Package ‘gamlss’

Description  Functions for fitting the Generalized Additive Models for Location Scale and Shape introduced by Rigby and Stasinopoulos (2005), <doi:10.1111/j.1467-9876.2005.00510.x>. The models use a distributional regression approach where all the parameters of the conditional distribution of the response variable are modelled using explanatory variables.

VC.test Vuong and Clarke tests
acfResid ACF plot of the residuals
additive.fit Implementing Backfitting in GAMLSS
bfp Functions to fit fractional polynomials in GAMLSS
calibration Calibrating centile curves
centiles Plots the centile curves for a GAMLSS object
centiles.com Comparing centiles from different GAMLSS models
centiles.pred Creating predictive centiles values
centiles.split Plots centile curves split by x for a GAMLSS object
coeff.gamlss Extract Model Coefficients in a GAMLSS fitted model
cs Specify a Smoothing Cubic Spline Fit in a GAMLSS Formula
deviance.gamlss Global Deviance of a GAMLSS model
devianceIncr The global deviance increment
dtop Detrended transformed Owen’s plot
edf Effective degrees of freedom from gamlss model
find.hyper A function to select values of hyper-parameters in a GAMLSS model
fitDist Fitting Different Parametric 'gamlss.family' Distributions.
fitted.gamlss Extract Fitted Values For A GAMLSS Model
fittedPlot Plots The Fitted Values of a GAMLSS Model
formula.gamlss Extract the Model Formula in a GAMLSS fitted model
gamlss Generalized Additive Models for Location Scale and Shape
gamlss-package Generalised Additive Models for Location Scale and Shape
gamlss.control Auxiliary for Controlling GAMLSS Fitting
gamlss.cs Support for Function cs() and scs()
gamlss.fp Support for Function fp()
gamlss.lo Support for Function lo()
gamlss.ps Support for Functions for smoothers
gamlss.random Support for Functions random() and re()
gamlss.scope  Generate a Scope Argument for Stepwise GAMLSS

gamlssML  Maximum Likelihood estimation of a simple GAMLSS model

gamlssVGD  A Set of Functions for selecting Models using Validation or Test Data Sets and Cross Validation

gen.likelihood  A function to generate the likelihood function from a GAMLSS object

getPEF  Getting the partial effect function from a continuous term in a GAMLSS model

getQuantile  Getting the partial quantile function for a term

getSmo  Extracting Smoother information from a GAMLSS fitted object

glim.control  Auxiliary for Controlling the inner algorithm in a GAMLSS Fitting

histDist  This function plots the histogram and a fitted (GAMLSS family) distribution to a variable

histSmo  Density estimation using the Poisson trick

lms  A function to fit LMS curves for centile estimation

lo  Specify a loess fit in a GAMLSS formula

loglogSurv  Survival function plots for checking the tail behaviour of the data

lpred  Extract Linear Predictor Values and Standard Errors For A GAMLSS Model

model.frame.gamlss  Extract a model.frame, a model matrix or terms from a GAMLSS object for a given distributional parameter

numeric.deriv  An internal GAMLSS function for numerical derivatives

par.plot  A function to plot parallel plot for repeated measurement data

pcat  Reduction for the Levels of a Factor.

pdf.plot  Plots Probability Distribution Functions for GAMLSS Family

plot.gamlss  Plot Residual Diagnostics for an GAMLSS Object

plot.histSmo  A Plotting Function for density estimator object histSmo

plot2way  Function to plot two interaction in a GAMLSS model

polyS  Auxiliary support for the GAMLSS

predict.gamlss  Extract Predictor Values and Standard Errors For New Data In a GAMLSS Model

print.gamlss  Prints a GAMLSS fitted model

prof.dev  Plotting the Profile Deviance for one of the Parameters in a GAMLSS model

prof.term  Plotting the Profile: deviance or information
criterion for one of the terms (or
hyper-parameters) in a GAMLSS model
ps P-Splines Fits in a GAMLSS Formula
quantSheets Quantile Sheets
random Specify a random intercept model in a GAMLSS formula
refit Refit a GAMLSS model
residuals.gamlss Extract Residuals from GAMLSS model
ri Specify ridge or lasso Regression within a GAMLSS Formula
rqres.plot Creating and Plotting Randomized Quantile Residuals
rvcov Robust Variance-Covariance matrix of the parameters from a fitted GAMLSS model
stepGAIC Choose a model by GAIC in a Stepwise Algorithm
summary.gamlss Summarizes a GAMLSS fitted model
term.plot Plot regression terms for a specified parameter of a fitted GAMLSS object
update.gamlss Update and Re-fit a GAMLSS Model
wp Worm plot
z.scores Z-scores for lms objects

acfResid  ACF plot of the residuals

Description

This plot display the ACF and PACF of the residuals of a gamlss or other fitted model (provided that they have been standardised appropriately. Is is approriate for time series data.

Usage

acfResid(obj = NULL, resid = NULL)

Arguments

obj  A gamlss model or other fitted model where the resid() function applies exist
resid  if obj does not exist the argument here will be used

Details

The ACF abd PACF for the residuals r, squared residuals r^2, r^3 and r^4 are plotted

Value

The relevant plots are displayed

data(co2)
m1 <- gamlss(co2 ~ pb(as.numeric(time(co2))) + factor(cycle(co2)))
acfResid(m1)

Description

This function is not to be used on its own. It is used for backfitting in the GAMLSS fitting algorithms and it is based on the equivalent function written by Trevor Hastie in the gam() S-plus implementation, (Chambers and Hastie, 1991).

Usage

additive.fit(x, y, w, s, who, smooth.frame, maxit = 30, tol = 0.001,
             trace = FALSE, se = TRUE, ...)

Arguments

x the linear part of the explanatory variables
y the response variable
w the weights
s the matrix containing the smoothers
who the current smoothers
smooth.frame the data frame used for the smoothers
maxit maximum number of iterations in the backfitting
tol the tolerance level for the backfitting
trace whether to trace the backfitting algorithm
se whether standard errors are required
... for extra arguments

Details

This function should not be used on its own

Value

Returns a list with the linear fit plus the smoothers

**bfp**

*Functions to fit fractional polynomials in GAMLSS*

**Description**

The function `bfp` generate a power polynomial basis matrix which (for given powers) can be used to fit power polynomials in one x-variable. The function `fp` takes a vector and returns it with several attributes. The vector is used in the construction of the model matrix. The function `fp()` is not used for fitting the fractional polynomial curves but assigns the attributes to the vector to aid gamlss in the fitting process. The function doing the fitting is `gamlss.fp()` which is used at the backfitting function `additive.fit` (but never used on its own). The (experimental) function `pp` can be use to fit power polynomials as in \( a + b_1 x^{p_1} + b_2 x^{p_2} \), where \( p_1 \) and \( p_2 \) have arbitrary values rather restricted as in the `fp` function.

**Usage**

```r
bfp(x, powers = c(1, 2), shift = NULL, scale = NULL)
fp(x, npoly = 2, shift = NULL, scale = NULL)
pp(x, start = list(), shift = NULL, scale = NULL)
```
 Arguments

x the explanatory variable to be used in functions bfp() or fp(). Note that this is different from the argument x use in gamlss.fp (a function used in the backfitting but not by straight by the user)

powers a vector containing as elements the powers in which the x has to be raised

shift a number for shifting the x-variable. The default values is zero, if x is positive, or the minimum of the positive difference in x minus the minimum of x

scale a positive number for scaling the x-variable. The default values is $10^{\text{sign}(\log_{10}(\text{range}))} \times \text{trunc}(\text{abs}(\log_{10}(\text{range})))$

npoly a positive indicating how many fractional polynomials should be considered in the fit. Can take the values 1, 2 or 3 with 2 as default

start a list containing the starting values for the non-linear maximization to find the powers. The results from fitting the equivalent fractional polynomials can be used here

Details

The above functions are an implementation of the fractional polynomials introduced by Royston and Altman (1994). The three functions involved in the fitting are loosely based on the fractional polynomials implementation in S-plus written by Gareth Amber in 1999, (unfortunately the URL link for his work no longer exist). The function bfp generates the right design matrix for the fitting a power polynomial of the type $a + b_1 x^{p_1} + b_2 x^{p_2} + \ldots + b_k x^{p_k}$. For given powers $p_1, p_2, \ldots, p_k$ given as the argument powers in bfp() the function can be used to fit power polynomials in the same way as the functions poly() or bs() (of package splines) are used to fit orthogonal or piecewise polynomials respectively. The function fp(), which is working as a smoother in gamlss, is used to fit the best fractional polynomials within a set of power values. Its argument npoly determines whether one, two or three fractional polynomials should used in the fitting. For a fixed number npoly the algorithm looks for the best fitting fractional polynomials in the list $c(-2,-1,-0.5,0,0.5,1,2,3)$. Note that npoly=3 is rather slow since it fits all possible combinations 3-way combinations at each backfitting interaction. The function gamlss.fp() is an internal function of GAMLSS allowing the fractional polynomials to be fitted in the backfitting cycle of gamlss, and should be not used on its own.

Value

The function bfp returns a matrix to be used as part of the design matrix in the fitting.

The function fp returns a vector with values zero to be included in the design matrix but with attributes useful in the fitting of the fractional polynomials algorithm in gamlss.fp.

Warning

Since the model constant is included in both the design matrix X and in the backfitting part of fractional polynomials, its values is wrongly given in the summary. Its true values is the model constant minus the constant from the fractional polynomial fitting ???. What happens if more that one fractional polynomials are fitted?

Examples

data(abdom)
# fits polynomials with power 1 and .5
mod1 <- gamlss(y~bfp(x,c(1,0.5)),data=abdom)
# fit the best of one fractional polynomial
m1 <- gamlss(y~fp(x,1),data=abdom)
# fit the best of two fractional polynomials
m2 <- gamlss(y~fp(x,2),data=abdom)
# fit the best of three fractional polynomials
m3 <- gamlss(y~fp(x,3),data=abdom)
# get the coefficient for the second model
m2$mu.coefSmo
# now power polynomials using the best 2 fp c()
m4 <- gamlss(y ~ pp(x, c(1,3)), data = abdom)
# This is not good idea in this case because
# if you look at the fitted values you see what it went wrong
plot(y~x,data=abdom)
lines(fitted(m2,"mu")~abdom$x,col="red")
lines(fitted(m4,"mu")~abdom$x,col="blue")
calibration

Description

This function can be used when the fitted model centiles do not coincide with the sample centiles.

Usage

calibration(object, xvar, cent = c(0.4, 2, 10, 25, 50, 75, 90, 98, 99.6),
            legend = FALSE, fan = FALSE, ...)

Arguments

object a gamlss fitted object
xvar The explanatory variable
cent a vector with elements the % centile values for which the centile curves have to be evaluated
legend whether legend is required
fan whether to use the fan version of centiles
... other argument pass on to centiles() function

Details

The function finds the sample quantiles of the residuals of the fitted model (the z-scores) and use them as sample quantile in the argument cent of the centiles() function. This procedure is appropriate if the fitted model centiles do not coincide with the sample centiles and when this failure is the same in all values of the explanatory variable xvar.

Value

A centile plot is produced and the sample centiles below each centile curve are printed (or saved)

centiles

Plots the centile curves for a GAMLSS object

Description

This function centiles() plots centile curves for distributions belonging to the GAMLSS family of distributions. The function also tabulates the sample percentages below each centile curve (for comparison with the model percentages given by the argument cent.) The function centiles.fan() plots a fan-chart of the centile curves. A restriction of the functions is that it applies to models with one explanatory variable only.

Usage

centiles(obj, xvar, cent = c(0.4, 2, 10, 25, 50, 75, 90, 98, 99.6),
    legend = TRUE, ylab = "y", xlab = "x", main = NULL,
    main.gsub = "@", xleg = min(xvar), yleg = max(obj$y),
    xlim = range(xvar), ylim = range(obj$y), save = FALSE,
    plot = TRUE, points = TRUE, pch = 15, cex = 0.5, col = gray(0.7),
    col.centiles = 1:length(cent) + 2, lty.centiles = 1, lwd.centiles = 1, ...)
centiles.fan(obj, xvar, cent = c(0.4, 2, 10, 25, 50, 75, 90, 98, 99.6),
    ylab = "y", xlab = "x", main = NULL, main.gsub = "@",
    xleg = min(xvar), yleg = max(obj$y), xlim = range(xvar),
    ylim = range(obj$y), points = FALSE, median = TRUE, pch = 15,
    cex = 0.5, col = gray(0.7),
    colors = c("cm", "gray", "rainbow", "heat", "terrain", "topo"), ...)

Arguments

obj a fitted gamlss object from fitting a gamlss distribution
xvar the unique explanatory variable
cent a vector with elements the % centile values for which the centile curves have to be evaluated
legend whether a legend is required in the plot or not, the default is legend=TRUE
ylab the y-variable label
xlab the x-variable label
main the main title here as character. If NULL the default title "centile curves using NO" (or the relevant distributions name) is shown
main.gsub if the main.gsub (with default "@") appears in the main title then it is substituted with the default title.
xleg position of the legend in the x-axis
yleg position of the legend in the y-axis
xlim the limits of the x-axis
ylim the limits of the y-axis
save whether to save the sample percentages or not with default equal to FALSE. In this case the sample percentages are printed but are not saved
plot whether to plot the centiles. This option is useful for centile.split
pch the character to be used as the default in plotting points see par
cex size of character see par
col plotting colour see par
col.centiles Plotting colours for the centile curves
lty.centiles line type for the centile curves
lwd.centiles The line width for the centile curves
colors the different colour schemes to be used for the fan-chart. The following are available c("cm", "gray", "rainbow", "heat", "terrain", "topo"),
points whether the data points should be plotted, default is TRUE for centiles() and FALSE for centiles.fan()
median whether the median should be plotted (only in centiles.fan())
... for extra arguments

Details

Centiles are calculated using the fitted values in obj and xvar must correspond exactly to the predictor in obj to plot correctly.

col.centiles, lty.centiles and lwd.centiles may be vector arguments and are recycled to the length cent if necessary.

Value

A centile plot is produced and the sample centiles below each centile curve are printed (or saved)
centiles

**Warning**

This function is appropriate only when one continuous explanatory variable is fitted in the model

# default plot
centiles(h,xvar=abdom$x)
# control of colours and lines
centiles(h, xvar=abdom$x, col.cent=c(2,3,4,5,1,5,4,3,2,1),
     lwd.cent=c(1,1,1,2,1,1,1,1,1,1))
#Control line types
centiles(h, xvar=abdom$x, col.cent=1, cent=c(.5,2.5,50,97.5,99.5),
lty.centiles=c(3,2,1,2,3),lwd.cent=c(1,1,2,1,1))
# control of the main title
centiles(h, xvar=abdom$x, main="Abdominal data \n @")
# the fan-chart
centiles.fan(h,xvar=abdom$x, colors="rainbow")
rm(h)
Description

This function compares centiles curves for more than one GAMLSS objects. It is based on the `centiles` function. The function also tabulates the sample percentages below each centile curve (for comparison with the model percentages given by the argument `cent`). A restriction of the function is that it applies to models with one explanatory variable only.

Usage

```r
centiles.com(obj, ..., xvar, cent = c(0.4, 10, 50, 90, 99.6),
             legend = TRUE, ylab = "y", xlab = "x", xleg = min(xvar),
             yleg = max(obj$y), xlim = range(xvar), ylim = NULL,
             no.data = FALSE, color = TRUE, main = NULL, plot = TRUE)
```

Arguments

- `obj`: a fitted gamlss object from fitting a gamlss continuous distribution
- `...`: optionally more fitted GAMLSS model objects
- `xvar`: the unique explanatory variable
- `cent`: a vector with elements the % centile values for which the centile curves have to be evaluated
- `legend`: whether a legend is required in the plot or not, the default is `legend=TRUE`
- `ylab`: the y-variable label
- `xlab`: the x-variable label
- `xleg`: position of the legend in the x-axis
- `yleg`: position of the legend in the y-axis
- `xlim`: the limits of the x-axis
- `ylim`: the limits of the y-axis
- `no.data`: whether the data should plotted, default `no.data=FALSE` or not `no.data=TRUE`
- `color`: whether the fitted centiles are shown in colour, `color=TRUE` (the default) or not `color=FALSE`
- `main`: the main title
- `plot`: whether to plot the centiles

Value

Centile plots are produced for the different fitted models and the sample centiles below each centile curve are printed.
Warning

This function is appropriate only when one continuous explanatory variable is fitted in the model

Examples

data(abdom)
h1<-gamlss(y~cs(x,df=3), sigma.formula=-cs(x,1),family=BCT, data=abdom)
h2<-gamlss(y~pb(x), sigma.formula=-pb(x), family=BCT, data=abdom )
centiles.com(h1,h2,xvar=abdom$x)
rm(h1,h2)

Description

This function creates predictive centiles curves for new x-values given a GAMLSS fitted model. The function has three options: i) for given new x-values and given percentage centiles calculates a matrix containing the centiles values for y, ii) for given new x-values and standard normalized centile values calculates a matrix containing the centiles values for y, iii) for given new x-values and new y-values calculates the z-scores. A restriction of the function is that it applies to models with only one explanatory variable.
Usage

```
centiles.pred(obj, type = c("centiles", "z-scores", "standard-centiles"),
xname = NULL, xvalues = NULL, power = NULL, yval = NULL,
cent = c(0.4, 2, 10, 25, 50, 75, 90, 98, 99.6),
dev = c(-4, -3, -2, -1, 0, 1, 2, 3, 4), calibration = FALSE,
plot = FALSE, legend = TRUE,
...)```

Arguments

- **obj**: a fitted gamlss object from fitting a gamlss continuous distribution
- **type**: the default, "centiles", gets the centiles values given in the option cent. type="standard-centiles" gets the standard centiles given in the dev. type="z-scores" gets the z-scores for given y and x new values
- **xname**: the name of the unique explanatory variable (it has to be the same as in the original fitted model)
- **xvalues**: the new values for the explanatory variable where the prediction will take place
- **power**: if power transformation is needed (but read the note below)
- **yval**: the response values for a given x required for the calculation of "z-scores"
- **cent**: a vector with elements the % centile values for which the centile curves have to be evaluated
- **dev**: a vector with elements the standard normalized values for which the centile curves have to be evaluated in the option type="standard-centiles"
- **calibration**: whether to calibrate the "centiles", the default is calibrate=FALSE
- **plot**: whether to plot the "centiles" or the "standard-centiles", the default is plot=FALSE
- **legend**: whether a legend is required in the plot or not, the default is legend=TRUE
- **...**: for extra arguments

Value

- a vector (for option type="z-scores") or a matrix for options type="centiles" or type="standard-centiles" containing the appropriate values

Warning

See example below of how to use the function when power transformation is used for the x-variables

Note

The power option should be only used if the model

aa <- gamlss(y~pb(nx),sigma.fo=-pb(nx), data=abdom, family=BCT)
centiles(aa, xvar=abdom$x)
# getting the centiles at x equal to 12, 14, ...40
mat <- centiles.pred(aa, xname="nx", xvalues=seq(12,40,2), power=0.5,
data=newd, plot=TRUE)
# plot all prediction points
xxx <- rep(mat[,1],9)
yyy <- unlist(mat[,2:10])
points(xxx,yyy,col="red")
# the idea is that if the transformed x-variable is used in the fit
# the power argument has to used in centiles.pred()
# End(Not run)

---

**centiles.split**

Plots centile curves split by x for a GAMLSS object

**Description**

This function plots centiles curves for separate ranges of the unique explanatory variable x. It is similar to the centiles function but the range of x is split at a user defined values xcut.point.
centiles.split

into r separate ranges. The functions also tabulates the sample percentages below each centile curve for each of the r ranges of x (for comparison with the model percentage given by cent) The model should have only one explanatory variable.

Usage

`centiles.split(obj, xvar, xcut.points = NULL, n.inter = 4, cent = c(0.4, 2, 10, 25, 50, 75, 90, 98, 99.6), legend = FALSE, main = NULL, main.gsub = "@", ylab = "y", xlab = "x", ylim = NULL, overlap = 0, save = TRUE, plot = TRUE, ...)`

Arguments

- **obj**: a fitted gamlss object from fitting a gamlss continuous distribution
- **xvar**: the unique explanatory variable
- **xcut.points**: the x-axis cut off points e.g. c(20,30). If xcut.points=NULL then the n.inter argument is activated
- **n.inter**: if xcut.points=NULL this argument gives the number of intervals in which the x-variable will be splited, with default 4
- **cent**: a vector with elements the % centile values for which the centile curves are to be evaluated
- **legend**: whether a legend is required in the plots or not, the default is legend=FALSE
- **main**: the main title as character. If NULL the default title (shown the intervals) is shown
- **main.gsub**: if the main.gsub (with default "@") appears in the main title then it is substituted with the default title.
- **ylab**: the y-variable label
- **xlab**: the x-variable label
- **ylim**: the range of the y-variable axis
- **overlap**: how much overlapping in the xvar intervals. Default value is overlap=0 for non overlapping intervals
- **save**: whether to save the sample percentages or not with default equal to TRUE. In this case the functions produce a matrix giving the sample percentages for each interval
- **plot**: whether to plot the centiles. This option is useful if the sample statistics only are to be used
- **...**: for extra arguments

Value

Centile plots are produced and the sample centiles below each centile curve for each of the r ranges of x can be saved into a matrix.
Warning

This function is appropriate when only one continuous explanatory variable is fitted in the model.

**coef.gamlss**

*Extract Model Coefficients in a GAMLSS fitted model*

**Description**

`coef.gamlss` is the GAMLSS specific method for the generic function `coef` which extracts model coefficients from objects returned by modelling functions. ‘coefficients’ is an alias for `coef`. 
Usage

