Package ‘gdistance’

May 7, 2018

Type Package
Title Distances and Routes on Geographical Grids
Version 1.2-2
Date 2018-05-06
Author Jacob van Etten
Depends R (>= 3.2.0), raster (>= 1.9-19), methods, igraph (>= 0.7.0), Matrix
Imports sp, stats
Maintainer Jacob van Etten <jacobvanetten@yahoo.com>
Description Calculate distances and routes on geographic grids.
License GPL (>= 2)
LazyLoad yes
NeedsCompilation no
Repository CRAN

gdistance-package    gdistance: geographic distance calculations

Description

Calculate distances and routes on geographic grids.

Details

Package: gdistance
Type: Package
Version: 1.1-1
Date: 2011-01-04
License: GPL (>=3)
LazyLoad: yes

Distances can be calculated following these steps.
1. Read spatial grid data into the R environment, using the raster package. Function: raster.
2. Construct an object of the class TransitionLayer or TransitionStack. Function: transition.
4. Get coordinates for the starting and end points of routes.
5. Calculate distances and routes. Functions: accCost, costDistance, commuteDistance, rSPDistance,
   shortestPath, passage, pathInc.

Author(s)

raster

accCost  Accumulated Cost Surface

Description
Calculates the accumulated cost surface from one or more origins.

Usage
accCost(x, fromCoords)

Arguments
x object of class TransitionLayer
fromCoords origin point locations (SpatialPoints, matrix or numeric class)

Details
If more than one coordinate is supplied in fromCoords, the function calculates the minimum least-cost distance from any origin point.
The function uses Dijkstra’s algorithm (as implemented in the igraph package).

Value
RasterLayer

Author(s)
Jacob van Etten <jacobvanetten@yahoo.com>

adjacencyFromTransition

Adjacent cells

Description
Identify pairs of cells that are adjacent.

Usage
adjacencyFromTransition(x)

Arguments

x TransitionLayer

Details
Extracts the indices of those cells that are connected (e.g. cells i,j that have a non-zero value in the transition matrix).

Cell numbers are unique indices of cells in the original grid. By convention, cell numbers start with 1 in the upper-left corner of the grid and increase from left to right and from top to bottom.

Value
A two column matrix with each row containing a pair of adjacent cells.

adjacent

Examples

r <- raster(nrows=6, ncols=7, xmn=0, xmx=7, ymn=0, ymx=6, crs="+proj=utm +units=m")
r[] <- runif(6*7)
T <- transition(r, function(x) 1/mean(x), 8)
adjacencyFromTransition(T)

---

ArithMath-methods

Arithmetic and mathematical operations with objects of Transition* classes

Description

Standard arithmetic operators for computations with Transition* objects and numeric values. Transition objects must have the same extent and resolution. All arithmetic and mathematical operations that work on the sparse matrices are available for Transition* objects.

Value

Transition* object or numeric.

Author(s)

Jacob van Etten

Examples

# create a new raster and set all its values to unity.
raster <- raster(nrows=18, ncols=36)
raster <- setValues(raster, rep(1, ncell(raster)))

# create TransitionLayer objects
tr1 <- transition(raster, mean, 4)
tr2 <- tr1

# arithmetic operations
tr3 <- tr1 * tr2
tr4 <- tr3 * 4

# mathematical operations
tr5 <- sqrt(tr4)
### commuteDistance

<table>
<thead>
<tr>
<th>commuteDistance</th>
<th>Commute-time distance</th>
</tr>
</thead>
</table>

#### Description

Calculates the resistance distance between points.

#### Usage

`commuteDistance (x, coords)`

#### Arguments

- **x** TransitionLayer object
- **coords** point locations coordinates (of SpatialPoints, matrix or numeric class)

#### Details

This function calculates the expected random-walk commute time between nodes in a graph. It is defined as the effective distance (resistance distance) between the selected nodes multiplied by the volume of the graph, which is the sum of the conductance weights of all the edges in the graph (Chandra et al. 1997). The result represents the average number of steps that is needed to commute between the nodes during a random walk.

The function implements the algorithm given by Fouss et al. (2007).

Before calculating commute-time distances from a TransitionLayer object, see if you need to apply the function `geoCorrection`.

