

```r
MMregeda_control(intercept = TRUE, InitialEst, Soptions, eff, effshape, 
refsteps = 3, tol = 1e-07, conflev, nocheck = FALSE, plot = FALSE)
```

Arguments

- **intercept**: Indicator for constant term. Scalar. If `intercept=TRUE`, a model with constant term will be fitted (default), else, no constant term will be included.
- **InitialEst**: Starting values of the MM-estimator, a list with the following elements: `loc`, a $p \times 1$ vector, location vector estimate and `scale`, a scalar, estimate of the scale. If empty (default) the program will use S estimators. In this last case it is possible to specify the options given in function Sreg.
- **Soptions**: Options to pass to Sreg, an Sreg_control object. The options are: `Srhofunc`, `Snsamp`, `Srefsteps`, `Sreftol`, `Srefstepsbestr`, `Sreftolbestr`, `Sminsctol`, `Sbestr`. See function Sreg_control for more details on these options. It is necessary to add to the S options the letter S at the beginning. For example, if you want to use the optimal rho function the supplied option is 'Srhofunc','optimal'. For example, if you want to use 3000 subsets, the supplied option is 'Snsamp',3000
- **eff**: Vector defining nominal efficiency (i.e. a series of numbers between 0.5 and 0.99). The default value is the sequence `seq(0.5, 0.99, 0.01)`
- **effshape**: Location or scale efficiency. If `effshape=1` efficiency refers to shape efficiency else (default) efficiency refers to location efficiency.
- **refsteps**: Number of refining iterations in each subsample (default is `refsteps=3`). `refsteps = 0` means "raw-subsampling" without iterations.
- **tol**: Scalar controlling tolerance in the MM loop. The default value is `tol=1e-6`. 

Examples

```r
## Not run:
(out <- fsreg(Y~., data=hbk, method="MM", monitoring=TRUE))
class(out)
summary(out)
```
## End(Not run)

---

**Description**

Creates an object of class MMregeda_control to be used with the fsreg() function, containing various control parameters.

**Usage**

MMregeda_control(intercept = TRUE, InitialEst, Soptions, eff, effshape, 
refsteps = 3, tol = 1e-07, conflev, nocheck = FALSE, plot = FALSE)
MMreg_control

conflev  Confidence level which is used to declare units as outliers. Usually conflev=0.95, 0.975, 0.99 (individual alpha) or conflev=1-0.05/n, 1-0.025/n, 1-0.01/n (simultaneous alpha). Default value is 0.975

nocheck  Check input arguments, scalar. If nocheck=TRUE no check is performed on matrix y and matrix X. Notice that y and X are left unchanged. In other words the additional column of ones for the intercept is not added. As default nocheck=FALSE.

plot  Plot on the screen. Scalar. If plots=TRUE the plot of minimum deletion residual with envelopes based on n observations and the scatterplot matrix with the outliers highlighted is produced. If plots=2 the user can also monitor the intermediate plots based on envelope superimposition. If plots=FALSE (default) no plot is produced.

Details

Creates an object of class MMregeda_control to be used with the fsreg() function, containing various control parameters.

Value

An object of class "MMregeda_control" which is basically a list with components the input arguments of the function mapped accordingly to the corresponding Matlab function.

## End(Not run)
```

---

**MMreg_control**  Creates an **MMreg_control** object

**Description**

Creates an object of class MMreg_control to be used with the fsreg() function, containing various control parameters for calling the MATLAB function MMreg().
Usage

MMreg_control(intercept = TRUE, InitialEst, Soptions, eff, effshape, rhofunc = c("bisquare", "optimal", "hyperbolic", "hampel"), rhofuncparam, refsteps = 3, tol = 1e-07, conflev, msg = TRUE, nocheck = FALSE, plot = FALSE)

Arguments

intercept Indicator for constant term. Scalar. If intercept=TRUE, a model with constant term will be fitted (default), else, no constant term will be included.

InitialEst Starting values of the MM-estimator, a list with the following elements: loc, a $p \times 1$ vector, location vector estimate and scale, a scaler, estimate of the scale. If empty (default) the program will use S estimators. In this last case it is possible to specify the options given in function Sreg.

Soptions Options to pass to Sreg, an Sreg_control object. The options are: Srhofunc, Snsamp, Srefsteps, Sreftol, Srefstepsbestr, Sreftolbestr, Sminsctol, Sbestr. See function Sreg_control for more details on these options.

It is necessary to add to the S options the letter S at the beginning. For example, if you want to use the optimal rho function the supplied option is 'Srhofunc','optimal'. For example, if you want to use 3000 subsets, the supplied option is 'Snsamp',3000

eff Scalar defining nominal efficiency (i.e. a number between 0.5 and 0.99). The default value is 0.95.

effshape Location or scale efficiency. If effshape=1 efficiency refers to shape efficiency else (default) efficiency refers to location efficiency.

rhofunc Specifies the rho function which must be used to weight the residuals. Possible values are 'bisquare' 'optimal' 'hyperbolic' 'hampel'.

1. 'bisquare' uses Tukey's rho and psi functions. See TBrho and TBpsi.
2. 'optimal' uses optimal rho and psi functions. See OPTrho and OPTpsi.
3. 'hyperbolic' uses hyperbolic rho and psi functions. See HYPrho and HYPpsi.
4. 'hampel' uses Hampel rho and psi functions. See HArho and HAPsi.

The default is 'bisquare'.

rhofuncparam Additional parameters for the specified rho function. For hyperbolic rho function it is possible to set up the value of k = sup CVC (the default value of k is 4.5).

For Hampel rho function it is possible to define parameters a, b and c (the default values are a=2, b=4, c=8)

refsteps Number of refining iterations in each subsample (default is refsteps=3). refsteps = 0 means "raw-subsampling" without iterations.

tol Scalar controlling tolerance in the MM loop. The default value is tol=1e-6

conflev Confidence level which is used to declare units as outliers. Usually conflev=0.95, 0.975, 0.99 (individual alpha) or conflev=1-0.05/n, 1-0.025/n, 1-0.01/n (simultaneous alpha). Default value is 0.975
**Description**

Plots the trajectories of the monitored scaled (squared) residuals
Usage

resfwdplot(out, xlim, ylim, xlab, ylab, main, lwd, lty, col, cex.lab, cex.axis, xvalues, fg.thresh, fg.unit, fg.labstep, fg.lwd, fg.lty, fg.col, fg.mark, fg.cex, bg.thresh, bg.style, tag, datatooltip, label, nameX, namey, msg, databrush, standard, fground, bground, ...)

Arguments

out An object returned by one of the monitoring functions (see FSReda_control, Sregeda_control and MMregeda_control). The object is one of fsreda.object, sregeda.object or mmregeda.object.

The needed elements of out are

1. RES: matrix containing the residuals monitored in each step of the forward search or any other robust procedure. Every row is associated with a residual (unit). This matrix can be created using function FSReda, Sregeda, MMRegeda.
2. Un: (for FSR only) - matrix containing the order of entry in the subset of each unit (required only when datatooltip is true or databrush is not empty).
3. bdp: (for Sreg only) - vector containing a sequence of breakdown point values to monitor on.
4. eff: (for MMreg only) - vector containing a sequence of efficiency values to monitor on.
5. y: a vector containing the response (required only when option databrush is requested).
6. X: a matrix containing the explanatory variables (required only when option databrush is requested).
7. bols: (n-init+1) x (p+1) matrix containing the estimated beta coefficients monitored in each step of the robust procedure (required only when option databrush is requested and suboption multivarfit is requested).

xlim Control x scale in plot. Vector with two elements controlling minimum and maximum on the x axis. Default is to use automatic scale.

ylim Control y scale in plot. Vector with two elements controlling minimum and maximum on the y axis. Default is to use automatic scale.

xlab a title for the x axis

ylab a title for the y axis

main an overall title for the plot

lwd The line width, a positive number, defaulting to 1

lty The line type. Line types can either be specified as an integer (1=solid (default), 2=dashed, 3=dotted, 4=dotdash, 5=longdash, 6=twodash) or as one of the character strings "solid", "dashed", "dotted", "dotdash", "longdash", or "twodash". The latter two are not supported by Matlab.
Colors to be used for the highlighted units.

The magnification to be used for x and y labels relative to the current setting of cex.

The magnification to be used for axis annotation relative to the current setting of cex.

Values for the x axis. Numeric vector of ncol(RES) controlling the x axis coordinates. The default value of xvalues is (nrow(RES) - ncol(RES) + 1):nrow(RES).

(alternative to fg.unit) numeric vector of length 1 or 2 which specifies the highlighted trajectories. If length(fg.thresh) == 1 the highlighted trajectories are those of units that throughout the search had at least once a residual greater (in absolute value) than thresh. The default value is fg.thresh = 2.5. If length(fg.thresh) == 2 the highlighted trajectories are those of units that throughout the search had a residual at least once bigger than fg.thresh[2] or smaller than fg.thresh[1].

(vector containing the list of the units to be highlighted. If fg.unit is supplied, fg.thresh is ignored.

Numeric vector which specifies the steps of the search where to put labels for the highlighted trajectories (units). The default is to put the labels at the initial and final steps of the search. fg.labstep = ' ' means no label.

The line width for the highlighted trajectories (units). Default is 1.

The line type for the highlighted trajectories (units). Line types can either be specified as an integer (1 = solid (default), 2 = dashed, 3 = dotted, 4 = dotdash, 5 = longdash, 6 = twodash) or as one of the character strings "solid", "dashed", "dotted", "dotdash", "longdash", or "twodash". The latter two are not supported by Matlab.

Colors to be used for the highlighted units.

Controls whether to plot highlighted trajectories as symbols. If fg.mark = TRUE each line is plotted using a different symbol else no marker is used (default).

controls the font size of the labels of the trajectories in foreground.

Numeric vector of length 1 or 2 which specifies how to define the unimportant trajectories. Unimportant trajectories will be plotted using a colormap, in grey or will be hidden. If length(bg.thresh) == 1 the irrelevant units are those which always had a residual smaller (in absolute value) than thresh. If length(bg.thresh) == 2 the irrelevant units are those which always had a residual greater than bg.thresh[1] and smaller than bg.thresh[2]. The default is: bg.thresh = 2.5 if n > 100 and bg.thresh = -Inf if n <= 100 i.e. to treat all trajectories as important if n <= 100 and, if n > 100, to reduce emphasis only to trajectories having in all steps of the search a value of scaled residual smaller than 2.5.

Specifies how to plot the unimportant trajectories as defined in option bg.thresh.

When n>100 the default option is bg.style='faint'. When n <= 100 and bg.thresh == -Inf option bstyle is ignored. Remark: bground= " is equivalent to -Inf that is all trajectories are considered relevant.
tag

Plot handle. String which identifies the handle of the plot which is about to be created. The default is to use tag 'pl_resfwd'. Notice that if the program finds a plot which has a tag equal to the one specified by the user, then the output of the new plot overwrites the existing one in the same window else a new window is created.

datatooltip

Interactive clicking. It is inactive if this parameter is missing or empty. The default is datatooltip=TRUE, i.e. the user can select with the mouse an individual residual trajectory in order to have information about the corresponding unit. The information displayed depends on the estimator in use.

For example for class fsreda.object the information concerns the label and the step of the search in which the unit enters the subset. If datatooltip is a list it may contain the following fields:

1. DisplayStyle determines how the data cursor displays. Possible values are 'datatip' and 'window' (default). 'datatip' displays data cursor information in a small yellow text box attached to a black square marker at a data point you interactively select. 'window' displays data cursor information for the data point you interactively select in a floating window within the figure.

2. SnapToDataVertex: specifies whether the data cursor snaps to the nearest data value or is located at the actual pointer position. Possible values are SnapToDataVertex='on' (default) and SnapToDataVertex='off'.

3. LineColor: controls the color of the trajectory selected with the mouse. It can be an RGB triplet of values between 0 and 1, or character vector indicating a color name. Note that a RGB vector can be conveniently chosen with our MATLAB class FSColor, see documentation.

4. SubsetLinesColor: enables to control the color of the trajectories of the units that are in the subset at a given step of the search (if resfwdplot() is applied to an object of class fsreda.object) or have a weight greater than 0.9 (if resfwdplot() is applied to an object of class sregeda.object or mmregeda.object). This can be done (repeatedly) with a left mouse click in proximity of the step of interest. A right mouse click will terminate the selection by marking with a up-arrow the step corresponding to the highlighted lines. The highlighted lines by default are in red, but a different color can be specified as RGB triplet or character of color name. Note that a RGB vector can be conveniently chosen with our MATLAB class FSColor, see documentation. By default SubsetLinesColor='", i.e. the modality is not active. Any initialization for SubsetLinesColor which cannot be interpreted as RGB vector will be converted to blue, i.e. SubsetLinesColor will be forced to be [0 0 1]. If SubsetLinesColor is not empty the previous option LineColor is ignored.

label

Character vector containing the labels of the units (optional argument used when datatooltip=TRUE. If this field is not present labels row1, ..., rown will be automatically created and included in the pop up datatooltip window).

nameX

Add variable labels in plot. A vector of strings of length p containing the labels of the variables of the regression dataset. If it is empty (default) the sequence X1, ..., Xp will be created automatically.

namey

Add response label. A string containing the label of the response
**msg**

Controls whether to display or not messages on the screen. If `msg==1` (default) messages are displayed on the screen about step in which signal took place else no message is displayed on the screen.

**databrush**

Interactive mouse brushing. If `databrush` is missing or empty (default), no brushing is done. The activation of this option (`databrush` is a scalar or a list) enables the user to select a set of trajectories in the current plot and to see them highlighted in the `y|X` plot, i.e., a matrix of scatter plots of `y` against each column of `X`, grouped according to the selection(s) done by brushing. If the plot `y|X` does not exist it is automatically created. In addition, brushed units are automatically highlighted in the minimum deletion residual plot if it is already open.

The extension to the following plots will be available in future versions of the toolbox:

1. monitoring leverage plot;
2. maximum studentized residual;
3. $s^2$ and $R^2$;
4. Cook distance and modified Cook distance;
5. deletion t statistics.

Note that the window style of the other figures is set equal to that which contains the monitoring residual plot. In other words, if the monitoring residual plot is docked all the other figures will be docked too.

If `databrush=TRUE` the default selection tool is a rectangular brush and it is possible to brush only once (that is persist="").

If `databrush=list(...)`, it is possible to use all optional arguments of function `selectdataFS()` and the following optional argument:

1. **persist**. Persist is an empty value or a character containing 'on' or 'off'. The default value is `persist=""`, that is brushing is allowed only once. If `persist="on"` or `persist="off"` brushing can be done as many times as the user requires. If `persist="on"` then the unit(s) currently brushed are added to those previously brushed. It is possible, every time a new brushing is done, to use a different color for the brushed units. If `persist="off"` every time a new brush is performed units previously brushed are removed.

2. **bivarfit**. Whether to superimpose bivariate least square lines on the plot (if `plot=TRUE`). This option adds one or more least squares lines, based on SIMPLE REGRESSION of `y` on `Xi`, to the plots of `y|Xi`. The default is `bivarfit=FALSE`: no line is fitted. If `bivarfit=1`, a single OLS line is fitted to all points of each bivariate plot in the scatter matrix `y|Xi`. If `bivarfit=2`, two OLS lines are fitted: one to all points and another to the group of the genuine observations. The group of the potential outliers is not fitted. If `bivarfit=0` one OLS line is fitted to each group. This is useful for the purpose of fitting mixtures of regression lines. If `bivarfit='i1'` or `bivarfit='i2'`, etc. an OLS line is fitted to a specific group, the one with index 'i' equal to 1, 2, 3 etc. Again, useful in case of mixtures.

3. **multivarfit**. Whether to superimpose multivariate least square lines. This option adds one or more least square lines, based on MULTIVARIATE REGRESSION of `y` on `X`, to the plots of `y|X`. The default is `multivarfit=FALSE`: no line is fitted. If `multivarfit=1`, a single OLS line is fitted to all points of
each bivariate plot in the scatter matrix y|X. The line added to the scatter plot y|Xi is avconst + Ci*Xi, where Ci is the coefficient of Xi in the multivariate regression and avconst is the effect of all the other explanatory variables different from Xi evaluated at their centroid (that is overline(y)'C)). If multivarfit=2, same action as with multivarfit=1 but this time we also add the line based on the group of unselected observations (i.e. the normal units).

4. labeladd Add outlier labels in plot. If labeladd=TRUE, we label the outliers with the unit row index in matrices X and y. The default value is labeladd=FALSE, i.e. no label is added.

standard (MATLAB-style arguments) appearance of the plot in terms of xlim, ylim, axes labels and their font size style, color of the lines, etc.
fground MATLAB-style arguments for the fground trajectories in foregroud.
bground MATLAB-style arguments for the fground trajectories in backgroud.
...
potential further arguments passed to lower level functions.

