Package ‘geometry’

December 4, 2019

License GPL (>= 3)

Title Mesh Generation and Surface Tessellation

Description Makes the 'Qhull' library <http://www.qhull.org>
available in R, in a similar manner as in Octave and MATLAB. Qhull
computes convex hulls, Delaunay triangulations, halfspace
intersections about a point, Voronoi diagrams, furthest-site
Delaunay triangulations, and furthest-site Voronoi diagrams. It
runs in 2D, 3D, 4D, and higher dimensions. It implements the
Quickhull algorithm for computing the convex hull. Qhull does not
support constrained Delaunay triangulations, or mesh generation of
non-convex objects, but the package does include some R functions
that allow for this.

bary2cart

Conversion of Barycentric to Cartesian coordinates

Description

Given the barycentric coordinates of one or more points with respect to a simplex, compute the Cartesian coordinates of these points.

Usage

bary2cart(X, Beta)

Arguments

X Reference simplex in $N$ dimensions represented by a $N + 1$-by-$N$ matrix
Beta $M$ points in barycentric coordinates with respect to the simplex X represented by a $M$-by-$N + 1$ matrix

Value

$M$-by-$N$ matrix in which each row is the Cartesian coordinates of corresponding row of Beta

Author(s)

David Sterratt

See Also

cart2bary

Examples

```r
## Define simplex in 2D (i.e. a triangle)
X <- rbind(c(0, 0),
           c(0, 1),
           c(1, 0))
## Cartesian coordinates of points
beta <- rbind(c(0, 0.5, 0.5),
               c(0.1, 0.8, 0.1))
## Plot triangle and points
trimesh(rbind(1:3), X)
text(X[,1], X[,2], 1:3) # Label vertices
P <- bary2cart(X, beta)
points(P)
```
Conversion of Cartesian to Barycentric coordinates.

Description
Given the Cartesian coordinates of one or more points, compute the barycentric coordinates of these points with respect to a simplex.

Usage
\texttt{cart2bary(X, P)}

Arguments
\begin{itemize}
\item \texttt{X} \quad \text{Reference simplex in } N \text{ dimensions represented by a } N + 1 \text{-by-} N \text{ matrix}
\item \texttt{P} \quad M \text{-by-} N \text{ matrix in which each row is the Cartesian coordinates of a point.}
\end{itemize}

Details
Given a reference simplex in \( N \) dimensions represented by a \( N + 1 \)-by-\( N \) matrix an arbitrary point \( P \) in Cartesian coordinates, represented by a 1-by-\( N \) row vector, can be written as
\[
P = \beta X
\]
where \( \beta \) is an \( N + 1 \) vector of the barycentric coordinates. A criterion on \( \beta \) is that
\[
\sum_i \beta_i = 1
\]
Now partition the simplex into its first \( N \) rows \( X_N \) and its \( N + 1 \)th row \( X_{N+1} \). Partition the barycentric coordinates into the first \( N \) columns \( \beta_N \) and the \( N + 1 \)th column \( \beta_{N+1} \). This allows us to write
\[
P_{N+1} - X_{N+1} = \beta_N X_N + \beta_{N+1} X_{N+1} - X_{N+1}
\]
which can be written
\[
P_{N+1} - X_{N+1} = \beta_N (X_N - 1_N X_{N+1})
\]
where \( 1_N \) is an \( N \)-by-1 matrix of ones. We can then solve for \( \beta_N \):
\[
\beta_N = (P_{N+1} - X_{N+1})(X_N - 1_N X_{N+1})^{-1}
\]
and compute
\[
\beta_{N+1} = 1 - \sum_{i=1}^{N} \beta_i
\]
This can be generalised for multiple values of \( P \), one per row.

Value
\( M \)-by-\( N + 1 \) matrix in which each row is the barycentric coordinates of corresponding row of \( P \). If the simplex is degenerate a warning is issued and the function returns NULL.
Note

Based on the Octave function by David Bateman.

Examples

```r
## Define simplex in 2D (i.e. a triangle)
X <- rbind(c(0, 0),
           c(0, 1),
           c(1, 0))

## Cartesian coordinates of points
P <- rbind(c(0.5, 0.5),
           c(0.1, 0.8))

## Plot triangle and points
trimesh(rbind(1:3), X)
text(X[,1], X[,2], 1:3) # Label vertices
points(P)
cart2bary(X, P)
```

cart2pol

Transform Cartesian coordinates to polar or cylindrical coordinates.

Description

The inputs \( x, y, \) (and \( z \)) must be the same shape, or scalar. If called with a single matrix argument then each row of \( C \) represents the Cartesian coordinate \((x, y, z)\).