```r
## S3 method for class 'gamlss'
coef(object, what = c("mu", "sigma", "nu", "tau"),
      parameter = NULL, ... )
```

ccoefAll(obj, deviance = FALSE, ...)

Arguments

- `object, obj` a GAMLSS fitted model
- `what` which parameter coefficient is required, default `what="mu"`
- `parameter` equivalent to `what` (more obvious name)
- `deviance` whether to print also the deviance.
- `...` for extra arguments

Value

Coefficients extracted from the GAMLSS model object.

rm(h)
```
Specify a Smoothing Cubic Spline Fit in a GAMLSS Formula

Description

The functions cs() and scs() are using the cubic smoothing splines function smooth.spline() to do smoothing. They take a vector and return it with several attributes. The vector is used in the construction of the model matrix. The functions do not do the smoothing, but assigns the attributes to the vector to aid gamlss in the smoothing. The function doing the smoothing is gamlss.cs(). This function use the R function smooth.spline() which is then used by the backfitting function additive.fit() which is based on the original GAM implementation described in Chambers and Hastie (1992). The function gamlss.scs() differs from the function cs() in that allows cross validation of the smoothing parameters unlike the cs() which fixes the effective degrees of freedom, df. Note that the recommended smoothing function is now the function pb() which allows the estimation of the smoothing parameters using a local maximum likelihood. The function pb() is based on the penalised beta splines (P-splines) of Eilers and Marx (1996).

The (experimental) function vc is now defunct. For fitting varying coefficient models, Hastie and Tibshirani (1993) use the function pvc().

Usage

cs(x, df = 3, spar = NULL, c.spar = NULL, control = cs.control(...), ...)
scs(x, df = NULL, spar = NULL, control = cs.control(...), ...)
cs.control(cv = FALSE, all.knots = TRUE, nknots = NULL, keep.data = TRUE,
  df.offset = 0, penalty = 1.4, control.spar = list(), ...)

Arguments

x
the univariate predictor, (or expression, that evaluates to a numeric vector). For the function vc the x argument is the vector which has its (linear) coefficient change with r

df
the desired equivalent number of degrees of freedom (trace of the smoother matrix minus two for the constant and linear fit). The real smoothing parameter (spar below) is found such that df=tr(S)-2, where S is the implicit smoother matrix. Values for df should be greater than 0, with 0 implying a linear fit.

spar
smoothing parameter, typically (but not necessarily) in (0,1]. The coefficient lambda of the integral of the squared second derivative in the fit (penalised log likelihood) criterion is a monotone function of ‘spar’, see the details in smooth.spline.

c.spar
This is an option to be used when the degrees of freedom of the fitted gamlss object are different from the ones given as input in the option df. The default values used are the ones given the option control.spar in the R function smooth.spline() and they are c.spar=c(-1.5,2). For very large data sets e.g. 10000 observations, the upper limit may have to increase for example to c.spar=c(-1.5,2.5). Use this option if you have received the warning 'The output df are different from the input, change the control.spar'. c.spar
can take both vectors or lists of length 2, for example `c.spar=c(-1.5,2.5)` or `c.spar=list(-1.5,2.5)` would have the same effect.

- **control**: control for the function `smooth.spline()`, see below
- **cv**: see the R function `smooth.spline()`
- **all.knots**: see the R function `smooth.spline()`
- **nknots**: see the R function `smooth.spline()`
- **keep.data**: see the R function `smooth.spline()`
- **df.offset**: see the R function `smooth.spline()`
- **penalty**: see the R function `smooth.spline()`, here the default value is 1.4
- **control.spar**: see above `c.spar` or the equivalent argument in the function `smooth.spline`...
  for extra arguments

### Details

Note that `cs` itself does no smoothing; it simply sets things up for the function `gamlss()` which in turn uses the function `additive.fit()` for backfitting which in turn uses `gamlss.cs()`

Note that `cs()` and `scs()` functions behave differently at their default values that is if `df` and `lambda` are not specified. `cs(x)` by default will use 3 extra degrees of freedom for smoothing for `x`. `scs(x)` by default will estimate `lambda` (and the degrees of freedom) automatically using generalised cross validation (GCV). Note that if GCV is used the convergence of the `gamlss` model can be less stable compared to a model where the degrees of freedom are fixed. This will be true for small data sets.

### Value

the vector `x` is returned, endowed with a number of attributes. The vector itself is used in the construction of the model matrix, while the attributes are needed for the backfitting algorithms `additive.fit()`. Since smoothing splines includes linear fits, the linear part will be efficiently computed with the other parametric linear parts of the model.

### Warning

For a user who wishes to compare the `gamlss()` results with the equivalent `gam()` results in S-plus: make sure when using S-plus that the convergence criteria `epsilon` and `bf.epsilon` in `control.gam()` are decreased sufficiently to ensure proper convergence in S-plus. Also note that the degrees of freedom are defined on top of the linear term in `gamlss`, but on top of the constant term in S-plus, (so use an extra degrees of freedom in S-plus in order to obtain comparable results to those in `gamlss`).

Change the upper limit of `spar` if you received the warning 'The output df are different from the input, change the control.spar'.

For large data sets do not use expressions, e.g. `cs(x^0.5)` inside the `gamlss` function command but evaluate the expression, e.g. `nx=x^0.5`, first and then use `cs(nx)`.

### Note

The degrees of freedom `df` are defined differently from that of the `gam()` function in S-plus. Here `df` are the additional degrees of freedom excluding the constant and the linear part of `x`. For example `df=4` in `gamlss()` is equivalent to `df=5` in `gam()` in S-plus.

deviance.gamlss  

**Global Deviance of a GAMLSS model**

---

**Description**

Returns the global, $-2\times\log(\text{likelihood})$, or the penalized, $-2\times\log(\text{likelihood}) + \text{penalties}$, deviance of a fitted GAMLSS model object.

**Usage**

```r
## S3 method for class 'gamlss'
deviance(object, what = c("G", "P"), ...)
```

**Arguments**

- **object**: a GAMLSS fitted model
- **what**: put "G" for Global or "P" for Penalized deviance
- **...**: for extra arguments

**Details**

deviance is a generic function which can be used to extract deviances for fitted models. deviance.gamlss is the method for a GAMLSS object.

**Value**

The value of the global or the penalized deviance extracted from a GAMLSS object.

devianceIncr  The global deviance increment

Description

The global deviance increment is the contribution of each individual observation to the global de-
viance. The function devianceIncr() can be used to extract the global deviance increment for a
fitted gamlss model or for a new (test/validation) data set. Large values for global deviance incre-
ment indicate a bad fit and for new data a bad prediction.

Usage

devianceIncr(obj, newdata = NULL)

Arguments

obj  a gamlss object
newdata  test data set to check the global deviance increment.

Value

Returns a vector of the global deviance increments for each observation.

**dtop**

*Detrended transformed Owen’s plot*

**Description**

Provides single or multiple detrended transformed Owen’s plot, Owen (1995), for a GAMLSS fitted objects or any other fitted object which has the method resid(). This is a diagnostic tool for checking whether the normalised quantile residuals are coming from a normal distribution or not. This could be true if the horizontal line is within the confidence intervals.

**Usage**

```r
dtop(object = NULL, xvar = NULL, resid = NULL, 
type = c("Owen", "JW"), 
conf.level = c("95", "99"), n.inter = 4, 
xcut.points = NULL, overlap = 0, 
show.given = TRUE, cex = 1, pch = 21, 
line = TRUE, ...)```

**Arguments**

- `object` a GAMLSS fitted object or any other fitted object which has the method resid().
- `xvar` the explanatory variable against which the detrended Owen’s plots will be plotted.
- `resid` if the object is not specified the residual vector can be given here.
- `conf.level` 95 (default) or 99 percent confidence interval for the plots.
- `n.inter` the number of intervals in which the explanatory variable `xvar` will be cut.
- `xcut.points` the x-axis cut off points e.g. c(20,30). If `xcut.points=NULL` then the `n.inter` argument is activated.
- `overlap` how much overlapping in the `xvar` intervals. Default value is `overlap=0` for non overlapping intervals.
- `show.given` whether to show the x-variable intervals in the top of the graph, default is `show.given=TRUE`.
- `cex` the `cex` plotting parameter with default `cex=1`.
- `pch` the `pch` plotting parameter with default `pch=21`.
- `line` whether the detrended empirical cdf should be plotted or not.
- `...` for extra arguments.
Details

If the xvar argument is not specified then a single detrended Owen’s plot is used, see Owen (1995). In this case the plot is a detrended nonparametric likelihood confidence band for a distribution function. That is, if the horizontal lines lies within the confidence band then the normalised residuals could have come from a Normal distribution and consequently the assumed response variable distribution is reasonable. If the xvar is specified then we have as many plots as n.iter. In this case the x-variable is cut into n.iter intervals with an equal number observations and detrended Owen’s plots for each interval are plotted. This is a way of highlighting failures of the model within different ranges of the explanatory variable.

Value

A plot is returned.

Effective degrees of freedom from gamlss model

Description

The functions edf() and edfAll() can be used to obtained the effective degrees of freedom for different additive terms for the distribution parameters in a gamlss model.

Usage

\[
edf(obj, what = c(\text{"mu"}, \text{"sigma"}, \text{"nu"}, \text{"tau"}), \text{parameter= NULL, print = TRUE}, \ldots)\]

\[
edfAll(obj, \ldots)\]

Arguments

- **obj**: A gamlss fitted model
- **what**: which of the four parameters mu, sigma, nu or tau.
- **parameter**: equivalent to what
- **print**: whether to print the label
- **...**: for extra arguments

Value

The function edfAll() re turns a list of edf for all the fitted parameters. The function edf() a vector of edf.

Note

The edf given are the ones fitted in the backfitting so the usually contained (depending on the additive term) the contact and the linear part.

m1<- gamlss(y~pb(x1)+pb(x2)+pb(x6), data=usair)
edfAll(m1)
edf(m1)
```

find.hyper

*A function to select values of hyper-parameters in a GAMLSS model*

Description

This function selects the values of hyper parameters and/or non-linear parameters in a GAMLSS model. It uses the R function optim which then minimises the generalised Akaike information criterion (GAIC) with a user defined penalty.

Usage

```r
find.hyper(model = NULL, parameters = NULL, other = NULL, k = 2,
            steps = c(0.1), lower = -Inf, upper = Inf, method = "L-BFGS-B",
            ...)
```

Arguments

- **model**
  - this is a GAMLSS model in `quote()`. e.g. `quote(gamlss(y~cs(x,df=p[1]),sigma.fo=-cs(x,df=p[2]),data=abdom))` where `p[1]` and `p[2]` denote the parameters to be estimated

- **parameters**
  - the starting values in the search of the optimum hyper-parameters and/or non-linear parameters e.g. `parameters=c(3,3)`

- **other**
  - this is used to optimise other non-parameters, for example a transformation of the explanatory variable of the kind `x^p[3]`, `others=quote(nx<-x^p[3])` where `nx` is now in the model formula

- **k**
  - specifies the penalty in the GAIC, (the default is 2) e.g. `k=3`

- **steps**
  - the steps taken in the optimisation procedure [see the `ndeps` option in `optim()`], by default is set to 0.1 for all hyper parameters and non-linear parameters

- **lower**
  - the lower permissible level of the parameters i.e. `lower=c(1,1)` this does not apply if a method other than the default method "L-BFGS-B" is used
upper | the upper permissible level of the parameters i.e. \texttt{upper=c(30,10)}, this is not apply if a method other than the default method "L-BFGS-B" is used
method | the method used in \texttt{optim()} to numerically minimise the GAIC over the hyper-parameters and/or non-linear parameters. By default this is "L-BFGS-B" to allow box-restriction on the parameters
... | for extra arguments to be passed to the \texttt{R} function \texttt{optim()} used in the optimisation

Details
This historically was an experimental function which worked well for the search of the optimum degrees of freedom and non-linear parameters (e.g. power parameter $\lambda$ used to transform $x$ to $x^\lambda$). With the introduction of the P-Spline smoothing function \texttt{pb()} the function \texttt{find.hyper()} became almost redundant. \texttt{find.hyper()} takes lot longer than \texttt{pb()} to find automatically the hyper parameters while both method produce similar results. See below the examples for a small demonstration.

Value
The function turns the same output as the function \texttt{optim()}

- \texttt{par} | the optimum hyper-parameter values
- \texttt{value} | the minimised value of the GAIC
- \texttt{counts} | A two-element integer vector giving the number of calls to ‘\texttt{fn}’ and ‘\texttt{gr}’ respectively
- \texttt{convergence} | An integer code. ‘0’ indicates successful convergence. see the function \texttt{optim()} for other errors
- \texttt{message} | A character string giving any additional information returned by the optimiser, or ‘NULL’

Warning
It may be slow to find the optimum

**fitDist**  
*Fitting Different Parametric gamlss.family Distributions.*

**Description**

The function `fitDist()` is using the function `gamlssML()` to fit all relevant parametric `gamlss.family` distributions, specified by the argument `type`, to a single data vector (with no explanatory variables). The final marginal distribution is the one selected by the generalised Akaike information criterion with penalty \( k \). The default is \( k=2 \) i.e AIC.

The function `fitDistPred()` is using the function `gamlssMLpred()` to fit all relevant (marginal) parametric `gamlss.family` distributions to a single data vector (similar to `fitDist()` but the final model is selected by the minimum prediction global deviance. The user has to specify the training and validation/test samples.

The function `chooseDist()` is using the function `update.gamlss()` to fit all relevant parametric (conditional) `gamlss.family` distributions to a given fitted `gamlss` model. The output of the function is a matrix with rows the different distributions (from the argument `type`) and columns the different GAIC’s. The default argument for \( k \) are 2, for AIC, 3.84, for Chi square, and \( \log(n) \) for BIC. No final model is given by the function like for example in `fitDist()`. The function `getOrder()` can be used to rank the columns of the resulting table (matrix). The final model can be refitted using `update()`, see the examples.

**Usage**

```r
fitDist(y, k = 2,
        type = c("realAll", "realline", "realplus", "real0to1", "counts", "binom"),
        try.gamlss = FALSE, extra = NULL, data = NULL, trace = FALSE, ...)

fitDistPred(y,
            type = c("realAll", "realline", "realplus", "real0to1", "counts", "binom"),
            try.gamlss = FALSE, extra = NULL, data = NULL, rand = NULL,
            newdata = NULL, trace = FALSE, ...)

chooseDist(object, k = c(2, 3.84, round(log(length(object$y)), 2)),
            type = c("realAll", "realline", "realplus", "real0to1", "counts", "binom","extra"),
            extra = NULL, trace = FALSE,
```

---
parallel = c("no", "multicore", "snow"), ncpus = 1L, cl = NULL, ...

chooseDistPred(object, type = c("realAll", "realline", "realplus", "real0tol", "counts", "binom", "extra"), extra = NULL, trace = FALSE, parallel = c("no", "multicore", "snow"), ncpus = 1L, cl = NULL, newdata = NULL, rand = NULL, ...)

getOrder(obj, column = 1)

Arguments

y
the data vector

object, obj
a GAMLSS fitted model

k
the penalty for the GAIC with default values k=2 the standard AIC. In the case of the function chooseDist() k can be a vector i.e. k= c(2,4,6) so more than one GAIC are saved.

type
the type of distribution to be tried see details

try.gamlss
this applies to functions fitDist() and fitDistPred(). It allows if gamlssML() fail to fit the model to try gamlss instead. This will slow up things for big data.

extra
whether extra distributions should be tried, which are not in the type list. Note that the function chooseDist() allows the fitting of only the ‘extra’ distributions. This can be achieved if extra is set i.e. extra=c("GA", "IG", "GG") and type is set to extra i.e. type="extra".

data
the data frame where y can be found, only for functions fitDist() and fitDistPred()

rand
For fitDistPred() a factor with values 1 (for fitting) and 2 (for predicting).

newdata
The prediction data set (validation or test).

trace
whether to print during fitting. Note that when parallel is 'multicore' or "snow" "trace" is not produce any output.

parallel
The type of parallel operation to be used (if any). If missing, the default is "no".

ncpus
integer: number of processes to be used in parallel operation: typically one would choose this to the number of available CPUs.

cl
This is useful for snow clusters, i.e. parallel = "snow", when the clusters are created in advance. If not supplied, a cluster on the local machine is created for the duration of the call.

column
which column of the output matrix to be ordered according to best GAIC

...
for extra arguments to be passed to gamlssML() to gamlss()

Details

The following are the different type argument:

- realAll: All the gamlss.family continuous distributions defined on the real line, i.e. realline and the real positive line i.e. realplus
The `fitDist()` function uses the `gamlssML()` function to fit the different models, the function `fitDistPred()` uses `gamlssMLpred()` and the function `chooseDist()` uses `update.gamlss()`. The function `fitDist()` uses the function `gamlssML()` to fit the different models, the function `fitDistPred()` uses `gamlssMLpred()` and the function `chooseDist()` uses `update.gamlss()`.