```
resindexplot

Plots the residuals from a regression analysis versus index number or any other variable

Description

The function resindexplot() plots the residuals from a regression analysis versus index number or any other variable. The residuals come from an output object of any of the regression functions or a simply a vector of values. In order to use the databrush option, the residuals must come from one of the fsdaR regression functions.

Usage

resindexplot(out, x, xlim, ylim, xlab, ylab, main, numlab, indlab, conflev, cex.axis, cex.lab, lwd, nameX, namey, tag, col, cex, databrush, ...)

Arguments

- **out**: A vector containing the residuals from a regression analysis or an object returned by one of the regression functions (see FSR_control, LXS_control, Sreg_control and MMreg_control). The object is one of fsl.object, fsdalts.object, fsdalms.object, sreg.object or mmreg.object. The needed elements of out are at least residuals, but if the option databrush is used, also X and y will be needed.
- **x**: The vector to be plotted on the x-axis. As default the sequence 1:length(residuals) will be used.
- **xlim**: Control x scale in plot. Vector with two elements controlling minimum and maximum on the x axis. Default is to use automatic scale.
- **ylim**: Control y scale in plot. Vector with two elements controlling minimum and maximum on the y axis. Default is to use automatic scale.
- **xlab**: a title for the x axis
- **ylab**: a title for the y axis
- **main**: an overall title for the plot
- **numlab**: Number of points to be identified in plots (see also indlab). By default the five points with largest values will be identified. If numlab is a single number containing scalar k, the units with the k largest residuals are labelled in the plots. If numlab is a vector, the units inside vector numlab are labelled in the plots. The default value of numlab=5 and the units with the 5 largest residuals will be labelled. If numlib=0 or numlib=NULL no labelling will be done.
- **indlab**: Which points to be identified in plots (see also numlab) - the units with indexes in the vector indlab are labelled in the plots.
- **conflev**: Confidence interval for the horizontal bands (a numeric vector). It can be a vector of different confidence level values. Remark: confidence interval is based on the chi^2 distribution
cex.axis: The magnification to be used for axis annotation relative to the current setting of cex.

cex.lab: The magnification to be used for x and y labels relative to the current setting of cex.

lwd: The line width, a positive number, defaulting to 1.

tag: Figure tag (character). Tag of the figure which will host the `resindexplot`. The default tag is `iscodepl_resindex`.

col: Fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). Can be 'none' or 'auto' or color name(string) or RGB triplet.

cex: Size of the point symbols. The magnification to be used relative to the current setting of cex.

nameX: Add variable labels in plot. A vector of strings of length p containing the labels of the variables of the regression dataset. If it is empty (default) the sequence X1,...,Xp will be created automatically.

namey: Add response label. A string containing the label of the response.

databrush: Interactive mouse brushing. If databrush is missing or empty (default) or databrush=FALSE, no brushing is done. The activation of this option (databrush is a scalar or a list) enables the user to select a set of trajectories in the current plot and to see them highlighted in the y|X plot, i.e. a matrix of scatter plots of y against each column of X, grouped according to the selection(s) done by brushing. If the plot y|X does not exist it is automatically created. In addition, brushed units are automatically highlighted in the minimum deletion residual plot if it is already open. The extension to the following plots will be available in future versions of the package:

1. monitoring leverage plot;
2. maximum studentized residual;
3. s^2 and R^2;
4. Cook distance and modified Cook distance;
5. deletion t statistics.

Note that the window style of the other figures is set equal to that which contains the monitoring residual plot. In other words, if the monitoring residual plot is docked all the other figures will be docked too.