Usage

cart2pol(x, y = NULL, z = NULL)

Arguments

- **x**: \( x \)-coordinates or matrix with three columns
- **y**: \( y \)-coordinates (optional, if \( x \) is a matrix)
- **z**: \( z \)-coordinates (optional, if \( x \) is a matrix)

Value

A matrix \( P \) where each row represents one polar/(cylindrical) coordinate \((\theta, r, (, z))\).

pol2cart, cart2sph, sph2cart

cart2sph

Transform Cartesian to spherical coordinates

Usage

cart2sph(x, y = NULL, z = NULL)

Arguments

x x-coordinates or matrix with three columns
y y-coordinates (optional, if x) is a matrix
z z-coordinates (optional, if x) is a matrix

Value

Matrix with columns:

theta the angle relative to the positive x-axis
phi the angle relative to the xy-plane
r the distance to the origin (\(\theta, \phi, \rho\))

convhulln  

*Compute smallest convex hull that encloses a set of points*

**Description**

Returns information about the smallest convex complex of a set of input points in $N$-dimensional space (the convex hull of the points). By default, indices to points forming the facets of the hull are returned; optionally normals to the facets and the generalised surface area and volume can be returned. This function interfaces the Qhull library.

**Usage**

```r
cvhulln(p, options = "Tv", output.options = NULL, 
return.non.triangulated.facets = FALSE)
```

**Arguments**

- `p` An $M$-by-$N$ matrix. The rows of `p` represent $M$ points in $N$-dimensional space.
- `options` String containing extra options for the underlying Qhull command; see details below and Qhull documentation at `../doc/qhull/html/qconvex.html#synopsis`.
- `output.options` String containing Qhull options to generate extra output. Currently `n` (normals) and `FA` (generalised areas and volumes) are supported; see ‘Value’ for details. If `output.options` is `TRUE`, select all supported options.
- `return.non.triangulated.facets` logical defining whether the output facets should be triangulated; `FALSE` by default.

**Value**

By default (`return.non.triangulated.facets` is `FALSE`), return an $M$-by-$N$ matrix in which each row contains the indices of the points in `p` forming an $N - 1$-dimensional facet. e.g In 3 dimensions, there are 3 indices in each row describing the vertices of 2-dimensional triangles.

If `return.non.triangulated.facets` is `TRUE` then the number of columns equals the maximum number of vertices in a facet, and each row defines a polygon corresponding to a facet of the convex hull with its vertices followed by NAs until the end of the row.

If the `output.options` or `options` argument contains `FA` or `n`, return a list with class `convhulln` comprising the named elements:

- `p` The points passed to `convhulln`
- `hull` The convex hull, represented as a matrix indexing `p`, as described above
- `area` If `FA` is specified, the generalised area of the hull. This is the surface area of a 3D hull or the length of the perimeter of a 2D hull. See `../doc/qhull/html/qh-optf.html#FA`.
- `vol` If `FA` is specified, the generalised volume of the hull. This is volume of a 3D hull or the area of a 2D hull. See `../doc/qhull/html/qh-optf.html#FA`.
- `normals` If `n` is specified, this is a matrix hyperplane normals with offsets. See `../doc/qhull/html/qh-opto.html#n`. 

```r
```
Note

This function was originally a port of the Octave convhulln function written by Kai Habel.
See further notes in delaunayn.

Examples

## Points in a sphere
ps <- matrix(rnorm(3000), ncol=3)
ps <- sqrt(3)*ps/drop(sqrt((ps^2) %*% rep(1, 3)))
ts.surf <- t(convhulln(ps)) # see the qhull documentations for the options
## Not run:
rgl.triangles(ps[ts.surf,1],ps[ts.surf,2],ps[ts.surf,3],col="blue",alpha=.2)
for(i in 1:(8*360)) rgl.viewpoint(i/8)
## End(Not run)

## Square
pq <- rbox(0, C=0.5, D=2)
# Return indices only
convhulln(pq)
# Return convhulln object with normals, generalised area and volume
ch <- convhulln(pq, output.options=TRUE)
plot(ch)

## Cube
pc <- rbox(0, C=0.5, D=3)
# Return indices of triangles on surface
convhulln(pc)
# Return indices of squares on surface
convhulln(pc, return.non.triangulated.facets=TRUE)
delaunayn

**Description**

The Delaunay triangulation is a tessellation of the convex hull of the points such that no \( N \)-sphere defined by the \( N \)-triangles contains any other points from the set.

**Usage**

```r
delaunayn(p, options = NULL, output.options = NULL, full = FALSE)
```

**Arguments**

- `p` An \( M \)-by-\( N \) matrix whose rows represent \( M \) points in \( N \)-dimensional space.
- `options` String containing extra control options for the underlying Qhull command; see the Qhull documentation (../doc/qhull/html/qdelaun.html) for the available options.
  - The Qbb option is always passed to Qhull. The remaining default options are Qcc Qc Qt Qz for \( N < 4 \) and Qcc Qc Qt Qx for \( N \geq 4 \). If neither of the QJ or Qt options are supplied, the Qt option is passed to Qhull. The Qt option ensures all Delaunay regions are simplical (e.g., triangles in 2D). See ../doc/qhull/html/qdelaun.html for more details. Contrary to the Qhull documentation, no degenerate (zero area) regions are returned with the Qt option since the R function removes them from the triangulation.
  - *If options is specified, the default options are overridden.* It is recommended to use output.options for options controlling the outputs.
- `output.options` String containing Qhull options to control output. Currently Fn (neighbours) and Fa (areas) are supported. Causes an object of return value for details. If output.options is TRUE, select all supported options.
- `full` Deprecated and will be removed in a future release. Adds options Fa and Fn.

