Package ‘geometry’
February 18, 2019

License GPL (>= 3)
Title Mesh Generation and Surface Tessellation
Description Makes the ‘Qhull’ library <http://www.qhull.org> available in R, in a similar manner as in Octave and MATLAB. Qhull computes convex hulls, Delaunay triangulations, halfspace intersections about a point, Voronoi diagrams, furthest-site Delaunay triangulations, and furthest-site Voronoi diagrams. It runs in 2D, 3D, 4D, and higher dimensions. It implements the Quickhull algorithm for computing the convex hull. Qhull does not support constrained Delaunay triangulations, or mesh generation of non-convex objects, but the package does include some R functions that allow for this.

Conversion of Barycentric to Cartesian coordinates

Description

Given the barycentric coordinates of one or more points with respect to a simplex, compute the Cartesian coordinates of these points.

Usage

bary2cart(X, Beta)

Arguments

X Reference simplex in N dimensions represented by a N + 1-by-N matrix
Beta M points in barycentric coordinates with respect to the simplex X represented by a M-by-N + 1 matrix

Value

M-by-N matrix in which each row is the Cartesian coordinates of corresponding row of Beta

Author(s)

David Sterratt

See Also

cart2bary

Examples

## Define simplex in 2D (i.e. a triangle)
X <- rbind(c(0, 0),
          c(0, 1),
          c(1, 0))

## Cartesian coordinates of points
beta <- rbind(c(0, 0.5, 0.5),
              c(0.1, 0.8, 0.1))

## Plot triangle and points
trimesh(rbind(1:3), X)
text(X[,1], X[,2], 1:3) # Label vertices
P <- bary2cart(X, beta)
points(P)
Description

Given the Cartesian coordinates of one or more points, compute the barycentric coordinates of these points with respect to a simplex.

Usage

cart2bary(X, P)

Arguments

X    Reference simplex in \( N \) dimensions represented by a \( N + 1 \)-by-\( N \) matrix
P    \( M \)-by-\( N \) matrix in which each row is the Cartesian coordinates of a point.

Details

Given a reference simplex in \( N \) dimensions represented by a \( N + 1 \)-by-\( N \) matrix an arbitrary point \( P \) in Cartesian coordinates, represented by a 1-by-\( N \) row vector, can be written as

\[
P = \beta X
\]

where \( \beta \) is an \( N + 1 \) vector of the barycentric coordinates. A criterion on \( \beta \) is that

\[
\sum_i \beta_i = 1
\]

Now partition the simplex into its first \( N \) rows \( X_N \) and its \( N + 1 \)th row \( X_{N+1} \). Partition the barycentric coordinates into the first \( N \) columns \( \beta_N \) and the \( N + 1 \)th column \( \beta_{N+1} \). This allows us to write

\[
P_{N+1} - X_{N+1} = \beta_N X_N + \beta_{N+1} X_{N+1} - X_{N+1}
\]

which can be written

\[
P_{N+1} - X_{N+1} = \beta_N (X_N - 1_N X_{N+1})
\]

where \( 1_N \) is an \( N \)-by-1 matrix of ones. We can then solve for \( \beta_N \):

\[
\beta_N = (P_{N+1} - X_{N+1})(X_N - 1_N X_{N+1})^{-1}
\]

and compute

\[
\beta_{N+1} = 1 - \sum_{i=1}^N \beta_i
\]

This can be generalised for multiple values of \( P \), one per row.

Value

\( M \)-by-\( N + 1 \) matrix in which each row is the barycentric coordinates of corresponding row of \( P \). If the simplex is degenerate a warning is issued and the function returns NULL.
**Note**

Based on the Octave function by David Bateman.

**Author(s)**

David Sterratt

**See Also**

bary2cart

**Examples**

```r
## Define simplex in 2D (i.e. a triangle)
X <- rbind(c(0, 0),
           c(0, 1),
           c(1, 0))
## Cartesian coordinates of points
P <- rbind(c(0.5, 0.5),
           c(0.1, 0.8))
## Plot triangle and points
trimesh(rbind(1:3), X)
text(X[,1], X[,2], 1:3) # Label vertices
points(P)
cart2bary(X, P)
```

---

**Example Usage**

```r
cart2pol(x, y = NULL, z = NULL)
```

**Arguments**

- `x` x-coordinates or matrix with three columns
- `y` y-coordinates (optional, if `x`) is a matrix
- `z` z-coordinates (optional, if `x`) is a matrix

**Value**

A matrix `P` where each row represents one polar/(cylindrical) coordinate (`theta, r, (, z)`).

Kai Habel
David Sterratt

See Also

pol2cart, cart2sph, sph2cart

cart2sph

If called with a single matrix argument then each row of c represents the Cartesian coordinate (x, y, z).