#### Value

distance matrix (S3 class dist or matrix)

#### Author(s)

Jacob van Etten <jacobvanetten@yahoo.com>

#### References

geoCorrection

Examples

# Create a new raster and set all its values to unity.
> r <- raster(nrows=18, ncols=36)
> r <- setValues(r, rep(1, ncell(raster)))

# Create a Transition object from the raster
> tr <- transition(r, function(x) 1/mean(x), 4)

# Create two sets of coordinates
> sP1 <- SpatialPoints(cbind(c(65, 5, -65), c(55, 35, -35)))
> sP2 <- SpatialPoints(cbind(c(50, 15, -40), c(80, 20, -5)))

# Calculate the resistance distance between the points
> commuteDistance(tr, sP1)

Description

This is a class union, providing a convenient class for coordinates in several formats. The class accepts coordinates in any of the following formats: 1. SpatialPoints 2. two-columned matrix 3. vector of length 2

Author(s)

Jacob van Etten <jacobvanetten@yahoo.com>

Examples

> showClass("Coords")
Description

Calculate the least-cost distance between points.

Usage

costDistance(x, fromCoords, toCoords)

Arguments

x
object of class TransitionLayer

fromCoords
first set of point locations (of SpatialPoints, matrix or numeric class)

toCoords
second, optional set of point locations (of SpatialPoints, matrix or numeric class)

Details

Cost units between cells are defined as the reciprocal of the values in the transition matrix.

The function uses Dijkstra’s algorithm, as implemented in the igraph package.

A projection correction is needed for accuracy in the case of grid data for a longlat raster (see function geoCorrection).

Value

distance matrix (S3 class dist or matrix)

Author(s)

Jacob van Etten <jacobvanetten@yahoo.com>

costDistance(tr2, sp1, sp2)

---

gendist

*Genetic distances and coordinates of haplogroup R1b1b2 populations in Europe*

Description

gendist: Genetic distances between 23 populations of Y-chromosome haplogroup R1b1b2 in Europe, calculated from haplotype microsatellite data (see source). The distance measure used is the negative logarithm of the shared proportion of alleles.

popCoord: Geographic coordinates of the same populations.

Usage

genDist

Format

dist object (gendist) and dataframe (popCoord)

Source

Distances calculated from Table S1 in Balaresque et al. (2010). Coordinates from Table 1.
References

---

**geoCorrection**

**Geographic Correction**

**Description**

Correct Transition* objects taking into account local distances

**Usage**

`geoCorrection(x, type, ...)`

**Arguments**

- **x**: object of class Transition*
- **type**: type of correction: "c", "r", or missing (only required for lonlat, see below)
- **...**: mutpl: matrix with correction factor (TRUE) or corrected values (FALSE, the default); scl: scale the correction values (default is FALSE)

**Details**

Geographic correction is necessary for all objects of the class Transition that are either: (1) based on a grid in a geographic (lonlat) projection and covering a large area; (2) made with directions > 4.

The function will correct for map distortion, as well as for diagonal connections between grid cells (which cover a longer distance than vertical or horizontal connections).

When working with lonlat grids, users should also anticipate whether they will use methods based on either least-cost or random walks, and set the `type` argument accordingly. In the case of least-cost distances, the correction is only done in East-West direction. In the case of random walks there should be an additional correction which reduces the conductance in North-South direction (`type="r"`).

The correction is done by dividing conductance values by the inter-cell distance. Distances are calculated as great-circle distances for lonlat grids (see function `isLonLat()`) and Euclidean distances for all other grids.

In the case of randomised shortest paths, the need for correction is somewhat in between these two correction methods. We have not developed an analytical solution for this problem yet. With very low values for theta, you may choose the correction for random walks, and for high values the one for least-cost paths. Users who want to work with intermediate values of theta are encouraged to experiment with different solutions.

The values are scaled to get values near 1 if the argument `scl` is set to TRUE. This is desirable for subsequent calculations involving random walk calculations. Values are divided by the W-E inter-cell distance (at the centre of the grid).
normalize

Value
Transition* object

Author(s)
Jacob van Etten <jacobvanetten@yahoo.com>

Examples

```r
r <- raster(ncol=36,nrow=18)
r <- setValues(r, rep(1, times = ncell(r)))
tr <- transition(r, mean, directions = 8)

# directly
tr1 <- geoCorrection(tr, type = "c", multpl = FALSE)

# the same, but with a separate correction matrix
trCorr <- geoCorrection(tr, type = "c", multpl = TRUE)
tr2 <- tr * trCorr
```

Description
Normalize the transition matrix.

