gginnards-package  gginnards: Explore the Innards of 'ggplot2' Objects

Description

Extensions to 'ggplot2' providing low-level debug tools: statistics and geometries echoing their data argument. Layer manipulation: deletion, insertion, extraction and reordering of layers. Deletion of unused variables from the data object embedded in "ggplot" objects.

Details

The new facilities for cleanly defining new stats and geoms added to package 'ggplot2' in version 2.0.0 gave origin to this package. I needed tools to help me learn how layers work and to debug the extensions to 'ggplot2' that I was developing. I share them through this package in the hope that they will help other users of 'ggplot2' understand how this this very popular graphics package works internally. The vignettes provide examples of how to use these tools both for debugging and learning how ggplots are stored.

Extensions provided:

- "Debug" stats and a "debug" geom that print to the console a summary of their data input.
- Functions for inspecting and manipulating the list of layers of a ggplot object.
- Functions for exploring and manipulating the data embedded in ggplot objects, including dropping unused variables.

**delete_layers**

**Layer manipulation.**

**Description**

Delete, move or append one or more layers in a ggplot object.

**Usage**

```r
delete_layers(x, match_type = NULL, idx = NULL)

append_layers(x, object, position = "top")
```

**See Also**

- Report bugs at [https://github.com/aphalo/gginnards/issues](https://github.com/aphalo/gginnards/issues)

**Examples**

```r
# echo the 'data' and 'params' as received by 'draw_panel()
 ggplot(mtcars, aes(cyl, mpg, color = factor(cyl))) +
   geom_point() +
   geom_debug_panel()

# echo the 'data' and 'params' as received by 'draw_group()
 ggplot(mtcars, aes(cyl, mpg, color = factor(cyl))) +
   geom_point() +
   geom_debug_group()

# echo the 'data' and 'params' as received by 'draw_panel()
 ggplot(mtcars, aes(cyl, mpg, colour = factor(cyl))) +
   stat_summary(fun.data = "mean_se") +
   stat_summary(fun.data = "mean_se", geom = "debug_panel")

# echo the 'data' received by 'compute_panel()
 ggplot(mtcars, aes(cyl, mpg, color = factor(cyl))) +
   geom_point() +
   stat_debug_panel()

# echo the 'data' received by 'compute_group()
 ggplot(mtcars, aes(cyl, mpg, color = factor(cyl))) +
   geom_point() +
   stat_debug_group()
```
move_layers(x, match_type = NULL, position = "top", idx = NULL)
shift_layers(x, match_type = NULL, idx = NULL, shift = 1L)
which_layers(x, match_type = NULL, idx = NULL)
extract_layers(x, match_type = NULL, idx = NULL)
top_layer(x)
bottom_layer(x)
num_layers(x)

Arguments

x an object of class gg to be operated upon.
match_type The name of the ggproto object class for the geom(s), position(s) or stat(s) matching that of the layers to be operated upon.
idx integer vector Index into the list of layers used to select the layers to be operated upon.
object a ggplot layer created by a geom_ or stat_ function or a list of such layers or an empty list.
position character or integer, the position of the layer immediately above of which to move or append the moved or appended layers.
shift integer.

Details

These functions must be used with care as they select all layers matching the provided geom, position or stat ggproto object class. Layers added with a stat do use a geom, and vice versa.

One and only one of match_type and idx must be passed a non-null argument.

In plots with several layers, it is possible that more than one layer matches the class name passed to match_type. It is also possible to pass a numeric vector with multiple indexes through parameter idx. In both cases multiple layers will be operated upon, but their relative positions will remain unchanged.

If a numeric vector with multiple position indexes is supplied as argument for position, the top-most position will be used. As indexing in R starts at 1, passing 0 or "bottom" as argument for position puts the moved or appended layer(s) behind all other layers (prepends the layer).

Value

An edited copy of x for delete_layers, append_layers and move_layers. An integer vector of indexes giving the positions of the matching layers in the list of layers contained in x in the case of which_layers.
Note

The functions described here are not expected to be useful in everyday plotting as one can more easily change the order in which layers are added to a ggplot. However, if one uses high level methods or functions that automatically produce a full plot using `ggplot2` internally, one may need to add, move or delete layers so as to profit from such canned methods and retain enough flexibility.