**Value**

If output.options is NULL (the default), return the Delaunay triangulation as a matrix with \( M \) rows and \( N + 1 \) columns in which each row contains a set of indices to the input points \( p \). Thus each row describes a simplex of dimension \( N \), e.g. a triangle in 2D or a tetrahedron in 3D.

If the output.options argument is TRUE or is a string containing Fn or Fa, return a list with class delaunayn comprising the named elements:

- `tri` The Delaunay triangulation described above
- `areas` If TRUE or if Fa is specified, an \( M \)-dimensional vector containing the generalised area of each simplex (e.g. in 2D the areas of triangles; in 3D the volumes of tetrahedra). See ../doc/qhull/html/qh-optf.html#Fa.
- `neighbours` If TRUE or if Fn is specified, a list of neighbours of each simplex. See ../doc/qhull/html/qh-optf.html#Fn
Note

This function interfaces the Qhull library and is a port from Octave (http://www.octave.org) to R. Qhull computes convex hulls, Delaunay triangulations, halfspace intersections about a point, Voronoi diagrams, furthest-site Delaunay triangulations, and furthest-site Voronoi diagrams. It runs in 2D, 3D, 4D, and higher dimensions. It implements the Quickhull algorithm for computing the convex hull. Qhull handles round-off errors from floating point arithmetic. It computes volumes, surface areas, and approximations to the convex hull. See the Qhull documentation included in this distribution (the doc directory ../doc/qhull/index.html).

Qhull does not support constrained Delaunay triangulations, triangulation of non-convex surfaces, mesh generation of non-convex objects, or medium-sized inputs in 9D and higher. A rudimentary algorithm for mesh generation in non-convex regions using Delaunay triangulation is implemented in distmesh2d (currently only 2D).

Author(s)

Raoul Grasman and Robert B. Gramacy; based on the corresponding Octave sources of Kai Habel.