If databrush=TRUE the default selection tool is a rectangular brush and it is possible to brush only once (that is persist=""). If databrush=list(...), it is possible to use all optional arguments of function `selectdataFS()` and the following optional argument:

1. persist: Persist is an empty value or a character containing 'on' or 'off'. The default value is persist="", that is brushing is allowed only once. If persist="on" or persist="off" brushing can be done as many time as the user requires. If persist='on' then the unit(s) currently brushed are added to those previously brushed. It is possible, every time a new brushing is done, to use a different color for the brushed units. If persist='off' every time a new brush is performed units previously brushed are removed.
2. bivarfit: This option adds one or more least square lines based on SIMPLE REGRESSION to the plots of y|X, depending on the selected groups. The default is bivarfit=FALSE: no line is fitted. If bivarfit=1, a single OLS line is fitted to all points of each bivariate plot in the scatter matrix y|X. If bivarfit=2, two OLS lines are fitted: one to all points and another to the group of the genuine observations. The group of the potential outliers is not fitted. If bivarfit=0 one OLS line is fitted to each group. This is useful for the purpose of fitting mixtures of regression lines. If bivarfit='i1' or bivarfit='i2', etc. an OLS line is fitted to a specific group, the one with index 'i' equal to 1, 2, 3 etc. Again, useful in case of mixtures.

3. multivarfit: Whether to superimpose multivariate least square lines. This option adds one or more least square lines, based on MULTIVARIATE REGRESSION of y on X, to the plots of y|Xi. The default is multivarfit=FALSE: no line is fitted. If multivarfit=1, a single OLS line is fitted to all points of each bivariate plot in the scatter matrix y|X. The line added to the scatter plot y|Xi is avconst + Ci*Xi, where Ci is the coefficient of Xi in the multivariate regression and avconst is the effect of all the other explanatory variables different from Xi evaluated at their centroid (that is overline(y)'C)). If multivarfit=2, same action as with multivarfit=1 but this time we also add the line based on the group of unselected observations (i.e. the normal units).

4. labeladd: Add outlier labels in plot. If labeladd=TRUE, we label the outliers with the unit row index in matrices X and y. The default value is labeladd=FALSE, i.e. no label is added.

... potential further arguments passed to lower level functions.

Examples

## Not run:
out <- freg(stack.loss~., data=stackloss)
resindexplot(out, conflev=c(0.95,0.99), col="green")

## End(Not run)
Computes S estimators in multivariate analysis

Usage

smult(x, monitoring = FALSE, plot = FALSE, bdp, nsamp, conflev = 0.975, nocheck = FALSE, trace = FALSE, ...)

Arguments

x An n x p data matrix (n observations and p variables). Rows of x represent observations, and columns represent variables. Missing values (NA's) and infinite values (Inf's) are allowed, since observations (rows) with missing or infinite values will automatically be excluded from the computations.

monitoring Whether to perform monitoring of Mahalanobis distances and other specific quantities

plot Plots the Mahalanobis distances against index number. If plot=FALSE (default) or plot=0 no plot is produced. The confidence level used to draw the confidence bands for the MD is given by the input option conflev. If conflev is not specified a nominal 0.975 confidence interval will be used. If plot=2 a scatter plot matrix with the outliers highlighted is produced. If plot is a list it may contain the following fields:

• labeladd If labeladd=1, the outliers in the spm are labelled with the unit row index. The default value is labeladd="", i.e. no label is added
• nameY character vector containing the labels of the variables. As default value, the labels which are added are Y1, ...Yp.

bdp Measures the fraction of outliers the algorithm should resist. In this case any value greater than 0 but smaller or equal than 0.5 will do fine (default is bdp=0.5). Note that given bdp nominal efficiency is automatically determined.

nsamp Number of subsamples which will be extracted to find the robust estimator. If nsamp=0 all subsets will be extracted. They will be (n choose p). If the number of all possible subset is <1000 the default is to extract all subsets otherwise just 1000.

conflev confidence interval for the horizontal bands. It can be a vector of different confidence level values, e.g. c(0.95, 0.99, 0.999). The confidence interval is based on the chi^2 distribution.

nocheck It controls whether to perform checks on matrix Y. If nocheck=TRUE, no check is performed.

trace Whether to print intermediate results. Default is trace=FALSE.

... potential further arguments passed to lower level functions.
Details

This function follows the lines of MATLAB/R code developed during the years by many authors. For more details see http://www.econ.kuleuven.be/public/NDBAE06/programs/ and the R package CovSest. The core of these routines, e.g., the resampling approach, however, has been completely redesigned, with considerable increase of the computational performance.

Value

Depending on the input parameter monitoring, one of the following objects will be returned:

1. smult.object
2. smulteda.object

summary(out)

## Generate contaminated data (200, 3)
n <- 200
p <- 3
set.seed(123456)
X <- matrix(rnorm(n*p), nrow=n)
Xcont <- X

out1 <- smult(Xcont, trace=TRUE) # no plots (plot defaults to FALSE)
names(out1)

## plot=TRUE - generates: (1) a plot of Mahalanobis distances against
## index number. The confidence level used to draw the confidence bands for
## the MD is given by the input option conflev. If conflev is
## not specified a nominal 0.975 confidence interval will be used and
## (2) a scatter plot matrix with the outliers highlighted.

(out1 <- smult(Xcont, trace=TRUE, plot=TRUE))

## plots is a list: the spm shows the labels of the outliers.
```
smult.object

Description of smult.object Objects

Description

An object of class `smult.object` holds information about the result of a call to `smult`.

Value

The object itself is basically a `list` with the following components:

- **loc**: p-by-1 vector containing S estimate of location.
- **shape**: p-by-p matrix containing robust estimate of the shape matrix. Remark: det(shape)=1.
- **scale**: robust estimate of the scale.
- **cov**: `scale^2 * shape`: robust estimate of covariance matrix.
- **bs**: a (p+1) vector containing the units forming best subset associated with S estimate of location.
- **md**: n-by-1 vector containing the estimates of the robust Mahalanobis distances (in squared units). This vector contains the distances of each observation from the location of the data, relative to the scatter matrix cov.
- **outliers**: A vector containing the list of the units declared as outliers using confidence level specified in input scalar `conflev`.
- **conflev**: Confidence level that was used to declare outliers.
- **singsub**: Number of subsets without full rank. Notice that `singsub > 0.1*(number of subsamples)` produces a warning.
- **weights**: n x 1 vector containing the estimates of the weights.
- **X**: the data matrix X

The object has class "smult".
Examples

```r
## Not run:
data(hbk)
(out <- smult(hbk[,1:3]))
class(out)
summary(out)

## End(Not run)
```

Description of `smulteda.object` Objects

Description

An object of class `smulteda.object` holds information about the result of a call to `smult` with monitoring=TRUE.

Value

The object itself is basically a list with the following components:

- **Loc**: length(bdp)-by-p matrix containing $S$ estimate of location for each value of bdp.
- **Shape**: p-by-p-by-length(bdp) 3D array containing robust estimate of the shape for each value of bdp. Remark: det(shape) = 1.
- **Scale**: length(bdp) vector containing robust estimate of the scale for each value of bdp.
- **Cov**: p-by-p-by-length(bdp) 3D array containing robust estimate of covariance matrix for each value of bdp. Note that scale(i)^2 * shape[,i] = robust estimate of covariance matrix.
- **Bs**: (p+1)-by-length(bdp) matrix containing the units forming best subset for each value of bdp.
- **MAL**: n-by-length(bdp) matrix containing the estimates of the robust Mahalanobis distances (in squared units) for each value of bdp.
- **Outliers**: n-by-length(bdp) matrix containing flags for the outliers. Boolean matrix containing the list of the units declared as outliers for each value of bdp using confidence level specified in input scalar `conflev`.
- **Weights**: n x length(bdp) matrix containing the weights for each value of bdp.
- **conflev**: Confidence level that was used to declare outliers.
- **singsub**: Number of subsets without full rank. Notice that `singsub > 0.1*(number of subsamples)` produces a warning.
- **bdp**: vector which contains the values of bdp which have been used.
- **X**: the data matrix X.

The object has class "smulteda".
### sreg.object

#### Description of sreg Objects

**Description**

An object of class `sreg.object` holds information about the result of a call to `fsreg`.

**Value**

The object itself is basically a list with the following components:

- `beta`: p-by-1 vector containing the estimated regression parameters (in step n-k).
- `scale`: scalar containing the estimate of the scale (sigma).
- `bs`: p x 1 vector containing the units forming best subset associated with S estimate of regression coefficient.
- `residuals`: residuals.
- `fittedvalues`: fitted values.
- `outliers`: k x 1 vector containing the list of the k units declared as outliers or NULL if the sample is homogeneous.
- `conflev`: Confidence level which is used to declare units as outliers. Usually `conflev=0.95, 0.975, 0.99` (individual alpha) or `conflev=1-0.05/n, 1-0.025/n, 1-0.01/n` (simultaneous alpha). Default value is 0.975.
- `singsub`: Number of subsets without full rank. Notice that `singsub > 0.1*(number of subsamples)` produces a warning.
- `weights`: n x 1 vector containing the estimates of the weights.
- `rhofunc`: Specifies the rho function which has been used to weight the residuals.
- `rhofuncparam`: Vector which contains the additional parameters for the specified rho function which has been used. For hyperbolic rho function the value of k = `sup CVC`. For Hampel rho function the parameters a, b and c.
- `X`: the data matrix X.
- `y`: the response vector y.

The object has class "sreg".

### Examples

```
## Not run:
data(hbk)
(out <- smult(hbk[,1:3], monitoring=TRUE))
class(out)
summary(out)