Description

Transform Cartesian to spherical coordinates

Usage

cart2sph(x, y = NULL, z = NULL)

Arguments

x x-coordinates or matrix with three columns
y y-coordinates (optional, if x) is a matrix
z z-coordinates (optional, if x) is a matrix

Value

Matrix with columns:

theta the angle relative to the positive x-axis
phi the angle relative to the xy-plane
r the distance to the origin (θ, θ, θ)

sph2cart, cart2pol, pol2cart
convhulln

Compute smallest convex hull that encloses a set of points

Description

Returns an index matrix to the points of simplices (“triangles”) that form the smallest convex simplicial complex of a set of input points in \(N\)-dimensional space. This function interfaces the Qhull library.

Usage

```r
convhulln(p, options = "Tv", output.options = NULL,
    return.non.triangulated.facets = FALSE)
```

Arguments

- **p**: An \(M\)-by-\(N\) matrix. The rows of \(p\) represent \(M\) points in \(N\)-dimensional space.
- **options**: String containing extra options for the underlying Qhull command; see details below and Qhull documentation at ..//doc/qhull/html/qconvex.html#synopsis.
- **output.options**: String containing Qhull options to control output. Currently \(n\) (normals) and \(fa\) (generalised areas and volumes) are supported. Causes an object of return value for details. If output.options is TRUE, select all supported options.
- **return.non.triangulated.facets**: logical defining whether the output facets should be triangulated; FALSE by default.

Details

For silent operation, specify the option `pp`.

Value

If `return.non.triangulated.facets` is FALSE (default), return an \(M\)-by-\(N\) index matrix of which each row defines an \(N\)-dimensional “triangle”.

If `return.non.triangulated.facets` is TRUE then the number of columns equals the maximum number of vertices in a facet, and each row defines a polygon corresponding to a facet of the convex hull with its vertices followed by NAs until the end of the row. The indices refer to the rows in \(p\).

If the `output.options` or `options` argument contains `FA` or `n`, return a list with class `convhulln` comprising the named elements:

- **hull**: The convex hull, represented as a matrix, as described above
- **area**: If `FA` is specified, the generalised area of the hull. This is the surface area of a 3D hull or the length of the perimeter of a 2D hull. See ..//doc/qhull/html/qh-optf.html#FA.
- **vol**: If `FA` is specified, the generalised volume of the hull. This is volume of a 3D hull or the area of a 2D hull. See ..//doc/qhull/html/qh-optf.html#FA.
normals If n is specified, this is a matrix hyperplane normals with offsets. See ../doc/qhull/html/qh-opto.html#n.

Note
This is a port of the Octave’s (http://www.octave.org) geometry library. The Octave source was written by Kai Habel.
See further notes in delunayn.

for(i in 1:(8*360)) rgl.viewpoint(i/8)
## End(Not run)

delaunayn

Delaunay triangulation in N dimensions

Description
The Delaunay triangulation is a tessellation of the convex hull of the points such that no N-sphere defined by the N-triangles contains any other points from the set.

Usage
delaunayn(p, options = NULL, output.options = NULL, full = FALSE)
Arguments

- **p**: An \( M \)-by-\( N \) matrix whose rows represent \( M \) points in \( N \)-dimensional space.
- **options**: String containing extra control options for the underlying Qhull command; see the Qhull documentation (../doc/qhull/html/qdelaun.html) for the available options. The \( qbb \) option is always passed to Qhull. The default options are \( qcc \ qc \ qt \ qz \) for \( N < 4 \) and \( qcc \ qc \ qt \ qx \) for \( N \geq 4 \). If neither of the \( qJ \) or \( qt \) options are supplied, the \( qt \) option is passed to Qhull. The \( qt \) option ensures all Delaunay regions are simplical (e.g., triangles in 2D). See ../doc/qhull/html/qdelaun.html for more details. Contrary to the Qhull documentation, no degenerate (zero area) regions are returned with the \( qt \) option since the R function removes them from the triangulation. *If options is specified, the default options are overridden.* It is recommended to use `output.options` for options controlling the outputs.

- **output.options**: String containing Qhull options to control output. Currently \( fn \) (neighbours) and \( fa \) (areas) are supported. Causes an object of return value for details. If `output.options` is `TRUE`, select all supported options.
- **full**: Deprecated and will be removed in a future release. Adds options `Fa` and `Fn`.

Value

If neither of the Qhull options \( Fn \) or \( Fa \) are specified, return the Delaunay triangulation as a matrix with \( M \) rows and \( N + 1 \) columns in which each row contains a set of indices to the input points \( p \). Thus each row describes a simplex of dimension \( N \), e.g. a triangle in 2D or a tetrahedron in 3D.