Usage

```r
normalize(x, ...)
```

Arguments

- `x` object of class Transition*
- `...` optional argument method (see below)

Details
Normalization of the weighted adjacency matrix in the Transition* object. Matrix values are divided by their respective row-sums, column-sums, or the product of the square-roots of both (symmetric normalization). The default method is row-normalization. To use the other normalization methods, users can set the optional method argument to either "col" or "symm". For random walk calculations a symmetric matrix is needed (method = "symm").

Value
TransitionLayer object
Author(s)

Jacob van Etten <jacobvanetten@yahoo.com>

References

Examples

```r
r <- raster(ncol=36,nrow=18)
r <- setValues(r,rep(1,times=nCell(r)))
tr <- transition(r, mean, directions=8)

tr1 <- normalize(tr)
tr2 <- normalize(tr, method="symm")
```

---

**overlap**  
*Overlap and nonoverlap of trajectories*

Description

Special functions to calculate the degree of overlap and nonoverlap between trajectories

Usage

```r
overlap(a, b)
nonoverlap(a, b)
```

Arguments

- `a`  
  matrix object
- `b`  
  matrix object

Details

These functions are used by the `pathInc()` as defaults.

Value

- `matrix`

Note

The functions are provided here to assist the user in defining alternative measures of overlap / nonoverlap.
Author(s)

Jacob van Etten <jacobvanetten@yahoo.com>

---

Probability of passage

Description

Calculates for each cell the number of passages of a random-walk or randomised shortest paths with given origin(s) and destination(s). Either the total or the net number of passages can be calculated. In the case of multiple origins or destinations, each receives equal weight.

Usage

passage(x, origin, goal, theta, ...)

Arguments

- **x**: Object of class Transition
- **origin**: SpatialPoints, matrix or numeric object with coordinates or RasterLayer object with origin cells set to TRUE
- **goal**: SpatialPoints, matrix or numeric object with coordinates or RasterLayer object with origin cells set to TRUE
- **theta**: If zero or missing, a random walk results. If a numeric value $0 < \theta < 20$ is given, randomised shortest paths are calculated; $\theta$ is the degree from which the path randomly deviates from the shortest path
- **...**: Additional arguments: totalNet ("total" or "net"), and output ("RasterLayer" or "Transition")

Details

The net number of passages between $i$ and $j$ is defined as: $| \text{passages from } i \text{ to } j - \text{passages from } j \text{ to } i |$.

Defaults for additional argument totalNet is "net" and for output it is "RasterLayer".

Random walk requires a symmetric transition matrix.

Value

RasterLayer or Transition object, depending on the output argument.

commuteDistance, pathInc

Examples

```r
# create a new raster and set all its values to unity.
raster <- raster(nrows=18, ncols=36)
raster <- setValues(raster, rep(1, ncell(raster)))

# create a Transition object from the raster
tr <- transition(raster, mean, 4)
trC <- geoCorrection(tr, type="c", scl=TRUE)
trR <- geoCorrection(tr, type="r", scl=TRUE)

# create two coordinates
sp1 <- SpatialPoints(cbind(-105, 55))
sp2 <- SpatialPoints(cbind(105, -55))

# randomised shortest paths with theta = 2
rsPraster <- passage(trC, sp1, sp2, 2)
plot(rsPraster)
points(sp1)
points(sp2)

# randomised shortest paths with theta = 0.05
rsPraster <- passage(trC, sp1, sp2, 0.05)
plot(rsPraster)
points(sp1)
points(sp2)

# randomised shortest paths with theta = 0.05 and total
rsPraster <- passage(trC, sp1, sp2, 0.05, totalNet = "total")
plot(rsPraster)
points(sp1)
points(sp2)

# random walk
rwraster <- passage(trR, sp1, sp2)
plot(rwraster)
points(sp1)
points(sp2)
```
Description

Calculate the overlap and non-overlap of paths departing from a common origin. Two algorithms are available: random walk and randomised shortest paths.

