Package ‘gbm’

March 11, 2015

Version 2.1.1
Date 2015-03-10
Title Generalized Boosted Regression Models
Author Greg Ridgeway <gregridgeway@gmail.com> with contributions from others
Maintainer Harry Southworth <harry.southworth@gmail.com>
Depends R (>= 2.9.0), survival, lattice, splines, parallel
Suggests RUnit
License GPL (>= 2) | file LICENSE
URL http://code.google.com/p/gradientboostedmodels/
NeedsCompilation yes
Repository CRAN
Date/Publication 2015-03-11 09:02:32

  gbm ................................................................. 6
  gbm-internal ....................................................... 13
  gbm.object .......................................................... 14
  gbm.perf ............................................................. 15
Description

This package implements extensions to Freund and Schapire’s AdaBoost algorithm and J. Friedman’s gradient boosting machine. Includes regression methods for least squares, absolute loss, logistic, Poisson, Cox proportional hazards partial likelihood, multinomial, t-distribution, AdaBoost exponential loss, Learning to Rank, and Huberized hinge loss.

Details

Package: gbm
Version: 2.1
Date: 2013-05-10
Depends: R (>= 2.9.0), survival, lattice, mgcv
License: GPL (version 2 or newer)
URL: http://code.google.com/p/gradientboostedmodels/

---

**basehaz.gbm**

*Baseline hazard function*

**Description**

Computes the Breslow estimator of the baseline hazard function for a proportional hazard regression model

**Usage**

```r
basehaz.gbm(t, delta, f.x,
  t.eval = NULL,
  smooth = FALSE,
  cumulative = TRUE)
```
Arguments

- **t**: the survival times
- **delta**: the censoring indicator
- **f.x**: the predicted values of the regression model on the log hazard scale
- **t.eval**: values at which the baseline hazard will be evaluated
- **smooth**: if TRUE, `basehaz.gbm` will smooth the estimated baseline hazard using Friedman’s super smoother `supsmu`
- **cumulative**: if TRUE, the cumulative survival function will be computed

Details

The proportional hazard model assumes \( h(t|x) = \lambda(t) \exp(f(x)) \). `gbm` can estimate the \( f(x) \) component via partial likelihood. After estimating \( f(x) \), `basehaz.gbm` can compute the a nonparametric estimate of \( \lambda(t) \).

Value

A vector of length equal to the length of `t` (or of length `t.eval` if `t.eval` is not NULL) containing the baseline hazard evaluated at `t` (or at `t.eval` if `t.eval` is not NULL). If `cumulative` is set to TRUE then the returned vector evaluates the cumulative hazard function at those values.

---

**calibrate.plot**

*Calibration plot*

Description

An experimental diagnostic tool that plots the fitted values versus the actual average values. Currently developed for only distribution="bernoulli".
Usage

```r
calibrate.plot(y, p, 
distribution = "bernoulli", 
replace = TRUE, 
line.par = list(col = "black"), 
shade.col = "lightyellow", 
shade.density = NULL, 
rug.par = list(side = 1), 
xlab = "Predicted value", 
ylab = "Observed average", 
xlim = NULL, ylim = NULL, 
knots = NULL, df = 6, 
...)
```

Arguments

- `y`: the outcome 0-1 variable
- `p`: the predictions estimating E(y|x)
- `distribution`: the loss function used in creating p. bernoulli and poisson are currently the only special options. All others default to squared error assuming gaussian
- `replace`: determines whether this plot will replace or overlay the current plot. replace=FALSE is useful for comparing the calibration of several methods
- `line.par`: graphics parameters for the line
- `shade.col`: color for shading the 2 SE region. shade.col=NA implies no 2 SE region
- `shade.density`: the density parameter for polygon
- `rug.par`: graphics parameters passed to rug
- `xlab`: x-axis label corresponding to the predicted values
- `ylab`: y-axis label corresponding to the observed average
- `xlim`, `ylim`: x and y-axis limits. If not specified the function will select limits
- `knots`, `df`: these parameters are passed directly to ns for constructing a natural spline smoother for the calibration curve
- `...`: other graphics parameters passed on to the plot function

Details

Uses natural splines to estimate E(y|p). Well-calibrated predictions imply that E(y|p) = p. The plot also includes a pointwise 95 band.

Value

`calibrate.plot` returns no values.