If the `output.options` argument contains `Fn` or `Fa`, return a list with class `delaunayn` comprising the named elements:

- **tri**: The Delaunay triangulation described above.
- **areas**: If `Fa` is specified, an \( M \)-dimensional vector containing the generalise area of each simplex (e.g. in 2D the areas of triangles; in 3D the volumes of tetrahedra). See ../doc/qhull/html/qh-optf.html#Fa.
- **neighbours**: If `Fn` is specified, a list of neighbours of each simplex. See ../doc/qhull/html/qh-optf.html#Fn

Note

This function interfaces the Qhull library and is a port from Octave (http://www.octave.org) to R. Qhull computes convex hulls, Delaunay triangulations, halfspace intersections about a point, Voronoi diagrams, furthest-site Delaunay triangulations, and furthest-site Voronoi diagrams. It runs in 2D, 3D, 4D, and higher dimensions. It implements the Quickhull algorithm for computing the convex hull. Qhull handles round-off errors from floating point arithmetic. It computes volumes, surface areas, and approximations to the convex hull. See the Qhull documentation included in this distribution (the doc directory ../doc/qhull/index.html).

Qhull does not support constrained Delaunay triangulations, triangulation of non-convex surfaces, mesh generation of non-convex objects, or medium-sized inputs in 9D and higher. A rudimentary algorithm for mesh generation in non-convex regions using Delaunay triangulation is implemented in distmesh2d (currently only 2D).
Author(s)

Raoul Grasman and Robert B. Gramacy; based on the corresponding Octave sources of Kai Habel.

distmesh2d A simple mesh generator for non-convex regions

Description

An unstructured simplex requires a choice of mesh points (vertex nodes) and a triangulation. This is a simple and short algorithm that improves the quality of a mesh by relocating the mesh points according to a relaxation scheme of forces in a truss structure. The topology of the truss is reset using Delaunay triangulation. A (sufficiently smooth) user supplied signed distance function (fd) indicates if a given node is inside or outside the region. Points outside the region are projected back to the boundary.
distmesh2d

Usage

distmesh2d(fd, fh, h0, bbox, p = NULL, pfix = array(0, dim = c(0, 2)), ...
  , dptol = 0.001, ttol = 0.1, Fscale = 1.2, deltat = 0.2,
  geps = 0.001 * h0, deps = sqrt(.Machine$double.eps) * h0,
  maxiter = 1000, plot = TRUE)

Arguments

  fd Vectorized signed distance function, for example mesh.dcircle or mesh.diff,
        accepting an n-by-2 matrix, where n is arbitrary, as the first argument.

  fh Vectorized function, for example mesh.hunif, that returns desired edge length
        as a function of position. Accepts an n-by-2 matrix, where n is arbitrary, as its
        first argument.

  h0 Initial distance between mesh nodes. (Ignored if p is supplied)

  bbox Bounding box cbind(c(xmin,xmax), c(ymin,ymax))

  p An n-by-2 matrix. The rows of p represent locations of starting mesh nodes.

  pfix nfix-by-2 matrix with fixed node positions.

  ... parameters to be passed to fd and/or fh

  dptol Algorithm stops when all node movements are smaller than dptol

  ttol Controls how far the points can move (relatively) before a retriangulation with
        delaunayn.

  Fscale “Internal pressure” in the edges.

  deltat Size of the time step in Euler’s method.

  geps Tolerance in the geometry evaluations.

  deps Stepsize Δx in numerical derivative computation for distance function.

  maxiter Maximum iterations.

  plot logical. If TRUE (default), the mesh is plotted as it is generated.

Details

This is an implementation of original Matlab software of Per-Olof Persson.

Excerpt (modified) from the reference below:

‘The algorithm is based on a mechanical analogy between a triangular mesh and a 2D truss structure.
In the physical model, the edges of the Delaunay triangles of a set of points correspond to bars of a
truss. Each bar has a force-displacement relationship $f(\ell, \ell_0)$ depending on its current length $\ell$ and
its unextended length $\ell_0$.

‘External forces on the structure come at the boundaries, on which external forces have normal
orientations. These external forces are just large enough to prevent nodes from moving outside the
boundary. The position of the nodes are the unknowns, and are found by solving for a static force
equilibrium. The hope is that (when fh = function(p) return(rep(1,nrow(p)))), the lengths
of all the bars at equilibrium will be nearly equal, giving a well-shaped triangular mesh.’

See the references below for all details. Also, see the comments in the source file.
Value

n-by-2 matrix with node positions.