## sum of generalised areas is total volume of cube
sum(tc1$areas)
```
A simple mesh generator for non-convex regions

Description
An unstructured simplex requires a choice of mesh points (vertex nodes) and a triangulation. This is a simple and short algorithm that improves the quality of a mesh by relocating the mesh points according to a relaxation scheme of forces in a truss structure. The topology of the truss is reset using Delaunay triangulation. A (sufficiently smooth) user supplied signed distance function (fd) indicates if a given node is inside or outside the region. Points outside the region are projected back to the boundary.

Usage
distmesh2d(fd, fh, h0, bbox, p = NULL, pfix = array(0, dim = c(0, 2)),
..., dptol = 0.001, ttol = 0.1, Fscale = 1.2, deltat = 0.2,
geps = 0.001 * h0, deps = sqrt(.Machine$double.eps) * h0,
maxiter = 1000, plot = TRUE)

Arguments

- **fd**: Vectorized signed distance function, for example `mesh.dcircle` or `mesh.diff`, accepting an n-by-2 matrix, where n is arbitrary, as the first argument.
- **fh**: Vectorized function, for example `mesh.hunif`, that returns desired edge length as a function of position. Accepts an n-by-2 matrix, where n is arbitrary, as its first argument.
- **h0**: Initial distance between mesh nodes. (Ignored if p is supplied)
- **bbox**: Bounding box `cbind(c(xmin,xmax),c(ymin,ymax))`
- **p**: An n-by-2 matrix. The rows of p represent locations of starting mesh nodes.
- **pfix**: nfix-by-2 matrix with fixed node positions.
- **dptol**: Algorithm stops when all node movements are smaller than dptol
- **ttol**: Controls how far the points can move (relatively) before a retriangulation with `delaunayn`.
- **Fscale**: “Internal pressure” in the edges.
- **deltat**: Size of the time step in Euler’s method.
- **geps**: Tolerance in the geometry evaluations.
- **deps**: Stepsize $\Delta x$ in numerical derivative computation for distance function.
- **maxiter**: Maximum iterations.
- **plot**: logical. If TRUE (default), the mesh is plotted as it is generated.
Details

This is an implementation of original Matlab software of Per-Olof Persson.

Excerpt (modified) from the reference below:

‘The algorithm is based on a mechanical analogy between a triangular mesh and a 2D truss structure. In the physical model, the edges of the Delaunay triangles of a set of points correspond to bars of a truss. Each bar has a force-displacement relationship \( f(\ell, \ell_0) \) depending on its current length \( \ell \) and its unextended length \( \ell_0 \).’

‘External forces on the structure come at the boundaries, on which external forces have normal orientations. These external forces are just large enough to prevent nodes from moving outside the boundary. The position of the nodes are the unknowns, and are found by solving for a static force equilibrium. The hope is that (when \( fh = \text{function}(p) \text{return}(\text{rep}(1,\text{nrow}(p)))) \), the lengths of all the bars at equilibrium will be nearly equal, giving a well-shaped triangular mesh.’

See the references below for all details. Also, see the comments in the source file.

Value

\( n \)-by-2 matrix with node positions.

Wishlist

- Implement in C/Fortran
- Implement an \( n \)D version as provided in the Matlab package

    # continue on previous mesh

distmeshnd

A simple mesh generator for non-convex regions in n-D space

Description

An unstructured simplex requires a choice of mesh points (vertex nodes) and a triangulation. This is a simple and short algorithm that improves the quality of a mesh by relocating the mesh points according to a relaxation scheme of forces in a truss structure. The topology of the truss is reset using Delaunay triangulation. A (sufficiently smooth) user supplied signed distance function (fd) indicates if a given node is inside or outside the region. Points outside the region are projected back to the boundary.

Usage

distmeshnd(fdist, fh, h, box, pfix = array(dim = c(0, ncol(box))), ..., ptol = 0.001, ttol = 0.1, deltat = 0.1, geps = 0.1 * h, deps = sqrt(.Machine$double.eps) * h)

Arguments

fdist Vectorized signed distance function, for example mesh.dsphere, accepting an m-by-n matrix, where m is arbitrary, as the first argument.
fh Vectorized function, for example mesh.hunif, that returns desired edge length as a function of position. Accepts an m-by-n matrix, where n is arbitrary, as its first argument.
h Initial distance between mesh nodes.
box 2-by-n matrix that specifies the bounding box. (See distmesh2d for an example.)
pfix nfix-by-2 matrix with fixed node positions.
... parameters that are passed to fdist and fh
ptol Algorithm stops when all node movements are smaller than dptol
ttol Controls how far the points can move (relatively) before a retriangulation with delaunayn.
deltat Size of the time step in Euler’s method.
geps Tolerance in the geometry evaluations.
deps Stepsize ∆x in numerical derivative computation for distance function.
Details

This is an implementation of original Matlab software of Per-Olof Persson.

Excerpt (modified) from the reference below:

‘The algorithm is based on a mechanical analogy between a triangular mesh and a n-D truss structure. In the physical model, the edges of the Delaunay triangles of a set of points correspond to bars of a truss. ---

**dot**

*Compute the dot product of two vectors*

**Description**

If x and y are matrices, calculate the dot-product along the first non-singleton dimension. If the optional argument d is given, calculate the dot-product along this dimension.

**Usage**

```r
dot(x, y, d = NULL)
```

**Arguments**

- `x`: Matrix of vectors
- `y`: Matrix of vectors
- `d`: Dimension along which to calculate the dot product

**Value**

Vector with length of dth dimension

**Author(s)**

David Sterratt

---

**entry.value**

*Retrieve or set a list of array element values*

**Description**

entry.value retrieves or sets the values in an array a at the positions indicated by the rows of a matrix idx.

**Usage**