Examples

```r
# Don't want R CMD check to think there is a dependency on rpart
# so comment out the example
#library(rpart)
data(kyphosis)
#y <- as.numeric(kyphosis$Kyphosis)-1
#x <- kyphosis$Age
#glm1 <- glm(y~poly(x,2),family=binomial)
#p <- predict(glm1,type="response")
#calibrate.plot(y, p, xlim=c(0,0.6), ylim=c(0,0.6))
```

---

**gbm**

*Generalized Boosted Regression Modeling*

**Description**

Fits generalized boosted regression models.

**Usage**

```r
gbm(formula = formula(data),
    distribution = "bernoulli",
    data = list(),
    weights,
    var.monotone = NULL,
    n.trees = 100,
    interaction.depth = 1,
    n.minobsinnode = 10,
    shrinkage = 0.001,
    bag.fraction = 0.5,
    train.fraction = 1.0,
    cv.folds=0,
    keep.data = TRUE,
    verbose = "CV",
    class.stratify.cv=NULL,
    n.cores = NULL)

gbm.fit(x, y,
         offset = NULL,
         misc = NULL,
```

```r
```
distribution = "bernoulli",
w = NULL,
var.monotone = NULL,
n.trees = 100,
interaction.depth = 1,
n.minobsinnode = 10,
shrinkage = 0.001,
bag.fraction = 0.5,
nTrain = NULL,
train.fraction = NULL,
keep.data = TRUE,
verbose = TRUE,
var.names = NULL,
response.name = "y",
group = NULL)

Arguments

formula a symbolic description of the model to be fit. The formula may include an offset
term (e.g. y~offset(n)+x). If keep.data=FALSE in the initial call to gbm then it
is the user’s responsibility to resupply the offset to gbm.more.

distribution either a character string specifying the name of the distribution to use or a list
with a component name specifying the distribution and any additional param-
eters needed. If not specified, gbm will try to guess: if the response has only
2 unique values, bernoulli is assumed; otherwise, if the response is a factor,
multinomial is assumed; otherwise, if the response has class "Surv", coxph is
assumed; otherwise, gaussian is assumed.
Currently available options are "gaussian" (squared error), "laplace" (absolute
loss), "tdist" (t-distribution loss), "bernoulli" (logistic regression for 0-1 out-
comes), "huberized" (huberized hinge loss for 0-1 outcomes), "multinomial"
(classification when there are more than 2 classes), "adaboost" (the AdaBoost
exponential loss for 0-1 outcomes), "poisson" (count outcomes), "coxph" (right
censored observations), "quantile", or "pairwise" (ranking measure using the
LambdaMart algorithm).
If quantile regression is specified, distribution must be a list of the form
list(name="quantile", alpha=0.25) where alpha is the quantile to estimate.
The current version’s quantile regression method does not handle non-constant
weights and will stop.
If "tdist" is specified, the default degrees of freedom is 4 and this can be con-
trolled by specifying distribution=list(name="tdist", df=DF) where DF
is your chosen degrees of freedom.
If "pairwise" regression is specified, `distribution` must be a list of the form `list(name="pairwise",group=...,metric=...,max.rank=...)` (metric and max.rank are optional, see below). `group` is a character vector with the column names of data that jointly indicate the group an instance belongs to (typically a query in Information Retrieval applications). For training, only pairs of instances from the same group and with different target labels can be considered. `metric` is the IR measure to use, one of

- **conc**: Fraction of concordant pairs; for binary labels, this is equivalent to the Area under the ROC Curve
- **mrr**: Mean reciprocal rank of the highest-ranked positive instance
- **map**: Mean average precision, a generalization of mrr to multiple positive instances
- **ndcg**: Normalized discounted cumulative gain. The score is the weighted sum (DCG) of the user-supplied target values, weighted by log(rank+1), and normalized to the maximum achievable value. This is the default if the user did not specify a metric.

`ndcg` and `conc` allow arbitrary target values, while binary targets \{0,1\} are expected for `map` and `mrr`. For `ndcg` and `mrr`, a cut-off can be chosen using a positive integer parameter `max.rank`. If left unspecified, all ranks are taken into account.

Note that splitting of instances into training and validation sets follows group boundaries and therefore only approximates the specified `train.fraction` ratio (the same applies to cross-validation folds). Internally, queries are randomly shuffled before training, to avoid bias.

Weights can be used in conjunction with pairwise metrics, however it is assumed that they are constant for instances from the same group.