Wishlist

- *Implement in C/Fortran
- *Implement an nD version as provided in the Matlab package
- *Translate other functions of the Matlab package

  # continue on previous mesh
```
distmeshnd

A simple mesh generator for non-convex regions in n-D space

Description

An unstructured simplex requires a choice of mesh points (vertex nodes) and a triangulation. This is a simple and short algorithm that improves the quality of a mesh by relocating the mesh points according to a relaxation scheme of forces in a truss structure. The topology of the truss is reset using Delaunay triangulation. A (sufficiently smooth) user supplied signed distance function (fd) indicates if a given node is inside or outside the region. Points outside the region are projected back to the boundary.

Usage

```
distmeshnd(fdist, fh, h, box, pfix = array(dim = c(0, ncol(box))), ..., 
ptol = 0.001, ttol = 0.1, deltat = 0.1, geps = 0.1 * h, 
deps = sqrt(Machine$double.eps) * h)
```

Arguments

- **fdist**: Vectorized signed distance function, for example `mesh.dsphere`, accepting an m-by-n matrix, where m is arbitrary, as the first argument.
- **fh**: Vectorized function, for example `mesh.hunif`, that returns desired edge length as a function of position. Accepts an m-by-n matrix, where n is arbitrary, as its first argument.
- **h**: Initial distance between mesh nodes.
- **box**: 2-by-n matrix that specifies the bounding box. (See `distmesh2d` for an example.)
- **pfix**: nfix-by-2 matrix with fixed node positions.
- **ptol**: Algorithm stops when all node movements are smaller than dptol
- **ttol**: Controls how far the points can move (relatively) before a retriangulation with `delaunayn`.
- **deltat**: Size of the time step in Euler’s method.
- **geps**: Tolerance in the geometry evaluations.
- **deps**: Stepsize $\Delta x$ in numerical derivative computation for distance function.

Details

This is an implementation of original Matlab software of Per-Olof Persson.

Excerpt (modified) from the reference below:

‘The algorithm is based on a mechanical analogy between a triangular mesh and a n-D truss structure. In the physical model, the edges of the Delaunay triangles of a set of points correspond to bars of a truss. Each bar has a force-displacement relationship $f(\ell, \ell_0)$ depending on its current length $\ell$ and its unextended length $\ell_0$.‘
\texttt{distmeshnd}

External forces on the structure come at the boundaries, on which external forces have normal orientations. These external forces are just large enough to prevent nodes from moving outside the boundary. The position of the nodes are the unknowns, and are found by solving for a static force equilibrium. The hope is that (when $\text{fh} = \text{function(p) return(rep(1,nrow(p))))}$), the lengths of all the bars at equilibrium will be nearly equal, giving a well-shaped triangular mesh.

See the references below for all details. Also, see the comments in the source file of \texttt{distmesh2d}.

**Value**

$m$-by-$n$ matrix with node positions.

**Wishlist**

- *Implement in C/Fortran
- *Translate other functions of the Matlab package

## End(Not run)
```
dot

Compute the dot product of two vectors

Description

If x and y are matrices, calculate the dot-product along the first non-singleton dimension. If the optional argument d is given, calculate the dot-product along this dimension.

Usage

dot(x, y, d = NULL)

Arguments

x Matrix of vectors
y Matrix of vectors
d Dimension along which to calculate the dot product

Value

Vector with length of dth dimension

Author(s)

David Sterratt

entry.value

Retrieve or set a list of array element values

Description

entry.value retrieves or sets the values in an array a at the positions indicated by the rows of a matrix idx.

Usage

entry.value(a, idx)

Arguments

a An array.
idx Numerical matrix with the same number of columns as the number of dimensions of a. Each row indices a cell in a of which the value is to be retrieved or set.
value An array of length nrow(idx).
extprod3d

Compute external- or ‘cross’- product of 3D vectors.

Description

Computes the external product

\[(x_2y_3 - x_3y_2, x_3y_1 - x_1y_3, x_1y_2 - x_2y_1)\]

of the 3D vectors in \(x\) and \(y\).

Usage

\texttt{extprod3d(x, y, drop = TRUE)}

Arguments

\begin{itemize}
  \item \texttt{x} \quad n\text{-by-}3 matrix. Each row is one \(x\)-vector
  \item \texttt{y} \quad n\text{-by-}3 matrix. Each row is one \(y\)-vector
  \item \texttt{drop} \quad logical. If \texttt{TRUE} and if the inputs are one row matrices or vectors, then delete the dimensions of the array returned.
\end{itemize}

Value

If \(n\) is greater than 1 or \texttt{drop} is \texttt{FALSE}, \(n\text{-by-}3\) matrix; if \(n\) is 1 and \texttt{drop} is \texttt{TRUE}, a vector of length 3.