**Value**

For the functions `fitDist()` and `fitDistPred()` a `gamlssML` object is return (the one which minimised the GAIC or VDEV respectively) with two extra components:

- `fits` an ordered list according to the GAIC of the fitted distribution
- `failed` the distributions where the `gamlssML()` (or `gamlss()`) fits have failed

For the function `chooseDist()` a matrix is returned, with rows the different distributions and columns the different GAIC's set by k.

fitted.gamlss  # Extract Fitted Values For A GAMLSS Model

**Description**

`fitted.gamlss` is the GAMLSS specific method for the generic function `fitted` which extracts fitted values for a specified parameter from a GAMLSS objects. `fitted.values` is an alias for it. The function `fv()` is similar to `fitted.gamlss()` but allows the argument `what` not to be character

**Usage**

```r
## S3 method for class 'gamlss'
fitted(object, what = c("mu", "sigma", "nu", "tau"),
       parameter = NULL, ...)
fv(obj, what = c("mu", "sigma", "nu", "tau"), parameter = NULL, ...)
```

**Arguments**

- `object` a GAMLSS fitted model
- `obj` a GAMLSS fitted model
- `what` which parameter fitted values are required, default `what="mu"
- `parameter` equivalent to `what`
- `...` for extra arguments

**Value**

Fitted values extracted from the GAMLSS object for the given parameter.

**Author(s)**

Mikis Stasinopoulos <d.stasinopoulos@londonmet.ac.uk>

**References**

(see also [https://www.gamlss.com/](https://www.gamlss.com/).)
### Description

This function, applicable only to a model with a single explanatory variable, plots the fitted values for all the parameters of a GAMLSS model against the (one) explanatory variable. It is also useful for comparing the fits for more than one model.

### Usage

```r
fittedPlot(object, ..., x = NULL, color = TRUE, line.type = FALSE, xlab = NULL)
```

### Arguments

- **object**: a fitted GAMLSS model object (with only one explanatory variable)
- **...**: optionally more fitted GAMLSS model objects
- **x**: The unique explanatory variable
- **color**: whether the fitted lines plots are shown in colour, `color = TRUE` (the default) or not `color = FALSE`
- **line.type**: whether the line type should be different or not. The default is `line.type = FALSE`
- **xlab**: the x-label

### Value

A plot of the fitted values against the explanatory variable

formula.gamlss Extract the Model Formula in a GAMLSS fitted model

Description

formula.gamlss is the GAMLSS specific method for the generic function formula which extracts the model formula from objects returned by modelling functions.

Usage

## S3 method for class 'gamlss'
formula(x, what = c("mu", "sigma", "nu", "tau"),
parameter= NULL, ... )

Arguments

x a GAMLSS fitted model
what which parameter coefficient is required, default what="mu"
parameter equivalent to what
... for extra arguments
Value

Returns a model formula

Author(s)

Mikis Stasinopoulos <d.stasinopoulos@londonmet.ac.uk>

References

See Also

gamlss, deviance.gamlss, fitted.gamlss

Examples

data(aids)
h<-gamlss(y~poly(x,3)+qrt, family=PO, data=aids) #
formula(h,"mu")
rm(h)

Description

Returns an object of class "gamlss", which is a generalized additive model for location scale and shape (GAMLSS). The function *gamlss()* is very similar to the *gam()* function in S-plus (now also in R in package *gam*), but can fit more distributions (not only the ones belonging to the exponential family) and can model all the parameters of the distribution as functions of the explanatory variables (e.g. using linear, non-linear, smoothing, loess and random effects terms).

This implementation of *gamlss()* allows modelling of up to four parameters in a distribution family, which are conventionally called mu, sigma, nu and tau.

The function *gamlssNews()* shows what is new in the current implementation.
Usage

```r
gamlss(formula = formula(data), sigma.formula = ~1,
       nu.formula = ~1, tau.formula = ~1, family = NO(),
       data, weights = NULL,
       contrasts = NULL, method = RS(), start.from = NULL,
       mu.start = NULL, sigma.start = NULL,
       nu.start = NULL, tau.start = NULL,
       mu.fix = FALSE, sigma.fix = FALSE, nu.fix = FALSE,
       tau.fix = FALSE, control = gamlss.control(...),
       i.control = glim.control(...), ...)
is.gamlss(x)
gamlssNews()
```

Arguments

- **formula**: a formula object, with the response on the left of an ~ operator, and the terms, separated by + operators, on the right. Nonparametric smoothing terms are indicated by pb() for penalised beta splines, cs for smoothing splines, lo for loess smooth terms and random or ra for random terms, e.g. y~cs(x, df=5)+x1+x2+x3. Additional smoothers can be added by creating the appropriate interface. Interactions with nonparametric smooth terms are not fully supported, but will not produce errors; they will simply produce the usual parametric interaction.

- **sigma.formula**: a formula object for fitting a model to the sigma parameter, as in the formula above, e.g. sigma.formula=cs(x, df=5). It can be abbreviated to sigma.fo=cs(x, df=5).

- **nu.formula**: a formula object for fitting a model to the nu parameter, e.g. nu.fo=x

- **tau.formula**: a formula object for fitting a model to the tau parameter, e.g. tau.fo=cs(x, df=2)

- **family**: a `gamlss.family` object, which is used to define the distribution and the link functions of the various parameters. The distribution families supported by `gamlss()` can be found in `gamlss.family`. Functions such as BI() (binomial) produce a family object. Also can be given without the parentheses i.e. BI. Family functions can take arguments, as in BI(mu.link=probit)

- **data**: a data frame containing the variables occurring in the formula, e.g. data=aids. If this is missing, the variables should be on the search list.

- **weights**: a vector of weights. Note that this is not the same as in the glm() or gam() function. Here weights can be used to weight out observations (like in subset) or for a weighted likelihood analysis where the contribution of the observations to the likelihood differs according to weights. The length of weights must be the same as the number of observations in the data. By default, the weight is set to one. To set weights to vector w use weights=w

- **contrasts**: list of contrasts to be used for some or all of the factors appearing as variables in the model formula. The names of the list should be the names of the corresponding variables. The elements should either be contrast-type matrices (matrices with as many rows as levels of the factor and with columns linearly independent of each other and of a column of ones), or else they should be functions that compute such contrast matrices.
method the current algorithms for GAMLSS are RS(), CG() and mixed(). i.e. method=RS() will use the Rigby and Stasinopoulos algorithm, method=CG() will use the Cole and Green algorithm and mixed(2,10) will use the RS algorithm twice before switching to the Cole and Green algorithm for up to 10 extra iterations

start.from a fitted GAMLSS model which the fitted values will be used as staring values for the current model

mu.start vector or scalar of initial values for the location parameter mu e.g. mu.start=4

sigma.start vector or scalar of initial values for the scale parameter sigma e.g. sigma.start=1

nu.start vector or scalar of initial values for the parameter nu e.g. nu.start=3

tau.start vector or scalar of initial values for the location parameter tau e.g. tau.start=2

mu.fix whether the mu parameter should be kept fixed in the fitting processes e.g. mu.fix=FALSE

sigma.fix whether the sigma parameter should be kept fixed in the fitting processes e.g. sigma.fix=FALSE

nu.fix whether the nu parameter should be kept fixed in the fitting processes e.g. nu.fix=FALSE

tau.fix whether the tau parameter should be kept fixed in the fitting processes e.g. tau.fix=FALSE

control this sets the control parameters of the outer iterations algorithm. The default setting is the gamlss.control function

i.control this sets the control parameters of the inner iterations of the RS algorithm. The default setting is the glim.control function

... for extra arguments

x an object

Details
The Generalized Additive Model for Location, Scale and Shape is a general class of statistical models for a univariate response variable. The model assumes independent observations of the response variable y given the parameters, the explanatory variables and the values of the random effects. The distribution for the response variable in the GAMLSS can be selected from a very general family of distributions including highly skew and/or kurtotic continuous and discrete distributions, see gamlss.family. The systematic part of the model is expanded to allow modelling not only of the mean (or location) parameter, but also of the other parameters of the distribution of y, as linear parametric and/or additive nonparametric (smooth) functions of explanatory variables and/or random effects terms. Maximum (penalized) likelihood estimation is used to fit the (non)parametric models. A Newton-Raphson/Fisher scoring algorithm is used to maximize the (penalized) likelihood. The additive terms in the model are fitted using a backfitting algorithm.

is.gamlss is a short version is is(object,"gamlss")

Value
Returns a gamlss object with components

family the distribution family of the gamlss object (see gamlss.family)

parameters the name of the fitted parameters i.e. mu, sigma, nu, tau
call  the call of the gamlss function
y    the response variable
control  the gamlss fit control settings
weights  the vector of weights
G.deviance  the global deviance
N    the number of observations in the fit
rqres   a function to calculate the normalized (randomized) quantile residuals of the
        object
iter   the number of external iterations in the fitting process
type   the type of the distribution or the response variable (continuous or discrete)
method  which algorithm is used for the fit, RS(), CG() or mixed()
converged whether the model fitting has have converged
residuals  the normalized (randomized) quantile residuals of the model
mu.fv   the fitted values of the mu model, also sigma.fv, nu.fv, tau.fv for the other
        parameters if present
mu.lp   the linear predictor of the mu model, also sigma.lp, nu.lp, tau.lp for the other
        parameters if present
mu.wv   the working variable of the mu model, also sigma.wv, nu.wv, tau.wv for the
        other parameters if present
mu.wt   the working weights of the mu model, also sigma.wt, nu.wt, tau.wt for the other
        parameters if present
mu.link  the link function for the mu model, also sigma.link, nu.link, tau.link for the other
        parameters if present
mu.terms  the terms for the mu model, also sigma.terms, nu.terms, tau.terms for the other
        parameters if present
mu.x    the design matrix for the mu, also sigma.x, nu.x, tau.x for the other parameters
        if present
mu.qr   the QR decomposition of the mu model, also sigma.qr, nu.qr, tau.qr for the other
        parameters if present
mu.coefficients  the linear coefficients of the mu model, also sigma.coefficients, nu.coefficients,
        tau.coefficients for the other parameters if present
mu.formula  the formula for the mu model, also sigma.formula, nu.formula, tau.formula for
        the other parameters if present
mu.df    the mu degrees of freedom also sigma.df, nu.df, tau.df for the other parameters
        if present
mu.nl.df  the non linear degrees of freedom, also sigma.nl.df, nu.nl.df, tau.nl.df for the
        other parameters if present
df.fit  the total degrees of freedom use by the model
df.residual  the residual degrees of freedom left after the model is fitted
aic   the Akaike information criterion
sbc   the Bayesian information criterion
Warning

Respect the parameter hierarchy when you are fitting a model. For example a good model for \( \mu \) should be fitted before a model for \( \sigma \) is fitted.

Note

The following generic functions can be used with a GAMLSS object: `print`, `summary`, `fitted`, `coef`, `residuals`, `update`, `plot`, `deviance`, `formula`.

plot(mod)
rm(mod)
gamlss.control  Auxiliary for Controlling GAMLSS Fitting

Description
Auxiliary function as user interface for gamlss fitting. Typically only used when calling gamlss function with the option control.

Usage
gamlss.control(c.crit = 0.001, n.cyc = 20, mu.step = 1, sigma.step = 1, nu.step = 1,
tau.step = 1, gd.tol = Inf, iter = 0, trace = TRUE, autostep = TRUE,
save = TRUE, ...)

Arguments
c.crit       the convergence criterion for the algorithm
n.cyc        the number of cycles of the algorithm
mu.step      the step length for the parameter mu
sigma.step   the step length for the parameter sigma
nu.step      the step length for the parameter nu
tau.step     the step length for the parameter tau
gd.tol       global deviance tolerance level (set more recently to Inf to allow the algorithm to
               converged even if the global deviance change dramatically during the iterations)
iter         starting value for the number of iterations, typically set to 0 unless the function
             refit is used
trace        whether to print at each iteration (TRUE) or not (FALSE)
autostep     whether the steps should be halved automatically if the new global deviance is
             greater that the old one, the default is autostep=TRUE
save         save=TRUE, (the default), saves all the information on exit. save=FALSE saves
             only limited information as the global deviance and AIC. For example fitted
             values, design matrices and additive terms are not saved. The latest is useful
             when gamlss() is called several times within a procedure.
...           for extra arguments

Details
The step length for each of the parameters mu, sigma, nu or tau is very useful to aid convergence
if the parameter has a fully parametric model. However using a step length is not theoretically
justified if the model for the parameter includes one or more smoothing terms, (even thought it may
give a very approximate result).
The c.crit can be increased to speed up the convergence especially for a large set of data which
takes longer to fit. When ‘trace’ is TRUE, calls to the function cat produce the output for each
outer iteration.
Value

A list with the arguments as components.

gamlss.cs Support for Function cs() and scs()

Description

This is support for the functions cs(), and scs(). It is not intended to be called directly by users. The function gamlss.cs is using the R function smooth.spline

Usage

gamlss.cs(x, y, w, df = NULL, spar = NULL, xeval = NULL, ...)

Support for Function cs() and scs()
Arguments

x  the design matrix
y  the response variable
w  prior weights
df  effective degrees of freedom
spar  spar the smoothing parameter
xeval  used in prediction
...  for extra arguments

Value

Returns a class "smooth.spline" object with

residuals  The residuals of the fit
fitted.values  The smoothing values
var  the variance for the fitted smoother
lambda  the final value for spar
nl.df  the smoothing degrees of freedom excluding the constant and linear terms, i.e. (df-2)
coefSmo  this is a list containing among others the knots and the coefficients

gamlss.fp  Support for Function fp()

Description

Those are support for the functions fp() and pp. It is not intended to be called directly by users.

Usage

gamlss.fp(x, y, w, npoly = 2, xeval = NULL)
gamlss.pp(x, y, w)
Arguments

- **x**: the x for function `gamlss.fp` is referred to the design matrix of the specific parameter model (not to be used by the user).
- **y**: the y for function `gamlss.fp` is referred to the working variable of the specific parameter model (not to be used by the user).
- **w**: the w for function `gamlss.fp` is referred to the iterative weight variable of the specific parameter model (not to be used by the user).
- **npoly**: a positive indicating how many fractional polynomials should be considered in the fit. Can take the values 1, 2 or 3 with 2 as default.
- **xeval**: used in prediction.

Value

Returns a list with:

- **fitted.values**: fitted
- **residuals**: residuals
- **var**: the trace of the smoothing matrix
- **lambda**: the value of the smoothing parameter
- **coefSmo**: the coefficients from the smoothing fit
- **varcoeff**: the variance of the coefficients

Support for Function lo()

Description

This is support for the loess function lo(). It is not intended to be called directly by users. The function gamlss.lo is calling the R function loess.

Usage

gamlss.lo(x, y, w, xeval = NULL, ...)

Arguments

- **x**: the design matrix
- **y**: the response variable
- **w**: prior weights
- **xeval**: used in prediction
- **...**: further arguments passed to or from other methods.

Value

Returns an object

- **fitted**: the smooth values
- **residuals**: the residuals
- **var**: the variance of the smoother
- **nl.df**: the non-linear degrees of freedom
- **coefSmo**: with value NULL
- **lambda**: the value of span

Support for Functions for smoothers

Description

Those functions are support for the functions pb(), pbo(), ps(), ridge(), ri(), cy(), pvc(), and pbm(). The functions are not intended to be called directly by users.

Usage

- `gamlss.pb(x, y, w, xeval = NULL, ...)`
- `gamlss.pbo(x, y, w, xeval = NULL, ...)`
- `gamlss.ps(x, y, w, xeval = NULL, ...)`
- `gamlss.ri(x, y, w, xeval = NULL, ...)`
- `gamlss.cy(x, y, w, xeval = NULL, ...)`
- `gamlss.pvc(x, y, w, xeval = NULL, ...)`
- `gamlss.pbm(x, y, w, xeval = NULL, ...)`
- `gamlss.pbz(x, y, w, xeval = NULL, ...)`
- `gamlss.pbc(x, y, w, xeval = NULL, ...)`
- `gamlss.pbp(x, y, w, xeval = NULL, ...)`

Arguments

- `x` the x for function `gamlss.fp` is referred to the design matric of the specific parameter model (not to be used by the user)
- `y` the y for function `gamlss.fp` is referred to the working variable of the specific parameter model (not to be used by the user)
- `w` the w for function `gamlss.fp` is referred to the iterative weight variable of the specific parameter model (not to be used by the user)
- `xeval` used in prediction
- `...` further arguments passed to or from other methods.

Value

All function return fitted smoothers.

gamlss.random  Support for Functions random() and re()

Description

This is support for the functions random() and re() respectively. It is not intended to be called directly by users.

Usage

gamlss.random(x, y, w, xeval = NULL, ...)
gamlss.re(x, y, w, xeval = NULL, ...)

Arguments

x the explanatory design matrix
y the response variable
w iterative weights
xeval it used internally for prediction
... for extra arguments

Value

Returns a list with

y the fitted values
residuals the residuals
var the variance of the fitted values
lambda the final lambda, the smoothing parameter
coeffSmo with value NULL
gamlss.scope

Author(s)
Mikis Stasinopoulos, based on Trevor Hastie function gam.random

gamlss.scope Generate a Scope Argument for Stepwise GAMLSS

Description
Generates a scope argument for a stepwise GAMLSS.

Usage
gamlss.scope(frame, response = 1, smoother = "cs", arg = NULL, form = TRUE)

Arguments
frame a data or model frame
response which variable is the response; the default is the first
smoother what smoother to use; default is cs
arg any additional arguments required by the smoother
form should a formula be returned (default), or else a character version of the formula

Details
Each formula describes an ordered regimen of terms, each of which is eligible on their own for inclusion in the gam model. One of the terms is selected from each formula by step.gam. If a 1 is selected, that term is omitted.
Value

a list of formulas is returned, one for each column in frame (excluding the response). For a numeric variable, say x1, the formula is

\[ \sim 1 + x1 + cs(x1) \]

If x1 is a factor, the last smooth term is omitted.

**gamlssML**

*Maximum Likelihood estimation of a simple GAMLSS model*

**Description**

The function `gamlssML()` fits a `gamlss.family` distribution to single data set using a non linear maximisation algorithm in R. This is relevant only when explanatory variables do not exist.

The function `gamlssMLpred()` is similar to `gamlssML()` but it saves the *predictive* global deviance for the newdata. The newdata in `gamlssMLpred()` can be given with the arguments `newdata` or defining the factor `rand`. `rand` should be a binary factor `rand` splitting the original data set into a training set (value 1) and a validation/test set (values 2), see also `gamlssVGD`

**Usage**

```
gamlssML(formula, family = NO, weights = NULL, mu.start = NULL, sigma.start = NULL, nu.start = NULL, tau.start = NULL, mu.fix = FALSE, sigma.fix = FALSE, nu.fix = FALSE, tau.fix = FALSE, data, start.from = NULL, ...)
gamlssMLpred(response = NULL, data = NULL, family = NO, rand = NULL, newdata = NULL, ...)
```

**Arguments**

- **formula, response**
  a vector of data requiring the fit of a `gamlss.family` distribution or (only for the function `gamlssML`) a formula, for example, `y~1`, with no explanatory variables because they are ignored).

- **family**
  `gamlss.family` object, which is used to define the distribution and the link functions of the various parameters. The distribution families supported by `gamlssML()` can be found in `gamlss.family`

- **weights**
  a vector of weights. Here weights can be used to weight out observations (like in subset) or for a weighted likelihood analysis where the contribution of the observations to the likelihood differs according to weights. The length of weights must be the same as the number of observations in the data. By default, the weight is set to one. To set weights to vector say w use weights=w

- **mu.start, sigma.start, nu.start, tau.start**
  a scalar of initial values for the location parameter mu e.g. `mu.start=4`

- **mu.fix, sigma.fix, nu.fix, tau.fix**
  whether the mu parameter should be kept fixed in the fitting processes e.g. `mu.fix=FALSE`

- **data**
  a data frame in which variables specified in `formula` can be found.

- **start.from**
  a list containing the starting values of the parameters. All the parameters are included (in order) and if any parameter is missing its default starting value will be used.