For details and background on the algorithm, see e.g. Burges (2010).

**data**

an optional data frame containing the variables in the model. By default the variables are taken from `environment(formula)`, typically the environment from which `gbm` is called. If `keep.data=TRUE` in the initial call to `gbm` then `gbm` stores a copy with the object. If `keep.data=FALSE` then subsequent calls to `gbm.more` must resupply the same dataset. It becomes the user’s responsibility to resupply the same data at this point.

**weights**

an optional vector of weights to be used in the fitting process. Must be positive but do not need to be normalized. If `keep.data=FALSE` in the initial call to `gbm` then it is the user’s responsibility to resupply the weights to `gbm.more`.

**var.monotone**

an optional vector, the same length as the number of predictors, indicating which variables have a monotone increasing (+1), decreasing (-1), or arbitrary (0) relationship with the outcome.

**n.trees**

the total number of trees to fit. This is equivalent to the number of iterations and the number of basis functions in the additive expansion.

**cv.folds**

Number of cross-validation folds to perform. If `cv.folds>1` then `gbm`, in addition to the usual fit, will perform a cross-validation, calculate an estimate of generalization error returned in `cv.error`.
interaction.depth
The maximum depth of variable interactions. 1 implies an additive model, 2
implies a model with up to 2-way interactions, etc.

n.minobsinnode
minimum number of observations in the trees terminal nodes. Note that this is
the actual number of observations not the total weight.

shrinkage
a shrinkage parameter applied to each tree in the expansion. Also known as the
learning rate or step-size reduction.

bag.fraction
the fraction of the training set observations randomly selected to propose the
next tree in the expansion. This introduces randomness into the model fit. If
bag.fraction<1 then running the same model twice will result in similar but
different fits. gbm uses the R random number generator so set.seed can ensure
that the model can be reconstructed. Preferably, the user can save the returned
gbm.object using save.

train.fraction
The first train.fraction * nrow(data) observations are used to fit the gbm
and the remainder are used for computing out-of-sample estimates of the loss
function.

nTrain
An integer representing the number of cases on which to train. This is the
preferred way of specification for gbm.fit; The option train.fraction in
gbm.fit is deprecated and only maintained for backward compatibility. These
two parameters are mutually exclusive. If both are unspecified, all data is used
for training.

keep.data
a logical variable indicating whether to keep the data and an index of the data
stored with the object. Keeping the data and index makes subsequent calls to
gbm.more faster at the cost of storing an extra copy of the dataset.

object
a gbm object created from an initial call to gbm.

n.new.trees
the number of additional trees to add to object.

verbose
If TRUE, gbm will print out progress and performance indicators. If this option
is left unspecified for gbm.more then it uses verbose from object.

class.stratify.cv
whether or not the cross-validation should be stratified by class. Defaults to TRUE
for distribution="multinomial" and is only implemented for multinomial
and bernoulli. The purpose of stratifying the cross-validation is to help avoiding
situations in which training sets do not contain all classes.

x, y
For gbm.fit: x is a data frame or data matrix containing the predictor variables
and y is the vector of outcomes. The number of rows in x must be the same as
the length of y.

offset
a vector of values for the offset

misc
For gbm.fit: misc is an R object that is simply passed on to the gbm engine. It
can be used for additional data for the specific distribution. Currently it is only
used for passing the censoring indicator for the Cox proportional hazards model.

w
For gbm.fit: w is a vector of weights of the same length as the y.

var.names
For gbm.fit: A vector of strings of length equal to the number of columns of x
containing the names of the predictor variables.

response.name
For gbm.fit: A character string label for the response variable.
group

The number of CPU cores to use. The cross-validation loop will attempt to send different CV folds off to different cores. If n.cores is not specified by the user, it is guessed using the detectCores function in the parallel package. Note that the documentation for detectCores makes clear that it is not failsafe and could return a spurious number of available cores.

Details

See the gbm vignette for technical details.

This package implements the generalized boosted modeling framework. Boosting is the process of iteratively adding basis functions in a greedy fashion so that each additional basis function further reduces the selected loss function. This implementation closely follows Friedman’s Gradient Boosting Machine (Friedman, 2001).