## End(Not run)
```
**sregeda.object**

## Examples

```r
## Not run:
(out <- fsreg(Y~., data=hbk, method="S"))
class(out)
summary(out)
```

## End(Not run)

---

### sregeda.object Description of sregeda Objects

**Description**

An object of class *sregeda.object* holds information about the result of a call to *fsreg* when `method="S"` and `monitoring=TRUE`.

**Value**

The object itself is basically a *list* with the following components:

- **Beta**: Matrix containing the S estimator of regression coefficients for each value of `bdp`.
- **Scale**: Vector containing the estimate of the scale (sigma) for each value of `bdp`. This is the value of the objective function.
- **BS**: P x 1 vector containing the units forming best subset associated with S estimate of regression coefficient.
- **RES**: N x length(bdp) matrix containing the monitoring of scaled residuals for each value of `bdp`.
- **Weights**: N x length(bdp) matrix containing the estimates of the weights for each value of `bdp`.
- **Outliers**: Boolean matrix containing the list of the units declared as outliers for each value of bdp using confidence level specified in input scalar `conflev`.
- **conflev**: Confidence level which is used to declare units as outliers. Remark: conflev will be used to draw the horizontal line (confidence band) in the plot.
- **Singsub**: Number of subsets without full rank. Notice that `singsub[bdp[jj]] > 0.1*(number of subsamples)` produces a warning.
- **rhofunc**: Specifies the rho function which has been used to weight the residuals.
- **rhofuncparam**: Vector which contains the additional parameters for the specified rho function which has been used. For hyperbolic rho function the value of k =sup CVC. For Hampel rho function the parameters a, b and c.
- **X**: The data matrix X
- **y**: The response vector y

The object has class "sregeda".
## Sregeda_control

**Description**

Creates an object of class Sregeda_control to be used with the `fsreg()` function, containing various control parameters.

**Usage**

```r
Sregeda_control(intercept = TRUE, bdp = seq(0.5, 0.01, -0.01),
                 rhofunc = c("bisquare", "optimal", "hyperbolic", "hampel"), rhofuncparam,
                 nsamp = 1000, refsteps = 3, reftol = 1e-06, refstepsbestr = 50, reftolbestr = 1e-08,
                 minsctol = 1e-07, bestr = 5,
                 conflev, msg = TRUE, nocheck = FALSE, plot = FALSE)
```

**Arguments**

- `intercept` (Indicator for constant term. Scalar. If intercept=TRUE, a model with constant term will be fitted (default), else, no constant term will be included.)
- `bdp` (Breakdown point. It measures the fraction of outliers the algorithm should resist. In this case any value greater than 0 but smaller or equal than 0.5 will do fine. The default value of bdp is a sequence from 0.5 to 0.01 with step 0.01)
- `rhofunc` (Specifies the rho function which must be used to weight the residuals. Possible values are 'bisquare' 'optimal' 'hyperbolic' 'hampel'.
  1. 'bisquare' uses Tukey's rho and psi functions. See TBrho and TBpsi.
  2. 'optimal' uses optimal rho and psi functions. See OPTrho and OPTpsi.
  3. 'hyperbolic' uses hyperbolic rho and psi functions. See HYPrho and HYPpsi.
  4. 'hampel' uses Hampel rho and psi functions. See HARho and HAPsi. The default is 'bisquare'.
- `rhofuncparam` (Additional parameters for the specified rho function. For hyperbolic rho function it is possible to set up the value of k = sup CVC (the default value of k is 4.5).
  For Hampel rho function it is possible to define parameters a, b and c (the default values are a=2, b=4, c=8)
Sregeda_control

nsamp

Number of subsamples which will be extracted to find the robust estimator, scalar. If nsamp=0 all subsets will be extracted. They will be \( \binom{n}{p} \). If the number of all possible subset is <1000 the default is to extract all subsets otherwise just 1000.

refsteps

Number of refining iterations in each subsample (default is refsteps=3). refsteps = 0 means "raw-subsampling" without iterations.

reftol

Tolerance for the refining steps. The default value is 1e-6

refstepsbestr

Scalar defining number of refining iterations for each best subset (default = 50).

reftolbestr

Tolerance for the refining steps for each of the best subsets. The default value is reftolbestr=1e-8.

minsctol

Value of tolerance for the iterative procedure for finding the minimum value of the scale for each subset and each of the best subsets (It is used by subroutine minscale.m). The default value is minsctol=1e-7.

bestr

Defins the number of "best betas" to remember from the subsamples. These will be later iterated until convergence (default is bestr=5).

conflev

Confidence level which is used to declare units as outliers. Usually conflev=0.95, 0.975, 0.99 (individual alpha) or conflev=1-0.05/n, 1-0.025/n, 1-0.01/n (simultaneous alpha). Default value is 0.975

msg

Controls whether to display or not messages on the screen If msg==1 (default) messages are displayed on the screen about step in which signal took place else no message is displayed on the screen.

nocheck

Check input arguments, scalar. If nocheck=TRUE no check is performed on matrix y and matrix X. Notice that y and X are left unchanged. In other words the additional column of ones for the intercept is not added. As default nocheck=FALSE.

plot

Plot on the screen. Scalar. If plots=TRUE the plot of minimum deletion residual with envelopes based on n observations and the scatterplot matrix with the outliers highlighted is produced. If plots=2 the user can also monitor the intermediate plots based on envelope superimposition. If plots=FALSE (default) no plot is produced.

Details

Creates an object of class Sregeda_control to be used with the fsreg() function, containing various control parameters.

Value

An object of class "Sregeda_control" which is basically a list with components the input arguments of the function mapped accordingly to the corresponding Matlab function.

control=Sregeda_control(nsamp=500, rhofunc="hyperbolic")))

## End(Not run)

---

Sreg_control

*Creates an Sreg_control object*

Description

Creates an object of class Sreg_control to be used with the fsreg() function, containing various control parameters for calling the MATLAB function Sreg().

Usage

```r
Sreg_control(intercept = TRUE, bdp = 0.5,
rhofunc = c("bisquare", "optimal", "hyperbolic", "hampel"), rhofuncparam,
nsamp = 1000, refsteps = 3, reftol = 1e-06, refstepsbestr = 50, reftolbestr = 1e-08,
minsctol = 1e-07, bestr = 5,
confllev, msg = TRUE, nocheck = FALSE, plot = FALSE)
```

Arguments

- **intercept**: Indicator for constant term. Scalar. If intercept=TRUE, a model with constant term will be fitted (default), else, no constant term will be included.
- **bdp**: Breakdown point. It measures the fraction of outliers the algorithm should resist. In this case any value greater than 0 but smaller or equal than 0.5 will do fine. Note that given bdp nominal efficiency is automatically determined.
- **rhofunc**: Specifies the rho function which must be used to weight the residuals. Possible values are 'bisquare' 'optimal' 'hyperbolic' 'hampel'.
  1. 'bisquare' uses Tukey's rho and psi functions. See TBrho and TBpsi.
  2. 'optimal' uses optimal rho and psi functions. See OPTrho and OPTpsi.
  3. 'hyperbolic' uses hyperbolic rho and psi functions. See HYPrho and HYPpsi.
  4. 'hampel' uses Hampel rho and psi functions. See HARho and HAPsi.

The default is 'bisquare'.
- **rhofuncparam**: Additional parameters for the specified rho function. For hyperbolic rho function it is possible to set up the value of k = sup CVC (the default value of k is 4.5).

For Hampel rho function it is possible to define parameters a, b and c (the default values are a=2, b=4, c=8)
nsamp: Number of subsamples which will be extracted to find the robust estimator, scalar. If nsamp=0 all subsets will be extracted. They will be \( \binom{n}{p} \). If the number of all possible subset is <1000 the default is to extract all subsets otherwise just 1000.

refsteps: Number of refining iterations in each subsample (default is refsteps=3). refsteps = 0 means "raw-subsampling" without iterations.

reftol: Tolerance for the refining steps. The default value is 1e-6

refstepsbestr: Scalar defining number of refining iterations for each best subset (default = 50).

reftolbestr: Tolerance for the refining steps for each of the best subsets. The default value is reftolbestr=1e-8.

minsctol: Value of tolerance for the iterative procedure for finding the minimum value of the scale for each subset and each of the best subsets (It is used by subroutine minscale.m). The default value is minsctol=1e-7.

bestr: Defines the number of "best betas" to remember from the subsamples. These will be later iterated until convergence (default is bestr=5).

conflev: Confidence level which is used to declare units as outliers. Usually conflev=0.95, 0.975, 0.99 (individual alpha) or conflev=1-0.05/n, 1-0.025/n, 1-0.01/n (simultaneous alpha). Default value is 0.975

msg: Controls whether to display or not messages on the screen. If msg=1 (default) messages are displayed on the screen about step in which signal took place else no message is displayed on the screen.

nocheck: Check input arguments, scalar. If nocheck=TRUE no check is performed on matrix y and matrix X. Notice that y and X are left unchanged. In other words the additional column of ones for the intercept is not added. As default nocheck=FALSE.

summary.fsdalms  Summary Method for fsdalms objects

Description

`summary` method for class "fsdalms".

Usage

## S3 method for class 'fsdalms'
summary(object, correlation = FALSE, ...)

## S3 method for class 'summary.fsdalms'
print(x, digits = max(3, getOption("digits") - 3),
   signif.stars = getOption("show.signif.stars"), ...)

Arguments

object, x  an object of class "fsdalms" (or "summary.fsdalms"); usually, a result of a call to `fsreg`.
correlation  logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
digits  the number of significant digits to use when printing.
signif.stars  logical indicating if "significance stars" should be printed, see `printCoefmat`.
...  further arguments passed to or from other methods.

Details

`summary.fsdalms()` is the S3 method, simply returns an (S3) object of class "summary.fsdalms" for which there's a `print` method:

`print.summary.fsdalms` prints summary statistics for the forward search (FS) regression estimates. While the function `print.fsdalms` prints only the robust estimates of the coefficients, `print.summary.fsdalms` will print also the regression table.

Value

summary.fsdalms returns an `summary.fsdalms` object, whereas the print methods returns its first argument via `invisible`, as all print methods do.

See Also

`fsreg`, `summary`
Examples

```r
## Not run:

data(Animals, package = "MASS")
brain <- Animals[c(1:24, 26:25, 27:28),]
lbrain <- log(brain)
(fs <- fsreg(brain~body, data=lbrain, method="LTS"))
summary(fs)

## compare to the result of ltsReg() from 'robustbase'
(lts <- ltsReg(brain~body, data=lbrain))
summary(lts)

## End(Not run)
```

summary.fsdalts  

Summary Method for fsdalts objects

Description

`summary` method for class "fsdalts".

Usage