- **start.from**
  a list containing the starting values of the parameters. All the parameters are included (in order) and if any parameter is missing its default starting value will be used.
nu.fix     whether the nu parameter should be kept fixed in the fitting processes e.g. nu.fix=FALSE
tau.fix     whether the tau parameter should be kept fixed in the fitting processes e.g. tau.fix=FALSE
data       a data frame containing the variable y, e.g. data=aids. If this is missing, the variable should be on the search list.
start.from a gamlss object to start from the fitting or vector of length as many parameters in the distribution
rand For gamlssMLpred() a factor with values 1 (for fitting) and 2 (for predicting).
newdata The prediction data set (validation or test).
... for extra arguments

Details

The function gamlssML() fits a gamlss.family distribution to a single data set is using a non linear maximisation. in fact it uses the internal function MLE() which is a copy of the mle() function of package stat4. The function gamlssML() could be for large data faster than the equivalent gamlss() function which is designed for regression type of models.

The function gamlssMLpred() uses the function function gamlssML() to fit the model but then uses predict.gamlssML() to predict for newdata and saves the the prediction i) deviance increments, ii) global deviance iii) residuals.

Value

Returns a gamlssML object which behaves like a gamlss fitted objected

### Description

This is a set of function useful for selecting appropriate models.

The functions `gamlssVGD`, `VGD`, `getTGD`, `TGD` can be used when a subset of the data is used for validation or testing.

The function `stepVGD()` is a stepwise procedure for selecting an appropriate model for any of the parameters of the model minimising the test global deviance. The function `stepVGDAll.A()` can select a model using strategy A for all the parameters.

The functions `gamlssCV`, `CV` can be used for a k-fold cross validation.

### Usage

```r
## gamlssVGD formula = NULL, sigma.formula = ~1, nu.formula = ~1,
## tau.formula = ~1, data = NULL, family = NO,
## control = gamlss.control(trace = FALSE),
## rand = NULL, newdata = NULL, ...)
VGD(object, ...)

getTGD(object, newdata = NULL, ...)

TGD(object, ...)

## gamlssCV formula = NULL, sigma.formula = ~1, nu.formula = ~1,
## tau.formula = ~1, data = NULL, family = NO,
## control = gamlss.control(trace = FALSE),
## K.fold = 10, set.seed = 123, rand = NULL,
## parallel = c("no", "multicore", "snow"),
## ncpus = 1L, cl = NULL, ...)
CV(object, ...)

drop1TGD(object, scope, newdata, parameter = c("mu", "sigma", "nu", "tau"),
```
Arguments

formula A `gamlss` `mu` formula.
sigma.formula Formula for `sigma`.
nu.formula Formula for `nu`.
tau.formula Formula for `tau`.
data The data frame required for the fit.
family The `gamlss.family` distribution.
control The control for fitting the `gamlss` model.
rand For `gamlssVGD` a variable with values 1 (for fitting) and 2 (for predicting). For `gamlssCV` a variable with k values indicating the cross validation sets.
newdata The new data set (validation or test) for prediction.
object A relevant R object.
scope defines the range of models examined in the stepwise selection similar to `stepGAIC()` where you can see examples
sigma.scope defines the range of models examined in the stepwise selection for `sigma`
uu.scope defines the range of models examined in the stepwise selection for `nu`
tau.scope defines the range of models examined in the stepwise selection for `tau`
mu.try whether should try fitting models for `mu`
sigma.try whether should try fitting models for `sigma`
nu.try  whether should try fitting models for nu
tau.try  whether should try fitting models for tau
parameter  which distribution parameter is required, default what="mu"
sorted  should the results be sorted on the value of TGD
trace  f TRUE additional information may be given on the fits as they are tried.
direction  The mode of stepwise search, can be one of both, backward, or forward, with a default of both. If the scope argument is missing the default for direction is backward
keep  see stepGAIC() for explanation
steps  the maximum number of steps to be considered. The default is 1000.
K.fold  the number of subsets of the data used
set.seed  the seed to be used in creating rand
parallel  The type of parallel operation to be used (if any). If missing, the default is "no".
cpus  integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.
cl  An optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the call.
...  further arguments to be pass in the gamlss fit

Details

The function `gamlssVGD()` fits a gamlss model to the training data set determined by the arguments `rand` or `newdata`. The results is a `gamlssVGD` objects which contains the gamlss fit to the training data plus three extra components: i) VGD the global deviance applied to the validation data sets. ii) predictError which is VGD divided with the number of observations in the validation data set and iii) residVal the residuals for the validation data set.

The function `VGD()` extract the validated global deviance from one or more fitted `gamlssVGD` objects and can be used foe model comparison.

The function `getTGD()` operates different from the function `gamlssVGD()`. It assumes that the users already have fitted models using `gamlss()` and now he/she wants to evaluate the global deviance at a new (validation or test) data set.

The function `TGD()` extract the validated/test global deviance from one or more fitted `gamlssTGD` objects and can be use to compare models.

The `gamlssCV()` performs a k-fold cross validation on a gamlss models.

The function `CV()` extract the cross validated global deviance from one or more fitted `gamlssCV` objects and can be use to compare models.

The functions `add1TGD()`, `drop1TGD()` and `stepTGD` behave similar to `add1()`, `drop1()` and `stepGAIC()` functions respectively but they used validation or test deviance as the selection criterion rather than the GAIC.

Value

A fitted models of a set of global deviances.

**gen.likelihood**

*A function to generate the likelihood function from a GAMLSS object*

**Description**

This function generate a function with argument the parameters of the GAMLSS model which can evaluate the log-likelihood function.

**Usage**

`gen.likelihood(object)`

**Arguments**

| object | A gamlss fitted model |
Details

The purpose of this function is to help the function vcov() to get the right Hessian matrix after a model has fitted. Note that at the moment smoothing terms are considered as fixed.

Value

A function of the log-likelihood

Author(s)

Mikis Stasinopoulos <d.stasinopoulos@londonmet.ac.uk> Bob Rigby and Vlasios Voudouris

References

(see also https://www.gamlss.com/).

See Also

vcov

Examples

data(aids)
m1 <- gamlss(y~x+qrt, data=aids, family=NBI)
logL<-gen.likelihood(m1)
logL()
logLik(m1)
Description

This function can be used to calculate the partial effect and the elasticity of a continuous explanatory variable \( x \).

By 'partial effect' function we mean how \( x \) influence the parameter of interest given that the rest of explanatory terms for this parameter are on (specified) fixed values.

The function takes a GAMLSS object and for the range of the continuous variable \( x \), (by fixing the rest of the explanatory terms at specified values), calculates the effect that \( x \) has on the specific distribution parameter (or its predictor). The resulting function shows the effect that \( x \) has on the distribution parameter. The partial effect function which is calculated on a finite grit is then approximated using the \texttt{splinefun()} in R and its is saved.

The saved function can be used to calculate the elasticity of \( x \). The elasticity is the first derivative of the partial effect function and shows the chance of the parameter of interest for a small change in \( x \), by fixing the rest of the explanatory variables at specified values.

Usage

```r
getPEF(obj = NULL, term = NULL, data = NULL, n.points = 100,
       parameter = c("mu", "sigma", "nu", "tau"),
       type = c("response", "link"), how = c("median", "last"),
       fixed.at = list(), plot = FALSE)
```

Arguments

- `obj`: A `gamlss` object
- `term`: the continuous explanatory variable
- `data`: the data.frame (not needed if is declared on `obj`)
- `n.points`: the number of points in which the influence function for \( x \) need to be evaluated
- `parameter`: which distribution parameter
- `type`: whether against the parameter, "response", or the predictor "link"
- `how`: whether for continuous variables should use the median or the last observation in the data
- `fixed.at`: a list indicating at which values the rest of the explanatory terms should be fixed
- `plot`: whether to the plot the influence function and its first derivatives

Value

A function is created which can be used to evaluate the partial effect function at different values of \( x \).

getQuantile

Getting the partial quantile function for a term

Description

This function can be used to calculate the partial effect that an explanatory variable has on a specific quantile.

By ‘partial effect’ function we mean how the term influence the quantile given that the rest of explanatory terms are constant.

The function takes a GAMLSS object and for the range of a specified explanatory (by fixing the rest of the terms at specified values), calculates the effect that this term has on the a quantile of the distribution. That is, it shows the effect that the particular term has on the quantile. The ‘partial’
quantile is calculated on a finite grid of values and then the function is approximated (using the `splinefun()`) and saved.

The saved function can be used to calculate the first derivative. This first derivatives shows the chance of the quantile function for a small change in the explanatory variable, by fixing the rest of the explanatory variables at a constant values.

**Usage**

```r
getQuantile(obj = NULL, term = NULL, quantile = 0.9, data = NULL,
          n.points = 100, how = c("median", "last"),
          fixed.at = list(), plot = FALSE)
```

**Arguments**

- `obj` A `gamlss` object
- `term` an explanatory variable (at the moment works with with continuous)
- `quantile` the required quantile of the distribution
- `data` the data.frame (not needed if is declared on `obj`)
- `n.points` the number of points in which the quantile function needs evaluation
- `how` whether for extra continuous explanatory variables should fixed at the median or the last observation in the data
- `fixed.at` a list indicating at which values the rest of the explanatory terms should be fixed
- `plot` whether to plot the partial quantile function and its first derivatives

**Details**

The function `getQuantile()` relies on the `predictAll()` function to evaluate the distribution parameters at a grid (default 100 points) of the specified term (given that the the rest of the terms are fixed). Then the inverse cdf is used to calculate the partial quantile. The function then is approximated using `splinefun()` and saved.

**Value**

A function is created which can be used to evaluate the partial effect of the explanatory variable on a specified quantile.

{
  Qua <- getQuantile(m1, quantile=i,term="A",
                     fixed.at=list(Fl=120, B=0, loc=3))
  curve(Qua, 1900, 1985, lwd=1, lty=3, col="blue", add=T)
}
## End(Not run)
The function `getSmo()` extracts information from a fitted smoothing additive term.

**Usage**

```r
getSmo(object, what = c("mu", "sigma", "nu", "tau"),
       parameter = NULL, which = 1)
```

**Arguments**

- `object`: a GAMLSS fitted model
- `what`: which distribution parameter is required, default `what = "mu"`
- `parameter`: equivalent to `what`
- `which`: which smoothing term i.e. 1, 2 etc. Note that 0 means all.

**Details**

This function facilitates the extraction of information from a fitted additive terms. For example `getSmo(m1,"sigma",2)` is equivalent of `m1$sigma.coefSmo[[2]]`. To get the actual fitted values type `m1$sigma.s[[2]]`

**Value**

A list containing information about a fitted smoother or a fitted objects

**Author(s)**

Mikis Stasinopoulos and Bob Rigby

**References**

(see also [https://www.gamlss.com/](https://www.gamlss.com/)).
Examples

```r
data(usair)
t1<-gamlss(y~x1+pb(x5)+pb(x6), data=usair, family=GA)
# get the value for lambda for the second fitted term in mu
getSmo(t1, parameter="mu", 2)$lambda
```

---

glim.control

*Auxiliary for Controlling the inner algorithm in a GAMLSS Fitting*

Description

Auxiliary function used for the inner iteration of `gamlss` algorithm. Typically only used when calling `gamlss` function through the option `i.control`.

Usage

```r
glim.control(cc = 0.001, cyc = 50, glm.trace = FALSE, 
bf.cyc = 30, bf.tol = 0.001, bf.trace = FALSE, 
...)
```

Arguments

- **cc**: the convergence criterion for the algorithm
- **cyc**: the number of cycles of the algorithm
- **glm.trace**: whether to print at each iteration (TRUE or not (FALSE)
- **bf.cyc**: the number of cycles of the backfitting algorithm
- **bf.tol**: the convergence criterion (tolerance level) for the backfitting algorithm
- **bf.trace**: whether to print at each iteration (TRUE or not (FALSE, the default)
- **...**: for extra arguments

Value

A list with the arguments as components

Author(s)

Mikis Stasinopoulos <d.stasinopoulos@londonmet.ac.uk>, Bob Rigby
References

(see also [https://www.gamlss.com/](https://www.gamlss.com/)).

---

`histDist`  
*This function plots the histogram and a fitted (GAMLSS family) distribution to a variable*

Description

This function fits constants to the parameters of a GAMLSS family distribution and then plot the histogram and the fitted distribution.

Usage

`histDist(y, family = NO, freq = NULL, density = FALSE, nbins = 10, xlim = NULL, ylim = NULL, main = NULL, xlab = NULL, ylab = NULL, data = NULL, col.hist = "gray", border.hist = "blue", fg.hist = rainbow(12)[9], line.wd = 2, line.ty = c(1, 2), line.col = c(2, 3), col.main = "blue4", col.lab = "blue4", col.axis = "blue", ...)`
histDist

Arguments

y a vector for the response variable
family a gamlss.family distribution
freq the frequencies of the data in y if exist. freq is used as weights in the gamlss fit
density default value is FALSE. Change to TRUE if you would like a non-parametric density plot together with the parametric fitted distribution plot (for continuous variable only)
nbins The suggested number of bins (argument passed to truehist() of package MASS). Either a positive integer, or a character string naming a rule: "Scott" or "Freedman-Diaconis" or "FD". (Case is ignored.)
xlim the minimum and the maximum x-axis value (if the default values are out of range)
ylim the minimum and the maximum y-axis value (if the default values are out of range)
main the main title for the plot
xlab the label in the x-axis
ylab the label in the y-axis
data the data.frame
col.hist the colour of the histogram or barplot
border.hist the colour of the border of the histogram or barplot
fg.hist the colour of axis in the histogram or barplot
line.wd the line width of the fitted distribution
line.ty the line type of the fitted distribution
line.col the line color of the fitted distribution
col.main the colour for the main title
col.lab the colour of the labels
col.axis the color of the axis
... for extra arguments to be passed to the gamlss function

Details

This function first fits constants for each parameters of a GAMLSS distribution family using the gamlss function and then plots the fitted distribution together with the appropriate plot according to whether the y variable is of a continuous or discrete type. Histogram is plotted for continuous and barplot for discrete variables. The function truehist of Venables and Ripley’s MASS package is used for the histogram plotting.

Value

returns a plot
histSmo

histDist(y,family="NO", ylim=c(0,0.005), data=abdom) # bad fit use PE
histDist(y,family="PE",ymax=0.005, data=abdom, line.col="blue") # discere data counts
# Hand at al. p150 Leptinotarsa decemlineata
y <- c(0,1,2,3,4,6,7,8,10,11)
freq <- c(33,12,5,6,5,2,2,1,2)
histDist(y, "NBI", freq=freq) # the same as
histDist(rep(y,freq), "NBI")
```

histSmo  

**Density estimation using the Poisson trick**

Description

This set of functions use the old Poisson trick of discretising the data and then fitting a Poisson error model to the resulting frequencies (Lindsey, 1997). Here the model fitted is a smooth cubic spline curve. The result is a density estimator for the data.
Usage

```r
histSmo(y, lambda = NULL, df = NULL, order = 3, lower = NULL,
       upper = NULL, type = c(“freq”, “prob”),
       plot = FALSE, breaks = NULL,
       discrete = FALSE, ...)
histSmoC(y, df = 10, lower = NULL, upper = NULL, type = c(“freq”, “prob”),
         plot = FALSE, breaks = NULL,
         discrete = FALSE, ...)
histSmoO(y, lambda = 1, order = 3, lower = NULL, upper = NULL,
         type = c(“freq”, “prob”),
         plot = FALSE, breaks = NULL,
         discrete = FALSE, ...)
histSmoP(y, lambda = NULL, df = NULL, order = 3, lower = NULL,
         upper = NULL, type = c(“freq”, “prob”),
         plot = FALSE, breaks = NULL, discrete = FALSE,
         ...)
```

Arguments

- **y**: the variable of interest
- **lambda**: the smoothing parameter
- **df**: the degrees of freedom
- **order**: the order of the P-spline
- **lower**: the lower limit of the y-variable
- **upper**: the upper limit of the y-variable
- **type**: the type of histogram
- **plot**: whether to plot the resulting density estimator
- **breaks**: the number of break points to be used in the histogram and consequently the number of observations in the Poisson fit
- **discrete**: whether to treat the fitting density as a discrete distribution or not
- **...**: further arguments passed to or from other methods.

Details

Here are the methods used here:

i) The function `histSmoO()` uses Penalised discrete splines (Eilers, 2003). This function is appropriate when the smoothing parameter is fixed.

ii) The function `histSmoC()` uses smooth cubic splines and fits a Poisson error model to the frequencies using the `cs()` additive function of GAMLSS. This function is appropriate if the effective degrees of freedom are fixed in the model.

iii) The function `histSmoP()` uses Penalised cubic splines (Eilers and Marx 1996). It is fitting a Poisson model to the frequencies using the `pb()` additive function of GAMLSS. This function is appropriate if automatic selection of the smoothing parameter is required.

iv) The function `histSmo()` combines all the above functions in the sense that if lambda is fixed it uses `histSmoO()`, if the df’s are fixed it uses code `histSmoC()` and if none of these is specified it uses `histSmoP()`.
Value

Returns a histSmo S3 object. The object has the following components:

- `x` the middle points of the discretise data
- `counts` how many observation are on the discretise intervals
- `density` the density value for each discrete interval
- `hist` the hist object used to discretise the data
- `cdf` The resulting cumulative distribution function useful for calculating probabilities from the estimate density
- `nvcdf` The inverse cumulative distribution function
- `model` The fitted Poisson model only for histSmoP() and histSmoC()

## End(Not run)
Description

The function GAIC() calculates the Generalised Akaike information criterion (GAIC) for a given penalty $k$ for a fitted GAMLSS object.

The function AIC.gamlss() is the method associated with a GAMLSS object of the generic function AIC(). Note that GAIC() is a synonymous of the function AIC.gamlss.

The function IC() is an old version of GAIC().

The function GAIC.table() produces a table with different models as rows and different penalties, $k$, as columns.

The function GAIC.scaled() produces, for a given set of different fitted models or for a table produced by chooseDist(), the scaled Akaike values (see Burnham and Anderson (2002) section 2.9) for a similar concept the GAIC weights. The scaled Akaike should not be interpreted as posterior probabilities of models given the data but for model selection purpose they produce a scaled ranking of the model using their relative importance i.e. from the worst to the best model.

The function extractAIC is the method associated a GAMLSS object of the generic function extractAIC and it is mainly used in the stepAIC function.

The function Rsq compute a generalisation of the R-squared for not normal models.

Usage

IC(object, $k = 2$)
## S3 method for class 'gamlss'
AIC(object, ..., $k = 2$, $c = \text{FALSE}$)
GAIC(object, ..., $k = 2$, $c = \text{FALSE}$)
GAIC.table(object, ..., $k = c(2, 3.84, \text{round}(\log(\text{length}(\text{object}$y$)), 2)),$
\text{text.to.show=\text{NULL}}$
GAIC.scaled(object, ..., $k = 2$, $c = \text{FALSE}$, $\text{plot} = \text{TRUE},$
\text{text.cex = 0.7, which = 1, diff.dev = 1000,}$
\text{text.to.show = \text{NULL, col = \text{NULL, horiz = \text{FALSE}}}$
## S3 method for class 'gamlss'
extractAIC(fit, scale, $k = 2$, $c = \text{FALSE, ...}$)

Arguments

- **object** an gamlss fitted model(s) [or for GAIC.scaled() a table produced by chooseDist()].
- **fit** an gamlss fitted model
- **...** allows several GAMLSS object to be compared using a GAIC
- **k** the penalty with default $k=2.5$
- **c** whether the corrected AIC, i.e. AICc, should be used, note that it applies only when $k=2$
- **scale** this argument is not used in gamlss
- **plot** whether to plot the ranking in GAIC.scaled().
- **text.cex** the size of the models/families in the text of the plot of GAIC.scaled().
- **diff.dev** this argument prevents models with a difference in deviance greater than diff.dev from the ‘best’ model to be considered (or plotted).
which column of GAIC scaled to plot in GAIC.scaled().

text.to.show if NULL, GAIC.scaled() shows the model names otherwise the character in this list

col The colour of the bars in GAIC.scaled()

horiz whether to plot the bars vertically (default) or horizontaly

Value

The function IC() returns the GAIC for given penalty k of the GAMLSS object. The function AIC() returns a matrix contains the df’s and the GAIC’s for given penalty k. The function GAIC() returns identical results to AIC. The function GAIC.table() returns a table which its rows showing different models and its columns different k’s. The function extractAIC() returns vector of length two with the degrees of freedom and the AIC criterion.

A function to fit LMS curves for centile estimation

**Description**

This function is designed to help the user to easily construct growth curve centile estimation. It is applicable when only "one" explanatory variable is available (usually age).

**Usage**