```r
entry.value(a, idx)
```
Arguments

a    An array.
idx  Numerical matrix with the same number of columns as the number of dimensions of a. Each row indices a cell in a of which the value is to be retrieved or set.
value An array of length nrow(idx).

Value

entry.value(a, idx) returns a vector of values at the indicated cells. entry.value(a, idx) <- val changes the indicated cells of a to val.

Author(s)

Raoul Grasman

Examples

a = array(1:(4^4), c(4,4,4,4))
entry.value(a, cbind(1:4,1:4,1:4,1:4))
entry.value(a, cbind(1:4,1:4,1:4,1:4)) <- 0

entry.value(a, as.matrix(expand.grid(1:4,1:4,1:4,1:4)))
# same as `c(a[1:4,1:4,1:4,1:4])` which is same as `c(a)`

extprod3d

Compute external- or 'cross'- product of 3D vectors.

Description

Computes the external product

\[
(x_2y_3 - x_3y_2, x_3y_1 - x_1y_3, x_1y_2 - x_2y_1)
\]

drop = TRUE)

Usage

extprod3d(x, y, drop = TRUE)
Arguments

\( x \)  
\( n \times 3 \) matrix. Each row is one \( x \)-vector

\( y \)  
\( n \times 3 \) matrix. Each row is one \( y \)-vector

\( \text{drop} \)  
logical. If \( \text{TRUE} \) and if the inputs are one row matrices or vectors, then delete the dimensions of the array returned.

Value

If \( n \) is greater than 1 or \( \text{drop} \) is \( \text{FALSE} \), \( n \times 3 \) matrix; if \( n \) is 1 and \( \text{drop} \) is \( \text{TRUE} \), a vector of length 3.

Author(s)

Raoul Grasman

See Also

drop

Description

Find point that lies somewhere in intersection of two convex hulls. If such a point does not exist, return \( \text{NA} \). The feasible point is found using a linear program similar to the one suggested at .. //doc/qhull/html/qhalf.html#notes

Usage

\( \text{feasible.point}(\text{ch1}, \text{ch2}, \text{tol} = 0) \)

Arguments

\( \text{ch1} \)  
First convex hull with normals

\( \text{ch2} \)  
Second convex hull with normals

\( \text{tol} \)  
The point must be at least this far within the facets of both convex hulls
halfspacen(p, fp, options = "Tv")

Arguments

p 
An M-by-N+1 matrix. Each row of p represents a halfspace by a N-dimensional normal to a hyperplane and the offset of the hyperplane.

fp 
A “feasible” point that is within the space contained within all the halfspaces.

options 
String containing extra options, separated by spaces, for the underlying Qhull command; see Qhull documentation at ../doc/qhull/html/qhalf.html.

Value

A N-column matrix containing the intersection points of the hyperplanes ../doc/qhull/html/qhalf.html.

Note

halfspacen was introduced in geometry 0.4.0, and is still under development. It is worth checking results for unexpected behaviour.

Examples

p <- rbox(0, C=0.5)  # Generate points on a unit cube centered around the origin
ch <- convhulln(p, "n") # Generate convex hull, including normals to facets, with "n" option
# Intersections of half planes
# These points should be the same as the orginal points
pn <- halfspacen(ch$normals, c(0, 0, 0))

inhulln

Test if points lie in convex hull

Description

Tests if a set of points lies within a convex hull, returning a boolean vector in which each element is TRUE if the corresponding point lies within the hull and FALSE if it lies outwith the hull or on one of its facets.

Usage

inhulln(ch, p)

Arguments

ch    Convex hull produced using convhulln
p    An M-by-N matrix of points to test. The rows of p represent M points in N-dimensional space.

Value

A boolean vector with M elements

Note

inhulln was introduced in geometry 0.4.0, and is still under development. It is worth checking results for unexpected behaviour.

Examples

```r
p <- cbind(c(-1, -1, 1), c(-1, 1, -1))
ch <- convhulln(p)
## First point should be in the hull; last two outside
inhulln(ch, rbind(c(-0.5, -0.5),
    c( 1 , 1),
    c(10 , 0)))
## Test hypercube
p <- rbox(D=4, B=1)
ch <- convhulln(p)
tp <- cbind(seq(-1.9, 1.9, by=0.2), 0, 0, 0)
pin <- inhulln(ch, tp)
## Points on x-axis should be in box only betw,een -1 and 1
pin == (tp[,1] < 1 & tp[,1] > -1)
```

intersectn

**Compute convex hull of intersection of two sets of points**

**Description**

Compute convex hull of intersection of two sets of points

**Usage**

```r
intersectn(ps1, ps2, tol = 0, return.chs = TRUE, options = "Tv",
    fp = NULL, autoscale = FALSE)
```

**Arguments**

- `ps1`: First set of points
- `ps2`: Second set of points
- `tol`: Tolerance used to determine if a feasible point lies within the convex hulls of both points and to round off the points generated by the halfspace intersection, which sometimes produces points very close together.
- `return.chs`: If TRUE (default) return the convex hulls of the first and second sets of points, as well as the convex hull of the intersection.
- `options`: Options passed to `halfspacen`. By default this is "Tv".
- `fp`: Coordinates of feasible point, i.e. a point known to lie in the hulls of `ps1` and `ps2`. The feasible point is required for `halfspacen` to find the intersection. `intersectn` tries to find the feasible point automatically using the linear program in `feasible.point`, but currently the linear program fails on some examples where there is an obvious solution. This option overrides the automatic search for a feasible point.
- `autoscale`: Experimental in v0.4.2 Automatically scale the points to lie in a sensible numeric range. May help to correct some numerical issues.
**Value**

List containing named elements: ch1, the convex hull of the first set of points, with volumes, areas and normals (see `convhulln`); ch2, the convex hull of the first set of points, with volumes, areas and normals; ps, the intersection points of convex hulls ch1 and ch2; and ch, the convex hull of the intersection points, with volumes, areas and normals.

**Note**

`intersectn` was introduced in geometry 0.4.0, and is still under development. It is worth checking results for unexpected behaviour.