Examples

\begin{verbatim}
a = array(1:(4^4),c(4,4,4,4))
entry.value(a,cbind(1:4,1:4,1:4,1:4))
entry.value(a,cbind(1:4,1:4,1:4,1:4)) <- 0
entry.value(a, as.matrix(expand.grid(1:4,1:4,1:4,1:4)))
  # same as `c(a[1:4,1:4,1:4,1:4])` which is same as `c(a)`
\end{verbatim}
feasible.point

Author(s)
Raoul Grasman

See Also
drop

feasible.point  Find point in intersection of convex hulls

Description
Find point that lies somewhere in intersection of two convex hulls. If such a point does not exist, return NA. The feasible point is found using a linear program similar to the one suggested at .. /doc/qhull/html/qhalf.html#notes

Usage
feasible.point(ch1, ch2, tol = 0)

Arguments
ch1  First convex hull with normals
ch2  Second convex hull with normals
tol  The point must be at least this far within the facets of both convex hulls

halfspacen  Compute halfspace intersection about a point

Description
Compute halfspace intersection about a point

Usage
halfspacen(p, fp, options = "Tv")

Arguments
p  An n-by-dim+1 matrix. Each row of p represents a halfspace by a dim-dimensional normal to a hyperplane and the offset of the hyperplane.
fp  A “feasible” point that is within the space contained within all the halfspaces.
options  String containing extra options, separated by spaces, for the underlying Qhull command; see details below and Qhull documentation at http://www.qhull.org/html/qhalf.htm.
Value

A dim-column matrix containing the intersection points of the hyperplanes ../doc/qhull/html/qhalf.html. These points

convhulln

Examples

p <- rbox(0, C=0.5)  # Generate points on a unit cube centered around the origin
ch <- convhulln(p, "n")  # Generate convex hull, including normals to facets, with "n" option
# Intersections of half planes
# These points should be the same as the orginal points
pn <- halfspacen(ch$normals, c(0, 0, 0))

inhulln(ch, p)

Description

Tests if a set of points lies within a convex hull, returning a boolean vector in which each element is TRUE if the corresponding point lies within the hull and FALSE if it lies outwith the hull or on one of its facets.

Usage

inhulln(ch, p)

Arguments

ch  Convex hull produced using convhulln

p  An M-by-N matrix of points to test. The rows of p represent M points in N-dimensional space.
**Value**

A boolean vector with $M$ elements

**Author(s)**

David Sterratt

pin <- inhulln(ch, tp)
## Points on x-axis should be in box only between -1 and 1
pin == (tp[,1] < 1 & tp[,1] > -1)
```

---

**intersectn**

*Compute convex hull of intersection of two sets of points*

**Description**

Compute convex hull of intersection of two sets of points

**Usage**