In addition to many of the features documented in the Gradient Boosting Machine, gbm offers additional features including the out-of-bag estimator for the optimal number of iterations, the ability to store and manipulate the resulting gbm object, and a variety of other loss functions that had not previously had associated boosting algorithms, including the Cox partial likelihood for censored data, the poisson likelihood for count outcomes, and a gradient boosting implementation to minimize the AdaBoost exponential loss function.

gbm.fit provides the link between R and the C++ gbm engine. gbm is a front-end to gbm.fit that uses the familiar R modeling formulas. However, model.frame is very slow if there are many predictor variables. For power-users with many variables use gbm.fit. For general practice gbm is preferable.

Value

gbm, gbm.fit, and gbm.more return a gbm.object.

                  verbose=FALSE) # stop printing detailed progress

gbm-internal

**gbm internal functions**

**Description**

Helper functions for preprocessing data prior to building the model

**Usage**

guessDist(y)
getCVgroup(distribution, class.stratify.cv, y, i.train, cv.folds, group)
getStratify(strat, d)
checkMissing(x, y)
checkWeights(w, n)
checkID(id)
checkOffset(o, y)
getVarNames(x)
gbmClusterNames(n)

**Arguments**

- **y**
  - The response variable

- **d, distribution**
  - The distribution, either specified by the user or implied

- **class.stratify.cv**
  - Whether or not to stratify, if provided by the user

- **i.train**
  - Computed internally by gbm
gbm.object

The group, if using distribution='pairwise'

Whether or not to stratify

The number of cross-validation folds

The design matrix

The interaction depth

The weights

The number of cores to use in the cluster.

The offset

Details

These are functions used internally by gbm and not intended for direct use by the user.

---

gbm.object

*Generalized Boosted Regression Model Object*

Description

These are objects representing fitted gbms.

Value

- **initF**: the "intercept" term, the initial predicted value to which trees make adjustments
- **fit**: a vector containing the fitted values on the scale of regression function (e.g. log-odds scale for bernoulli, log scale for poisson)
- **train.error**: a vector of length equal to the number of fitted trees containing the value of the loss function for each boosting iteration evaluated on the training data
- **valid.error**: a vector of length equal to the number of fitted trees containing the value of the loss function for each boosting iteration evaluated on the validation data
- **cv.error**: if cv.folds<2 this component is NULL. Otherwise, this component is a vector of length equal to the number of fitted trees containing a cross-validated estimate of the loss function for each boosting iteration
- **oobag.improve**: a vector of length equal to the number of fitted trees containing an out-of-bag estimate of the marginal reduction in the expected value of the loss function. The out-of-bag estimate uses only the training data and is useful for estimating the optimal number of boosting iterations. See gbm.perf
- **trees**: a list containing the tree structures. The components are best viewed using pretty.gbm.tree
- **c.splits**: a list of all the categorical splits in the collection of trees. If the trees[[i]] component of a gbm object describes a categorical split then the splitting value will refer to a component of c.splits. That component of c.splits will be a vector of length equal to the number of levels in the categorical split variable. -1 indicates left, +1 indicates right, and 0 indicates that the level was not present in the training data
cv.fitted  If cross-validation was performed, the cross-validation predicted values on the scale of the linear predictor. That is, the fitted values from the ith CV-fold, for the model having been trained on the data in all other folds.

Structure

The following components must be included in a legitimate gbm object.

Author(s)

Greg Ridgeway <gregridgeway@gmail.com>

See Also

gbm

gbm.perf  GBM performance

Description

Estimates the optimal number of boosting iterations for a gbm object and optionally plots various performance measures

Usage

```r
gbm.perf(object,
plot.it = TRUE,
oobag.curve = FALSE,
overlay = TRUE,
method)
```

Arguments

- `object`  A gbm.object created from an initial call to gbm.
- `plot.it`  An indicator of whether or not to plot the performance measures. Setting plot.it=TRUE creates two plots. The first plot plots object$train.error (in black) and object$valid.error (in red) versus the iteration number. The scale of the error measurement, shown on the left vertical axis, depends on the distribution argument used in the initial call to gbm.
- `oobag.curve`  Indicates whether to plot the out-of-bag performance measures in a second plot.
- `overlay`  If TRUE and oobag.curve=TRUE then a right y-axis is added to the training and test error plot and the estimated cumulative improvement in the loss function is plotted versus the iteration number.
- `method`  Indicate the method used to estimate the optimal number of boosting iterations. method="oob" computes the out-of-bag estimate and method="test" uses the test (or validation) dataset to compute an out-of-sample estimate. method="cv" extracts the optimal number of iterations using cross-validation if gbm was called with cv.folds>1
gbm.roc.area

Value
gbm.perf returns the estimated optimal number of iterations. The method of computation depends on the method argument.