```r
# Two overlapping boxes
ps1 <- rbox(0, C=0.5)
p12 <- rbox(0, C=0.5) + 0.5
out <- intersectn(ps1, ps2)
message("Volume of 1st convex hull: ", out$ch1$vol)
message("Volume of 2nd convex hull: ", out$ch2$vol)
message("Volume of intersection convex hull: ", out$ch$vol)
```

---

**matmax**  

*Row-wise matrix functions*

**Description**

Compute maximum or minimum of each row, or sort each row of a matrix, or a set of (equal length) vectors.

**Usage**

`matmax(...)`

**Arguments**

...  

A numeric matrix or a set of numeric vectors (that are column-wise bind together into a matrix with `cbind`).
Value

matmin and matmax return a vector of length nrow(cbind(...)). matsort returns a matrix of dimension dim(cbind(...)) with in each row of cbind(...) sorted. matsort(x) is a lot faster than, e.g., t(apply(x,1,sort)). if x is tall (i.e., nrow(x)»ncol(x) and ncol(x)<30. If ncol(x)>30 then matsort simply calls 't(apply(x,1,sort))'. matorder returns a permutation which rearranges its first argument into ascending order, breaking ties by further arguments.

Examples

example(Unique)

Description

Signed distance from points p to boundary of circle to allow easy definition of regions in distmesh2d.

Usage

mesh.dcircle(p, radius = 1, ...)

Arguments

p A matrix with 2 columns (3 in mesh.dsphere), each row representing a point in the plane.

radius radius of circle

... additional arguments (not used)

Value

A vector of length nrow(p) containing the signed distances to the circle

Author(s)

Raoul Grasman; translated from original Matlab sources of Per-Olof Persson.

References

Examples

example(distmesh2d)

mesh.diff  

Difference, union and intersection operation on two regions

Description

Compute the signed distances from points p to a region defined by the difference, union or intersection of regions specified by the functions regionA and regionB. regionA and regionB must accept a matrix p with 2 columns as their first argument, and must return a vector of length nrow(p) containing the signed distances of the supplied points in p to their respective regions.

Usage

mesh.diff(p, regionA, regionB, ...)

Arguments

p       A matrix with 2 columns (3 in mesh.dsphere), each row representing a point in the plane.
regionA  vectorized function describing region A in the union / intersection / difference
regionB  vectorized function describing region B in the union / intersection / difference
...     additional arguments passed to regionA and regionB

Value

A vector of length nrow(p) containing the signed distances to the boundary of the region.

Author(s)

Raoul Grasman; translated from original Matlab sources of Per-Olof Persson.

See Also

distmesh2d, mesh.dcircle, mesh.drectangle mesh.dsphere
Description

Signed distance from points \( p \) to boundary of rectangle to allow easy definition of regions in \texttt{distmesh2d}.

Usage

\begin{verbatim}
mesh.drectangle(p, x1 = -1/2, y1 = -1/2, x2 = 1/2, y2 = 1/2, ...)
\end{verbatim}

Arguments

- \( p \): A matrix with 2 columns, each row representing a point in the plane.
- \( x1 \): lower left corner of rectangle
- \( y1 \): lower left corner of rectangle
- \( x2 \): upper right corner of rectangle
- \( y2 \): upper right corner of rectangle
- \( ... \): additional arguments (not used)

Value

A vector of length \( nrow(p) \) containing the signed distances

Author(s)

Raoul Grasman; translated from original Matlab sources of Per-Olof Persson.

References

- \url{http://persson.berkeley.edu/distmesh/}

### Description
Signed distance from points \( p \) to boundary of sphere to allow easy definition of regions in `distmeshnd`.

### Usage
`mesh.dsphere(p, radius = 1, ...)`

### Arguments
- **p**: A matrix with 2 columns (3 in `mesh.dsphere`), each row representing a point in the plane.
- **radius**: radius of sphere
- **...**: additional arguments (not used)

### Value
A vector of length `nrow(p)` containing the signed distances to the sphere

### Author(s)
Raoul Grasman; translated from original Matlab sources of Per-Olof Persson.

### References
- [http://persson.berkeley.edu/distmesh/](http://persson.berkeley.edu/distmesh/)

### See Also
- `distmeshnd`

### Examples
```r
element(distmeshnd)
```
pol2cart

**mesh.hunif**

*Uniform desired edge length*

**Description**

Uniform desired edge length function of position to allow easy definition of regions when passed as the fh argument of `distmesh2d` or `distmeshnd`.

**Usage**

```
mesh.hunif(p, ...)
```

**Arguments**

- `p` A n-by-m matrix, each row representing a point in an m-dimensional space.
- `...` additional arguments (not used)

**Value**

Vector of ones of length n.

**Author(s)**

Raoul Grasman; translated from original Matlab sources of Per-Olof Persson.

**See Also**

`distmesh2d` and `distmeshnd`.

---

pol2cart

*Transform polar or cylindrical coordinates to Cartesian coordinates.*

**Description**

The inputs `theta`, `r`, (and `z`) must be the same shape, or scalar. If called with a single matrix argument then each row of `P` represents the polar/(cylindrical) coordinate `(theta, r, z)`.

**Usage**