```r
lms(y, x, families = LMS, data = NULL, k = 2,
    cent = c(0.4, 2, 10, 25, 50, 75, 90, 98, 99.6),
    calibration = TRUE, trans.x = FALSE,
    fix.power = NULL, lim.trans = c(0, 1.5),
    prof = FALSE, step = 0.1, legend = FALSE,
    mu.df = NULL, sigma.df = NULL, nu.df = NULL,
    tau.df = NULL, c.crit = 0.01,
    method.pb = c("ML", "GAIC"), ...)
```

**Arguments**

- **y**  The response variable
- **x**  The unique explanatory variable
- **families**  a list of `gamlss` families with default `LMS=c("BCCGo","BCPe","BCTo")`
- **data**  the data frame
- **k**  the penalty to be used in the GAIC
- **cent**  a vector with elements the % centile values for which the centile curves have to be evaluated
- **calibration**  whether calibration is required with default `TRUE`
- **trans.x**  whether to check for transformation in x with default `FALSE`
- **fix.power**  if set it fix the power of the transformation for x
- **lim.trans**  the limits for the search of the power parameter for x
- **prof**  whether to use the profile GAIC of the power transformation
- **step**  if codeprof=TRUE is used this determine the step for the profile GAIC

</tr>
<tr>
<td></td>
<td>extra argument which can be passed to gamlss()</td>
</tr>
</tbody>
</table>

**Details**

This function should be used if the construction of the centile curves involves only one explanatory variable.

The model assumes that the response variable has a flexible distribution i.e. \( y \sim D(\mu, \sigma, \nu, \tau) \) where the parameters of the distribution are smooth functions of the explanatory variable i.e. \( g(\mu) = s(x) \), where \( g() \) is a link function and \( s() \) is a smooth function. Occasionally a power transformation in the x-axis helps the construction of the centile curves. That is, in this case the parameters are modelled by \( x^p \) rather than just \( x \), i.e. \( g(\mu) = s(x^p) \). The function lms() uses P-splines (pb()) as a smoother.

If a transformation is needed for \( x \) the function lms() starts by finding an optimum value for \( p \) using the simple model \( NO(\mu = s(x^p)) \). (Note that this value of \( p \) is not the optimum for the final chosen model but it works well in practice.)

After fitting a Normal error model for staring values the function proceeds by fitting several "appropriate" distributions for the response variable. The set of gamlss.family distributions to fit is specified by the argument families. The default families arguments is LMS=c("BCCGo", "BCPEo", "BCTo") that is the LMS class of distributions, Cole and Green (1992). Note that this class is only appropriate when \( y \) is positive (with no zeros). If the response variable contains negative values and zeros then use the argument families=theSHASH where theSHASH=c("NO", "SHASHo") or add any other list of distributions which you may think is appropriate. Justification of using the specific centile (0.38 2.27 9.12 22.0 25.25, 50, 74.75, 90.88, 97.72, 99.62) is given in Cole (1994).

**Value**

It returns a gamlss fitted object

**Note**

The function is fitting several models and for large data can be slow

m1 <- lms(y=head, x=age, data=db, trans.x=TRUE)

## End(Not run)
```

### lo

*Specify a loess fit in a GAMLSS formula*

**Description**

Allows the user to specify a loess fit within a GAMLSS model. This function is similar to the `lo` function in the `gam` implementation of package `gam` see Chambers and Hastie (1991).

The function `vis.lo()` allows plotting the results.
Usage

lo(formula, control = lo.control(...), ...)
lo.control(span = 0.75, enp.target = NULL,
    degree = 2, parametric = FALSE, drop.square = FALSE,
    normalize = TRUE, family = c("gaussian", "symmetric"),
    method = c("loess", "model.frame"),
    surface = c("interpolate", "direct"),
    statistics = c("approximate", "exact", "none"),
    trace.hat = c("exact", "approximate"),
    cell = 0.2, iterations = 4, iterTrace = FALSE, ...)
vis.lo(obj, se=-1, rug = FALSE, partial.resid = FALSE,
    col.term = "darkred", col.shaded = "gray",
    col.res = "lightblue", col.rug = "gray", lwd.term = 1.5,
    cex.res = 1, pch.res = par("pch"),
    type = c("persp", "contour"), col.surface = "gray",
    nlevels = 30, n.grid = 30, image = TRUE, ...)

Arguments

formula a formula specifying the explanatory variables
control a control to be passed to the loess function
... extra arguments
span the number of observations in a neighbourhood. This is the smoothing parameter
    for a loess fit.
  enp.target an alternative way to specify span, as the approximate equivalent number de-
    grees of freedom to be used. See also the help file of the R function loess. For
    consistency with the older version of lo the effective degrees of freedom df can
    be also specified instead of span, e.g. df=5
  degree the degree of local polynomial; can be 1 or 2. See also the help file of loess
  parametric should any terms be fitted globally rather than locally? See the help file of loess
  drop.square for fits with more than one predictor and degree=2, should the quadratic term be
    dropped for particular predictors?. See also help file of loess
  normalize should the predictors be normalized to a common scale if there is more than
    one? See the help file of loess
  family if "gaussian" fitting is by least-squares, and if "symmetric" a re-descending M
    estimator is used with Tukey's biweight function. See the help file of loess
  method fit the model or just extract the model frame. See the help file of loess
  surface should the fitted surface be computed exactly or via interpolation from a kd tree?
    See also the help file of loess.control
  statistics should the statistics be computed exactly or approximately? See the help file of
    loess.control
  trace.hat should the trace of the smoother matrix be computed exactly or approximately?
    See the help file of loess.control
cell if interpolation is used this controls the accuracy of the approximation via the maximum number of points in a cell in the kd tree. See the help file of loess.control

iterations the number of iterations used in robust fitting. See the help file of loess.control

iterTrace logical (or integer) determining if tracing information during the robust iterations (iterations>= 2) is produced. See the help file of loess.control

obj an lowss object fitted within gamlss

se if se>0 then standard errors surfaces are drawn in the 3-dimensional plot. Set se at the required level i.e se=1.96 will be an approximated 95% CI.

rug whether to plot a rug in the plot partial.resid whether to plot the partial residuals

col.term the colour of the line of fitted term
cex.res the shading of standard
col.shaded the shading of standard error intervals
col.res the colour of partial residuals
col.rug the colour of the rug

lwd.term the width of the line

pch.res The character for the partial residuals
type The type of the plot if the x’s are two dimensional

col.surface the colour of the fitted surface

nlevels the number of levels used in contour() plot.
n.grid The number of points to evaluate the surface

image whether to use image() or just contour

Details

Note that lo itself does no smoothing; it simply sets things up for the function gamlss.lo() which is used by the backfitting function gamlss.add().

Value

a loess object is returned.

Warning

In this version the first argument is a formula NOT a list as in the previous one

Note

Note that lo itself does no smoothing; it simply sets things up for gamlss.lo() to do the backfitting.

Author(s)

Mikis Stasinopoulos <d.stasinopoulos@londonmet.ac.uk>, Bob Rigby. (The original lo() function was based on the Trevor Hastie’s S-plus lo() function. See also the documentation of the loess function for the authorship of the function.)

loglogSurv

Survival function plots for checking the tail behaviour of the data

Description

The log-log Survival functions are design for checking the tails of a single response variable (no explanatory should be involved). There are three different function:

a) the function loglogSurv1() which plot the right tails of the empirical log-log Survival function against loglog(y), where y is the variable of interest. The coefficient of a linear fit to the plot can be used as an estimated for Type I tails (see Chapter 17 in Rigby et al. (2019) for definition of the different types of tails.)
b) the function `loglogSurv2()` which plot the right tails of the empirical log-log Survival function against \( \log(y) \). The coefficient of a linear fit to the plot can be used as an estimated for Type II tails.

c) the function `loglogSurv3()` which plot the (left or right) tails of the empirical log-log Survival function against \( y \). The coefficient of a linear fit to the plot can be used as an estimated for Type III tails.

The function `loglogSurv()` combines all the above functions.

The function `logSurv()` is design for exploring the heavy tails of a single response variable. It plots the empirical log-survival function of the right tail of the distribution or the empirical log-cdf function of the left tail against \( \log(y) \) for a specified probability of the tail. Then fits a linear, a quadratic and an exponential curve to the points of the plot. For distributions defined on the positive real line a good linear fit would indicate a Pareto type tail, a good quadratic fit a log-normal type tail and good exponential fit a Weibull type tail. Note that this function is only appropriate to investigate rather heavy tails and it is not very good to discriminate between different type of tails, as the `loglogSurv()`. The function `logSurv0()` plots but do not fit the curves.

The function `loglogplot()` plot the empirical log-survival function of all data against \( \log(y) \). The function `ECDF()` calculates the empirical commutative distribution function. It is similar to `ecdf()` but divides by \( n+1 \) rather \( n \), the number of conservations.

**Usage**

```r
loglogSurv(y, prob = 0.9, print = TRUE, title = NULL, lcol = gray(0.1),
          ltype = 1, plot = TRUE, ...)  
loglogSurv1(y, prob = 0.9, print = TRUE, title = NULL, lcol = gray(0.1),
            ltype = 1, ...) 
loglogSurv2(y, prob = 0.9, print = TRUE, title = NULL, lcol = gray(0.1),
            ltype = 1, ...) 
loglogSurv3(y, prob = 0.9, print = TRUE, title = NULL, lcol = gray(0.1),
            ltype = 1, ...) 
logSurv(y, prob = 0.9, tail = c("right", "left"), plot = TRUE,
       lines = TRUE, print = TRUE, title = NULL, lcol = c(gray(0.1),
          gray(0.2), gray(0.3)), ltype = c(1, 2, 3), ...) 
logSurv0(y, prob = 0.9, tail = c("right", "left"), plot = TRUE,
          title = NULL, ...) 
ECDF(y, weights=NULL) 
loglogplot(y, nplus1 = TRUE, ...) 
```
Arguments

- `y` a vector, the variable of interest
- `prob` what probability. The default is 0.90 which means 10% for "right" tail 90% for "left" tail
- `tail` which tail needs checking the right (default) of the left
- `plot` whether to plot with default equal TRUE
- `print` whether to print the coefficients with default equal TRUE
- `title` if a different title rather the default is needed
- `lcol` The line colour in the plot
- `lines` whether to plot the fitted lines
- `ltype` The line type in the plot
- `npus1` whether to divide by n+1 or n when calculating the ecdf
- `weights` prior weights for ECDF()
- `...` for extra argument in the plot command

Details

The functions `loglogSurv1()`, `loglogSurv3()` and `loglogSurv3()` take the upper part of an ordered variable, create its empirical survival function, and plot the log-log of this functions against \( \log(\log(y)) \), \( \log(y) \) and \( y \), respectively. Then they fit a line to the plot. The coefficients of the line can be interpreted as parameters determined the behaviour of the tail. The function `loglogSurv()` fits all three models and displays the best.

The function `logSurv()` takes the upper (or lower) part of an ordered variable and plots the log empirical survival function against \( \log(y) \). Also display three curves i) linear ii) quadratic and iii) exponential to determine what kind of tail relationship exist. Plotting the log empirical survival function against \( \log(y) \) often call in the literature the "log-log plot".

The function `loglogplot()` plots the whole log empirical survival function against \( \log(y) \) (not just the tail). The function `ECDF()` calculate the step function of the empirical cumulative distribution function.

More details can be found in Chapter 17 of "Rigby et al. (2019) book an old version on which can be found in [https://www.gamlss.com/](https://www.gamlss.com/)

Value

The functions create plots.

lpred

Extract Linear Predictor Values and Standard Errors For A GAMLSS Model

Description

lpred is the GAMLSS specific method which extracts the linear predictor and its (approximate) standard errors for a specified parameter from a GAMLSS objects. The lpred can be also used to extract the fitted values (with its approximate standard errors) or specific terms in the model (with its approximate standard errors) in the same way that the predict.lm() and predict.glm() functions can be used for lm or glm objects. The function lp extract only the linear predictor. If prediction is required for new data values then use the function predict.gamlss().

References

(see also https://www.gamlss.com/).
Usage

lpred(obj, what = c("mu", "sigma", "nu", "tau"), parameter= NULL,
    type = c("link", "response", "terms"),
    terms = NULL, se.fit = FALSE, ...)
lp(obj, what = c("mu", "sigma", "nu", "tau"), parameter= NULL, ... )

Arguments

obj         a GAMLSS fitted model
what        which distribution parameter is required, default what="mu"
parameter    equivalent to what
type        type="link" (the default) gets the linear predictor for the specified distribution parameter. type="response" gets the fitted values for the parameter while type="terms" gets the fitted terms contribution
terms       if type="terms", which terms to be selected (default is all terms)
se.fit      if TRUE the approximate standard errors of the appropriate type are extracted
...          for extra arguments

Value

If se.fit=FALSE a vector (or a matrix) of the appropriate type is extracted from the GAMLSS object for the given parameter in what. If se.fit=TRUE a list containing the appropriate type, fit, and its (approximate) standard errors, se.fit.

mod.lp
rm(mod, mod.t,mod.lp)

LR.test

Likelihood Ratio test for nested GAMLSS models

Description

The function performs a likelihood ration test for two nested fitted model.

Usage

LR.test(null, alternative, print = TRUE)

Arguments

null The null hypothesis (simpler) fitted model
alternative The alternative hypothesis (more complex) fitted model
print whether to print or save the result

Details

Warning: no checking whether the models are nested is performed.

Value

If print=FALSE a list with chi, df and p.val is produced.

model.frame.gamlss Extract a model.frame, a model matrix or terms from a GAMLSS object for a given distributional parameter

Description
model.frame.gamlss, model.matrix.gamlss and terms.gamlss are the gamlss versions of the generic functions model.frame, model.matrix and terms respectively.

Usage
```r
## S3 method for class 'gamlss'
model.frame(formula, what = c("mu", "sigma", "nu", "tau"),
            parameter= NULL, ...)
## S3 method for class 'gamlss'
terms(x, what = c("mu", "sigma", "nu", "tau"),
       parameter= NULL, ...)
## S3 method for class 'gamlss'
model.matrix(object, what = c("mu", "sigma", "nu", "tau"),
             parameter= NULL, ...)
```

Arguments

- **formula**: a gamlss object
- **x**: a gamlss object
- **object**: a gamlss object
- **what**: for which parameter to extract the model.frame, terms or model.frame
- **parameter**: equivalent to what
- **...**: for extra arguments
numeric.deriv

An internal GAMLSS function for numerical derivatives

Description

A function to calculate numerical derivatives.

Usage

numeric.deriv(expr, theta, delta = NULL, rho = sys.frame(sys.parent()))
Arguments

expr  The expression to be differentiated
theta  A character vector
delta  constant for the accuracy
rho  environment

details

This function is use by several GAMLSS functions but it is not for general use since there are more reliable function to do that in R.

Value

A vector of numerical derivatives

Note

Do not use this function unless you know what you are doing

Author(s)

Mikis Stasinopoulos

References

(see also https://www.gamlss.com/).
par.plot

A function to plot parallel plot for repeated measurement data

Description

This function can be used to plot parallel plots for each individual in a repeated measurement study. It is based on the coplot() function of R.

Usage

par.plot(formula = NULL, data = NULL, subjects = NULL, color = TRUE, show.given = TRUE, ...)

Arguments

formula

a formula describing the form of conditioning plot. A formula of the form y ~ x | a indicates that plots of y versus x should be produced conditional on the variable a. A formula of the form y ~ x | a * b indicates that plots of y versus x should be produced conditional on the two variables a and b.

data

a data frame containing values for any variables in the formula. This argument is compulsory.

subjects

a factor which distinguish between the individual participants

color

whether the parallel plot are shown in colour, color=TRUE (the default) or not color=FALSE

show.given

logical (possibly of length 2 for 2 conditioning variables): should conditioning plots be shown for the corresponding conditioning variables (default 'TRUE')

...

for extra arguments

Value

It returns a plot.

Note

Note that similar plot can be fount in the library nlme by Pinheiro and Bates

Author(s)

Mikis Stasinopoulos <d.stasinopoulos@londonmet.ac.uk>
References

(see also https://www.gamlss.com/).

par.plot(distance~age|Subject,data=Orthodont,subject=Subject,show.given=FALSE)

pcat

Reduction for the Levels of a Factor.

Description

The function is trying to merged similar levels of a given factor. Its based on ideas given by Tutz (2013).

Usage

pcat(fac, df = NULL, lambda = NULL, method = c("ML", "GAIC"), start = 0.001, Lp = 0, kappa = 1e-05, iter = 100, c.crit = 1e-04, k = 2)
gamlss.pcat(x, y, w, xeval = NULL, ...)
plotDF(y, factor = NULL, formula = NULL, data, along = seq(0, nlevels(factor)), kappa = 1e-06, Lp = 0, ...)
plotLambda(y, factor = NULL, formula = NULL, data, along = seq(-2, 2, 0.1), kappa = 1e-06, Lp = 0, ...)
Arguments

- **fac, factor**: a factor to reduce its levels
- **df**: the effective degrees of freedom df
- **lambda**: the smoothing parameter
- **method**: which method is used for the estimation of the smoothing parameter, "ML" or "GAIC" are allowed.
- **start**: starting value for lambda if it estimated using "ML" or "GAIC"
- **Lp**: The type of penalty required, Lp=0 is the default. Use Lp=1 for lasso type and different values for different required penalty.
- **kappa**: a regulation parameters used for the weights in the penalties.
- **iter**: the number of internal iteration allowed
- **c.crit**: the convergent criterion
- **k**: the penalty if "GAIC" method is used.
- **x**: explanatory factor
- **y**: the response or iterative response variable
- **w**: iterative weights
- **xeval**: indicator whether to predict
- **formula**: A formula
- **data**: A data frame
- **along**: a sequence of values
- ... for extra variables

Details

The `pcat()` is used for the fitting of the factor. The function shrinks the levels of the categorical factor (not towards the overall mean as the function `random()` is doing) but towards each other. This results to a reduction of the number if levels of the factors. Different norms can be used for the shrinkage by specifying the argument Lp.

Value

The function `pcat` reruns a vector endowed with a number of attributes. The vector itself is used in the construction of the model matrix, while the attributes are needed for the backfitting algorithms `additive.fit()`. The backfitting is done in `gamlss.pcat`.