```r
## S3 method for class 'fsdalts'
summary(object, correlation = FALSE, ...)
## S3 method for class 'summary.fsdalts'
print(x, digits = max(3, getOption("digits") - 3),
     signif.stars = getOption("show.signif.stars"), ...)
```

Arguments

- `object, x`  
an object of class "fsdalts" (or "summary.fsdalts"); usually, a result of a call to `fsreg`.
- `correlation`  
logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
- `digits`  
the number of significant digits to use when printing.
- `signif.stars`  
logical indicating if “significance stars” should be printer, see `printCoefmat`.
- `...`  
further arguments passed to or from other methods.

Details

`summary.fsdalts()`, the S3 method, simply returns an (S3) object of class "summary.fsdalts" for which there's a `print` method:

`print.summary.fsdalts` prints summary statistics for the forward search (FS) regression estimates. While the function `print.fsdalts` prints only the robust estimates of the coefficients, `print.summary.fsdalts` will print also the regression table.
Value

`summary.fsdalts` returns an `summary.fsdalts` object, whereas the print methods returns its first argument via `invisible`, as all print methods do.

See Also

`fsreg`, `summary`

Examples

```r
## Not run:
data(Animals, package = "MASS")
brain <- Animals[c(1:24, 26:25, 27:28),]
lbrain <- log(brain)
(fs <- fsreg(brain~body, data=lbrain, method="LTS"))
summary(fs)

## compare to the result of ltsReg() from 'robustbase'
(lts <- ltsReg(brain~body, data=lbrain))
summary(lts)

## End(Not run)
```

summary.fsr  

Summary Method for FSR objects

Description

`summary` method for class "fsr".

Usage

```r
## S3 method for class 'fsr'
summary(object, correlation = FALSE, ...)
## S3 method for class 'summary.fsr'
print(x, digits = max(3, getOption("digits") - 3),
      signif.stars = getOption("show.signif.stars"), ...)
```

Arguments

- `object, x` an object of class "fsr" (or "summary.fsr"); usually, a result of a call to `fsreg`.
- `correlation` logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
- `digits` the number of significant digits to use when printing.
- `signif.stars` logical indicating if “significance stars” should be printed, see `printCoefmat`.
- `...` further arguments passed to or from other methods.
Details

`summary.fsr()`, the S3 method, simply returns an (S3) object of class "summary.fsr" for which there’s a `print` method:

`print.summary.fsr` prints summary statistics for the forward search (FS) regression estimates. While the function `print.fsr` prints only the robust estimates of the coefficients, `print.summary.fsr` will print also the regression table.

Value

`summary.fsr` returns an `summary.fsr` object, whereas the print methods returns its first argument via `invisible`, as all print methods do.

brain <- Animals[c(1:24, 26:25, 27:28),]
lbrain <- log(brain)
(fs <- fsreg(brain~body, data=lbrain, method="FS"))
summary(fs)

## End(Not run)
```

swissbanknotes

Swiss banknote data

Description

Six variables measured on 100 genuine and 100 counterfeit old (printed before the second world war) Swiss 1000-franc bank notes (Flury and Riedwyl, 1988).

Usage

data(swissbanknotes)

Format

A data frame with 200 observations on the following 7 variables.

- `length` Length of bill, mm
- `left` Width of left edge, mm
- `right` Width of right edge, mm

```r
swissbanknotes
```
bottom  Bottom margin width, mm
      top    Top margin width, mm
    diagonal Length of image diagonal, mm
     class  1 = genuine, 2 = counterfeit

Source

References

Examples
data(swissbanknotes)
head(swissbanknotes)
plot(CovMcd(swissbanknotes[,1:6]), which="pairs", col=swissbanknotes$class)

---

swissheads  Swiss banknote data

Description
Six dimensions in millimetres of the heads of 200 twenty year old Swiss soldiers (Flury and Riedwyl, 1988, p. 218 and also Flury, 1997, p. 6).
The data were collected to determine the variability in size and shape of heads of young men in order to help in the design of a new protection mask for the Swiss army.

Usage
data(swissheads)

Format
A data frame with 200 observations on the following 6 variables.
minimal_frontal_breadth   Minimal frontal breadth, mm
breadth_angulus_mandibulae Breadth of angulus mandibulae, mm
true_facial_height        True facial height, mm
length_glabella_nasi      Length from glabella to apex nasi, mm
length_tragion_nasion     Length from tragion to nasion, mm
length_tragion_gnathion   Length from tragion to gnathion, mm

tclusteda.object

Objects returned by the function *tclustfsda* with the option monitoring=TRUE

Description
An object of class *tclusteda.object* holds information about the result of a call to *tclustfsda* with the option monitoring=TRUE.

Value
The functions print() and summary() are used to obtain and print a summary of the results. An object of class tclusteda is a list containing at least the following components:

call
the matched call

k
number of groups

alpha
trimming level

restrfactor
restriction factor

IDX
an n-by-length(alpha) vector containing assignment of each unit to each of the k groups. Cluster names are integer numbers from 1 to k. 0 indicates trimmed observations. The first column refers to alpha[1], the second column refers to alpha[2], ..., the last column refers to alpha[length(alpha)].

MU
a 3 dimensional array of size k-by-p-by-length(alpha) containing the monitoring of the centroid for each value of alpha. MU[,1], refers to alpha[1] ..., MU(,,length(alpha)) refers to alpha[length(alpha)]. The first row in each slice refers to group 1, second row refers to group 2, etc.

SIGMA
A list of length length(alpha) containing in element j, with j=1,2,...,length(alpha), the 3D array of size p-by-p-by-k containing the k (constrained) estimated covariance matrices associated with alpha[j].
Amon stands for alpha monitoring. Matrix of size \((\text{length(alpha)}-1)\times4\) which contains for two consecutive values of alpha the monitoring of three quantities (change in classification, change in centroid location, change in covariance location).

- 1st col = value of alpha.
- 2nd col = ARI index.
- 3rd col = squared Euclidean distance between centroids.
- 4th col = squared Euclidean distance between covariance matrices.

### Examples

```r
## Not run:
data(hbk)
(out <- tclustfsda(hbk[, 1:3], k=2, monitoring=TRUE))
class(out)
summary(out)
## End(Not run)
```

---

### Description

Partitions the points in the \(n\times v\) data matrix \(Y\) into \(k\) clusters. This partition minimizes the trimmed sum, over all clusters, of the within-cluster sums of point-to-cluster-centroid distances. Rows of \(Y\) correspond to points, columns correspond to variables. Returns in the output object of class `tclustfsda.object` an \(n\times1\) vector \(\text{idx}\) containing the cluster indices of each point. By default, `tclustfsda()` uses (squared), possibly constrained, Mahalanobis distances.

### Usage

```r
tclustfsda(x, k, alpha, restrfactor = 12, monitoring = FALSE,
plot = FALSE, nsamp, refsteps = 15, refcol = 1e-13,
equalweights = FALSE, mixt = 0, msg = TRUE, nocheck = FALSE,
startv1 = 1, restrtype = c("eigen", "deter"), UnitsSameGroup,
numpool, cleanpool, trace = FALSE, ...)
```

### Arguments

- **x**: An \(n\times p\) data matrix (\(n\) observations and \(p\) variables). Rows of \(x\) represent observations, and columns represent variables. Missing values (NA’s) and infinite values (Inf’s) are allowed, since observations (rows) with missing or infinite values will automatically be excluded from the computations.
- **k**: Number of groups.
alpha  
A scalar between 0 and 0.5 or an integer specifying the number of observations which have to be trimmed. If alpha=0, tclust reduces to traditional model based or mixture clustering (mclust): see for example the Matlab function gmdistribution.

More in detail, if $0 < \alpha < 1$ clustering is based on $h = \text{fix}(n \times (1-\alpha))$ observations, else if alpha is an integer greater than 1 clustering is based on $h = n - \text{floor}(\alpha)$. If monitoring=TRUE, alpha is a vector which specifies the values of trimming levels which have to be considered - contains decreasing elements which lie in the interval 0 and 0.5. For example if $\alpha = c(0.1, 0.05, 0)$, tclust() considers these 3 values of trimming level. The default for alpha is vector alpha=c(0.1, 0.05, 0). The sequence is forced to be monotonically decreasing.

restrfactor  
Positive scalar which constrains the allowed differences among group scatters. Larger values imply larger differences of group scatters. On the other hand a value of 1 specifies the strongest restriction forcing all eigenvalues/determinants to be equal and so the method looks for similarly scattered (respectively spherical) clusters. The default is to apply restrfactor to eigenvalues. In order to apply restrfactor to determinants it is necessary to use optional input argument restrtype.

monitoring  
If monitoring=TRUE TCLUST is performed for a series of values of the trimming factor alpha given k (number of groups) and given c (restriction factor). In order to increase the speed of the computations, parfor is used.

plot  
If plot=FALSE (default) or plot=0 no plot is produced. If plot=TRUE and monitoring=FALSE a plot with the classification is shown (using the spmplot function). The plot can be:

- for $p = 1$, a histogram of the univariate data,
- for $p = 2$, a bivariate scatterplot,
- for $p > 2$, a scatterplot matrix generated by the MATLAB function spmplot().

When $p \geq 2$ the following additional features are offered (for $p = 1$ the behaviour is forced to be as for plots=TRUE):

- plot = 'contourf' adds in the background of the bivariate scatterplots a filled contour plot. The colormap of the filled contour is based on grey levels as default. This argument may also be inserted in a field named 'type' of a list. In the latter case it is possible to specify the additional field 'cmap', which changes the default colors of the color map used. The field 'cmap' may be a three-column matrix of values in the range [0,1] where each row is an RGB triplet that defines one color. Check the colormap function for additional informations.

- plot = 'contour' adds in the background of the bivariate scatterplots a contour plot. The colormap of the contour is based on grey levels as default. This argument may also be inserted in a field named type of a list. In the latter case it is possible to specify the additional field cmap, which changes the default colors of the color map used. The field cmap may be a three-column matrix of values in the range [0,1] where each row is an RGB triplet that defines one color. Check the colormap() (MATLAB) function for additional information.
• plot = 'ellipse' superimposes confidence ellipses to each group in the bivariate scatterplots. The size of the ellipse is \( q \text{chisq}(0.95, 2) \), i.e., the confidence level used by default is 95 percent. This argument may also be inserted in a field named type of a list. In the latter case it is possible to specify the additional field conflev, which specifies the confidence level to use and it is a value between 0 and 1.

• plot = 'boxplotb' superimposes on the bivariate scatterplots the bivariate boxplots for each group, using the boxplotb function. This argument may also be inserted in a field named type of a list.