Usage

pathInc(x, origin, from, to, theta, weight, ...)

Arguments

- **x**: transition matrix (class Transition)
- **origin**: coordinates of the origin (one point location, SpatialPoints, matrix or numeric class)
- **from**: coordinates of the destinations (SpatialPoints, matrix or numeric class)
- **to**: second set of coordinates of the destinations (can be missing)
- **theta**: value > 0 and < 20 (randomised shortest paths) or missing (random walk)
- **weight**: weight matrix – Reciprocals of the non-zero values are used as weights. If missing, reciprocals of the transition matrix are used.
- **...**: an extra argument for functions to be defined manually (see below)

Details

This is a complex wrapper function that calculates to what extent dispersal routes overlap or do not overlap.

First, the function calculates the trajectories for all "from" and "to" locations, starting from a single "origin" location. These trajectories can either be based on random walks or randomised shortest paths (giving a value to theta).

Then, for all unique pairs of trajectories, it calculates the extent to which these trajectories overlap or diverge. These values are given back to the user as a list of (distance) matrices.

If only "from" coordinates are given, the function calculates symmetric distance matrices for all combinations of points in "from". If both "from" and "to" coordinates are given, the function calculates a matrix of values with rows for all locations in "from" and columns for all locations in "to".

Overlap is currently calculated as the minimum values of each pair of trajectories compared. Non-overlap uses the following formula: Nonoverlap = max(0,max(a,b) - min(a,b)) (see van Etten and Hijmans 2010). See the last example to learn how to use an alternative function.

Value

- list of dist objects or list of matrices
Author(s)

Jacob van Etten <jacobvanetten@yahoo.com>. Implementation of randomised shortest paths based on Matlab code by Marco Saerens.

References

Examples

```r
#Create TransitionLayer
r <- raster(ncol=36,nrow=18)
r <- setValues(r,rep(1,times=ncell(r)))
tr <- transition(r,mean,directions=4)

#Two different types of correction are required
trR <- geoCorrection(tr, type="r", multpl=FALSE)
trC <- geoCorrection(tr, type="c", multpl=FALSE)

#Create TransitionStack
ts <- stack(trR, trR)

#Points for origin and coordinates between which to calculate path (non)overlaps
sP0 <- SpatialPoints(cbind(0,0))
sP1 <- SpatialPoints(cbind(c(65,5,-65),c(-55,35,-35)))

#Randomised shortest paths
#rescaling is needed: exp(-theta * trC) should give reasonable values
trC <- trC / median(transitionMatrix(trC)@x) #divide by median of the non-zero values
pathInc(trC, origin=sP0, from=sP1, theta=2)

#Random walk
pathInc(trR, origin=sP0, from=sP1)

#TransitionStack as weights
pathInc(trR, origin=sP0, from=sP1, weight=ts)

#Demonstrate use of an alternative function
#The current default is to take the minimum of each pair of layers
altoverlap <- function(a, b)
{
  aV <- as.vector(a[,rep(1:ncol(a), each=ncol(b))])
bV <- as.vector(b[,rep(1:ncol(b), times=ncol(a))])
result <- matrix(aV * bV, nrow = nrow(a), ncol=ncol(a)*ncol(b))
return(result)
```
raster-methods

Description

Create a RasterLayer from a TransitionLayer object with a call to the generic function `raster`. The \( n \times n \) transition matrix of the TransitionLayer is transformed to form the values \( n \) cells of a raster.

The following methods to ‘reduce’ the transition matrix are available with the optional argument `reducemethod`:

- `colSums`
- `rowSums`
- `colMeans`
- `rowMeans`
- `NZcolMeans`
- `NZrowMeans`

The latter two methods only take into account the non-zero entries in the transition matrix. The default is `NZcolMeans`.

Value

RasterLayer

Author(s)

Jacob van Etten <jacobvanetten@yahoo.com>

Examples

```r
# create a new raster and set all its values to unity.
\r <- raster(nrows=18, ncols=36)
\r <- setValues(\r, runif(ncell(\r), 0, 1))

# create a Transition object from the raster
\tr1 <- transition(\r, mean, 8)

# asymmetric
\nasf <- function(x) max(x) - x[1] + x[2]
\ttr2 <- transition(\r, asf, 8, symm=FALSE)
```
#create RasterLayer objects
r1 <- raster(tr1)
r2 <- raster(tr2)
r3 <- raster(tr1, "colMeans")

---

**rSPDistance**

**Randomized shortest path distance**

**Description**

Calculates the randomized shortest path distance between points.