Author(s)
Greg Ridgeway <gregridgeway@gmail.com>

See Also
gbm, gbm.object

gbm.roc.area

Description
Functions to compute Information Retrieval measures for pairwise loss for a single group. The function returns the respective metric, or a negative value if it is undefined for the given group.

Usage
gbm.roc.area(obs, pred)
ir.measure.conc(y.f, max.rank)
ir.measure.auc(y.f, max.rank)
ir.measure.mrr(y.f, max.rank)
ir.measure.map(y.f, max.rank)
ir.measure.ndcg(y.f, max.rank)
perf.pairwise(y, f, group, metric="ndcg", w=NULL, max.rank=0)

Arguments
obs Observed value
pred Predicted value
metric What type of performance measure to compute.
y, y.f, f, w, group, max.rank
    Used internally.

Details
For simplicity, we have no special handling for ties; instead, we break ties randomly. This is slightly inaccurate for individual groups, but should have only a small effect on the overall measure.

gbm.conc computes the concordance index: Fraction of all pairs (i,j) with i<j, x[i] ! = x[j], such that x[j] < x[i]
If obs is binary, then gbm.roc.area(obs, pred) = gbm.conc(obs[order(-pred)]).
gbm.conc is more general as it allows non-binary targets, but is significantly slower.
gbmCrossVal

Value

The requested performance measure.

gbmCrossVal  

Cross-validate a gbm

Description

Functions for cross-validating gbm. These functions are used internally and are not intended for end-user direct usage.

Usage

```r
gbmCrossVal(cv.folds, nTrain, n.cores,  
class.stratify.cv, data,  
x, y, offset, distribution, w, var.monotone,  
n.trees, interaction.depth, n.minobsinnode,  
shrinkage, bag.fraction,  
var.names, response.name, group)
```

```r
gbmCrossValModelBuild(cv.folds, cv.group, n.cores,  
i.train, x, y, offset,  
distribution, w, var.monotone,  
n.trees, interaction.depth,  
n.minobsinnode, shrinkage,  
bag.fraction, var.names,  
response.name, group)
```
gbmDoFold(X, i.train, x, y, offset, distribution, w, var.monotone, n.trees, interaction.depth, n.minobsinnode, shrinkage, bag.fraction, cv.group, var.names, response.name, group, s)

gbmCrossValErr(cv.models, cv.folds, cv.group, nTrain, n.trees)

gbmCrossValPredictions(cv.models, cv.folds, cv.group, best.iter.cv, distribution, data, y)

Arguments

cv.folds The number of cross-validation folds.
nTrain The number of training samples.
n.cores The number of cores to use.
class.stratify.cv Whether or not stratified cross-validation samples are used.
data The data.
x The model matrix.
y The response variable.
offset The offset.
distribution The type of loss function. See gbm.
w Observation weights.
var.monotone See gbm.
n.trees The number of trees to fit.
interaction.depth The degree of allowed interactions. See gbm.
n.minobsinnode See gbm.
shrinkage See gbm.
bag.fraction See gbm.
var.names See gbm.
response.name See gbm.
group Used when distribution = "pairwise". See gbm.
i.train Items in the training set.
cv.models A list containing the models for each fold.
cv.group A vector indicating the cross-validation fold for each member of the training set.
best.iter.cv The iteration with lowest cross-validation error.
X Index (cross-validation fold) on which to subset.
s Random seed.
Details

These functions are not intended for end-user direct usage, but are used internally by gbm.

Value

A list containing the cross-validation error and predictions.

gbm

interact.gbm

Estimate the strength of interaction effects

Description

Computes Friedman’s H-statistic to assess the strength of variable interactions.