```r
intersectn(ps1, ps2, tol = 0, return.chs = TRUE)
```

**Arguments**

- **ps1**: First set of points
- **ps2**: Second set of points
- **tol**: Tolerance used to determine if a feasible point lies within the convex hulls of both points and to round off the points generated by the halfspace intersection, which sometimes produces points very close together.
- **return.chs**: If TRUE (default) return the convex hulls of the first and second sets of points, as well as the convex hull of the intersection.
Value

List containing named elements: ch1, the convex hull of the first set of points, with volumes, areas and normals (see \texttt{convhull}n; ch2, the convex hull of the first set of points, with volumes, areas and normals; ps, the intersection points of convex hulls ch1 and ch2; and ch, the convex hull of the intersection points, with volumes, areas and normals.

Author(s)

David Sterratt

Examples

\begin{verbatim}
# Two overlapping boxes
ps1 <- rbox(0, C=0.5)
p2 <- rbox(0, C=0.5) + 0.5
out <- intersectn(ps1, ps2)
message(paste("Volume of 1st convex hull:", out$ch1$vol))
message(paste("Volume of 2nd convex hull:", out$ch2$vol))
message(paste("Volume of intersection convex hull:", out$ch$vol))
\end{verbatim}

\begin{itemize}
  \item \texttt{matmax} (Row-wise matrix functions)
\end{itemize}

Description

Compute maximum or minimum of each row, or sort each row of a matrix, or a set of (equal length) vectors.

Usage

\begin{verbatim}
matmax(...)  
\end{verbatim}

Arguments

\begin{itemize}
  \item \ldots \hspace{1cm} A numeric matrix or a set of numeric vectors (that are column-wise bind together into a matrix with \texttt{cbind}).
\end{itemize}

Value

\texttt{matmin} and \texttt{matmax} return a vector of length \texttt{nrow(cbind(...)}. \texttt{matsort} returns a matrix of dimension \texttt{dim(cbind(...))} with in each row of \texttt{cbind(...)} sorted. \texttt{matsort(x)} is a lot faster than, e.g., \texttt{t(apply(x,1,sort))}, if \texttt{x} is tall (i.e., \texttt{nrow(x)»ncol(x)} and \texttt{ncol(x)<30}. If \texttt{ncol(x)>30} then \texttt{matsort} simply calls \texttt{t(apply(x,1,sort))}. \texttt{matorder} returns a permutation which rearranges its first argument into ascending order, breaking ties by further arguments.
mesh.dcircle

Author(s)
Raoul Grasman

Examples
example(Unique)

mesh.dcircle  Circle distance function

Description
Signed distance from points p to boundary of circle to allow easy definition of regions in distmesh2d.

Usage
mesh.dcircle(p, radius = 1, ...)

Arguments
p    A matrix with 2 columns (3 in mesh.dsphere), each row representing a point in the plane.
radius    radius of circle
...    additional arguments (not used)

Value
A vector of length nrow(p) containing the signed distances to the circle

Author(s)
Raoul Grasman; translated from original Matlab sources of Per-Olof Persson.

References
http://persson.berkeley.edu/distmesh/

See Also

Examples
example(distmesh2d)
mesh.drectangle

Difference, union and intersection operation on two regions

Description

Compute the signed distances from points p to a region defined by the difference, union or intersection of regions specified by the functions regionA and regionB. regionA and regionB must accept a matrix p with 2 columns as their first argument, and must return a vector of length nrow(p) containing the signed distances of the supplied points in p to their respective regions.

Usage

mesh.drectangle(p, regionA, regionB, ...)

Arguments

p A matrix with 2 columns (3 in mesh.dsphere), each row representing a point in the plane.
regionA vectorized function describing region A in the union / intersection / difference
regionB vectorized function describing region B in the union / intersection / difference
... additional arguments passed to regionA and regionB

Value

A vector of length nrow(p) containing the signed distances to the boundary of the region.

Author(s)

Raoul Grasman; translated from original Matlab sources of Per-Olof Persson.

See Also

distmesh2d, mesh.dcircle, mesh.drectangle mesh.dsphere

mesh.drectangle

Rectangle distance function

Description

Signed distance from points p to boundary of rectangle to allow easy definition of regions in distmesh2d.

Usage

mesh.drectangle(p, x1 = -1/2, y1 = -1/2, x2 = 1/2, y2 = 1/2, ...)

Notice

The region defined by regionA and regionB is the set of points that are in regionA or regionB but not in both.
mesh.dsphere

Arguments
p A matrix with 2 columns, each row representing a point in the plane.
x1 lower left corner of rectangle
y1 lower left corner of rectangle
x2 upper right corner of rectangle
y2 upper right corner of rectangle
... additional arguments (not used)

Value
a vector of length nrow(p) containing the signed distances

Author(s)
Raoul Grasman; translated from original Matlab sources of Per-Olof Persson.

References
http://persson.berkeley.edu/distmesh/

See Also

distmeshnd

Examples

example(distmeshnd)