**Usage**

```r
rSPDistance (x, from, to, theta, totalNet = "net", method=1)
```

**Arguments**

- `x` TransitionLayer object
- `from` point locations coordinates (of SpatialPoints, matrix or numeric class)
- `to` point locations coordinates (of SpatialPoints, matrix or numeric class)
- `theta` theta is the degree from which the path randomly deviates from the shortest path, \(0 < \theta < 20\)
- `totalNet` total or net movements between cells
- `method` method 1 (as defined in Saerens et al.) or method 2 (a modified version, see below in Details)

**Details**

The function implements the algorithm given by Saerens et al. (2009).

Method 1 implements the method as it is. Method 2 uses \(W = \exp(-\theta \ln(P))\).

**Value**

distance matrix (S3 class dist or matrix)

**Author(s)**

Jacob van Etten <jacobvanetten@yahoo.com>

**References**

**shortestPath**

**See Also**

`geoCorrection`

**Examples**

```r
# Create a new raster and set all its values to unity.
r <- raster(nrows=18, ncols=36)
r <- setValues(r, rep(1, ncell(raster)))

# Create a Transition object from the raster
tr <- transition(r, mean, 4)

# Create two sets of coordinates
sp1 <- SpatialPoints(cbind(c(65, 5, -65), c(55, 35, -35)))
sp2 <- SpatialPoints(cbind(c(50, 15, -40), c(80, 20, -5)))

# Calculate the RSP distance between the points
rSPDistance(tr, sp1, sp2, 1)
```

**Description**

Calculates the shortest path from an origin to a goal.

**Usage**

```r
shortestPath(x, origin, goal, ...)
```

**Arguments**

- `x` TransitionLayer object
- `origin` SpatialPoints, vector or matrix with coordinates, at the moment only the first cell is taken into account
- `goal` SpatialPoints, vector or matrix with coordinates
- `...` Additional argument: output

**Details**

As an additional argument output, the desired output object can be specified: either “TransitionLayer” (default), “TransitionStack” or “SpatialLines”. If there is more than one path either (1) transition values in the TransitionLayer get values of 1 / number of paths or (2) the SpatialLines object will contain more than one line.
Summary-methods

Value

Transition object.

Author(s)

Jacob van Etten <jacobvanetten@yahoo.com>.

costDistance, accCost

Examples

# example equivalent to that in the documentation on r.cost/r.drain in GRASS
r <- raster(nrows=6, ncols=7, xmn=0, xmx=7, ymn=0, ymx=6, crs="+proj=utm +units=m")

r[] <- c(2, 2, 1, 1, 5, 5, 5, 2, 2, 8, 8, 5, 2, 1, 7, 1, 1, 8, 2, 2, 2, 8, 7, 8, 8, 8, 8, 5, 8, 8, 1, 1, 5, 3, 9, 8, 1, 1, 2, 5, 3, 9)

T <- transition(r, function(x) 1/mean(x), 8)
# 1/mean: reciprocal to get permeability
T <- geoCorrection(T)

c1 <- c(5.5, 1.5)
c2 <- c(1.5, 5.5)

# make a SpatialLines object for visualization
sPath1 <- shortestPath(T, c1, c2, output="SpatialLines")
plot(r)
lines(sPath1)

# make a TransitionLayer for further calculations
sPath2 <- shortestPath(T, c1, c2)
plot(raster(sPath2))

Summary-methods

Description

The following summary methods are available:

mean, Median, max, min, range, prod, sum, any, all
Value

a TransitionLayer

Note

These methods compute a summary statistic based on cell values of layers in a TransitionStack. The result of these methods is always a single TransitionLayer.

