Package ‘ggpp’

August 12, 2023

Type Package
Title Grammar Extensions to ‘ggplot2’
Version 0.5.4
Date 2023-08-11
Maintainer Pedro J. Aphalo <pedro.aphalo@helsinki.fi>

Description Extensions to ‘ggplot2’ respecting the grammar of graphics paradigm. Geometries: geom_table(), geom_plot() and geom_grob() add insets to plots using native data coordinates, while geom_table_npc(), geom_plot_npc() and geom_grob_npc() do the same using ‘npc’ coordinates through new aesthetics ‘npcx’ and ‘npcy’. Statistics: select observations based on 2D density. Positions: radial nudging away from a center point and nudging away from a line or curve; combined stacking and nudging; combined dodging and nudging.

ggpp-package

Description

Extensions to `ggplot2` respecting the grammar of graphics paradigm. Geometries: `geom_table()`, `geom_plot()` and `geom_grob()` add insets to plots using native data coordinates, while `geom_table_npc()`, `geom_plot_npc()` and `geom_grob_npc()` do the same using "npc" coordinates through new aesthetics "npcx" and "npcy". Statistics: select observations based on 2D density. Positions: radial nudging away from a center point and nudging away from a line or curve; combined stacking and nudging; combined dodging and nudging.

Details

Package `ggpp` provides functions that extend the grammar of graphics as implemented in `ggplot2`. It attempts to stay true to the original grammar and to respect the naming conventions used in `ggplot2`.

Extensions provided:

- Geoms adding support for plot, table and grob insets within the grammar. Geoms using a parallel pseudo-scale based on native plot coordinates (npc) to allow annotations consistent with the grammar and so supporting facets and grouping. Geoms for annotations on the edges of the plotting area. Geom for easily drawing lines separating the quadrants of a plot.
- Stats for filtering-out/filtering-in observations in regions of a panel or group where the density of observations is high. Statistics simultaneously computing summaries, optionally using different functions, along x and y. Stat computing quadrant counts.
- Position functions implementing multi-directional nudging based on the data.
- Scales. Pseudo-scales supporting npc coordinates for x and y.
- Specializations of the `ggplot()` generic accepting time series objects of classes `ts` and `xts` as data argument.

Acknowledgements

We thank Kamil Slowikowski not only for contributing ideas and code examples to this package but also for adding new features to his package 'ggrepel' that allow new use cases for `stat_dens2d_labels()`, `position_nudge_center()`, `position_nudge_line()` and `position_nudge_to()` from this package. This package includes code copied and/or modified from that in package 'ggplot2'.

**annotate**

Annotations supporting NPC

Description

A revised version of `annotate()` from package 'ggplot2' adding support for `npcx` and `npcy` position aesthetics, allowing use of the geometries defined in the current package such as `geom_text_npc()`. It also has a parameter `label` that directly accepts data frames, ggplots and grobs as arguments in addition to objects of atomic classes like character. When package 'ggpmisc' is loaded this definition of `annotate()` overrides that in package 'ggplot2'.

Usage

```r
annotate(
  geom,
  x = NULL,
  y = NULL,
  xmin = NULL,
  xmax = NULL,
  ymin = NULL,
  ymax = NULL,
  xend = NULL,
  yend = NULL,
 npcx = NULL,
  npcy = NULL,
  label = NULL,
  ...,
  na.rm = FALSE
)
```
**Arguments**

- **geom** character Name of geom to use for annotation.
- **x, y, xmin, ymin, xmax, ymax, xend, yend, npcx, npcy** numeric Positioning aesthetics - you must specify at least one of these.
- **label** character, data.frame, ggplot or grob.
- **...** Other named arguments passed on to `layer()`. These are often aesthetics, used to set an aesthetic to a fixed value, like color = "red" or size = 3. They may also be parameters to the paired geom/stat.
- **na.rm** logical If FALSE, the default, missing values are removed with a warning. If TRUE, missing values are silently removed.