Examples

def - data.frame(
    gp = factor(rep(letters[1:3], each = 10)),
    y = rnorm(30)
)
p - ggplot(df, aes(gp, y)) +
    geom_point() +
    stat_summary(fun.data = "mean_se", colour = "red")
p
delete_layers(p, "GeomPoint")
delete_layers(p, "StatSummary")
move_layers(p, "GeomPoint", position = "top")
move_layers(p, "GeomPointrange", position = "bottom")
move_layers(p, "StatSummary", position = "bottom")
move_layers(p, "GeomPointrange", position = 1L)
append_layers(p, geom_line(colour = "orange"), position = "bottom")
append_layers(p, geom_line(colour = "orange"), position = 1L)
extract_layers(p, "GeomPoint")
ggplot(df, aes(gp, y)) + extract_layers(p, "GeomPoint")
which_layers(p, "GeomPoint")
num_layers(p)
top_layer(p)
bottom_layer(p)
num_layers(ggplot())
top_layer(ggplot())
bottom_layer(ggplot())

if (requireNamespace("sf", quietly = TRUE)) {
    nc - sf::st_read(system.file("shape/nc.shp", package = "sf"), quiet = TRUE)
    nc_3857 - sf::st_transform(nc, 3857)
    p.sf1 - ggplot() +
        geom_sf(data = nc)
    p.sf1
    num_layers(p.sf1)
    top_layer(p.sf1)
    append_layers(p.sf1,
        geom_sf(data = nc_3857, colour = "red", fill = NA),
        position = "top")
drop_vars

Explore and manipulate the embedded data.

Description

Automatically remove unused variables from the "default" data object embedded in a gg or ggplot object with drop_vars(). Explore data variables and their use with mapped_vars(), data_vars() and data_attributes().

Usage

```r
drop_vars(p, keep.vars = character(), guess.vars = TRUE)

mapped_vars(p, invert = FALSE)

data_vars(p)

data_attributes(p)
```

Arguments

- `p`: ggplot Plot object with embedded data.
- `keep.vars`: character Names of unused variables to be kept.
- `guess.vars`: logical Flag indicating whether to find used variables automatically.
- `invert`: logical If TRUE return indices for elements of data that are not mapped to any aesthetic or facet.
**Value**

A "ggplot" object that is a copy of \( p \) but containing only a subset of the variables in its default data.

character vector with names of mapped variables in the default data object.

character vector with names of all variables in the default data object.

list containing all attributes of the default data object.

**Warning!**

The current implementation drops variables only from the default data object. Data objects within layers are not modified.

**Note**

These functions are under development and not yet thoroughly tested! They are a demonstration of how one can manipulate the internals of \texttt{ggplot} objects created with \texttt{ggplot2} versions 3.1.0 and later. These functions may stop working after some future update to the \texttt{ggplot2} package. Although I will maintain this package for use in some of my other packages, there is no guarantee that I will be able to achieve this transparently.

Obviously, rather than using function \texttt{drop_vars()} after creating the \texttt{ggplot} object it is usually more efficient to select the variables of interest and pass a data frame containing only these to the \texttt{ggplot()} constructor.

**Examples**

```r
library(ggplot2)

p <- ggplot(mpg, aes(factor(year), (cty + hwy) / 2)) +
  geom_boxplot() +
  facet_grid(. ~ class)

mapped_vars(p) # those in use
mapped_vars(p, invert = TRUE) # those not used

p.dp <- drop_vars(p) # we drop unused vars

# number of columns in the data member
ncol(p$data)
ncol(p.dp$data)

# which vars are in the data member
data_vars(p)
data_vars(p.dp)

# which variables in data are used in the plot
mapped_vars(p)
mapped_vars(p.dp)

# the plots identical
```
```r
str(p, max.level = 0)
str(p.dp, max.level = 0) # smaller in size

str(p, components = "data")
str(p.dp, components = "data") # smaller in size

if (requireNamespace("sf", quietly = TRUE)) {
  nc <- sf::st_read(system.file("shape/nc.shp", package = "sf"), quiet = TRUE)
  p.sf <- ggplot(data = nc) +
         geom_sf()
  mapped_vars(p.sf)
  drop_vars(p.sf)
}
```

---

**Description**

The debug geoms are used to print to the console a summary of the object being received by geoms’ draw functions as input data and parameters objects.