Usage

interact.gbm(x, 
  data, 
  i.var = 1, 
  n.trees = x$n.trees)

Arguments

x a gbm.object fitted using a call to gbm

data the dataset used to construct x. If the original dataset is large, a random subsample may be used to accelerate the computation in interact.gbm

i.var a vector of indices or the names of the variables for compute the interaction effect. If using indices, the variables are indexed in the same order that they appear in the initial gbm formula.

n.trees the number of trees used to generate the plot. Only the first n.trees trees will be used
interact.gbm computes Friedman’s H-statistic to assess the relative strength of interaction effects in non-linear models. H is on the scale of [0-1] with higher values indicating larger interaction effects. To connect to a more familiar measure, if \( x_1 \) and \( x_2 \) are uncorrelated covariates with mean 0 and variance 1 and the model is of the form

\[
y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3
\]

then

\[
H = \frac{\beta_3}{\sqrt{\beta_1^2 + \beta_2^2 + \beta_3^2}}
\]

Note that if the main effects are weak, the estimated H will be unstable. For example, if (in the case of a two-way interaction) neither main effect is in the selected model (relative influence is zero), the result will be 0/0. Also, with weak main effects, rounding errors can result in values of H > 1 which are not possible.

Value

Returns the value of \( H \).

Author(s)

Greg Ridgeway <gregridgeway@gmail.com>

References

\[ \text{gbm, gbm.object} \]

Description

Plots the marginal effect of the selected variables by "integrating" out the other variables.

Usage

```r
## S3 method for class 'gbm'
plot(x,
     i.var = 1,
     n.trees = x$n.trees,
     continuous.resolution = 100,
     return.grid = FALSE,
     type = "link",
     ...)```
Arguments

- **x**: a `gbm.object` fitted using a call to `gbm`
- **i.var**: a vector of indices or the names of the variables to plot. If using indices, the variables are indexed in the same order that they appear in the initial `gbm` formula. If `length(i.var)` is between 1 and 3 then `plot.gbm` produces the plots. Otherwise, `plot.gbm` returns only the grid of evaluation points and their average predictions.
- **n.trees**: the number of trees used to generate the plot. Only the first `n.trees` trees will be used.
- **continuous.resolution**: The number of equally spaced points at which to evaluate continuous predictors.
- **return.grid**: if TRUE then `plot.gbm` produces no graphics and only returns the grid of evaluation points and their average predictions. This is useful for customizing the graphics for special variable types or for dimensions greater than 3.
- **type**: the type of prediction to plot on the vertical axis. See `predict.gbm`
- **...**: other arguments passed to the `plot` function

Details

`plot.gbm` produces low dimensional projections of the `gbm.object` by integrating out the variables not included in the `i.var` argument. The function selects a grid of points and uses the weighted tree traversal method described in Friedman (2001) to do the integration. Based on the variable types included in the projection, `plot.gbm` selects an appropriate display choosing amongst line plots, contour plots, and lattice plots. If the default graphics are not sufficient the user may set `return.grid=TRUE`, store the result of the function, and develop another graphic display more appropriate to the particular example.

Value

Nothing unless `return.grid` is true then `plot.gbm` produces no graphics and only returns the grid of evaluation points and their average predictions.

`gbm`, `gbm.object.plot`
**predict.gbm**  

*Predict method for GBM Model Fits*

**Description**

Predicted values based on a generalized boosted model object

**Usage**

```r
## S3 method for class 'gbm'
predict(object,  
newdata,  
n.trees,  
type="link",  
single.tree=FALSE,  
...)
```

**Arguments**

- `object`: Object of class inheriting from `gbm.object`
- `newdata`: Data frame of observations for which to make predictions
- `n.trees`: Number of trees used in the prediction. `n.trees` may be a vector in which case predictions are returned for each iteration specified
- `type`: The scale on which gbm makes the predictions
- `single.tree`: If `single.tree=TRUE` then `predict.gbm` returns only the predictions from tree(s) `n.trees`
- `...`: further arguments passed to or from other methods

**Details**

`predict.gbm` produces predicted values for each observation in `newdata` using the first `n.trees` iterations of the boosting sequence. If `n.trees` is a vector than the result is a matrix with each column representing the predictions from `gbm` models with `n.trees[1]` iterations, `n.trees[2]` iterations, and so on.

The predictions from `gbm` do not include the offset term. The user may add the value of the offset to the predicted value if desired.

If `object` was fit using `gbm.fit` there will be no Terms component. Therefore, the user has greater responsibility to make sure that `newdata` is of the same format (order and number of variables) as the one originally used to fit the model.
pretty.gbm.tree

Value

Returns a vector of predictions. By default the predictions are on the scale of f(x). For example, for the Bernoulli loss the returned value is on the log odds scale, poisson loss on the log scale, and coxph is on the log hazard scale.

If type="response" then gbm converts back to the same scale as the outcome. Currently the only effect this will have is returning probabilities for bernoulli and expected counts for poisson. For the other distributions "response" and "link" return the same.

gbm, gbm.object

Description

gbm stores the collection of trees used to construct the model in a compact matrix structure. This function extracts the information from a single tree and displays it in a slightly more readable form. This function is mostly for debugging purposes and to satisfy some users’ curiosity.

Usage

pretty.gbm.tree(object, i.tree = 1)

Arguments

object a gbm.object initially fit using gbm
i.tree the index of the tree component to extract from object and display

Value

pretty.gbm.tree returns a data frame. Each row corresponds to a node in the tree. Columns indicate

SplitVar index of which variable is used to split. -1 indicates a terminal node.
SplitCodePred if the split variable is continuous then this component is the split point. If the split variable is categorical then this component contains the index of object$c.split that describes the categorical split. If the node is a terminal node then this is the prediction.
LeftNode the index of the row corresponding to the left node.
RightNode the index of the row corresponding to the right node.
**Error Reduction**
the reduction in the loss function as a result of splitting this node.

**Weight**
the total weight of observations in the node. If weights are all equal to 1 then this is the number of observations in the node.

gbm, gbm.object

---

**print.gbm**

*Print model summary*

**Description**
Display basic information about a gbm object.

**Usage**