---

mesh.hunif  

Uniform desired edge length

Description

Uniform desired edge length function of position to allow easy definition of regions when passed as the \( f \)h argument of distmesh2d or distmeshnd.

Usage

mesh.hunif(p, ...)

Arguments

\( p \) A \( n \)-by-\( m \) matrix, each row representing a point in an \( m \)-dimensional space.

\( \ldots \) 

additional arguments (not used)

Value

Vector of ones of length \( n \).

Author(s)

Raoul Grasman; translated from original Matlab sources of Per-Olof Persson.
pol2cart

See Also

distmesh2d and distmeshnd.

pol2cart

Transform polar or cylindrical coordinates to Cartesian coordinates.

Description

The inputs theta, r, (and z) must be the same shape, or scalar. If called with a single matrix argument then each row of P represents the polar/(cylindrical) coordinate (theta, r, z).

Usage

pol2cart(theta, r = NULL, z = NULL)

Arguments

theta describes the angle relative to the positive x-axis.

r is the distance to the z-axis (0, 0, z).

z (optional) is the z-coordinate

Value

a matrix C where each row represents one Cartesian coordinate (x, y, z).

Author(s)

Kai Habel

David Sterratt

See Also

cart2pol, sph2cart, cart2sph
polyarea

Determines area of a polygon by triangle method.

Description

Determines area of a polygon by triangle method. The variables x and y define the vertex pairs, and must therefore have the same shape. They can be either vectors or arrays. If they are arrays then the columns of x and y are treated separately and an area returned for each.

Usage

polyarea(x, y, d = 1)

Arguments

x
X coordinates of vertices.
y
Y coordinates of vertices.
d
Dimension of array to work along.

Details

If the optional dim argument is given, then polyarea works along this dimension of the arrays x and y.

Value

Area(s) of polygon(s).

Author(s)

David Sterratt based on the octave sources by David M. Doolin

Examples

x <- c(1, 1, 3, 3, 1)
y <- c(1, 3, 3, 1, 1)
polyarea(x, y)
polyarea(cbind(x, x), cbind(y, y)) ## c(4, 4)
polyarea(cbind(x, x), cbind(y, y), 1) ## c(4, 4)
polyarea(rbind(x, x), rbind(y, y), 2) ## c(4, 4)
**rbox**  
*Generate various point distributions*

**Description**
Default is corners of a hypercube.

**Usage**
```
rbox(n = 3000, D = 3, B = 0.5, C = NA)
```

**Arguments**
- `n` number of random points in hypercube
- `D` number of dimensions of hypercube
- `B` bounding box coordinate - faces will be \(-B\) and \(B\) from origin
- `C` add a unit hypercube to the output - faces will be \(-C\) and \(C\) from origin

**Value**
Matrix of points

**Author(s)**
David Sterratt

---

**sph2cart**  
*Transform spherical coordinates to Cartesian coordinates*

**Description**
The inputs \(\theta\), \(\phi\), and \(r\) must be the same shape, or scalar. If called with a single matrix argument then each row of \(S\) represents the spherical coordinate \((\theta, \phi, r)\).

**Usage**
```
sph2cart(theta, phi = NULL, r = NULL)
```

**Arguments**
- `theta` describes the angle relative to the positive x-axis.
- `phi` is the angle relative to the xy-plane.
- `r` is the distance to the origin \((0, 0, 0)\).

If only a single return argument is requested then return a matrix \(C\) where each row represents one Cartesian coordinate \((x, y, z)\).
**surf.tri**

**Author(s)**
Kai Habel
David Sterratt

**See Also**
cart2sph, pol2cart, cart2pol

---

**surf.tri** *Find surface triangles from tetrahedral mesh*

**Description**
Find surface triangles from tetrahedral mesh typically obtained with `delaunayn`.

**Usage**
surf.tri(p, t)

**Arguments**
- **p**: An n-by-3 matrix. The rows of `p` represent `n` points in `dim`-dimensional space.
- **t**: Matrix with 4 columns, interpreted as output of `delaunayn`.

**Details**
surf.tri and `convhulln` serve a similar purpose in 3D, but surf.tri also works for non-convex meshes obtained e.g. with `distmeshnd`. It also does not produce currently unavoidable diagnostic output on the console as `convhulln` does at the Rterm console—i.e., surf.tri is silent.

**Value**
An m-by-3 index matrix of which each row defines a triangle. The indices refer to the rows in `p`.

**Note**
surf.tri was based on Matlab code for mesh of Per-Olof Persson ([http://persson.berkeley.edu/distmesh/](http://persson.berkeley.edu/distmesh/)).

**Author(s)**
Raoul Grasman

tetramesh  Render tetrahedron mesh (3D)

Description

tetramesh(T, X, col) uses the rgl package to display the tetrahedrons defined in the m-by-4 matrix T as mesh. Each row of T specifies a tetrahedron by giving the 4 indices of its points in X.

Usage

tetramesh(T, X, col = grDevices::heat.colors(nrow(T)), clear = TRUE,
...)

Arguments

- **T**
  - T is a m-by-3 matrix in trimesh and m-by-4 in tetramesh. A row of T contains indices into X of the vertices of a triangle/tetrahedron. T is usually the output of delaunayn.

- **X**
  - X is an n-by-2/n-by-3 matrix. The rows of X represent n points in 2D/3D space.
[to.mesh3d](