Author(s)

Jacob van Etten

Examples

# Create a new raster and set all its values to unity.
raster <- raster(nrows=18, ncols=36)
raster <- setValues(raster, rep(1, ncell(raster)))

# Create a Transition object from the raster
tr <- transition(raster, mean, 4)

trS <- stack(tr, tr*2)

# Apply a Summary method
trSum <- sum(trS)

# plot(raster(trMean))

---

**sumReciprocal**

Reciprocal of the sum of the reciprocals of conductance values in Transition* objects

Description

Reciprocal of the sum of the reciprocals of conductance Transition* objects

Usage

sumReciprocal(x1, x2)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x1</td>
<td>TransitionLayer object</td>
</tr>
<tr>
<td>x2</td>
<td>TransitionLayer object</td>
</tr>
</tbody>
</table>
Details

To calculate the total resistance of two resistors that are serially connected, we should add their resistance values. However, if we work with conductance values, we need to take the reciprocal of the summed reciprocals of the conductance values. This function does that when adding two TransitionLayers with conductance values (matrixValues(tr) == "conductance").

For a TransitionLayer with resistance values (matrixValues(tr) == "resistance"), the function will not take reciprocals for that object, but will still take a reciprocal for the final product (which will consequently have conductance values).

Value

TransitionLayer object containing conductance values.

Author(s)

Jacob van Etten <jacobvanetten@yahoo.com>

Examples

```r
# Create a new raster and set all its values to unity.
raster <- raster(nrows=18, ncols=36)
raster <- setValues(raster, rep(1, ncell(raster)))

# Create TransitionLayer objects
tr1 <- transition(raster, mean, 4)
tr2 <- tr1
matrixValues(tr1)

# Set one to resistance
matrixValues(tr2) <- "resistance"

# Sum the two objects
sumReciprocal(tr1, tr2)
```

transition 
Create an object of the class Transition

Description

Create a Transition object from a RasterLayer or RasterBrick object. Transition values are calculated with a user-defined function from the grid values.

Usage

```
transition (x, transitionFunction, directions, ...)
```
transition

Arguments

- **x**: RasterLayer or RasterBrick (raster package)
- **transitionFunction**: Function to calculate transition values from grid values
- **directions**: Directions in which cells are connected (4, 8, 16, or other), see adjacent
- ...
    - additional arguments, see methods 1 and 3 below

Details

Users may use one of three methods to construct a Transition* object with this function.

1) **TransitionLayer from RasterLayer**

   transition(x, transitionFunction, directions, symm)

   When a symmetric transition matrix is required, the user should supply a transitionFunction f that obeys f(i,j) = f(j,i) (a commutative function). The function transition does no commutativity check. To obtain an asymmetric transition matrix, a non-commutative function should be supplied and an additional argument ‘symm’ should be set to FALSE.

2) **TransitionLayer from RasterBrick**

   transition(x, transitionFunction="mahal", directions)

   This method serves to summarize several layers of data in a single distance measure. The distance between adjacent cells is the normalized reciprocal of the Mahalanobis distance (mean distance / (mean distance + distance ij)).

3) **TransitionStack from RasterLayer**

   In contrast with the above methods, this method produces resistance matrices by default.

   a) Continuous variables - barriers

      transition(x, transitionFunction="barriers", directions, symm, intervalBreaks)

      This method creates a TransitionStack with each layer containing a discrete boundary between areas in x. Areas are defined by intervals in x. The argument intervalBreaks is a vector of interval breaks corresponding to the values in x. If between a pair of cells i and j, min(i,j) < break AND max(i,j) > break, then the value ij in the transition matrix becomes 1. All other values in the transition matrix remain 0. The package classInt offers several methods to define intervals. If symm is changed from the default (TRUE) to "up" or "down", it will give either only the upslope (symm="up") or downslope (symm="down") barriers.

   b) Categorical variables - barriers

      transition(x, transitionFunction="barriers", directions)

      In this case, areas are defined as categories in the input raster. A raster with a categorical variable can be created with asFactor(). The layers of the resulting TransitionStack contain all possible combinations of categories. Which layer contains the combination of categories i and j out of n categories, can be determined with these formulae:

      if symm is TRUE: layer(i,j) = n*(j-1) - j*(j-1)/2 + i-j. if symm is FALSE and i>j: layer(i,j) = ((n*(j-1) - j*(j-1)/2 + i-j) * 2) - 1. if symm is FALSE and i<j: layer(i,j) = (n*(j-1) - j*(j-1)/2 + i-j) * 2.

   c) Categorical variables - areas

      transition(x, transitionFunction="areas", directions)
Here, areas are also a categorical variable (see under 3b). The layers in the resulting TransitionStack represent each one area. Connections between two cells which are each inside the area are set to 1. Connections between a cell inside and a cell outside the area are set to 0.5. Connections between two cells outside the area are set to 0.