```r
## S3 method for class 'gbm'
prient(x, ...)  
## S3 method for class 'gbm'
show(x, ...)  
```

**Arguments**

- `x` an object of class gbm.
- `...` arguments passed to print.default.

**Details**
Prints some information about the model object. In particular, this method prints the call to gbm(), the type of loss function that was used, and the total number of iterations.

If cross-validation was performed, the ‘best’ number of trees as estimated by cross-validation error is displayed. If a test set was used, the ‘best’ number of trees as estimated by the test set error is displayed.

The number of available predictors, and the number of those having non-zero influence on predictions is given (which might be interesting in data mining applications).

If multinomial, bernoulli or adaboost was used, the confusion matrix and prediction accuracy are printed (objects being allocated to the class with highest probability for multinomial and bernoulli). These classifications are performed on the entire training data using the model with the ‘best’ number of trees as described above, or the maximum number of trees if the ‘best’ cannot be computed.

If the ‘distribution’ was specified as gaussian, laplace, quantile or t-distribution, a summary of the residuals is displayed. The residuals are for the training data with the model at the ‘best’ number of trees, as described above, or the maximum number of trees if the ‘best’ cannot be computed.

**quantile.rug**  
*Quantile rug plot*

**Description**

Marks the quantiles on the axes of the current plot.

**Usage**

quantile.rug(x, prob=(0:10)/10,...)

**Arguments**

- **x**: a numeric vector.
- **prob**: the quantiles of `x` to mark on the x-axis.
- **...**: additional graphics parameters currently ignored.

**Value**

No return values

quantile.rug(x)
```

---

reconstructGBMdata  
*Reconstruct a GBM’s Source Data*

Description

Helper function to reconstitute the data for plots and summaries. This function is not intended for the user to call directly.

Usage

```r
reconstructGBMdata(x)
```

Arguments

- `x`  
a `gbm.object` initially fit using `gbm`

Value

Returns a data used to fit the gbm in a format that can subsequently be used for plots and summaries

Author(s)

Harry Southworth

gbm, gbm.object

---

relative.influence  
*Methods for estimating relative influence*

Description

Helper functions for computing the relative influence of each variable in the gbm object.

Usage

```r
relative.influence(object, n.trees, scale., sort.)
permutation.test.gbm(object, n.trees)
gbm.loss(y,f,w,offset,dist,baseline, group, max.rank)
```
relative.influence

Arguments

object  a gbm object created from an initial call to gbm.
n.trees  the number of trees to use for computations. If not provided, the function will guess: if a test set was used in fitting, the number of trees resulting in lowest test set error will be used; otherwise, if cross-validation was performed, the number of trees resulting in lowest cross-validation error will be used; otherwise, all trees will be used.
scale  whether or not the result should be scaled. Defaults to FALSE.
sort  whether or not the results should be (reverse) sorted. Defaults to FALSE.
y,f,w,offset,dist,baseline  For gbm.loss: These components are the outcome, predicted value, observation weight, offset, distribution, and comparison loss function, respectively.
group, max.rank  Used internally when distribution = \'pairwise\'.