The parameter plot can be also a list and in this case its elements are:

• type - specifies the type of plot as when plot option is a character. Therefore, plots$type can be one of 'contourf', 'contour', 'ellipse' or 'boxplotb'.

• cmap - used to set a colormap for the plot type (MATLAB style). For example, plot$cmap = 'autumn'. See the MATLAB help of colormap for a list of colormap possibilities.

• conflev - this is the confidence level for the confidence ellipses. It must be a scalar between 0 and 1.

If plot=TRUE and monitoring=TRUE two plots are shown. The first plot (monitor plot) shows three panels with the monitoring between two consecutive values of alpha: (i) the change in classification using ARI index (top panel), (ii) the change in centroids using squared euclidean distances (central panel) and (iii) the change in covariance matrices using squared euclidean distance (bottom panel).

The second plot (gscatter plot) shows a series of subplots which monitor the classification for each value of alpha. In order to make sure that consistent labels are used for the groups, between two consecutive values of alpha, we assign label r to a group if this group shows the smallest distance with group r for the previous value of alpha. The type of plot which is used to monitor the stability of the classification depends on the data dimensionality p.

• for p = 1, a histogram of the univariate data (the MATLAB function histFS() is called),

• for p = 2, a bivariate scatterplot (the MATLAB function gscatter() is called),

• for p > 2, a scatterplot of the first two principal components (function gscatter() is called and we show on the axes titles the percentage of variance explained by the first two principal components).

Also in the case of monitoring=TRUE the parameter plot can be a list and its elements are:

• name: character vector which enables to specify which plot to display. name = "gscatter" produces a figure with a series of subplots which show the classification for each value of alpha. name = "monitor" shows a figure with three panels which monitor between two consecutive values of alpha the change in classification using ARI index (top panel), the change in centroids using squared euclidean distances (central panel), the change in covariance matrices using squared euclidean distance (bottom panel). If this field is not specified, by default name=c("gscatter", "monitor") and both figures will be shown.
• alphasel: a numeric vector which specifies for which values of alpha it is possible to see the classification. For example if alphasel = c(0.05,0.02), the classification will be shown just for alpha=0.05 and alpha=0.02. If this field is not specified alphasel=alpha and therefore the classification is shown for each value of alpha.

nsamp

If a scalar, it contains the number of subsamples which will be extracted. If nsamp = 0 all subsets will be extracted. Remark - if the number of all possible subset is greater than 300 the default is to extract all subsets, otherwise just 300. If nsamp is a matrix it contains in the rows the indexes of the subsets which have to be extracted. nsamp in this case can be conveniently generated by function subsets(). nsamp can have k columns or k*(p+1) columns. If nsamp has k columns the k initial centroids each iteration i are given by X[nsamp[i,] ,] and the covariance matrices are equal to the identity. If nsamp has k*(p+1) columns, the initial centroids and covariance matrices in iteration i are computed as follows:

• X1 <- X[nsamp[i,.] ,]
• mean(X1[1:p+1,]) contains the initial centroid for group 1
• cov(X1[1:p+1,]) contains the initial cov matrix for group 1
• mean(X1[(p+2):(2*p+2),]) contains the initial centroid for group 2
• cov(X1[(p+2):(2*p+2),]) contains the initial cov matrix for group 2
• ...
• mean(X1[(k-1)*p+1):(k*(p+1),]) contains the initial centroids for group k
• cov(X1[(k-1)*p+1):(k*(p+1),]) contains the initial cov matrix for group k.

REMARK: If nsamp is not a scalar, the option startv1 given below is ignored. More precisely, if nsamp has k columns startv1 = 0 else if nsamp has k*(p+1) columns option startv1=1.

refsteps

Number of refining iterations in each subsample. Default is refsteps=15. refsteps = 0 means "raw-subsampling" without iterations.

tol

Tolerance of the refining steps. The default value is 1e-14

equalweights

A logical specifying whether cluster weights in the concentration and assignment steps shall be considered. If equalweights=TRUE we are (ideally) assuming equally sized groups, else if equalweights = false (default) we allow for different group weights. Please, check in the given references which functions are maximized in both cases.

mixt

Specifies whether mixture modelling or crisp assignment approach to model based clustering must be used. In the case of mixture modelling parameter mixt also controls which is the criterion to find the untrimmed units in each step of the maximization. If mixt >=1 mixture modelling is assumed else crisp assignment. The default value is mixt=0, i.e. crisp assignment. Please see for details the provided references. The parameter mixt also controls the criterion to select the units to trim. If mixt = 2 the h units are those which give the largest contribution to the likelihood, else if mixt=1 the criterion to select the h units is exactly the same as the one which is used in crisp assignment.

msg

Controls whether to display or not messages on the screen. If msg=TRUE (default) messages are displayed on the screen. If msg=2, detailed messages are displayed, for example the information at iteration level.
nocheck  Check input arguments. If nocheck=TRUE no check is performed on matrix $X$. The default nocheck=FALSE.

startv1  How to initialize centroids and covariance matrices. Scalar. If startv1=1 then initial centroids and covariance matrices are based on $(p+1)$ observations randomly chosen, else each centroid is initialized taking a random row of input data matrix and covariance matrices are initialized with identity matrices. The default value is startv1=1.

Remark 1: in order to start with a routine which is in the required parameter space, eigenvalue restrictions are immediately applied.

Remark 2 - option startv1 is used just if nsamp is a scalar (see for more details the help associated with nsamp).

restrtype  Type of restriction to be applied on the cluster scatter matrices. Valid values are 'eigen' (default), or 'deter'. "eigen" implies restriction on the eigenvalues while "deter" implies restriction on the determinants.

UnitsSameGroup  List of the units which must (whenever possible) have a particular label. For example UnitsSameGroup=c(20,26), means that group which contains unit 20 is always labelled with number 1. Similarly, the group which contains unit 26 is always labelled with number 2, (unless it is found that unit 26 already belongs to group 1). In general, group which contains unit UnitsSameGroup(r) where $r=2,...,\text{length}(kk)-1$ is labelled with number $r$ (unless it is found that unit UnitsSameGroup(r) has already been assigned to groups 1,2,...,$r-1$.

numpool  The number of parallel sessions to open. If numpool is not defined, then it is set equal to the number of physical cores in the computer.

cleanpool  Logical, indicating if the open pool must be closed or not. It is useful to leave it open if there are subsequent parallel sessions to execute, so that to save the time required to open a new pool.

trace  Whether to print intermediate results. Default is trace=FALSE.

...  potential further arguments passed to lower level functions.

Details

This iterative algorithm initializes $k$ clusters randomly and performs concentration steps in order to improve the current cluster assignment. The number of maximum concentration steps to be performed is given by input parameter refsteps. For approximately obtaining the global optimum, the system is initialized nsamp times and concentration steps are performed until convergence or refsteps is reached. When processing more complex data sets higher values of nsamp and refsteps have to be specified (obviously implying extra computation time). However, if more than 10 per cent of the iterations do not converge, a warning message is issued, indicating that nsamp has to be increased.

Value

Depending on the input parameter monitoring, one of the following objects will be returned:

1. tclustfsda.object
2. tclusteda.object

### tclustfsda.object

#### Objects returned by the function tclustfsda

#### Description

An object of class `tclustfsda.object` holds information about the result of a call to `tclustfsda`.

#### Value

The functions `print()` and `summary()` are used to obtain and print a summary of the results. An object of class `tclustfsda` is a list containing at least the following components:

- **call**: the matched call
- **muopt**: a k-by-p matrix containing cluster centroid locations. Robust estimate of final centroids of the groups
- **sigmaopt**: a p-by-p-by-k array containing estimated constrained covariance for the k groups
- **idx**: a vector of length n containing assignment of each unit to each of the k groups. Cluster names are integer numbers from 1 to k. 0 indicates trimmed observations.
- **size**: a matrix of size (k+1)-by-3. The 1st col is sequence from 0 to k (cluster name); the 2nd col is the number of observations in each cluster; the 3rd col is the percentage of observations in each cluster. Remark: 0 denotes unassigned units.
- **postprob**: n-by-k matrix containing posterior probabilities. postprob[i, j] contains posterior probability of unit i from component (cluster) j. For the trimmed units posterior probabilities are 0.
- **emp**: "Empirical" statistics computed on final classification. When convergence is reached, emp=0. When convergence is not obtained, this field is a list which contains the statistics of interest: idxemp (ordered from 0 to k*, k* being the number of groups with at least one observation and 0 representing the possible group of outliers), muemp, sigmaemp and sizemp, which are the empirical counterparts of idx, muopt, sigmaopt and size.
- **MIXMIX**: BIC which uses parameters estimated using the mixture loglikelihood and the maximized mixture likelihood as goodness of fit measure. Remark: this output is present just if mixt > 0.
- **MIXCLA**: BIC which uses parameters estimated using the mixture loglikelihood and the maximized mixture likelihood as goodness of fit measure. Remark: this output is present just if mixt > 0.
tclustIC

**CLACLA** BIC which uses the classification likelihood based on parameters estimated using the classification likelihood.

Remark: this output is present just if mixt > 0.

**notconver** number of subsets without convergence

**bs** a vector of length k containing the units forming initial subset associated with muopt.

**obj** value of the objective function which is minimized (value of the best returned solution).

**equalweights** if equalweights=TRUE means that in the clustering procedure we (ideally) assumed equal cluster weights else (codequalweights=FALSE means that we allowed for different cluster sizes.

**h** number of observations that have determined the centroids (number of untrimmed units).

**fullsol** a vector of size nsamp which contains the value of the objective function at the end of the iterative process for each extracted subsample.

**X** the original data matrix X.

### Examples

```r
## Not run:
data(hbk)
(out <- tclustfsda(hbk[, 1:3], k=2))
class(out)
summary(out)
## End(Not run)
```

**tclustIC** Performs cluster analysis by calling tclustfsda for different number of groups k and restriction factors c

### Description

Computes the values of BIC (MIXMIX), ICL (MIXCLA) or CLA (CLACLA), for different values of k (number of groups) and different values of c (restriction factor), for a prespecified level of trimming (the last two letters in the name stand for 'Information Criterion'). If Parallel Computing toolbox is installed, parfor is used to compute tclust for different values of c. In order to minimize randomness, given k, the same subsets are used for each value of c.