Note

Note that `pcat` itself does no smoothing; it simply sets things up for `gamlss.pcat()` to do the smoothing within the backfitting.

levels(getsmo(m1)$factor)
# -----------------------------------------------

## End(Not run)
Plots Probability Distribution Functions for GAMLSS Family

**Description**

A function to plot probability distribution functions (pdf) belonging to the gamlss family of distributions. This function allows either plotting of the fitted distributions for up to eight observations or plotting specified distributions belonging in the gamlss family.

**Usage**

```r
df.plot(obj = NULL, obs = c(1), family = NO(), mu = NULL, sigma = NULL, nu = NULL, tau = NULL, from = 0, to = 10, min = NULL, max = NULL, no.points = 201, no.title = FALSE, col = gray(0.4), y.axis.lim = 1.1, frame.plot = TRUE, ...)
```

**Arguments**

- `obj` An gamlss object e.g. `obj=model1` where `model1` is a fitted gamlss object
- `obs` A number or vector of up to length eight indicating the case numbers of the observations for which fitted distributions are to be displayed, e.g. `obs=c(23,58)` will display the fitted distribution for the 23th and 58th observations
- `family` This must be a gamlss family i.e. `family=NO`
- `mu` The value(s) of the location parameter mu for which the distribution has to be evaluated e.g `mu=c(3,7)`
- `sigma` The value(s) the scale parameter sigma for which the distribution has to be evaluated e.g `sigma=c(3,7)`
- `nu` The value(s) the parameter nu for which the distribution has to be evaluated e.g. `nu=3`
- `tau` The value(s) the parameter tau for which the distribution has be evaluated e.g. `tau=5`
- `from` Minimum value of the random variable y (identical to `min`)
- `to` Maximum value of the random variable y (identical to `max`)
- `min` Minimum value of the random variable y e.g. `min=0`
- `max` Maximum value of y e.g. `max=10`
- `no.points` the number fo point in which the function will be evaluated
- `no.title` Whether you need title in the plot, default is `no.title=FALSE`
- `col` the colot of the lines
- `y.axis.lim` the limits for the y-axis
- `frame.plot` whether to frame the individual plots
- `...` for extra arguments, Note that usuful argument can be `col.axis`, `col.lab`, `cex.axis`, `cex.lab` etc.
Details

This function can be used to plot distributions of the GAMLSS family. If the first argument \texttt{obj} is specified and it is a GAMLSS fitted object, then the fitted distribution of this model at specified observation values (given by the second argument \texttt{obs}) is plotted for a specified y-variable range (arguments \texttt{min}, \texttt{max}, and \texttt{step}).

If the first argument is not given then the \texttt{family} argument has to be specified and the pdf is plotted at specified values of the parameters \texttt{mu}, \texttt{sigma}, \texttt{nu}, \texttt{tau}. Again the range of the y-variable has to be given.

Value

plot(s) of the required pdf(s) are returned

Warning

The range of some distributions depends on the fitted parameters

Note

The range of the y values given by min, max and step are very important in the plot

## End(Not run)

plot.gamlss

Description

This function provides four plots for checking the normalized (randomized for a discrete response distribution) quantile residuals of a fitted GAMLSS object, referred to as residuals below: a plot of residuals against fitted values, a plot of the residuals against an index or a specific explanatory variable, a density plot of the residuals and a normal Q-Q plot of the residuals. If argument ts=TRUE then the first two plots are replaced by the autocorrelation function (ACF) and partial autocorrelation function (PACF) of the residuals.

Usage

## S3 method for class 'gamlss'
plot(x, xvar = NULL, parameters = NULL, ts = FALSE,
     summaries = TRUE, ...)

Arguments

x          a GAMLSS fitted object
xvar       an explanatory variable to plot the residuals against
parameters  plotting parameters can be specified here
ts        set this to TRUE if ACF and PACF plots of the residuals are required
summaries  set this to FALSE if no summary statistics of the residuals are required
...       further arguments passed to or from other methods.

Details

This function provides four plots for checking the normalized (randomized) quantile residuals (called residuals) of a fitted GAMLSS object. Randomization is only performed for discrete response variables. The four plots are:

- residuals against the fitted values (or ACF of the residuals if ts=TRUE)
- residuals against an index or specified x-variable (or PACF of the residuals if ts=TRUE)
plot.gamlss

- kernel density estimate of the residuals
- QQ-normal plot of the residuals

For time series response variables option ts=TRUE can be used to plot the ACF and PACF functions of the residuals.

Value

Returns four plots related to the residuals of the fitted GAMLSS model and prints summary statistics for the residuals if the summary=T

plot2way

Function to plot two interaction in a GAMLSS model

Description
This function is designed to plot a factor to factor interaction in a GAMLSS model.

Usage
plot2way(obj, terms = list(), what = c("mu", "sigma", "nu", "tau"),
          parameter= NULL, show.legend = TRUE, ...)

Arguments
  obj  A gamlss model
  terms this should be a character vector with the names of the two factors to be plotted
  what which parameters? mu, sigma, nu, or tau
  parameter equivalent to what
  show.legend whether to show the legend in the two way plot
  ... Further arguments

Details
This is an experimental function which should be use with prudence since no other check is done on whether this interaction interfere with other terms in the model

Value
The function creates a 2 way interaction plot

Author(s)
Mikis Stasinopoulos

**polyS**

**Auxiliary support for the GAMLSS**

**Description**

These two functions are similar to the `poly` and `polym` in R. Are needed for the `gamlss.lo` function of GAMLSS and should not be used on their own.

**Usage**

```r
polyS(x, ...) poly.matrix(m, degree = 1)
```

**Arguments**

- `x` a variable
- `m` a variable
- `degree` the degree of the polynomial
- `...` for extra arguments
Value

Returns a matrix of orthogonal polynomials

Warning

Not be use by the user

predict.gamlss Extract Predictor Values and Standard Errors For New Data In a GAMLSS Model

Description

predict.gamlss is the GAMLSS specific method which produce predictors for a new data set for a specified parameter from a GAMLSS objects. The predict.gamlss can be used to extract the linear predictors, fitted values and specific terms in the model at new data values in the same way that the predict.lm() and predict.glm() functions can be used for lm or glm objects. Note that linear predictors, fitted values and specific terms in the model at the current data values can also be extracted using the function lpred() (which is called from predict if new data is NULL).
Usage

```r
## S3 method for class 'gamlss'
predict(object, what = c("mu", "sigma", "nu", "tau"),
parameter = NULL,
newdata = NULL, type = c("link", "response", "terms"),
terms = NULL, se.fit = FALSE, data = NULL, ...)
predictAll(object, newdata = NULL, type = c("response", "link", "terms"),
terms = NULL, se.fit = FALSE, use.weights = FALSE,
data = NULL, y.value = "median",
set.to = .Machine$double.xmin,
output = c("list", "matrix"), ...)
```

Arguments

- `object`: a GAMLSS fitted model
- `what`: which distribution parameter is required, default `what="mu"`
- `parameter`: equivalent to `what`
- `newdata`: a data frame containing new values for the explanatory variables used in the model
- `type`: the default, gets the linear predictor for the specified distribution parameter. `type="response"` gets the fitted values for the parameter while `type="terms"` gets the fitted terms contribution
- `terms`: if `type="terms"`, which terms to be selected (default is all terms)
- `se.fit`: if TRUE the approximate standard errors of the appropriate type are extracted if exist
- `use.weights`: if `use.weights=TRUE` the old data and the `newdata` are merged and the model is refitted with weights equal to the prior weights for the old data observation and equal to a very small value (see option `set.to`) for the `newdata` values. This trick allows to obtain standard errors for all parameters
- `data`: the data frame used in the original fit if is not defined in the call
- `y.value`: how to get the response values for the `newdata` if they do not exist. The default is taking the median, `y.value="median"`. Other function like "max", "min" are allowed. Also numerical values.
- `set.to`: what values the weights for the `newdata` should take
- `output`: whether the output to be a 'list' (default) or a 'matrix'

Details

The predict function assumes that the object given in `newdata` is a data frame containing the right x-variables used in the model. This could possible cause problems if transformed variables are used in the fitting of the original model. For example, let us assume that a transformation of age is needed in the model i.e. `nage<-age^.5`. This could be fitted as `mod<-gamlss(y~cs(age^.5), data=mydata)` or as `nage<-age^.5; mod<-gamlss(y~cs(nage), data=mydata)`. The later could more efficient if the data are in thousands rather in hundreds. In the first case, the code `predict(mod, newdata=data.frame(age=c(34,56)))`
would produce the right results. In the second case a new data frame has to be created containing the old data plus any new transform data. This data frame has to be declared in the data option. The option newdata should contain a data.frame with the new names and the transformed values in which prediction is required, (see the last example).

Value

A vector or a matrix depending on the options.

Note

This function is under development

print.gamlss  
Prints a GAMLSS fitted model

Description

print.gamlss is the GAMLSS specific method for the generic function print which prints objects returned by modelling functions.

Usage

## S3 method for class 'gamlss'
print(x, digits = max(3, getOption("digits") - 3), ...)

Arguments

x  
a GAMLSS fitted model
digits  
the number of significant digits to use when printing
...  
for extra arguments

Value

Prints a gamlss object

Plotting the Profile Deviance for one of the Parameters in a GAMLSS model

Description

This functions plots the profile deviance of one of the (four) parameters in a GAMLSS model. It can be used if one of the parameters mu, sigma, nu or tau is a constant (not a function of explanatory variables) to obtain a profile confidence intervals.

Usage

prof.dev(object, which = NULL, min = NULL, max = NULL, step = NULL, length = 7, startlastfit = TRUE, plot = TRUE, perc = 95, col="darkgreen")

Arguments

  object       A fitted GAMLSS model
  which        which parameter to get the profile deviance e.g. which="tau"
  min          the minimum value for the parameter e.g. min=1
  max          the maximum value for the parameter e.g. max=20
  step         how often to evaluate the global deviance (defines the step length of the grid for the parameter) e.g. step=1
  length       the length if step is not set, default equal 7
  startlastfit whether to start fitting from the last fit or not, default value is startlastfit=TRUE
  plot         whether to plot, plot=TRUE or save the results, plot=FALSE
  perc         what % confidence interval is required
  col          The colour of the profile line
Details

This function can be used to provide likelihood based confidence intervals for a parameter for which a constant model (i.e. no explanatory model) is fitted and consequently for checking the adequacy of a particular values of the parameter. This can be used to check the adequacy of one distribution (e.g. Box-Cox Cole and Green) nested within another (e.g. Box-Cox power exponential). For example one can test whether a Box-Cox Cole and Green (Box-Cox-normal) distribution or a Box-Cox power exponential is appropriate by plotting the profile of the parameter \( \tau \). A profile deviance showing support for \( \tau=2 \) indicates adequacy of the Box-Cox Cole and Green (i.e. Box-Cox normal) distribution.

Value

Return a profile plot (if the argument plot=TRUE) and an \texttt{ProfLikelihood.gamlss} object if saved. The object contains:

- \texttt{values} the values at the grid where the parameter was evaluated
- \texttt{fun} the function which approximates the points using splines
- \texttt{min} the minimum values in the grid
- \texttt{max} the maximum values in the grid
- \texttt{max.value} the value of the parameter maximising the Profile deviance (or GAIC)
- \texttt{CI} the profile confidence interval (if global deviance is used)
- \texttt{criterion} which criterion was used

Warning

A dense grid (i.e. small step) evaluation of the global deviance can take a long time, so start with a sparse grid (i.e. large step) and decrease gradually the step length for more accuracy.

prof.term

Plotting the Profile: deviance or information criterion for one of the terms (or hyper-parameters) in a GAMLSS model

Description

This functions plots the profile deviance for a chosen parameter included in the linear predictor of any of the mu, sigma, nu or tau models so profile confidence intervals can be obtained. In can also be used to plot the profile of a specified information criterion for any hyper-parameter when smooth additive terms are used.

Usage

prof.term(model = NULL, criterion = c("GD", "GAIC"), penalty = 2.5,
other = NULL, min = NULL, max = NULL, step = NULL,
length = 7, xlabel = NULL, plot = TRUE, perc = 95,
start.prev = TRUE, col="darkgreen")

Arguments

model this is a GAMLSS model, e.g.
model=gamlss(y~cs(x,df=this),sigma.fo=~cs(x,df=3),data=abdom). where
this indicates the (hyper)parameter to be profiled
criterion whether global deviance ("GD") or information criterion ("GAIC") is profiled. The default is global deviance criterion="GD"
penalty The penalty value if information criterion is used in criterion, default penalty=2.5
other this can be used to evaluate an expression before the actual fitting of the model (Make sure that those expressions are well define in the global environment)
min the minimum value for the parameter e.g. min=1
max the maximum value for the parameter e.g. max=20
step how often to evaluate the global deviance (defines the step length of the grid for the parameter) e.g. step=1
length  if the step is left NULL then length is considered for evaluating the grid for the parameter. It has a default value of 11
xlabel  if a label for the axis is required
plot  whether to plot, plot=TRUE the resulting profile deviance (or GAIC)
perc  what % confidence interval is required
start.prev  whether to start from the previous fitted model parameters values or not (default is TRUE)
col  the color of the profile line

Details
This function can be use to provide likelihood based confidence intervals for a parameter involved in terms in the linear predictor(s). These confidence intervals are more accurate than the ones obtained from the parameters’ standard errors. The function can also be used to plot a profile information criterion (with a given penalty) against a hyper-parameter. This can be used to check the uniqueness in hyper-parameter determination using for example find.df.

Value
Return a profile plot (if the argument plot=TRUE) and an ProfLikelihood.gamlss object if saved. The object contains:

values  the values at the grid where the parameter was evaluated
fun  the function which approximates the points using splines
min  the minimum values in the grid
max  the maximum values in the grid
max.value  the value of the parameter maximising the Profile deviance (or GAIC)
CI  the profile confidence interval (if global deviance is used)
criterion  which criterion was used

Warning
A dense grid (i.e. small step) evaluation of the global deviance can take a long time, so start with a sparse grid (i.e. large step) and decrease gradually the step length for more accuracy.

**P-Splines Fits in a GAMLSS Formula**

Description

There are several function which use P-spline methodology:

a) pb(), the current version of P-splines which uses SVD in the fitting and therefore is the most reliable

b) pbo() and pbp(), older versions of P-splines. The first uses a simple matrix algebra in the fits. The second is the last version of pb() with SVD but uses different method for prediction.

c) pbc() the new version of cycle P-splines (using SVD)

d) cy() the older version of cycle P-splines.

e) pbm() for fitting monotonic P-splines (using SVD)

f) pbz() for fitting P-splines which allow the fitted curve to shrink to zero degrees of freedom

g) ps() the original P-splines with no facility of estimating the smoothing parameters and

j) pvc() penalised varying coefficient models.

k) pvp() older version of pb() where the prediction was different (it is here in case someone would like to compare the results).
Theoretical explanation of the above P-splines can be found in Eilers et al. (2016)

The functions take a vector and return it with several attributes. The vector is used in the construction of the design matrix $X$ used in the fitting. The functions do not do the smoothing, but assign the attributes to the vector to aid gamlss in the smoothing. The functions doing the smoothing are `gamlss.pb()`, `gamlss.pbo()`, `gamlss.pbc()` `gamlss.cy()` `gamlss.pvc()`, `gamlss.pbm()`, `gamlss.pbz` and `gamlss.ps()` which are used in the backfitting function `additive.fit`.

The function `pb()` is more efficient and faster than the original penalised smoothing function `ps()`. After December 2014 the `pb()` function has changed radically to improved performance. The older version of the `pb()` function is called now `pbo()`. `pb()` allows the estimation of the smoothing parameters using different local (performance iterations) methods. The method are "ML", "ML-1", "EM", "GAIC" and "GCV".

The function `pbo()` fits monotonic smooth functions, that is functions which increase or decrease monotonically depending on the value of the argument `mono` which takes the values "up" or "down".

The function `pbz()` is similar to `pb()` with the extra property that when lambda becomes very large the resulting smooth function goes to a constant rather than to a linear function. This is very useful for model selection. The function is based on Maria Durban idea of using a double penalty, one of order 2 and one of order 1. The second penalty only applies if the effective df are close to 2 (that is if a linear is already selected).

The function `pbc()` fits a cycle penalised beta regression spline such as the last fitted value of the smoother is equal to the first fitted value. `cy()` is the older version.

The function `pvc()` fits varying coefficient models see Hastie and Tibshirani(1993) and it is more general and flexible than the old `vc()` function which was based on cubic splines.

The function `getZmatrix()` creates a (random effect) design matrix $Z$ which can be used to fit a P-splines smoother using the `re()` function. (The `re()` is an interface with the random effect function `lme` of the package `nlme`.

**Usage**

```r
pb(x, df = NULL, lambda = NULL, max.df=NULL, 
    control = pb.control(...), ...) 
pbo(x, df = NULL, lambda = NULL, control = pbo.control(...), ...) 
ppb(x, df = NULL, lambda = NULL, control = ppb.control(...), ...) 
pbo.control(inter = 20, degree = 3, order = 2, start = 10, quantiles = FALSE, 
    method = c("ML", "GAIC", "GCV", "EM", "ML-1"), k = 2, ...) 
pb.control(inter = 20, degree = 3, order = 2, start = 10, quantiles = FALSE, 
    method = c("ML", "GAIC", "GCV"), k = 2, ...) 
ppb.control(inter = 20, degree = 3, order = 2, start = 10, quantiles = FALSE, 
    method = c("ML", "GAIC", "GCV"), k = 2, ...) 
pbc(x, df = NULL, lambda = NULL, max.df=NULL, 
    control = pbc.control(...), ...) 
pbc.control(inter = 20, degree = 3, order = 2, start = 10, 
    method = c("ML", "GAIC", "GCV"), k = 2, sin = TRUE, ...) 
cy(x, df = NULL, lambda = NULL, control = cy.control(...), ...) 
cy.control(inter = 20, degree = 3, order = 2, start = 10, 
    method = c("ML", "GAIC", "GCV", "EM", "ML-1"), k = 2, ts=FALSE, ...) 
pvc(x, df = NULL, lambda = NULL, by = NULL, control = pvc.control(...), ...) 
pvc.control(inter = 20, degree = 3, order = 2, start = 10, quantiles = FALSE, 
```
method = c("ML", "GAIC", "GCV"), k = 2, ...) 
ps(x, df = NULL, lambda = NULL, mono=c("up", "down"),
control = pbm.control(...), ...)

pbm(x, df = NULL, lambda = NULL, mono=c("up", "down"),
control = pbm.control(...), ...)

pbm.control(inter = 20, degree = 3, order = 2, start = 10, quantiles = FALSE,
method=c("ML", "GAIC", "GCV"), k=2, kappa = 1e10, ...)

pbz(x, df = NULL, lambda = NULL, control = pbz.control(...), ...)

pbz.control(inter = 20, degree = 3, order = 2, start = c(1e-04, 1e-04),
quantiles = FALSE, method = c("ML", "GAIC", "GCV"), k = 2, lim = 3, ...)

ps(x, df = 3, lambda = NULL, ps.intervals = 20, degree = 3, order = 3)

getzmatrix(x, xmin = NULL, xmax = NULL, inter = 20, degree = 3, order = 3)

Arguments

x the univariate predictor
df the desired equivalent number of degrees of freedom (trace of the smoother matrix minus two for the constant and linear fit)
lambda the smoothing parameter
max.df the limit of how large the effective degrees of freedom should be allowed to be
control setting the control parameters
by a factor, for fitting different smoothing curves to each level of the factor or a continuous explanatory variable in which case the coefficients of the by variable change smoothly according to x i.e. beta(x)*z where z is the by variable.