**Usage**

```r
gemm_debug_panel(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  dbgfun.data = "head",
  dbgfun.data.args = list(),
  dbgfun.params = "summary",
  dbgfun.params.args = list(),
  dbgfun.print = "print",
  dbgfun.print.args = list(),
  parse = NULL,
  orientation = NULL,
  nudge_x = 0,
  nudge_y = 0,
  position = "identity",
  na.rm = FALSE,
)```
show.legend = FALSE,
inherit.aes = TRUE,
...
)

geom_debug(
    mapping = NULL,
data = NULL,
stat = "identity",
summary.fun = "head",
summary.fun.args = list(),
parse = NULL,
orientation = NULL,
nudge_x = 0,
nudge_y = 0,
position = "identity",
na.rm = FALSE,
show.legend = FALSE,
inherit.aes = TRUE,
...
)

geom_debug_group(
    mapping = NULL,
data = NULL,
stat = "identity",
dbgfun.data = "head",
dbgfun.data.args = list(),
dbgfun.params = "summary",
dbgfun.params.args = list(),
dbgfun.print = "print",
dbgfun.print.args = list(),
pars = NULL,
orientation = NULL,
nudge_x = 0,
nudge_y = 0,
position = "identity",
na.rm = FALSE,
show.legend = FALSE,
inherit.aes = TRUE,
...
)

Arguments

mapping Set of aesthetic mappings created by `aes` or `aes_*`. If specified and `inherit.aes = TRUE` (the default), is combined with the default mapping at the top level of the plot. You only need to supply `mapping` if there isn’t a mapping defined for the plot.
data A data frame. If specified, overrides the default data frame defined at the top level of the plot.

stat The statistical transformation to use on the data for this layer, as a string.

dbgfun.data, dbgfun.params, summary.fun
The functions as character strings giving their names or as named or anonymous function objects, to be used to summarize the data and the params objects received as input by the geometry.

dbgfun.data.args, dbgfun.params.args, summary.fun.args
A named list of additional arguments to be passed to dbgfun.data and dbgfun.params.

dbgfun.print A function used to print the data object received as input.

dbgfun.print.args
A named list. Currently ignored!

parse, orientation
Ignored. Helps avoid warnings.

nudge_x, nudge_y
Horizontal and vertical adjustments to nudge the starting position. The units for nudge_x and nudge_y are the same as for the data units on the x-axis and y-axis.

position Position adjustment, either as a string, or the result of a call to a position adjustment function.

na.rm If FALSE (the default), removes missing values with a warning. If TRUE silently removes missing values.

show.legend logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

inherit.aes If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.

other arguments passed on to layer. There are three types of arguments you can use here:

• Aesthetics: to set an aesthetic to a fixed value, like color = "red" or size = 3.
• Other arguments to the layer, for example you override the default stat associated with the layer.
• Other arguments passed on to the stat.

Details

It can be useful when debugging the code of statistics or to learn how the stats and geoms work in ‘ggplot2’ (>= 3.0.0).

The intended use of geom_debug_panel() and geom_debug_group() is to explore the data as they are used in a plot layer to produce graphical output. Geometries can be defined using draw functions that receive as input data corresponding to a single group at a time, or draw functions that receive as input all data to be drawn in a panel at a time, possibly including multiple groups. Function geom_debug() is identical to geom_debug_panel(), and included for backwards compatibility.

These debug geoms are very unusual in that they do not produce visible graphic output. They "draw" a grid.null() grob (graphical object) when the plot is rendered. Also, differently to
normal geometries, they print the data and params objects or a summary of them to the R console. The summary is obtained using the functions passed as arguments to their formal parameter dbgfun.data and dbgfun.params. The data and params objects are passed as the first positional argument to these functions and the values they return are printed.

If dbgfun.data = "I" is passed, the data object is printed as is. In contrast, if dbgfun.data = NULL is passed, the data object summary and its printing are not skipped. The mechanism is identical for dbgfun.params and params.

Nudging with nudge_x and nudge_y behave as in geom_text. Arguments passed to position are obeyed. So the effects of positions are reflected in the data object printed or summarized to the R console. The arguments passed to parse and orientation are currently ignored.

Many aesthetics are defined as optional so that they are accepted silently by geom_debug() and handled by 'ggplot2' as usual. Given the number available extensions to 'ggplot2', it is likely that some are missing.

The names of dbgfun.data() and dbgfun.params() are included in the section headers of the printout, together with panels and groups.

In most cases, the definitions of the debug and print functions must be available when the "gg" object is printed and the plot rendered.

Value

The panel function of this geometry always returns a nullGrob, the legend is also set to nullGrob. This geometry used for its text printing side effect.

Note

geom_debug() is a synonym of geom_debug_panel(), for backwards compatibility. Not to be used in new code.

See Also

To access data, scales and grobs in a built ggplot, see ggplot_build.

Examples

# echo to the R console \code{data} as received by geoms
ggplot(mtcars, aes(cyl, mpg, color = factor(cyl))) +
geom_point() +
geom_debug_panel()

```r
```
geom_null

A null geom or 'no-op' geom.
geom_null

Description

The null geom can be used to silence graphic output from a stat, such as `stat_debug_group()` and `stat_debug_panel()` defined in this same package. No visible graphical output is returned. An invisible `grid::grid_null()` grob is returned instead.

Usage