### Usage

```r
tclustIC(x, kk = 1:5, cc = c(1, 2, 4, 8, 16, 32, 64, 128), alpha = 0,
whichIC = c("ALL", "MIXMIX", "MIXCLA", "CLACLA"), nsamp,
refsteps = 15, reftol = 1e-14, equalweights = FALSE, msg = TRUE,
nocheck = FALSE, plot = FALSE, starttv1 = 1,
restrtype = c("eigen", "deter"), UnitsSameGroup, numpool, cleanpool,
trace = FALSE, ...)
```

Arguments

x
An n x p data matrix (n observations and p variables). Rows of x represent observations, and columns represent variables. Missing values (NA's) and infinite values (Inf's) are allowed, since observations (rows) with missing or infinite values will automatically be excluded from the computations.

kk
an integer vector specifying the number of mixture components (clusters) for which the BIC is to be calculated. By default kk=1:5.

c
an vector specifying the values of the restriction factor which have to be considered. By default cc=c(1,2,4,8,16,32,64,128).

alpha
Global trimming level. A scalar between 0 and 0.5 or an integer specifying the number of observations which have to be trimmed. If alpha=0 all observations are considered. By default alpha=0. More in detail, if 0 < alpha < 1 clustering is based on h = fix(n * (1-alpha)) observations, else if alpha is an integer greater than 1 clustering is based on h = n -floor(alpha).

whichIC
A character value which specifies which information criteria must be computed for each k (number of groups) and each value of the restriction factor c. Possible values for whichIC are:

- "MIXMIX": a mixture model is fitted and for computing the information criterion the mixture likelihood is used. This option corresponds to the use of the Bayesian Information criterion (BIC). In output just the matrix MIXMIX is given.
- "MIXCLA": a mixture model is fitted but to compute the information criterion the classification likelihood is used. This option corresponds to the use of the Integrated Complete Likelihood (ICL). In the output just the matrix MIXCLA is given.
- "CLA": everything is based on the classification likelihood. This information criterion will be called CLA. In the output just the matrix CLA is given.
- "ALL": both classification and mixture likelihood are used. In this case all three information criteria CLA, ICL and BIC are computed. In the output all three matrices MIXMIX, MIXCLA and CLA are given.

nsamp
If a scalar, it contains the number of subsamples which will be extracted. If nsamp = 0 all subsets will be extracted. Remark - if the number of all possible subset is greater than 300 the default is to extract all subsets, otherwise just 300. If nsamp is a matrix it contains in the rows the indexes of the subsets which have to be extracted. nsamp in this case can be conveniently generated by function subsets(). nsamp can have k columns or k * (p + 1) columns. If nsamp has k columns the k initial centroids each iteration i are given by X[nsamp[i, ,]] and the covariance matrices are equal to the identity. If nsamp has k * (p + 1) columns, the initial centroids and covariance matrices in iteration i are computed as follows:

- X1 <- X[nsamp[i , ,]]
- mean(X1[1:p + 1, ,]) contains the initial centroid for group 1
• \( \text{cov}(X_1[1:p+1,]) \) contains the initial cov matrix for group 1
• \( \text{mean}(X_1[(p+2):(2*p+2),]) \) contains the initial centroid for group 2
• \( \text{cov}(X_1[(p+2):(2*p+2),]) \) contains the initial cov matrix for group 2
• ...
• \( \text{mean}(X_1[(k-1)*p+1):(k*(p+1),]) \) contains the initial centroids for group k
• \( \text{cov}(X_1[(k-1)*p+1):(k*(p+1),]) \) contains the initial cov matrix for group k.

REMARK: If \( n_{\text{samp}} \) is not a scalar, the option \text{startv1} given below is ignored. More precisely, if \( n_{\text{amp}} \) has \( k \) columns \text{startv1} = 0 else if \( n_{\text{amp}} \) has \( k*(p+1) \) columns option \text{startv1}=1.

\[ \text{refsteps} \]
Number of refining iterations in each subsample. Default is \text{refsteps}=15. \text{refsteps} = 0 means "raw-subsampling" without iterations.

\[ \text{reftol} \]
Tolerance of the refining steps. The default value is 1e-14

\[ \text{equalweights} \]
A logical specifying whether cluster weights in the concentration and assignment steps shall be considered. If \text{equalweights} = \text{TRUE} we are (ideally) assuming equally sized groups, else if \text{equalweights} = \text{false} (default) we allow for different group weights. Please, check in the given references which functions are maximized in both cases.

\[ \text{msg} \]
Controls whether to display or not messages on the screen. If \text{msg} = \text{TRUE} (default) messages are displayed on the screen. If \text{msg}=2, detailed messages are displayed, for example the information at iteration level.

\[ \text{nocheck} \]
Check input arguments. If \text{nocheck} = \text{TRUE} no check is performed on matrix \( X \). The default \text{nocheck} = \text{FALSE}.

\[ \text{plot} \]
If \text{plot} = \text{TRUE}, a plot of the BIC (MIXMIX), ICL (MIXCLA) curve and CLA-CLA is shown on the screen. The plots which are shown depend on the input option whichIC.

\[ \text{startv1} \]
How to initialize centroids and covariance matrices. Scalar. If \text{startv1}=1 then initial centroids and covariance matrices are based on \( (p+1) \) observations randomly chosen, else each centroid is initialized taking a random row of input data matrix and covariance matrices are initialized with identity matrices. The default value is \text{startv1}=1.

Remark 1: in order to start with a routine which is in the required parameter space, eigenvalue restrictions are immediately applied.

Remark 2 - option \text{startv1} is used just if \( n_{\text{amp}} \) is a scalar (see for more details the help associated with \( n_{\text{amp}} \)).

\[ \text{restrtype} \]
Type of restriction to be applied on the cluster scatter matrices. Valid values are 'eigen' (default), or 'deter'. "eigen" implies restriction on the eigenvalues while "deter" implies restriction on the determinants.

\[ \text{UnitsSameGroup} \]
List of the units which must (whenever possible) have a particular label. For example \text{UnitsSameGroup}=c(20,26), means that group which contains unit 20 is always labelled with number 1. Similarly, the group which contains unit 26 is always labelled with number 2, (unless it is found that unit 26 already belongs to group 1). In general, group which contains unit \text{UnitsSameGroup}(r) where \( r=2, \ldots, \text{length(kk)}-1 \) is labelled with number \( r \) (unless it is found that unit \text{UnitsSameGroup}(r) has already been assigned to groups 1, 2, \ldots, \( r-1 \)).
tclustic.object

Objects returned by the function tclustIC

Description

An object of class tclustic.object holds information about the result of a call to tclustIC.

numpool  The number of parallel sessions to open. If numpool is not defined, then it is set
equal to the number of physical cores in the computer.

cleanpool  Logical, indicating if the open pool must be closed or not. It is useful to leave it
open if there are subsequent parallel sessions to execute, so that to save the time
required to open a new pool.

trace  Whether to print intermediate results. Default is trace=FALSE.

...  potential further arguments passed to lower level functions.

Value

An S3 object of class tclustic.object

Examples

## Not run:
data(geyser2)
out <- tclustIC(geyser2, whichIC="MIXMIX", plot=FALSE, alpha=0.1)
out
summary(out)

## End(Not run)
Value

The functions `print()` and `summary()` are used to obtain and print a summary of the results. An object of class `tclustIC` is a list containing at least the following components:

- `call`: the matched call
- `kk`: a vector containing the values of k (number of components) which have been considered. This vector is identical to the optional argument `kk` (default is `kk=1:5`).
- `cc`: a vector containing the values of c (values of the restriction factor) which have been considered. This vector is identical to the optional argument `cc` (default is `cc=c(1,2,4,8,16,32,64,128)`).
- `alpha`: trimming level
- `whichIC`: Information criteria used
  - `CLACLA`: a matrix of size `length(kk)`-times-`length(cc)` containing the value of the penalized classification likelihood. This output is present only if `whichIC="CLACLA"` or `whichIC="ALL"`.
  - `IDXCLA`: a matrix of lists of size `length(kk)`-times-`length(cc)` containing the assignment of each unit using the classification model. This output is present only if `whichIC="CLACLA"` or `whichIC="ALL"`.
  - `MIXMIX`: a matrix of size `length(kk)`-times-`length(cc)` containing the value of the penalized mixture likelihood. This output is present only if `whichIC="MIXMIX"` or `whichIC="ALL"`.
  - `IDXMIX`: a matrix of lists of size `length(kk)`-times-`length(cc)` containing the assignment of each unit using the classification model. This output is present only if `whichIC="MIXMIX"` or `whichIC="ALL"`.
  - `MIXCLA`: a matrix of size `length(kk)`-times-`length(cc)` containing the value of the ICL criterion. This output is present only if `whichIC="MIXCLA"` or `whichIC="ALL"`.

Examples

```r
## Not run:
data(hbk)
(out <- tclustIC(hbk[, 1:3]))
class(out)
summary(out)
## End(Not run)
```

`tclustICplot` Plots information criterion as a function of c and k, based on the solutions obtained by `tclustIC`
Description

The function `tclustICplot()` takes as input an object of class `tclustic.object`, the output of function `tclustIC` (that is a series of matrices which contain the values of the information criteria BIC/ICL/CLA for different values of k and c) and plots them as function of c or of k. The plot enables interaction in the sense that, if option databrush has been activated, it is possible to click on a point in the plot and to see the associated classification in the scatter plot matrix.

Usage

`tclustICplot(out, whichIC = c("ALL", "MIXMIX", "MIXCLA", "CLACLA"), tag, datatooltip, databrush, nameY, trace = FALSE, ...)

Arguments

`out` An S3 object of class `tclustic.object` (output of `tclustIC`) containing the values of the information criteria BIC (MIXMIX), ICL (MIXCLA) or CLA (CLACLA), for different values of k (number of groups) and different values of c (restriction factor), for a prespecified level of trimming.

`whichIC` Specifies the information criterion to use for the plot. See code `tclustIC()` for the possible values of whichIC.

`tag` plot handle. String which identifies the handle of the plot which is about to be created. The default is to use tag 'pl_IC'. Notice that if the program finds a plot which has a tag equal to the one specified by the user, then the output of the new plot overwrites the existing one in the same window else a new window is created.

`datatooltip` Interactive clicking. It is inactive if this parameter is set to FALSE. The default is `datatooltip=TRUE`, the user can select with the mouse a solution in order to have the following information:

- 1) value of k which has been selected
- 2) value of c which has been selected
- 3) values of the information criterion
- 4) frequency distribution of the associated classification.