**Details**

Note that all position aesthetics are scaled (i.e., they will expand the limits of the plot so they are visible), but all other aesthetics are set. This means that layers created with this function will never affect the legend.

**Value**

A plot layer instance.

**Note**

To use the original definition of `annotate()` after loading package 'ggpmisc', use `ggplot2::annotate()`.

**Examples**

```
p <- ggplot(mtcars, aes(x = wt, y = mpg)) + geom_point()
# Works as ggplot2::annotate()
p + annotate("text", x = 5, y = 32, label = "Some text")
p + annotate("label", x = c(2, 5), y = c(15, 32),
label = c("A", "B"))
p + annotate("table", x = 5, y = 30,
label = data.frame(A = 1:2, B = letters[1:2]))
p + annotate("plot", x = 5.5, y = 34,
label = p + theme_bw(9))
p + annotate("rect", xmin = 3, xmax = 4.2, ymin = 12, ymax = 21, alpha = .2)
p + annotate("segment", x = 2.5, xend = 4, y = 15, yend = 25, colour = "blue")
p + annotate("pointrange", x = 3.5, y = 20, ymin = 12, ymax = 28,
colour = "red", size = 1.5)
# But ggpmisc::annotate() also works with npcx and npcy pseudo-aesthetics
p + annotate("label_npc", npcx = c(0.1, 0.9), npcy = c(0.1, 0.9),
label = c("A", "B"))
p + annotate("text_npc", npcx = 0.9, npcy = 0.9, label = "Some text")
```

compute_npcx

**compute_npcx**

Convert character-encoded positions to npc units and shift positions to avoid overlaps when group-
ing is active. If numeric, validate npc values.

**Usage**

```r
compute_npcx(x, group = 1L, h.step = 0.1, margin.npc = 0.05, each.len = 1)
compute_npcy(y, group = 1L, v.step = 0.1, margin.npc = 0.05, each.len = 1)
```

**Arguments**

- `x` numeric or if character, one of "right", "left", "centre", "center" or "middle".
- `group` integer vector, ggplot's group id. Used to shift coordinates to avoid overlaps.
- `margin.npc` numeric [0..1] The margin added towards the nearest plotting area edge when converting character coordinates into npc. Usually < 1.
- `each.len` integer The number of steps per group.
- `y` numeric or if character, one of "top", "bottom", "centre", "center" or "middle".

**Details**

These functions use NPC (normalized plot coordinates) instead of data coordinates. They translate named positions into numeric values in [0..1] and they can also shift the position according to the group, e.g., for each increase in the group number displace the position inwards or outwards, by a user-supplied distance. They make it possible to set automatically set default positions for grouped text labels.

Out of bounds numeric values are constrained to [0..1]. Unrecognized character values are silently converted into NA_integer_.

```r
p + annotate("text_npc",npcx = "right",npcy = "top", label = "Some text")
p + annotate("table_npc",npcx = 0.9,npcy = 0.9,
   label = data.frame(A = 1:2, B = letters[1:2]))
p + annotate("plot_npc",npcx = 1,npcy = 1,
   label = p + theme_bw(9))
p + annotate("plot_npc",npcx = c(0, 1),npcy = c(0, 1),
   label = list(p + theme_bw(9), p + theme_grey(9)),
   vp.width = 0.3, vp.height = 0.4)
```
**Value**

A numeric vector with values in the range [0..1] representing npc coordinates.

**Note**

These functions are used by several layer functions in packages ‘ggpp’ and ‘ggpmisc’, and can be useful to developers of other ‘ggplot2’ extensions.

**Examples**

```r
compute_npcx("right")
compute_npcx(c("left", "right"))
compute_npcy("bottom")
compute_npcy("bottom", group = 1L:3L)
compute_npcy("bottom", group = 2L)
compute_npcy(0.5)
compute_npcx(1)
```

**Description**

Chose between a pair of contrasting dark and light colors based on a weighted mean of RGB channels of a color. This function implements a simple approach to the choice for a color of a plot element to ensure it is visible against a background color.