```r
geom_null(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  position = "identity",
  na.rm = FALSE,
  show.legend = FALSE,
  inherit.aes = TRUE,
  ...
)
```

Arguments

- `mapping`: Set of aesthetic mappings created by `aes`. If specified and `inherit.aes = TRUE` (the default), are combined with the default mapping at the top level of the plot. You only need to supply `mapping` if there isn’t a mapping defined for the plot.
- `data`: A data frame. If specified, overrides the default data frame defined at the top level of the plot.
- `stat`: The statistical transformation to use on the data for this layer, as a string.
- `position`: Position adjustment, either as a string, or the result of a call to a position adjustment function.
- `na.rm`: If `FALSE` (the default), removes missing values with a warning. If `TRUE` silently removes missing values.
- `show.legend`: logical. Should this layer be included in the legends? `NA`, the default, includes if any aesthetics are mapped. `FALSE` never includes, and `TRUE` always includes.
- `inherit.aes`: If `FALSE`, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. `borders`.
- `...`: other arguments passed on to `layer`. There are three types of arguments you can use here:
  - Aesthetics: to set an aesthetic to a fixed value, like `color = "red"` or `size = 3`.
  - Other arguments to the layer, for example you override the default `stat` associated with the layer.
  - Other arguments passed on to the stat.

Value

A plot layer instance. Mainly used for the side-effect of printing to the console the data object.
Note

This geom is very unusual in that it does not produce visible graphic output. It only returns a `grid.null` grob (graphical object). However, it accepts for consistency all the same parameters as normal geoms, which have no effect on the graphical output, except for `show.legend`.

Examples

```r
ggplot(mtcars) +
  geom_null()

ggplot(mtcars, aes(cyl, mpg)) +
  geom_null()

# shape data

if (requireNamespace("sf", quietly = TRUE)) {
  nc <- sf::st_read(system.file("shape/nc.shp", package = "sf"), quiet = TRUE)

  ggplot(data = nc) +
    geom_null()
}
```

---

**stat_debug_group**

*Print to console data received by statistics as input*

Description

`stat_debug_group` and `stat_debug_panel` apply a function to data and, most importantly, echo to the R console their data input or a summary of it.

Usage

```r
stat_debug_group(
  mapping = NULL,
  data = NULL,
  geom = "null",
  fun.data = "I",
  fun.data.args = list(),
  dbgfun.data = "head",
  dbgfun.data.args = list(),
  geom.dbgfun.data = "head",
  geom.dbgfun.data.args = list(),
  geom.dbgfun.params = NULL,
  geom.dbgfun.params.args = list(),
  dbgfun.print = "print",
  dbgfun.print.args = list(),
  position = "identity",
)```
Arguments

mapping | The aesthetic mapping, usually constructed with `aes` or `aes_`. Only needs to be set at the layer level if you are overriding the plot defaults.
data | A layer specific dataset - only needed if you want to override the plot defaults.
geom | The geometric object to use display the data.
fun.data | A function taking a data frame as its first argument and returning a data frame. This function does the computations generating the value passed from the statistic to the downstream geometry.
fun.data.args | A named list of additional arguments to be passed to `fun.data`.
dbgfun.data, geom.dbgfun.data, geom.dbgfun.params | A functions used to summarise the data and parameters objects received as input by the statistic and geometry.
dbgfun.data.args, geom.dbgfun.data.args, geom.dbgfun.params.args | A named list of arguments.
dbgfun.print | A function used to print the summary of the data object received as input by the statistic, also visible to the geometry, and used by `geom_debug()`.
dbgfun.print.args | A named list. Currently ignored!
stat_debug_group

position The position adjustment to use for overlapping points on this layer
na.rm a logical value indicating whether NA values should be stripped before the computation proceeds.
show.legend logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.
inherit.aes If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.

... other arguments passed on to layer. This can include aesthetics whose values you want to set, not map. See layer for more details.

Details

These stats are meant to be used for the side-effect of printing to the console the data object received as input by the compute_group() or compute_panel() function, or a summary of it. These data objects are the same as those received as input by any other statistics passed the same arguments. By default, the applied function is I(), the identity function.

In principle any geom can be passed as argument to override geom = "null". However, geom = "debug_panel" and geom = "debug_group" are treated as special cases and functions geom.dbgfun.data and geom.dbgfun.params, and lists geom.dbgfun.data.args and geom.dbgfun.params.args renamed and passed to the geometry. Arguments passed to these four formal parameters are not passed to other geometries.

Keep in mind that this stat sets default mappings only for the x and/or y aesthetics, additional mappings can be set using aes(), possibly together with after_stat().