```
pol2cart(theta, r = NULL, z = NULL)
```

**Arguments**

- `theta` describes the angle relative to the positive x-axis.
- `r` is the distance to the z-axis `(0, 0, z).`
- `z` (optional) is the z-coordinate
polyarea

Value

a matrix C where each row represents one Cartesian coordinate \((x, y, z)\).

Author(s)

Kai Habel
David Sterratt

See Also

cart2pol, sph2cart, cart2sph

---

**polyarea**

*Determines area of a polygon by triangle method.*

**Description**

Determines area of a polygon by triangle method. The variables \(x\) and \(y\) define the vertex pairs, and must therefore have the same shape. They can be either vectors or arrays. If they are arrays then the columns of \(x\) and \(y\) are treated separately and an area returned for each.

**Usage**

polyarea(x, y, d = 1)

**Arguments**

- \(x\): X coordinates of vertices.
- \(y\): Y coordinates of vertices.
- \(d\): Dimension of array to work along.

**Details**

If the optional \(d\) argument is given, then polyarea works along this dimension of the arrays \(x\) and \(y\).

**Value**

Area(s) of polygon(s).

**Author(s)**

David Sterratt based on the octave sources by David M. Doolin
Examples

```r
x <- c(1, 1, 3, 3, 1)
y <- c(1, 3, 3, 1, 1)
polyarea(x, y)
polyarea(cbind(x, x), cbind(y, y)) # c(4, 4)
polyarea(cbind(x, x), cbind(y, y), 1) # c(4, 4)
polyarea(rbind(x, x), rbind(y, y), 2) # c(4, 4)
```

---

rbox

Generate various point distributions

Description

Default is corners of a hypercube.

Usage

```r
rbox(n = 3000, D = 3, B = 0.5, C = NA)
```

Arguments

- `n`: number of random points in hypercube
- `D`: number of dimensions of hypercube
- `B`: bounding box coordinate - faces will be ~B and B from origin
- `C`: add a unit hypercube to the output - faces will be ~C and C from origin

Value

Matrix of points

Author(s)

David Sterratt

---

sph2cart

Transform spherical coordinates to Cartesian coordinates

Description

The inputs theta, phi, and r must be the same shape, or scalar. If called with a single matrix argument then each row of S represents the spherical coordinate (theta, phi, r).

Usage

```r
sph2cart(theta, phi = NULL, r = NULL)
```
surf.tri

Arguments
theta describes the angle relative to the positive x-axis.
phi is the angle relative to the xy-plane.
r is the distance to the origin (0, 0, 0).
If only a single return argument is requested then return a matrix C where each row represents one Cartesian coordinate (x, y, z).

cart2sph, pol2cart, cart2pol

surf.tri Find surface triangles from tetrahedral mesh

Description
Find surface triangles from tetrahedral mesh typically obtained with delaunayn.

Usage
surf.tri(p, t)

Arguments
p An n-by-3 matrix. The rows of p represent n points in dim-dimensional space.
t Matrix with 4 columns, interpreted as output of delaunayn.

Details
surf.tri and convhulln serve a similar purpose in 3D, but surf.tri also works for non-convex meshes obtained e.g. with distmeshnd. It also does not produce currently unavoidable diagnostic output on the console as convhulln does at the Rterm console—i.e., surf.tri is silent.

Value
An m-by-3 index matrix of which each row defines a triangle. The indices refer to the rows in p.

Note
surf.tri was based on Matlab code for mesh of Per-Olof Persson (http://persson.berkeley.edu/distmesh/).
Author(s)
Raoul Grasman

rgl::rgl.spheres( 1x, 1y,.124,;radius=.015+.25,col="black")
```

## End(Not run)

tetramesh

Render tetrahedron mesh (3D)

Description
tetramesh(T,X,col) uses the rgl package to display the tetrahedrons defined in the m-by-4 matrix T as mesh. Each row of T specifies a tetrahedron by giving the 4 indices of its points in X.

Usage
tetramesh(T, X, col = grDevices::heat.colors(nrow(T)), clear = TRUE, ...)

to.mesh3d

Convert convhulln object to RGL mesh

Description

Convert convhulln object to RGL mesh

Usage

to.mesh3d(x, ...)

Arguments

x  convhulln object

... Arguments to qmesh3d or tmesh3d

## Not run:
# example delaunayn
d = c(-1,1)
pc = as.matrix(rbind(expand.grid(d,d,d),0))
tc = delaunayn(pc)

# example tetramesh
clr = rep(1,3) %o% (1:nrow(tc)+1)
rgl::rgl.viewpoint(60,fov=20)
rgl::rgl.light(270,60)
tetramesh(tc,pc,alpha=0.7,col=clr)

## End(Not run)
Value

mesh3d object, which can be displayed in RGL with dot3d, wire3d or shade3d

See Also

as.mesh3d

trimesh

Display triangles mesh (2D)

Description

trimesh(T, p) displays the triangles defined in the m-by-3 matrix T and points p as a mesh. Each row of T specifies a triangle by giving the 3 indices of its points in X.

Usage

trimesh(T, p, p2, add = FALSE, axis = FALSE, boxed = FALSE, ...)

Arguments

T

T is a m-by-3 matrix. A row of T contains indices into X of the vertices of a triangle. T is usually the output of delaunayn.

p

A vector or a matrix.

p2

if p is not a matrix p and p2 are bind to a matrix with cbind.

add

Add to existing plot in current active device?

axis

Draw axes?

boxed

Plot box?