Value

Transition object

Author(s)

Jacob van Etten <jacobvanetten@yahoo.com>

Examples

#Create a new raster and set all its values to unity.
r <- raster(nrows=18, ncols=36)
r <- setValues(r, runif(ncell(r)))

#Create a Transition object from the raster
tr <- transition(r, transitionFunction=mean, directions=4)
tr #the sparse matrix is of class dsCMatrix (symmetric)

#Create an asymmetric transition matrix
#first, an arbitrary non-commutative function
f <- function(x) max(x) - x[1] + x[2]
tr2 <- transition(r, f, 4, symm=FALSE)
tr2 #the sparse matrix is of class dgCMatrix (=asymmetric)

#Barriers - interval breaks
tr3 <- transition(r, "barriers", 8, intervalBreaks=c(0.25, 0.5, 0.75))
nlayers(tr3)

#Barriers - categories
r <- round(r * 2)
r <- asFactor(r)
tr4 <- transition(r, "barriers", 8)
nlayers(tr4)
plot(raster(tr4[[2]]))

#Areas
r <- round(r * 2)
r <- asFactor(r)
tr5 <- transition(r, "areas", 8)
nlayers(tr5)
plot(raster(tr5[[2]]))
Transition slots

Extract or change elements of Transition* objects

Description

These functions are to be used to access slots of Transition* objects.

Usage

transitionMatrix(x, inflate)
transitionCells(x)
matrixValues(x)

Arguments

x object of class Transition*
inflate logical (default is TRUE)

Description

TransitionLayer and TransitionStack (or Transition*) are the core classes of the package gdistance. They are the main input into the functions to calculate distances and routes.

An object of the class TransitionLayer contains two main elements: a. a transition matrix with transition values between connected cells in a raster - an object of class sparseMatrix (package Matrix); b. information on the extent, resolution and projection of the underlying raster - an object of class Raster (package raster).

All slots belong to these two elements from other package, except two additional slots: 1. slot transitionCells, which is only used internally in the package; 2. slot matrixValues indicates if the nonzero values of the transition matrix contains conductance or resistance values.

Class TransitionStack contains one or more transition matrices.

Class Transition is the union of TransitionLayer and TransitionStack.

Objects from the Class

Objects can be created by calls of the form new("Transition", nrows, ncols, xmin, xmax, ymin, ymax, projection)
Transition* methods

Slots

transitionMatrix: Object of class "sparseMatrix"
transitionCells: Object of class "integer"
matrixValues: Object of class "character"
ncols: Object of class "integer"
nrows: Object of class "integer"
crs: Object of class "CRS" (sp package)
extent: Object of class "Extent"
layernames: Object of class "vector"

Extends

Class "Raster".

Author(s)

Jacob van Etten <jacobvanetten@yahoo.com>

Examples

showClass("TransitionLayer")

tr <- new("TransitionLayer", nrows=as.integer(36), ncols=as.integer(18),
extent=extent(c(xmin=-180, xmax=180, ymin=-90, ymax=90)),
crs=CRS("+proj=longlat +datum=WGS84"))

tr <- new("TransitionLayer", nrows=as.integer(36), ncols=as.integer(18),
extent=extent(c(xmin=-180, xmax=180, ymin=-90, ymax=90)),
crs=CRS(""))

Description

Methods for functions [ and [<- for object of the class TransitionLayer. Methods for functions [[] and [[]<- for object of the class TransitionStack.

Also see adjacencyFromTransition.
Examples

# Create a new raster and set all its values to unity.
r <- raster(nrows=18, ncols=36)
r <- setValues(r, rep(1, ncell(r)))

# Create TransitionLayer objects
tr1 <- transition(r, mean, 4)
tr2 <- tr1

# Extracting and replacing
tr1[cbind(1:9,1:9)] <- tr2[cbind(1:9,1:9)]
tr1[1:9,1:9] <- tr2[1:9,1:9]
tr1[1:5,1:5]