... for extra arguments
inter the no of break points (knots) in the x-axis
degree the degree of the piecewise polynomial
order the required difference in the vector of coefficients
start the lambda starting value if the local methods are used, see below
quantiles if TRUE the quantile values of x are use to determine the knots
ts if TRUE assumes that it is a seasonal factor
method The method used in the (local) performance iterations. Available methods are "ML", "ML-1", "EM", "GAIC" and "GCV"
k the penalty used in "GAIC" and "GCV"
mono for monotonic P-splines whether going "up" or "down"
kappa the smoothing hyper-parameter for the monotonic part of smoothing
ps.intervals the no of break points in the x-axis
xmin minimum value for creating the B-spline
xmax maximum value for creating the B-spline
sin whether to use the sin penalty or not
lim at which level the second penalty of order 1 should start
Details

The `ps()` function is based on Brian Marx function which can be found in his website. The `pb()`, `cy()`, `pvc()` and `pbm()` functions are based on Paul Eilers's original R functions. Note that `ps()` and `pb()` functions behave differently at their default values if `df` and `lambda` are not specified. `ps(x)` by default uses 3 extra degrees of freedom for smoothing `x`. `pb(x)` by default estimates lambda (and therefore the degrees of freedom) automatically using a "local" method. The local (or performance iterations) methods available are: (i) local Maximum Likelihood, "ML", (ii) local Generalized Akaike information criterion, "GAIC", (iii) local Generalized Cross validation "GCV" (iv) local EM-algorithm, "EM" (which is very slow) and (v) a modified version of the ML, "ML-1" which produce identical results with "EM" but faster.

The function `pb()` fits a P-spline smoother.

The function `pbm()` fits a monotonic (going up or down) P-spline smoother.

The function `pbc()` fits a P-spline smoother where the beginning and end are the same.

The `pvc()` fits a varying coefficient model.

Note that the local (or performance iterations) methods can occasionally make the convergence of gamlss less stable compared to models where the degrees of freedom are fixed.

Value

the vector `x` is returned, endowed with a number of attributes. The vector itself is used in the construction of the model matrix, while the attributes are needed for the backfitting algorithms `additive.fit()`.

Warning

There are occasions where the automatic local methods do not work. One accusation which came to our attention is when the range of the response variable values is very large. Scaling the response variable will solve the problem.

Q.stats

A function to calculate the Q-statistics

Description

This function calculates and prints the Q-statistics (or Z-statistics) which are useful to test normality of the residuals within a range of an independent variable, for example age in centile estimation, see Royston and Wright (2000).

Usage

Q.stats(obj = NULL, xvar = NULL, resid = NULL, xcut.points = NULL, n.inter = 10, zvals = TRUE, save = TRUE, plot = TRUE, digits.xvar = getOption("digits"), ...)

Arguments

obj a GAMLSS object
xvar a unique explanatory variable
resid quantile or standardised residuals can be given here instead of a GAMLSS object in obj. In this case the function behaves differently (see details below)
xcut.points the x-axis cut off points e.g. c(20,30). If xcut.points=NULL then the n.inter argument is activated
n.inter if xcut.points=NULL this argument gives the number of intervals in which the x-variable will be split, with default 10
zvals if TRUE the output matrix contains the individual Z-statistics rather that the Q statistics
save whether to save the Q-statistics or not with default equal to TRUE. In this case the functions produce a matrix giving individual Q (or z) statistics and the final aggregate Q’s
plot whether to plot a visual version of the Q statistics (default is TRUE)
digits.xvar to control the number of digits of the xvar in the plot
... for extra arguments
Details

Note that the function Q.stats behaves differently depending whether the obj or the resid argument is set. The obj argument produces the Q-statistics (or Z-statistics) table appropriate for centile estimation (therefore it expect a reasonable large number of observations). The argument resid allows any model residuals, (not necessary GAMLSS), suitable standardised and is appropriate for any size of data. The resulting table contains only the individuals Z-statistics.

Value

A table containing the Q-statistics or Z-statistics. If plot=TRUE it produces also an graphical representation of the table.

quantSheets

**Quantile Sheets**

**Description**

The quantile sheets function quantSheets() is based on the work of Sabine Schnabe and Paul Eiler (see references below). The estimation of the quantile curves is done simultaneously by also smoothing in the direction of y as well as x. This avoids (but do not eliminate completely) the problem of crossing quantiles.

**Usage**

```r
quantSheets(y, x, x.lambda = 1, p.lambda = 1, data = NULL,
            cent = 100 * pnorm((-4:4) * 2/3),
            control = quantSheets.control(...), print = TRUE, ...)
```

```r
quantSheets.control(x.inter = 10, p.inter = 10, degree = 3, logit = FALSE,
                     order = 2, kappa = 0, n.cyc = 100, c.crit = 1e-05, plot = TRUE,
                     power = NULL, ...)
```

```r
findPower(y, x, data = NULL, lim.trans = c(0, 1.5), prof = FALSE,
          k = 2, c.crit = 0.01, step = 0.1)
```

```r
z.scoresQS(object, y, x, plot = FALSE, tol = NULL)
```

**Arguments**

- **y**: the y variable
- **x**: the x variable
- **x.lambda**: smoothing parameter in the direction of x
- **p.lambda**: smoothing parameter in the direction of y (probabilities)
- **data**: the data frame
- **cent**: the centile values where the quantile sheets is evaluated
- **control**: for the parameters controlling the algorithm
- **print**: whether to print the sample percentages
- **x.inter**: number of intervals in the x direction for the B-splines
- **p.inter**: number of intervals in the probabilities (y-direction) for the B-splines
- **degree**: the degree for the B-splines
- **logit**: whether to use logit(p) instead of p (probabilities) for the y-axis
- **order**: the order of the penalty
- **kappa**: is a ridge parameter set to zero (for no ridge effect)
- **n.cyc**: number of cycles of the algorithm
c.crit  convergence criterion of the algorithm
plot    whether to plot the resulting quantile sheets
power   The value of the power transformation in the x axis if needed
lim.trans the limits for looking for the power transformation parameter using findPower()
prof    whether to use the profile GAIC or optim() to the parameter the power transformation
k       the GAIC penalty
step    the steps for the profile GAIC if the argument prof of findPower() is TRUE
object  a fitted quantSheets object
tol     how far out from the range of the y variable should go for estimating the distribution of y using the flexDist() function
...     for further arguments

Details

The advantage of quantile sheets is that they estimates simultaneously all the quantiles. This almost eliminates the problem of crossing quantiles. The method is very fast and useful for exploratory tool. The function needs two smoothing parameters. Those two parameters have to specified by the user. They are not estimated automatically. They can be selected by visual inspection.

The disadvantages of quantile sheets comes from the fact that like all non-parametric techniques do not have a goodness of fit measure to change how good is the models and the residuals based diagnostics are not existence since it is difficult to define residuals in this set up.

In this implementation we do provide residuals by using the flexDist() function from package gamlss.dist. This is based on the idea that by knowing the quantiles of the distribution we can reconstruct non parametrically the distribution itself and this is what flexDist() is doing. As a word of caution, such a construct is based on several assumptions and depends on several smoothing parameters. Treat those residuals with caution. The same caution should apply to the function z.scoresQS().

Value

Using the function quantSheets() a quantSheets object is returned having the following methods: print(), fitted(), predict() and resid().
Using findPower() a single values of the power parameter is returned.
Using z.scoresQS a vector of z-scores is returned.

data(abdom)
ml <- quantSheets(y,x, data=abdom)
head(fitted(ml))
p1 <- predict(ml, newdata=c(20,30,40))
matpoints(c(20,30,40), p1)
z.scoresQS(ml,y=c(150, 300),x=c(20, 30) )
# If we needed a power transformation not appropriate for this data
findPower(y,x, data=abdom)
```

random

Specify a random intercept model in a GAMLSS formula

Description

They are two functions for fitting random effects within a GAMLSS model, `random()` and `re()`.

The function `random()` is based on the original `random()` function of Trevor Hastie in the package `gam`. In our version the function has been modified to allow a "local" maximum likelihood estimation of the smoothing parameter `lambda`. This method is equivalent to the PQL method of Breslow and Clayton (1993) applied at the local iterations of the algorithm. In fact for a GLM model and a simple random effect it is equivalent to `glmmPQL()` function in the package `MASS` see Venables and Ripley (2002). Venables and Ripley (2002) claimed that this iterative method was first introduced by Schall (1991). Note that in order for the "local" maximum likelihood estimation procedure to operate both argument `df` and `lambda` has to be `NULL`.

The function `re()` is an interface for calling the `lme()` function of the package `nlme`. This gives the user the ability to fit complicated random effect models while the assumption of the normal distribution for the response variable is relaxed. The theoretical justification comes again from the fact that this is a PQL method, Breslow and Clayton (1993).
Usage

random(x, df = NULL, lambda = NULL, start=10)

re(fixed = ~1, random = NULL, correlation = NULL, method = "ML",
level = NULL, ...)

Arguments

x a factor

df the target degrees of freedom

lambda the smoothing parameter lambda which can be viewed as a shrinkage parameter.

start starting value for lambda if local Maximul likelihood is used.

fixed a formula specify the fixed effects of the lme() model. This, in most cases can be also included in the gamlss parameter formula

random a formula or list specufying the random effect part of the model as in lme() function

correlation the correlation structure of the lme() model

method which method,"ML" (the default), or "REML"

level this argument has to be set to zero (0) if when use predict() you want to get the marginal contribution

... this can be used to pass arguments for lmeControl()

Details

The function random() can be seen as a smoother for use with factors in gamlss(). It allows the fitted values for a factor predictor to be shrunk towards the overall mean, where the amount of shrinking depends either on lambda, or on the equivalent degrees of freedom or on the estimated sigma parameter (default). Similar in spirit to smoothing splines, this fitting method can be justified on Bayesian grounds or by a random effects model. Note that the behavior of the function is different from the original Hastie function. Here the function behaves as follows: i) if both df and lambda are NULL then the PQL method is used ii) if lambda is not NULL, lambda is used for fitting iii) if lambda is NULL and df is not NULL then df is used for fitting.

Since factors are coded by model.matrix() into a set of contrasts, care has been taken to add an appropriate "contrast" attribute to the output of random(). This zero contrast results in a column of zeros in the model matrix, which is aliased with any column and is hence ignored.

The use of the function re() requires knowledge of the use of the function lme() of the package nlme for the specification of the appropriate random effect model. Some care should betaken whether the data set is

Value

x is returned with class "smooth", with an attribute named "call" which is to be evaluated in the backfitting additive.fit() called by gamlss()

refit

Refit a GAMLSS model

Description
This function refits a GAMLSS model. It is useful when the algorithm has not converged after 20 outer iteration (the default value)

Usage
refit(object, ...)

Arguments
- object: a GAMLSS fitted model which has not converged
- ...: for extra arguments

Details
This function is useful when the iterations have reached the maximum value set by the code(n.cyc) of the gamlss.control function and the model has not converged yet

Value
Returns a GAMLSS fitted model

Note
The function update does a very similar job

**residuals.gamlss** | *Extract Residuals from GAMLSS model*

**Description**

`residuals.gamlss` is the GAMLSS specific method for the generic function `residuals` which extracts the residuals for a fitted model. The abbreviated form `resid` is an alias for `residuals`.

**Usage**

```r
## S3 method for class 'gamlss'
residuals(object, what = c("z-scores", "mu", "sigma", "nu", "tau"),
type = c("simple", "weighted", "partial"),
terms=NULL, ...)
```

**Arguments**

- `object` a GAMLSS fitted model
- `what` specify whether the standardized residuals are required, called here the "z-scores", or residuals for a specific parameter
- `type` the type of residual if residuals for a parameter are required
- `terms` if type is "partial" this specifies which term is required
- `...` for extra arguments

**Details**

The "z-scores" residuals saved in a GAMLSS object are the normalized (randomized) quantile residuals (see Dunn and Smyth, 1996). Randomization is only needed for the discrete family distributions, see also `rqres.plot`. Residuals for a specific parameter can be "simple" = (working variable - linear predictor), "weighted" = sqrt(working weights)*(working variable - linear predictor) or "partial" = (working variable - linear predictor)+contribution of specific terms.
Value

a vector or a matrix of the appropriate residuals of a GAMLSS model. Note that when weights are used in the fitting the length of the residuals can be different from $N$ the length of the fitted values. Observations with weights equal to zero are not appearing in the residuals. Also observations with frequencies as weights will appear more than once according to their frequencies.

Note

The "weighted" residuals of a specified parameter can be zero and one if the square of first derivative have been used in the fitting of this parameter

plot(aids$x,resid(h))
plot(aids$x,resid(h,"sigma") )
rm(h)
Specify ridge or lasso Regression within a GAMLSS Formula

Description

The function ri() allow the user to fit a ridge regression within GAMLSS. It allows the coefficients of a set of explanatory variables to be shrunk towards zero. The amount of shrinking depends either on lambda, or on the equivalent degrees of freedom (df). The type of shrinking depends on the argument Lp see example.

Usage

```r
ri(X = NULL, x.vars = NULL, df = NULL, lambda = NULL,
   method = c("ML", "GAIC"), order = 0, start = 10, Lp = 2,
   kappa = 1e-05, iter = 100, c.crit = 1e-06, k = 2)
```

Arguments

- **X**: A matrix of explanatory variables which is standardised (mean=0, sd=1) automatically. Note that in order to get predictions you should use the option x.vars which variables from the data.frame declared in data needs to be included.
- **x.vars**: A vector of character strings giving the names of the columns of x that should be included in the model.
- **df**: the effective degrees of freedom df
- **lambda**: the smoothing parameter lambda
- **method**: which method is used for the estimation of the smoothing parameter, ‘ML’ or ‘GAIC’ are allowed.
- **order**: the order of the difference applied to the coefficients with default zero. (Do not change this unless there is some ordering in the explanatory variables).
- **start**: starting value for lambda if it estimated using ‘ML’ or ‘GAIC’
- **Lp**: The type of penalty required, Lp=2 a proper ridge regression is the default. Use codeLp=1 for lasso and different values for different penalties.
- **kappa**: a regulation parameters used for the weights in the penalties.
- **iter**: the number of internal iteration allowed see details.
- **c.crit**: c.crit is the convergent criterion
- **k**: k is the penalty if ‘GAIC’ method is used.

Details

This implementation of ridge and related regressions is based on an idea of Paul Eilers which used weights in the penalty matrix. The type of weights are defined by the argument Lp. Lp=2 is the standard ridge regression. Lp=1 fits a lasso regression while Lp=0 allows a "best subset" regression see Hastie et al (2009) page 71.
Value

x is returned with class "smooth", with an attribute named "call" which is to be evaluated in the backfitting additive.fit() called by gamlss()

            data=usair)
# lasso
m2<- gamlss(y~ri(x.vars=c("x1","x2","x3","x4","x5","x6"), Lp=1),
            data=usair)
# best subset
m3<- gamlss(y~ri(x.vars=c("x1","x2","x3","x4","x5","x6"), Lp=0),
            data=usair)
#------- plotting the coefficients
op <- par(mfrow=c(3,1))
plot(getSmo(m1)) #
plot(getSmo(m2))
plot(getSmo(m3))
par(op)
Description

This function plots worm plots, van Buuren and Fredriks M. (2001), or QQ-plots of the normalized randomized quantile residuals (Dunn and Smyth, 1996) for a model using a discrete GAMLSS family distribution.

Usage

rqres.plot(obj = NULL, howmany = 6, plot.type = c("few", "all"),
          type = c("wp", "QQ"), xlim = NULL, ylim = NULL, ...)
get.rqres(obj = NULL, howmany = 10, order = FALSE)

Arguments

obj a fitted GAMLSS model object from a "discrete" type of family
howmany The number randomise quantile residuals required i.e. howmany=6
plot.type whether to plot few of the randomised quantile residual realisations, "few" in
          a separate plots (there must be less than 8) or all "all" in one plot (with their
          median)
type whether to plot worm plots "wp"or QQ plots "QQ" with default worm plots
xlim setting manually the xlim of the graph
ylim setting manually the ylim of the graph
order whether to order the ealization of randomised quantile residuals
... for extra arguments to be passed to wp()

Details

For discrete family distributions, the `gamlss()` function saves on exit one realization of randomized quantile residuals which can be plotted using the generic function `plot()` which calls the `plot.gamlss`. Looking at only one realization can be misleading, so the current function creates QQ-plots for several realizations. The function allows up to 10 QQ-plots to be plotted. Occasionally one wishes to create a lot of realizations and then take a median of them (separately for each ordered value) to create a single median realization. The option all in combinations with the option howmany creates a QQ-plot of the medians of the normalized randomized quantile residuals. These 'median' randomized quantile residuals can be saved using the option (save=TRUE).

Value

If save it is TRUE then the vector of the median residuals is saved.

### Rsq

**Generalised (Pseudo) R-squared for GAMLSS models**

**Description**

This function gives the generalised R-squared of Nagelkerke (1991) for a GAMLSS model.

**Usage**

```r
Rsq(object, type = c("Cox Snell", "Cragg Uhler", "both"))
```
Arguments

object  a GAMLSS object
type    which definition of R squared. Can be the “Cox Snell” or the Nagelkerke, ”Cragg Uhler” or ”both”.

Details

The Rsq() function uses the definition for R-squared:

\[ R^2 = 1 - \left( \frac{L(0)}{L(\hat{\theta})} \right)^{2/n} \]

where \( L(0) \) is the null model (only a constant is fitted to all parameters) and \( L(\hat{\theta}) \) is the current fitted model. This definition sometimes is referred to as the Cox & Snell R-squared. The Nagelkerke/Cragg & Uhler’s definition divides the above with

\[ 1 - L(0)^{2/n} \]

Value

The Rsq() produces a single value if type=”Cox Snell” or ”Cragg Uhler” and a list if type=”both”.

Note

The null model is fitted using the function gamlssML() which can create warning messages

**rvcov**

Robust Variance-Covariance matrix of the parameters from a fitted GAMLSS model

---

**Description**

The function `rvcov()` is designed for providing robust standard errors for the parameters estimates of a GAMLSS fitted model. The same result can be achieved by using `vcov(fitted_model, robust=TRUE)`. The function `get.()` gets the $K$ matrix (see details below).

**Usage**