Value

A copy of its data input, which is an object of class "data.frame" or inheriting from "data.frame".

Computed variables

- x x at centre of range
- y y at centre of range
- nrow nrow() of data object
- ncol ncol() of data object
- colnames colnames() of data object
- colclasses class() of x and y columns in data object
- group all distinct values in group as passed in data object
- PANEL all distinct values in PANEL as passed in data object

Examples

```r
my.df <- data.frame(x = rep(1:10, 2),
                    y = rep(c(1,2), c(10,10)) + rnorm(20),
                    group = rep(c("A","B"), c(10,10)))
```
# by default head() is used to show the top rows of the data object
# and geom_null() to silence the data returned by the stat
ggplot(my.df, aes(x,y)) +
  geom_point() +
  stat_debug_group()

# geom_debug prints the data returned by the stat
ggplot(my.df, aes(x,y)) +
  geom_point() +
  stat_debug_group(geom = "debug_panel")

# geom_debug prints the data returned by the stat
ggplot(my.df, aes(x,y)) +
  geom_point() +
  stat_debug_group(geom = "debug_panel",
                  geom.dbgfun.params = "summary")

# to print only the the data returned by the stat
# we pass as summary function a function that always returns NULL
ggplot(my.df, aes(x,y)) +
  geom_point() +
  stat_debug_group(geom = "debug_panel",
                  dbgfun.data = function(x) {NULL})

  ggplot(my.df, aes(x,y)) +
  geom_point() +
  stat_debug_group(aes(label = paste("group:", group)),
                  geom = "text")

# here we show all the data object
  ggplot(my.df, aes(x,y)) +
  geom_point() +
  stat_debug_group(dbgfun.data = "I")

# with grouping
  ggplot(my.df, aes(x,y, colour = group)) +
  geom_point() +
  stat_debug_group()

  ggplot(my.df, aes(x,y, colour = group)) +
  geom_point() +
  stat_debug_panel()

  ggplot(my.df, aes(x, y, colour = group)) +
  geom_point() +
  stat_debug_group(dbgfun.data = "nrow")

  ggplot(my.df, aes(x, y)) +
  geom_point() +
  facet_wrap(~group) +
  stat_debug_group()

# by default head() is used to show the top rows of data object
```
str(my.df, aes(group,y)) +
geom_point() +
stat_debug_group()
```

**str**  
Show the structure of a ggplot object.

**Description**

A str() method tailored to objects of class "ggplot". It adds to the output the size of the object, and the ability to subset individual components.

**Usage**

```r
## S3 method for class 'ggplot'
str(
  object,  
  ...,
  max.level = 1,
  components = TRUE,
  vec.len = 2,
  list.len = 99,
  give.attr = FALSE,
  comp.str = "$ ",
  nest.lev = 0,
  indent.str = paste(rep.int(" ", max(0, nest.lev + 1)), collapse = "."),
  size = TRUE
)
```

**Arguments**

- **object**: ggplot Plot object with embedded data.
- **max.level**: integer Maximum depth of recursion (of lists within lists ...) to be printed.
- **components**: Vector of components to print, as indexes into object.
- **vec.len**: integer Approximate maximum length allowed when showing the first few values of a vector.
- **list.len**: integer Maximum number of components to show of any list that will be described.
- **give.attr**: logical Flag, determining whether a description of attributes will be shown.
- **comp.str**: character String to be used for separating list components.
- **nest.lev**: numeric current nesting level in the recursive calls to str().
- **indent.str**: character String used for each level of indentation.
- **size**: logical Flag, should the size of the object in bytes be printed?
Value

A NULL is returned invisibly. While a description of the structure of p or its components will be printed in outline form as a "side-effect", with indentation for each level of recursion, showing the internal storage mode, class(es) if any, attributes, and first few elements of each data vector. By default each level of list recursion is indicated and attributes enclosed in angle brackets.

Note

In the case of objects with a nested structure \texttt{str()} is called recursively and dispatched according to the class of each nested member.

See Also

A \texttt{summary} method for class \texttt{ggplot} is defined by package ‘ggplot2’. Method \texttt{summary()} provides a more compact description of "\texttt{ggplot}" objects than method \texttt{str()}. Here we provide a wrapper on R’s \texttt{str()} with different default arguments. A summary does not directly describe how the different components of an R object are stored, while the structure does.

Examples

\begin{verbatim}
 p <- ggplot(mpg, aes(factor(year), (cty + hwy) / 2)) +
   geom_boxplot() +
   geom_point(color = "red") +
   facet_grid(. ~ class) +
   ggtitle("Example plot")

 p