**Usage**

```r
dark_or_light(
  colors,
  threshold = 0.45,
  dark.color = "black",
  light.color = "white"
)
```

**Arguments**

- **colors**: A vector of color definitions or color names in the background.
- **threshold**: numeric A value of luminance in [0..1] indicating the switch point between dark and light background.
- **dark.color**, **light.color**: A color definition or color name to return as dark and light colors to contrast light and dark backgrounds respectively.
Details

The switch between dark and light color is based on a quick and dirty approximation of the luminance of colors computed from RGB values. This easily computed approximation seems to work well enough. The default threshold chosen for a switch between black and white may need to be adjusted for other pairs of colors. Graphic devices can differ in the color spaces they support, but this is unlikely to affect the choice between black and white or other pairs of colors with large differences in luminance.

Note

The current implementation of `dark_or_light()` ignores alpha, the transparency component, of all its arguments.

Examples

```r
dark_or_light("yellow")
dark_or_light("darkblue")
dark_or_light(c("darkblue", "yellow", "red"))
dark_or_light("#FFFFFF")
dark_or_light("#FFFFFF", dark.color = "darkblue", light.color = "lightgrey")
dark_or_light("#000000", dark.color = "darkblue", light.color = "lightgrey")
```

---

gem_grob

Inset graphical objects

Description

`geom_grob` and `geom_grob_npc` add Grobs as insets to the ggplot using syntax similar to that of `geom_text`, `geom_text_s` and `geom_text_npc`. In most respects they behave as any other ggplot geometry: they add a layer containing one or more grobs and grouping and faceting works as usual. The most common use of `geom_grob` is to add data labels that are graphical objects rather than text. `geom_grob_npc` is used to add grobs as annotations to plots, but contrary to layer function `annotate()`, `geom_grob_npc` is data driven and respects grouping and facets, thus plot insets can differ among panels. Of these two geoms only `geom_grob` supports the plotting of segments, as `geom_grob_npc` uses a coordinate system that is unrelated to data units and data.

Usage

```r
geom_grob(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  position = "identity",
  ...,  
nudge_x = 0,
```
nudge_y = 0,
default.colour = "black",
default.color = default.colour,
colour.target = "segment",
color.target = colour.target,
default.alpha = 1,
alpha.target = "segment",
add.segments = TRUE,
box.padding = 0.25,
point.padding = 1e-06,
segment.linewidth = 0.5,
min.segment.length = 0,
ar = NULL,
na.rm = FALSE,
show.legend = FALSE,
inherit.aes = FALSE
)

geom_grob_npc(
  mapping = NULL,
data = NULL,
stat = "identity",
position = "identity",
...
na.rm = FALSE,
show.legend = FALSE,
inherit.aes = FALSE
)

Arguments

mapping The aesthetic mapping, usually constructed with aest. Only needs to be set at the layer level if you are overriding the plot defaults.
data A layer specific dataset - only needed if you want to override the plot defaults.
stat The statistical transformation to use on the data for this layer, as a string.
position Position adjustment, either as a string, or the result of a call to a position adjustment function.
... other arguments passed on to layer. This can include aesthetics whose values you want to set, not map. See layer for more details.
nudge_x, nudge_y Horizontal and vertical adjustments to nudge the starting position of each text label. The units for nudge_x and nudge_y are the same as for the data units on the x-axis and y-axis.
default.colour, default.color A colour definition to use for elements not targeted by the colour aesthetic.
colour.target, color.target A vector of character strings; "all", "text", "box" and "segment" or "none".
default.alpha numeric in [0, 1] A transparency value to use for elements not targeted by the alpha aesthetic.

alpha.target A vector of character strings; "all", "text", "segment", "box", "box.line", and "box.fill" or "none".

add.segments logical Display connecting segments or arrows between original positions and displaced ones if both are available.

box.padding, point.padding numeric By how much each end of the segments should shortened in mm.

segment.linewidth numeric Width of the segments or arrows in mm.

min.segment.length numeric Segments shorter that the minimum length are not rendered, in mm.

arrow specification for arrow heads, as created by arrow

na.rm If FALSE (the default), removes missing values with a warning. If TRUE silently removes missing values.

show.legend logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

inherit.aes If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.