```r
rvcov(object, type = c("vcov", "cor", "se", "coef", "all"),
      hessian.fun = c("R", "PB") )
get.K(object, what = c("K", "Deriv"))
```

**Arguments**

- `object` a GAMLSS fitted object
- `type` this argument for `rvcov()` function whether variance-covariance matrix, correlation matrix, standard errors or all of them
- `what` this an argument for the function `get.K()` allowing to get either $K$ or the first derivative of the likelihood with respect to the parameters (the $\beta$'s in the GAMLSS notation).
- `hessian.fun` How to obtain numerically the Hessian i) using `optimHess()`, option "R" ii) using a function by Pinheiro and Bates taken from package nlme, option "PB".

**Details**

The robust standard errors are calculated for the robust sandwich estimator of the variance-covariance given by $S = V K V$ where $V$ is the standard variance-covariance matrix (the inverse of the information matrix) and $K$ is an estimate of the variance of he first derivatives of he likelihood. The function `get.K()` is use the get the required $K$ matrix.

**Value**

A variance covariance matrix or other relevant output

**stepGAIC**

Choose a model by GAIC in a Stepwise Algorithm

**Description**

The function `stepGAIC()` performs stepwise model selection using a Generalized Akaike Information Criterion (GAIC). It is based on the function `stepAIC()` given in the library MASS of Venables and Ripley (2002). The function has been changed recently to allow parallel computation. The parallel computations are similar to the ones performed in the function `boot()` of the boot package.
Note that since version 4.3-5 of `gamlss` the `stepGAIC()` do not have the option of using the function `stepGAIC.CH` through the argument `additive`.

Note that `stepGAIC()` is relying to the `dropterm()` and `addterm()` methods applied to `gamlss` objects. `drop1()` and `add1()` are equivalent methods to the `dropterm()` and `addterm()` respectively but with different default arguments (see the examples).

The function `stepGAIC.VR()` is the old version of `stepGAIC()` with no parallel computations.

The function `stepGAIC.CH()` is based on the R function `step.gam()` (see Chambers and Hastie (1991)) and it is more suited for model with smoothing additive terms when the degrees of freedom for smoothing are fixed in advance. This is something which rarely used these days, as most of the smoothing functions allow the calculations of the smoothing parameter, see for example the additive function `pb()`.

The functions `stepGAIC.VR()` and `stepGAIC.CH()` have been adapted to work with `gamlss` objects and the main difference is the scope argument, see below.

While the functions `stepGAIC()` is used to build models for individual parameters of the distribution of the response variable, the functions `stepGAICAll.A()` and `stepGAICAll.A()` are building models for all the parameters.

The functions `stepGAICAll.A()` and `stepGAICAll.B()` are based on the `stepGAIC()` function but use different strategies for selecting a appropriate final model.

`stepGAICAll.A()` has the following strategy:

**Strategy A:**

i) build a model for `mu` using a forward approach.

ii) given the model for `mu` build a model for `sigma` (forward)

iii) given the models for `mu` and `sigma` build a model for `nu` (forward)

iv) given the models for `mu`, `sigma` and `nu` build a model for `tau` (forward)

v) given the models for `mu`, `sigma`, `nu` and `tau` check whether the terms for `nu` are needed using backward elimination.

vi) given the models for `mu`, `sigma`, `nu` and `tau` check whether the terms for `sigma` are needed (backward).

vii) given the models for `mu`, `sigma`, `nu` and `tau` check whether the terms for `mu` are needed (backward).

Note for this strategy to work the scope argument should be set appropriately.

`stepGAICAll.B()` uses the same procedure as the function `stepGAIC()` but each term in the scope is fitted to all the parameters of the distribution, rather than the one specified by the argument what of `stepGAIC()`. The `stepGAICAll.B()` relies on the `add1All()` and `drop1All()` functions for the selection of variables.

**Usage**

```r
stepGAIC(object, scope, direction = c("both", "backward", "forward"),
         trace = T, keep = NULL, steps = 1000, scale = 0,
         what = c("mu", "sigma", "nu", "tau"), parameter= NULL, k = 2,
         parallel = c("no", "multicore", "snow"), ncpus = 1L, cl = NULL,
         ...)
```

```r
stepGAICAll.A(object, scope, direction = c("both", "backward", "forward"),
               what = c("mu", "sigma", "nu", "tau"), parameter= NULL, k = 2,
               parallel = c("no", "multicore", "snow"), ncpus = 1L, cl = NULL,
               ...)
```

```r
stepGAICAll.B(object, scope, direction = c("both", "backward", "forward"),
               what = c("mu", "sigma", "nu", "tau"), parameter= NULL, k = 2,
               parallel = c("no", "multicore", "snow"), ncpus = 1L, cl = NULL,
               ...)
```
...)

stepGAIC.VR(object, scope, direction = c("both", "backward", "forward"),
trace = T, keep = NULL, steps = 1000, scale = 0,
what = c("mu", "sigma", "nu", "tau"), parameter = NULL, k = 2,
...

stepGAIC.CH(object, scope = gamlss.scope(model.frame(object)),
direction = c("both", "backward", "forward"), trace = T,
keep = NULL, steps = 1000, what = c("mu", "sigma", "nu", "tau"),
parameter = NULL, k = 2, ...)

stepGAICAll.A(object, scope = NULL, sigma.scope = NULL, nu.scope = NULL,
tau.scope = NULL, mu.try = TRUE, sigma.try = TRUE,
u nu.try = TRUE, tau.try = TRUE,
parallel = c("no", "multicore", "snow"), ncpus = 1L,
c l = NULL, ...)

stepGAICAll.B(object, scope, direction = c("both", "backward", "forward"),
trace = T, keep = NULL, steps = 1000, scale = 0, k = 2,
parallel = c("no", "multicore", "snow"), ncpus = 1L,
c l = NULL, ...)

drop1All(object, scope, test = c("Chisq", "none"), k = 2, sorted = FALSE,
trace = FALSE, parallel = c("no", "multicore", "snow"),
cpus = 1L, cl = NULL, ...)

add1All(object, scope, test = c("Chisq", "none"), k = 2, sorted = FALSE,
trace = FALSE, parallel = c("no", "multicore", "snow"),
cpus = 1L, cl = NULL, ...)

Arguments

object an gamlss object. This is used as the initial model in the stepwise search.
scope defines the range of models examined in the stepwise search. For the function
stepAIC() this should be either a single formula, or a list containing compo-
nents upper and lower, both formulae. See the details for how to specify the
formulae and how they are used. For the function stepGAIC the scope defines
the range of models examined in the step-wise search. It is a list of formulas,
with each formula corresponding to a term in the model. A 1 in the formula
allows the additional option of leaving the term out of the model entirely. +
direction the mode of stepwise search, can be one of both, backward, or forward, with a
default of both. If the scope argument is missing the default for direction is
backward.
trace if positive, information is printed during the running of stepAIC. Larger values
may give more information on the fitting process.
keep a filter function whose input is a fitted model object and the associated 'AIC' statistic, and whose output is arbitrary. Typically 'keep' will select a subset of the components of the object and return them. The default is not to keep anything.

steps the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.

scale scale is nor used in gamlss

what which distribution parameter is required, default what="mu"

parameter equivalent to what

k the multiple of the number of degrees of freedom used for the penalty. Only 'k = 2' gives the genuine AIC: 'k = log(n)' is sometimes referred to as BIC or SBC.

parallel The type of parallel operation to be used (if any). If missing, the default is "no".

ncpus integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.

c1 An optional parallel or snow cluster for use if parallel = "snow". If not supplied, a cluster on the local machine is created for the duration of the call.

sigma.scope scope for sigma if different to scope in stepGAICAll.A()

nu.scope scope for nu if different to scope in stepGAICAll.A()

tau.scope scope for tau if different to scope in stepGAICAll.A()

mu.try The default value is is TRUE, set to FALSE if no model for mu is needed

sigma.try The default value is TRUE, set to FALSE if no model for sigma is needed

nu.try The default value is TRUE, set to FALSE if no model for nu is needed

tau.try The default value is TRUE, set to FALSE if no model for tau is needed

test whether to print the chi-square test or not

sorted whether to sort the results

... any additional arguments to 'extractAIC'. (None are currently used.)

Details

The set of models searched is determined by the scope argument.

For the function stepGAIC.VR() the right-hand-side of its lower component is always included in the model, and right-hand-side of the model is included in the upper component. If scope is a single formula, it specifies the upper component, and the lower model is empty. If scope is missing, the initial model is used as the upper model.

Models specified by scope can be templates to update object as used by update.formula.

For the function stepGAIC.CH() each of the formulas in scope specifies a "regimen" of candidate forms in which the particular term may enter the model. For example, a term formula might be

\[ \sim x_1 + \log(x_1) + cs(x_1, df=3) \]

This means that x1 could either appear linearly, linearly in its logarithm, or as a smooth function estimated non-parametrically. Every term in the model is described by such a term formula, and the final model is built up by selecting a component from each formula.
The function `gamlss.scope` similar to the S `gam.scope()` in Chambers and Hastie (1991) can be used to create automatically term formulae from specified data or model frames.

The supplied model object is used as the starting model, and hence there is the requirement that one term from each of the term formulas of the parameters be present in the formula of the distribution parameter. This also implies that any terms in formula of the distribution parameter not contained in any of the term formulas will be forced to be present in every model considered.

When the smoother used in `gamlss` modelling belongs to the new generation of smoothers allowing the determination of the smoothing parameters automatically (i.e. `pb()`, `cy()`) then the function `stepGAIC.VR()` can be used for model selection (see example below).

**Value**

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the 'keep=' argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood

The function `stepGAICAll.A()` returns with a component "anovaAll" containing all the different anova tables used in the process.

summary.gamlss

### Description

`summary.gamlss` is the GAMLSS specific method for the generic function `summary` which summarize objects returned by modelling functions.

### Usage

```
## S3 method for class 'gamlss'
summary(object, type = c("vcov", "qr"),
  robust=FALSE, save = FALSE,
  hessian.fun = c("R", "PB"),
  digits = max(3, getOption("digits") - 3),...)
```

### Arguments

- **object**: a GAMLSS fitted model
- **type**: the default value `vcov` uses the `vcov()` method for `gamlss` to get the variance-covariance matrix of the estimated beta coefficients, see details below. The alternative `qr` is the original method used in `gamlss` to estimated the standard errors but it is not reliable since it do not take into the account the inter-correlation between the distributional parameters mu, sigma, nu and tau.
- **robust**: whether robust (sandwich) standard errors are required
- **save**: whether to save the environment of the function so to have access to its values
- **hessian.fun**: whether when calculate the Hessian should use the "R" function `optimHess()` or a function based on Pinheiro and Bates `nlme` package, "PB".
- **digits**: the number of digits in the output
- **...**: for extra arguments
Details

Using the default value type="vcov", the vcov() method for gamlss is used to get the variance covariance matrix (and consequently the standard errors) of the beta parameters. The variance covariance matrix is calculated using the inverse of the numerical second derivatives of the observed information matrix. This is a more reliable method since it take into the account the inter-correlation between the all the parameters. The type="qr" assumes that the parameters are fixed at the estimated values. Note that both methods are not appropriate and should be used with caution if smoothing terms are used in the fitting.

Value

Print summary of a GAMLSS object

Author(s)

Mikis Stasinopoulos <d.stasinopoulos@londonmet.ac.uk>, Bob Rigby and Calliope Akantziliotou

term.plot

Plot regression terms for a specified parameter of a fitted GAMLSS object

Description

Plots regression terms against their predictors, optionally with standard errors and partial residuals added. It is based on the R function `termplot` but is suitably changed to apply to GAMLSS objects.

Usage

```r
term.plot(object, what = c("mu", "sigma", "nu", "tau"),
          parameter = NULL, data = NULL,
          envir = environment(formula(object)), partial.resid = FALSE,
          rug = FALSE, terms = NULL, se = TRUE, ylim = c("common", "free"),
          scheme = c("shaded", "lines"), xlabs = NULL, ylabs = NULL,
          main = NULL, pages = 0, col.term = "darkred",
          col.se = "orange", col.shaded = "gray", col.res = "lightblue",
          col.rug = "gray", lwd.term = 1.5, lty.se = 2, lwd.se = 1,
          cex.res = 1, pch.res = par("pch"),
          ask = interactive() && nb.fig < n.tms && .Device != "postscript",
          use.factor.levels = TRUE, surface.gam = FALSE,
          polys = NULL, polys.scheme = "topo", ...)
```

Arguments

- **object**: a fitted GAMLSS object
- **what**: the required parameter of the GAMLSS distribution i.e. "mu"
- **parameter**: equivalent to `what`
- **data**: data frame in which variables in `object` can be found
- **envir**: environment in which variables in `object` can be found
- **partial.resid**: logical; should partial residuals be plotted or not
- **rug**: add rug plots (jitter 1-d histograms) to the axes?
- **terms**: which terms to be plotted (default `NULL` means all terms)
- **se**: plot point-wise standard errors?
- **ylim**: there are two options here a) "common" and b) "free". The "common" option plots all figures with the same ylim range and therefore allows the viewer to check the relative contribution of each terms compare to the rest. In the 'free' option the limits are computed for each plot seperately.
- **scheme**: whether the `se`'s should appear shaded or as lines
- **xlabs**: vector of labels for the x axes
- **ylabs**: vector of labels for the y axes
main logical, or vector of main titles; if 'TRUE', the model's call is taken as main title, 'NULL' or 'FALSE' mean no titles.

pages in how many pages the plot should appear. The default is 0 which allows different page for each plot

col.term the colour of the term line

col.se the colour of the se's lines

col.shaded the colour of the shaded area

col.res the colour of the partial residuals

col.rug the colour of the rug

lwd.term line width of the fitted terms

lty.se line type for standard errors

lwd.se line width for the standard errors

cex.res plotting character expansion for the partial residuals

pch.res characters for points in the partial residuals

ask logical; if 'TRUE', the user is asked before each plot, see 'par(ask=.)'.

use.factor.levels Should x-axis ticks use factor levels or numbers for factor terms?

surface.gam whether to use surface plot if a ga() term is fitted

polys The polygone information filr for MRF models

polys.scheme Color scheme for polygones for RMF models

... other graphical parameters

Details
The function uses the lpred function of GAMLSS. The 'data' argument should rarely be needed, but in some cases 'termplot' may be unable to reconstruct the original data frame. Using 'na.action=na.exclude' makes these problems less likely. Nothing sensible happens for interaction terms.

Value
a plot of fitted terms.

update.gamlss Update and Re-fit a GAMLSS Model

Description

update.gamlss is the GAMLSS specific method for the generic function update which updates and (by default) refits a GAMLSS model.

Usage

## S3 method for class 'gamlss'
update(object, formula., ..., what = c("mu", "sigma", "nu", "tau", "All"),
       parameter= NULL, evaluate = TRUE)

Arguments

object a GAMLSS fitted model
formula. the formula to update
... for updating argument in gamlss()
what the parameter in which the formula needs updating for example "mu", "sigma", "nu" "tau" or "All". If "All" all the formulae are updated. Note that the what argument has an effect only if only if the argument formula. is set
parameter equivalent to what
evaluate whether to evaluate the call or not

Value

Returns a GAMLSS call or fitted object.

VC.test

Vuong and Clarke tests

Description
The Vuong and Clarke tests for GAMLSS fitted models.

Usage

`VC.test(obj1, obj2, sig.lev = 0.05)`
Arguments

- obj1: The first fitted gamlss object
- obj2: The second fitted gamlss object
- sig.lev: Significance level used for testing.

Details

The Vuong (1989) and Clarke (2007) tests are likelihood-ratio-based tests for model selection that use the Kullback-Leibler information criterion. The implemented tests can be used for choosing between two bivariate models which are not necessarily nested.

In the Vuong test, the null hypothesis is that the two models are equally close to the actual model, whereas the alternative is that one model is closer. The test follows asymptotically a standard normal distribution under the null. Assume that the critical region is $(-c, c)$, where $c$ is typically set to 1.96. If the value of the test is greater than $c$ then we reject the null hypothesis that the models are equivalent in favour of the model in obj1. Vice versa if the value is smaller than $-c$ we reject the null hypothesis that the models are equivalent in favour of the model in obj2. If the value falls within $(-c, c)$ then we cannot discriminate between the two competing models given the data.

In the Clarke test, if the two models are statistically equivalent then the log-likelihood ratios of the observations should be evenly distributed around zero and around half of the ratios should be larger than zero. The test follows asymptotically a binomial distribution with parameters $n$ and 0.5. Critical values can be obtained as shown in Clarke (2007). Intuitively, the model in obj1 is preferred over that in obj2 if the value of the test is significantly larger than its expected value under the null hypothesis ($'coden/2$), and vice versa. If the value is not significantly different from $n/2$ then obj1 can be thought of as equivalent to obj2.

Value

For the Vuong test it returns its value and the decision and for the Clarke test returns the value the p-value and the decision. Decisions criteria are as discussed above.

# comparison of the models
VC.test(m0,m2)
VC.test(m0,m1)
VC.test(m1,m2)
```

Description

Provides a single plot or multiple worm plots for a GAMLSS fitted or more general for any fitted models where the method `resid()` exist and the residuals are defined sensibly. The worm plot (a de-trended QQ-plot), van Buuren and Fredriks M. (2001), is a diagnostic tool for checking the residuals within different ranges (by default not overlapping) of the explanatory variable(s).

Usage

```r
wp(object = NULL, xvar = NULL, resid = NULL, n.inter = 4,
   xcut.points = NULL, overlap = 0, xlim.all = 4,
   xlim.worm = 3.5, show.given = TRUE, line = TRUE,
   ylim.all = 12 * sqrt(1/length(resid)),
   ylim.worm = 12 * sqrt(n.inter/length(resid)),
   cex = 1, cex.lab = 1, pch = 21, bg = "wheat",
   col = "red", bar.bg = c(num = "light blue"), ...)
```

Arguments

- **object**: a GAMLSS fitted object or any other fitted model where the resid() method works (preferably it should be standardised or quantile residuals)
- **xvar**: the explanatory variable(s) against which the worm plots will be plotted. If only one variable is involved use xvar=x1 if two variables are involved use xvar=~x1+x2. See also note below for use of formula if the data argument is not found in the fitted model
resid  if object is missing this argument can be used to specify the residual vector
(again it should a quantile residuals or it be assumed to come from a normal
distribution)
n.inter  the number of intervals in which the explanatory variable xvar will be cut
xcut.points  the x-axis cut off points e.g. c(20,30). If xcut.points=NULL then the n.inter
argument is activated
overlap  how much overlapping in the xvar intervals. Default value is overlap=0 for
non overlapping intervals
xlim.all  for the single plot, this value is the x-variable limit, default is xlim.all=4
xlim.worm  for multiple plots, this value is the x-variable limit, default is xlim.worm=3.5
show.given  whether to show the x-variable intervals in the top of the graph, default is
show.given=TRUE
line  whether to plot the polynomial line in the worm plot, default value is line=TRUE
ylim.all  for the single plot, this value is the y-variable limit, default value is ylim.all=12\sqrt{1/length(fitted(object))}
ylim.worm  for multiple plots, this values is the y-variable limit, default value is ylim.worm=12\sqrt{n.inter/length(fitted(object))}
cex  the cex plotting parameter for changing the side of worm with default cex=1
cex.lab  the cex plotting parameter for changing the size of the axis labels
pch  the pch plotting parameter with default pch=21
bg  The background colour of the worm plot points
col  the colour of the fitted (and horizontal and vertical) lines
bar.bg  the colour of the bars when xvar is used
...  for extra arguments

Details

If the xvar argument is not specified then a single worm plot is used. In this case a worm plot is a
de-trended normal QQ-plot so departure from normality is highlighted.

If a single xvar is specified (with or without the use of a formula) i.e. xvar=x1 or xvar=~x1) then
we have as many worm plot as n.iter. In this case the x-variable is cut into n.iter intervals with
an equal number observations and de-trended normal QQ (i.e. worm) plots for each interval are
plotted. This is a way of highlighting failures of the model within different ranges of the the single
explanatory variable. The fitted coefficients from fitting cubic polymonials to the residuals (within
each x-variable interval) can be obtain by e.g. coeffs<-wp(model1,xvar=x,n.iter=9). van Bu-
uren and Fredriks M. (2001) used these residuals to identify regions (intervals) of the explanatory
variable within which the model does not fit adequately the data (called "model violation")

Two variables can be displayed with the use of a formula, i.e. xvar=~x1*x2. In this case the
n.iter can be a vector with two values.

Value

For multiple plots the xvar intervals and the coefficients of the fitted cubic polymonials to the
residuals (within each xvar interval) are returned.
Note

Note that the `wp()` function, if the argument object is used, is looking for the data argument of the object. If the argument data exists it uses its environment to find `xvar` (whether it is a formula or not). As a result if data exists within object `xvar=-x*f` can be used (assuming that `x` and `f` are in the data) otherwise the variable should be explicitly defined i.e. `xvar=-data$x*data$f`.