Details

This is not intended for end-user use. These functions offer the different methods for computing the relative influence in summary.gbm. gbm.loss is a helper function for permutation.test.gbm.

Value

By default, returns an unprocessed vector of estimated relative influences. If the scale and sort arguments are used, returns a processed version of the same.

summary.gbm
shrink.gbm

L1 shrinkage of the predictor variables in a GBM

Description

Performs recursive shrinkage in each of the trees in a GBM fit using different shrinkage parameters for each variable.

Usage

shrink.gbm(object, 
n.trees, 
lambda = rep(10, length(object$var.names)), 
...)

Arguments

Object

A gbm.object

n.trees

the number of trees to use

lambda

a vector with length equal to the number of variables containing the shrinkage parameter for each variable

...

other parameters (ignored)

Details

This function is currently experimental. Used in conjunction with a gradient ascent search for inclusion of variables.

Value

Predicted values from the shrunken tree

The value of the loss function associated with the predicted values

A vector with length equal to the number of variables containing the derivative of the objective function with respect to beta, the logit transform of the shrinkage parameter for each variable

Warning

This function is experimental.

shrink.gbm.pred, gbm

---

**shrink.gbm.pred**  
*Predictions from a shrunked GBM*

**Description**

Makes predictions from a shrunken GBM model.

**Usage**

```
shrink.gbm.pred(object, newdata, n.trees, lambda = rep(1, length(object$var.names)), ...)
```

**Arguments**

- `object`: a `gbm.object`
- `newdata`: dataset for predictions
- `n.trees`: the number of trees to use
- `lambda`: a vector with length equal to the number of variables containing the shrinkage parameter for each variable
- `...`: other parameters (ignored)

**Value**

A vector with length equal to the number of observations in newdata containing the predictions

**Warning**

This function is experimental

**Author(s)**

Greg Ridgeway <gregridgeway@gmail.com>

shrink.gbm, gbm
**Summary of a gbm object**

**Description**

Computes the relative influence of each variable in the gbm object.

**Usage**

```r
## S3 method for class 'gbm'
summary(object,
    cbars=length(object$var.names),
    n.trees=object$n.trees,
    plotit=TRUE,
    order=TRUE,
    method=relative.influence,
    normalize=TRUE,
    ...
)
```

**Arguments**

- **object**
  - A gbm object created from an initial call to `gbm`.
- **cbars**
  - The number of bars to plot. If order=TRUE the only the variables with the cbars largest relative influence will appear in the barplot. If order=FALSE then the first cbars variables will appear in the plot. In either case, the function will return the relative influence of all of the variables.
- **n.trees**
  - The number of trees used to generate the plot. Only the first n.trees trees will be used.
- **plotit**
  - An indicator as to whether the plot is generated.
- **order**
  - An indicator as to whether the plotted and/or returned relative influences are sorted.
- **method**
  - The function used to compute the relative influence. `relative.influence` is the default and is the same as that described in Friedman (2001). The other current (and experimental) choice is `permutation.test.gbm`. This method randomly permutes each predictor variable at a time and computes the associated reduction in predictive performance. This is similar to the variable importance measures Breiman uses for random forests, but gbm currently computes using the entire training dataset (not the out-of-bag observations).
- **normalize**
  - If FALSE then `summary.gbm` returns the unnormalized influence.
- **...**
  - Other arguments passed to the plot function.
**validate.gbm**

**Details**

For `distribution="gaussian"` this returns exactly the reduction of squared error attributable to each variable. For other loss functions this returns the reduction attributable to each variable in sum of squared error in predicting the gradient on each iteration. It describes the relative influence of each variable in reducing the loss function. See the references below for exact details on the computation.

**Value**

Returns a data frame where the first component is the variable name and the second is the computed relative influence, normalized to sum to 100.

**Author(s)**

Greg Ridgeway <gregridgeway@gmail.com>

**References**

gbm

---

**validate.gbm**

Test the gbm package.

**Description**

Run tests on gbm functions to perform logical checks and reproducibility.

**Usage**

`validate.gbm()`

**Details**

The function uses functionality in the RUnit package. A fairly small validation suite is executed that checks to see that relative influence identifies sensible variables from simulated data, and that predictions from GBMs with Gaussian, Cox or binomial distributions are sensible,

**Value**

An object of class RUnitTestData. See the help for RUnit for details.
Note

The test suite is not comprehensive.