If datatooltip is a list it may contain the following fields:

1. `DisplayStyle` determines how the data cursor displays. Possible values are 'datatip' and 'window' (default). 'datatip' displays data cursor information in a small yellow text box attached to a black square marker at a data point you interactively select. 'window' displays data cursor information for the data point you interactively select in a floating window within the figure.

2. `SnapToDataVertex`: specifies whether the data cursor snaps to the nearest data value or is located at the actual pointer position. Possible values are `SnapToDataVertex='on'` (default) and `SnapToDataVertex='off'`.

`databrush` Interactive mouse brushing. If databrush is missing or empty (default), no brushing is done. The activation of this option (databrush is `TRUE` or a list) enables the user to select a set of values of IC in the current plot and to see the corresponding classification highlighted in the scatterplot matrix. If the scatterplot matrix does...
not exist it is automatically created. Note that the window style of the other figures is set equal to that which contains the IC plot. In other words, if the IC plot is docked all the other figures will be docked too.

If databrush=TRUE the default selection tool is a rectangular brush and it is possible to brush only once (that is persist="").

If databrush=list(...), it is possible to use all optional arguments of the MATLAB function selectdataFS() and the following optional arguments:

- persist: Persist is an empty value or a character containing 'on' or 'off'. The default value is persist="", that is brushing is allowed only once. If persist="on" or persist="off" brushing can be done as many time as the user requires. If persist='on' then the unit(s) currently brushed are added to those previously brushed. It is possible, every time a new brushing is done, to use a different color for the brushed units. If persist='off' every time a new brush is performed units previously brushed are removed.
- label: add labels of brushed units in the monitoring plot.
- dispopt: controls how to fill the diagonals in the scatterplot matrix of the brushed solutions. Set dispopt="hist" (default) to plot histograms, or dispopt="box" to plot boxplots.

nameY Add variable labels in plot. A vector of strings of length p containing the labels of the variables in the dataset. If it is empty (default) the sequence X1,...,Xp will be created automatically.

trace Whether to print intermediate results. Default is trace=FALSE.

Examples

```r
## Not run:
data(geyser2)
out <- tclustIC(geyser2, whichIC="MIXMIX", plot=FALSE, alpha=0.1)
tclustICplot(out)
```
tclustICsol

*Extracts a set of best relevant solutions obtained by tclustIC*

Description

The function `tclustICsol()` takes as input an object of class `tclustic.object`, the output of function `tclustIC` (that is a series of matrices which contain the values of the information criteria BIC/ICL/CLA for different values of \( k \) and \( c \)) and extracts the first best solutions. Two solutions are considered equivalent if the value of the adjusted Rand index (or the adjusted Fowlkes and Mallows index) is above a certain threshold. For each tentative solution the program checks the adjacent values of \( c \) for which the solution is stable. A matrix with adjusted Rand indexes is given for the extracted solutions.

Usage

```r
tclustICsol(out, NumberOfBestSolutions = 5, ThreshRandIndex = 0.7,
whichIC = c("ALL", "CLACLA", "MIXMIX", "MIXCLA"), Rand = TRUE,
msg = TRUE, plot = FALSE, trace = FALSE, ...)
```

Arguments

- **out**: An S3 object of class `tclustic.object` (output of `tclustIC`) containing the values of the information criteria BIC (MIXMIX), ICL (MIXCLA) or CLA (CLACLA), for different values of \( k \) (number of groups) and different values of \( c \) (restriction factor), for a prespecified level of trimming.
- **NumberOfBestSolutions**: Number of best solutions to extract from BIC/ICL matrix. The default value of `NumberOfBestSolutions` is 5.
- **ThreshRandIndex**: Threshold to identify spurious solutions - the threshold of the adjusted Rand index to use to consider two solutions as equivalent. The default value of `ThreshRandIndex` is 0.7.
- **whichIC**: Specifies the information criterion to use to extract best solutions. Possible values for `whichIC` are:
  - `CLACLA` = in this case best solutions are referred to the classification likelihood.
  - `MIXMIX` = in this case in this case best solutions are referred to the mixture likelihood (BIC).
  - `MIXCLA` = in this case in this case best solutions are referred to ICL.
  - `ALL` = in this case best solutions both three solutions using classification and mixture likelihood are produced. In the output class out all the three matrices `MIXMIXbs`, `CLACLABs` and `MIXCLAbss` are given.

The default value is `whichIC="ALL"`.  
```
Rand

Index to use to compare partitions. If Rand=TRUE (default) the adjusted Rand index is used, else the adjusted Fowlkes and Mallows index is used.

msg

It controls whether to display or not messages (from MATLAB) on the screen. If msg=TRUE (default) messages about the progression of the search are displayed on the screen otherwise only error messages will be displayed.

plot

If plot=TRUE, the best solutions which have been found are shown on the screen.

trace

Whether to print intermediate results. Default is trace=FALSE.

... potential further arguments passed to lower level functions.

Value

An S3 object of class tclusticsol.object

Author(s)

FSDA team, <valentin.todorov@chello.at>

Examples

```r
## Not run:
data(geyser2)
out <- tclustIC(geyser2, whichIC="MIXMIX", plot=FALSE, alpha=0.1)

## Plot first two best solutions using as Information criterion MIXMIX
print("Best solutions using MIXMIX")
outMIXMIX <- tclustICsol(out, whichIC="MIXMIX", plot=TRUE, NumberofBestSolutions=2)
print(outMIXMIX$MIXMIXbs)

## End(Not run)
```
tclusticsol.object

Objects returned by the function tclustICsol

Description

An object of class tclusticsol.object holds information about the result of a call to tclustICsol.

Value

The functions print() and summary() are used to obtain and print a summary of the results. An object of class tclusticsol is a list containing at least the following components:

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>call</td>
<td>the matched call</td>
</tr>
<tr>
<td>kk</td>
<td>a vector containing the values of k (number of components) which have been considered. This vector is identical to the optional argument kk (default is kk=1:5).</td>
</tr>
<tr>
<td>cc</td>
<td>a vector containing the values of c (values of the restriction factor) which have been considered. This vector is identical to the optional argument cc (default is cc=c(1,2,4,8,16,32,64,128).</td>
</tr>
<tr>
<td>alpha</td>
<td>trimming level</td>
</tr>
<tr>
<td>whichIC</td>
<td>Information criteria used</td>
</tr>
<tr>
<td>MIXMIXbs</td>
<td>a matrix of lists of size NumberOfBestSolutions-times-5 which contains the details of the best solutions for MIXMIX (BIC). Each row refers to a solution. The information which is stored in the columns is as follows.</td>
</tr>
<tr>
<td></td>
<td>• 1st col = value of k for which solution takes place</td>
</tr>
<tr>
<td></td>
<td>• 2nd col = value of c for which solution takes place;</td>
</tr>
<tr>
<td></td>
<td>• 3rd col = a vector of length d which contains the values of c for which the solution is uniformly better.</td>
</tr>
<tr>
<td></td>
<td>• 4th col = a vector of length d + r which contains the values of c for which the solution is considered stable (i.e. for which the value of the adjusted Rand index (or the adjusted Fowlkes and Mallows index) does not go below the threshold defined in input option ThreshRandIndex).</td>
</tr>
<tr>
<td></td>
<td>• 5th col = string which contains 'true' or 'spurious'. The solution is labelled spurious if the value of the adjusted Rand index with the previous solutions is greater than ThreshRandIndex.</td>
</tr>
<tr>
<td>Remark:</td>
<td>the field MIXMIXbs is present only if whichIC=ALL or whichIC=&quot;MIXMIX&quot;.</td>
</tr>
<tr>
<td>MIXMIXbsari</td>
<td>a matrix of adjusted Rand indexes (or Fowlkes and Mallows indexes) associated with the best solutions for MIXMIX. A matrix of size NumberOfBestSolutions-times-NumberOfBestSolutions whose i,j-th entry contains the adjusted Rand index between classification produced by solution i and solution j, i,j=1,2,...,NumberOfBestSolutions.</td>
</tr>
<tr>
<td>Remark:</td>
<td>the field MIXMIXbsari is present only if whichIC=ALL or whichIC=&quot;MIXMIX&quot;.</td>
</tr>
</tbody>
</table>
ARIMIX  a matrix of adjusted Rand indexes between two consecutive value of c. Matrix of size \( k \)-by-\( \text{length}(cc) - 1 \). The first column contains the ARI indexes between \( cc[2] \) and \( cc[1] \) given \( k \). The second column contains the the ARI indexes between \( cc[3] \) and \( cc[2] \) given \( k \).
Remark: the field \texttt{ARIMIX} is present only if \texttt{whichIC=ALL} or \texttt{whichIC=“MIXMIX”} or \texttt{whichIC=“MIXCLA”}.

MIXCLAbs has the same structure as \texttt{MIXMIXbs} but referres to MIXCLA.
Remark: the field \texttt{MIXCLAbs} is present only if \texttt{whichIC=ALL} or \texttt{whichIC=“MIXCLA”}.

MIXCLAbsari has the same structure as \texttt{MIXMIXbsari} but referres to MIXCLA.
Remark: the field \texttt{MIXMIXbsari} is present only if \texttt{whichIC=ALL} or \texttt{whichIC=“MIXCLA”}.

CLACLAbs has the same structure as \texttt{MIXMIXbs} but referres to CLACLA.
Remark: the field \texttt{CLACLAbs} is present only if \texttt{whichIC=ALL} or \texttt{whichIC=“CLACLA”}.

CLACLAbsari has the same structure as \texttt{MIXMIXbsari} but referres to CLACLA.
Remark: the field \texttt{CLACLAbsari} is present only if \texttt{whichIC=ALL} or \texttt{whichIC=“CLACLA”}.

ARICLA  a matrix of adjusted Rand indexes between two consecutive value of c. Matrix of size \( k \)-by-\( \text{length}(cc) - 1 \). The first column contains the ARI indexes between \( cc[2] \) and \( cc[1] \) given \( k \). The second column contains the the ARI indexes between \( cc[3] \) and \( cc[2] \) given \( k \).
Remark: the field \texttt{ARICLA} is present only if \texttt{whichIC=ALL} or \texttt{whichIC=“CLACLA”}.