Details

You can modify the size of insets with the vp.width and vp.height aesthetics. These can take a number between 0 (smallest possible inset) and 1 (whole plotting area width or height). The default value for for both of these aesthetics is 1/5. Thus, in contrast to geom_text, geom_label, geom_text_s and geom_label_s the size of the insets remains the same relative to the size of the plotting area irrespective of the size the plot is rendered at. The aspect ratio of insets is preserved and size is adjusted until the whole inset fits within the viewport.

By default geom_grob uses position_nudge_center and justification "position", while geom_grob_npc uses position_nudge and justification "inward". In contrast to position_nudge, position_nudge_center and all other position functions defined in packages 'ggpp' keep the original coordinates thus allowing the plotting of connecting segments and arrows.

This geom_grob and geom_grob_npc require the use tibbles as argument for data, as the grobs should be stored as a list of graphics objects ("grob") to be mapped to the label aesthetic.

The x and y aesthetics determine the position of the whole inset grob, similarly to that of a text label, justification is interpreted as indicating the position of the grob with respect to its x and y coordinates in the data, and angle is used to rotate the grob as a whole.

Value

A plot layer instance.
Plot boundaries and clipping

The "width" and "height" of an inset as for a text element are 0, so stacking and dodging inset plots will not work by default, and axis limits are not automatically expanded to include all inset plots. Obviously, insets do have height and width, but they are physical units, not data units. The amount of space they occupy on the main plot is not constant in data units of the base plot: when you modify scale limits, inset plots stay the same size relative to the physical size of the base plot.

Alignment

You can modify text alignment with the vjust and hjust aesthetics. These can either be a number between 0 (right/bottom) and 1 (top/left) or a character ("left", "middle", "right", "bottom", "center", "top"). In addition, you can use special alignments for justification including "position", "inward" and "outward". Inward always aligns text towards the center of the plotting area, and outward aligns it away from the center of the plotting area. If tagged with _mean or _median (e.g., "outward_mean") the mean or median of the data in the panel along the corresponding axis is used as center. If the characters following the underscore represent a number (e.g., "outward_10.5") the reference point will be this value in data units. Position justification is computed based on the direction of the displacement of the position of the label so that each individual text or label is justified outwards from its original position. The default justification is "position".

If no position displacement is applied, or a position function defined in 'ggplot2' is used, these geometries behave similarly to the corresponding ones from package 'ggplot2' with a default justification of 0.5 and no segment drawn.

Position functions

Many layer functions from package 'ggpp' are designed to work seamlessly with position functions that keep, rather than discard, the original x and y positions in data when computing a new displaced position. See position_nudge_keep, position_dodge_keep, position_jitter_keep, position_nudge_center, position_nudge_line, position_nudge_to, position_dodgenudge, position_jitternudge, and position_stacknudge for examples and details of their use.

Note

The insets are stored nested within the main ggplot object and contain their own copy of the data, and are rendered as grid grobs as normal ggplots at the time the main ggplot is rendered. They can have different themes.

Use annotate as redefined in 'ggpp’ when adding insets as annotations (automatically available unless ‘ggpp’ is not attached). annotate cannot be used with thenpcx and npcy pseudo-aesthetics.