... Parameters to the rendering device. See the rgl package.

Author(s)

Raoul Grasman

See Also

tetramesh, rgl, delaunayn, convhulln, surf.tri

Examples

#example trimesh
p = cbind(x=rnorm(30), y=rnorm(30))
tt = delaunayn(p)
trimesh(tt, p)
**tsearch**  
*Search for the enclosing Delaunay convex hull*

**Description**
For \( t \leftarrow \text{delaunay}(\text{cbind}(x,y)) \), where \((x,y)\) is a 2D set of points, tsearch\((x,y,t,xi,yi)\) finds the index in \( t \) containing the points \((xi,yi)\). For points outside the convex hull the index is NA.

**Usage**
```r
tsearch(x, y, t, xi, yi, bary = FALSE, method = "quadtree")
```

**Arguments**
- `x`: X-coordinates of triangulation points
- `y`: Y-coordinates of triangulation points
- `t`: Triangulation, e.g. produced by `t <- \text{delaunayn}(\text{cbind}(x,y))`
- `xi`: X-coordinates of points to test
- `yi`: Y-coordinates of points to test
- `bary`: If TRUE return barycentric coordinates as well as index of triangle.
- `method`: One of "quadtree" or "orig". The Quadtree algorithm is much faster and new from version 0.4.0. The orig option uses the tsearch algorithm adapted from Octave code. Its use is deprecated and it may be removed from a future version of the package.

**Value**
If `bary` is FALSE, the index in \( t \) containing the points \((xi,yi)\). For points outside the convex hull the index is NA. If `bary` is TRUE, a list containing:
- `list("idx")`: the index in \( t \) containing the points \((xi,yi)\)
- `list("p")`: a 3-column matrix containing the barycentric coordinates with respect to the enclosing triangle of each point \((xi,yi)\).

**Note**
The original Octave function is Copyright (C) 2007-2012 David Bateman

**Author(s)**
Jean-Romain Roussel (Quadtree algorithm), David Sterratt (Octave-based implementation)

**See Also**
tsearchn, delaunayn
For \( t = \text{delaunayn}(x) \), where \( x \) is a set of points in \( N \) dimensions, \( \text{tsearchn}(x, t, x_i) \) finds the index in \( t \) containing the points \( x_i \). For points outside the convex hull, \( \text{id}x \) is \text{NA}. \text{tsearchn} also returns the barycentric coordinates \( p \) of the enclosing triangles.

Usage

\[
\text{tsearchn}(x, t, x_i, \ldots)
\]

Arguments

- \( x \): An \( N \)-column matrix, in which each row represents a point in \( N \)-dimensional space.
- \( t \): A matrix with \( N + 1 \) columns. A row of \( t \) contains indices into \( x \) of the vertices of an \( N \)-dimensional simplex. \( t \) is usually the output of \text{delaunayn}.
- \( x_i \): An \( M \)-by-\( N \) matrix. The rows of \( x_i \) represent \( M \) points in \( N \)-dimensional space whose positions in the mesh are being sought.
- \( \ldots \): Additional arguments

Details

If \( x \) is \text{NA} and the \( t \) is a \text{delaunayn} object produced by \text{delaunayn} with the \text{full} option, then use the Qhull library to perform the search. Please note that this is experimental in geometry version 0.4.0 and is only partly tested for 3D hulls, and does not yet work for hulls of 4 dimensions and above.

Value

A list containing:

- \( \text{id}x \): An \( M \)-long vector containing the indices of the row of \( t \) in which each point in \( x_i \) is found.
- \( p \): An \( M \)-by-\( N + 1 \) matrix containing the barycentric coordinates with respect to the enclosing simplex of each point in \( x_i \).

Note

Based on the Octave function Copyright (C) 2007-2012 David Bateman.

Author(s)

David Sterratt
**Unique**

**See Also**

tsearch, delaunayn

---

**Extract Unique Rows**

**Description**

‘Unique’ returns a vector, data frame or array like ‘x’ but with duplicate elements removed.

**Usage**

Unique(X, rows.are.sets = FALSE)

**Arguments**

- **X**: Numerical matrix.
- **rows.are.sets**: If `TRUE`, rows are treated as sets - i.e., to define uniqueness, the order of the rows does not matter.

**Value**

Matrix of the same number of columns as `x`, with the unique rows in `x` sorted according to the columns of `x`. If `rows.are.sets = TRUE` the rows are also sorted.

**Note**

‘Unique’ is (under circumstances) much quicker than the more generic base function ‘unique’.

**Author(s)**

Raoul Grasman

**Examples**

```r
# 'Unique' is faster than 'unique'
x = matrix(sample(1:(4*8),4*8),ncol=4)
y = x[sample(1:nrow(x),3000,TRUE), ]
gc(); system.time(unique(y))
gc(); system.time(Unique(y))

#
z = Unique(y)
x[matorder(x),]
z[matorder(z),]
```