```r

col The tetrahedron colour. See rgl documentation for details.
clear Should the current rendering device be cleared?

as.mesh3d

tramesh Display triangles mesh (2D)

Description

trimesh(T, p) displays the triangles defined in the m-by-3 matrix T and points p as a mesh. Each row of T specifies a triangle by giving the 3 indices of its points in X.

Usage

trimesh(T, p, p2, add = FALSE, axis = FALSE, boxed = FALSE, ...)

Arguments

T
A matrix. A row of T contains indices into X of the vertices of a triangle. T is usually the output of delaunayn.

p
A vector or a matrix.

p2
if p is not a matrix p and p2 are bind to a matrix with cbind.

add
Add to existing plot in current active device?

axis
Draw axes?

boxed
Plot box?

... Parameters to the rendering device. See the rgl package.

tt = delaunayn(p)
trimesh(tt,p)
tsearch  
*Search for the enclosing Delaunay convex hull*

**Description**

For \( t \leftarrow \text{delaunay}(\text{cbind}(x, y)) \), where \((x, y)\) is a 2D set of points, \( \text{tsearch}(x, y, t, xi, yi) \) finds the index in \( t \) containing the points \((xi, yi)\). For points outside the convex hull the index is \( \text{NA} \).

**Usage**

\[
\text{tsearch}(x, y, t, xi, yi, bary = \text{FALSE}, \text{method} = \text{"quadtree"})
\]

**Arguments**

- \( x \): X-coordinates of triangulation points
- \( y \): Y-coordinates of triangulation points
- \( t \): Triangulation, e.g. produced by \( t \leftarrow \text{delaunay}(\text{cbind}(x, y)) \)
- \( xi \): X-coordinates of points to test
- \( yi \): Y-coordinates of points to test
- \( \text{bary} \): If \( \text{TRUE} \) return barycentric coordinates as well as index of triangle.
- \( \text{method} \): One of "quadtree" or "orig". The Quadtree algorithm is much faster and new from version 0.4.0. The orig option uses the tsearch algorithm adapted from Octave code. Its use is deprecated and it may be removed from a future version of the package.

**Value**

If \( \text{bary} \) is \( \text{FALSE} \), the index in \( t \) containing the points \((xi, yi)\). For points outside the convex hull the index is \( \text{NA} \). If \( \text{bary} \) is \( \text{TRUE} \), a list containing:

- \( \text{list("idx")} \): the index in \( t \) containing the points \((xi, yi)\)
- \( \text{list("p")} \): a 3-column matrix containing the barycentric coordinates with respect to the enclosing triangle of each point \((xi, yi)\).

**Note**

The original Octave function is Copyright (C) 2007-2012 David Bateman

**Author(s)**

Jean-Romain Roussel (Quadtree algorithm), David Sterratt (Octave-based implementation)

**See Also**

tsearchn, delaunayn
tsearchn

Search for the enclosing Delaunay convex hull

Description

For \( t = \text{delaunayn}(x) \), where \( x \) is a set of points in \( N \) dimensions, \( \text{tsearchn}(x, t, xi) \) finds the index in \( t \) containing the points \( xi \). For points outside the convex hull, \( \text{idx} \) is \( \text{NA} \). \( \text{tsearchn} \) also returns the barycentric coordinates \( p \) of the enclosing triangles.

Usage

\[
\text{tsearchn}(x, t, xi, ...) 
\]

Arguments

\( x \)  
An \( N \)-column matrix, in which each row represents a point in \( N \)-dimensional space.

\( t \)  
A matrix with \( N + 1 \) columns. A row of \( t \) contains indices into \( x \) of the vertices of an \( N \)-dimensional simplex. \( t \) is usually the output of \( \text{delaunayn} \).

\( xi \)  
An \( M \)-by-\( N \) matrix. The rows of \( xi \) represent \( M \) points in \( N \)-dimensional space whose positions in the mesh are being sought.

\( ... \)  
Additional arguments

Details

If \( x \) is \( \text{NA} \) and the \( t \) is a \( \text{delaunayn} \) object produced by \( \text{delaunayn} \) with the full option, then use the Qhull library to perform the search. Please note that this is experimental in geometry version 0.4.0 and is only partly tested for 3D hulls, and does not yet work for hulls of 4 dimensions and above.

Value

A list containing:

\( \text{idx} \)  
An \( M \)-long vector containing the indices of the row of \( t \) in which each point in \( xi \) is found.

\( p \)  
An \( M \)-by-\( N + 1 \) matrix containing the barycentric coordinates with respect to the enclosing simplex of each point in \( xi \).

Note

Based on the Octave function Copyright (C) 2007-2012 David Bateman.

tsearch, delaunayn

---

**Unique**

**Extract Unique Rows**

**Description**

‘Unique’ returns a vector, data frame or array like ‘x’ but with duplicate elements removed.

**Usage**

Unique(X, rows.are.sets = FALSE)

**Arguments**

- **x**: Numerical matrix.
- **rows.are.sets**: If ‘TRUE’, rows are treated as sets - i.e., to define uniqueness, the order of the rows does not matter.

**Value**

Matrix of the same number of columns as x, with the unique rows in x sorted according to the columns of x. If rows.are.sets = TRUE the rows are also sorted.

**Note**

‘Unique’ is (under circumstances) much quicker than the more generic base function ‘unique’.

**Author(s)**

Raoul Grasman

**Examples**

```r
# 'Unique' is faster than 'unique'
x = matrix(sample(1:(4*8),4*8),ncol=4)
y = x[sample(1:nrow(x),3000,TRUE),]
gc(); system.time(unique(y))
gc(); system.time(Unique(y))

#
z = Unique(y)
x[matorder(x),]
z[matorder(z),]
```