References

The idea of implementing a geom_custom() for grobs has been discussed as an issue at https://github.com/tidyverse/ggplot2/issues/1399.

ggrid-package, geom_text, and other documentation of package 'ggplot2'.
Examples

```r
library(tibble)
df <- tibble(x = 2, y = 15, grob = list(grid::circleGrob(r = 0.2)))

# without nudging no segments are drawn
ggplot(data = mtcars,
       aes(wt, mpg)) +
       geom_point(aes(colour = factor(cyl))) +
       geom_grob(data = df,
                 aes(x, y, label = grob))

# with nudging segments are drawn
ggplot(data = mtcars,
       aes(wt, mpg)) +
       geom_point(aes(colour = factor(cyl))) +
       geom_grob(data = df,
                 aes(x, y, label = grob),
                 nudge_x = 0.5,
                 colour = "red",
                 hjust = 0.5,
                 vjust = 0.5)

# with nudging plotting of segments can be disabled
ggplot(data = mtcars,
       aes(wt, mpg)) +
       geom_point(aes(colour = factor(cyl))) +
       geom_grob(data = df,
                 aes(x, y, label = grob),
                 add.segments = FALSE,
                 nudge_x = 0.5,
                 hjust = 0.5,
                 vjust = 0.5)
```

---

**geom_label_npc**

*Text with Normalised Parent Coordinates*
**Description**

`geom_text_npc()` adds text directly to the plot. `geom_label_npc()` draws a rectangle behind the text, making it easier to read. The difference is that x and y mappings are expected to be given in npc graphic units, using pseudo-aesthetics. Their intended use is to add annotations to a plot.

**Usage**

```r
geom_label_npc(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  position = "identity",
  ..., 
  parse = FALSE,
  nudge_x = 0,
  nudge_y = 0,
  label.padding = grid::unit(0.25, "lines"),
  label.r = grid::unit(0.15, "lines"),
  label.size = 0.25,
  na.rm = FALSE,
  show.legend = FALSE,
  inherit.aes = FALSE
)
```

```r
geom_text_npc(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  position = "identity",
  ..., 
  parse = FALSE,
  nudge_x = 0,
  nudge_y = 0,
  check_overlap = FALSE,
  na.rm = FALSE,
  show.legend = FALSE,
  inherit.aes = FALSE
)
```

**Arguments**

- `mapping` - The aesthetic mapping, usually constructed with `aes`. Only needs to be set at the layer level if you are overriding the plot defaults.
- `data` - A layer specific data set - only needed if you want to override the plot defaults.
- `stat` - The statistical transformation to use on the data for this layer, as a string.
- `position` - Position adjustment, either as a string, or the result of a call to a position adjustment function.
other arguments passed on to \texttt{layer}. This can include aesthetics whose values you want to set, not map. See \texttt{layer} for more details.

\texttt{parse} \hspace{2cm} If \texttt{TRUE}, the labels will be parsed into expressions and displayed as described in \texttt{?plotmath}.

\texttt{check_overlap} \hspace{2cm} If \texttt{TRUE}, text that overlaps previous text in the same layer will not be plotted.

\texttt{label.padding} \hspace{2cm} Amount of padding around label. Defaults to 0.25 lines.

\texttt{label.r} \hspace{2cm} Radius of rounded corners. Defaults to 0.15 lines.

\texttt{label.size} \hspace{2cm} Size of label border, in mm.

\texttt{na.rm} \hspace{2cm} If \texttt{FALSE} (the default), removes missing values with a warning. If \texttt{TRUE} silently removes missing values.

\texttt{show.legend} \hspace{2cm} \texttt{logical}. Should this layer be included in the legends? \texttt{NA}, the default, includes if any aesthetics are mapped. \texttt{FALSE} never includes, and \texttt{TRUE} always includes.

\texttt{inherit.aes} \hspace{2cm} If \texttt{FALSE}, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. \texttt{borders}.

Details

This geom is identical to ’ggplot2’ \texttt{geom_text} except that it interprets \texttt{npcx} and \texttt{npcy} positions in \texttt{npc} units. It translates \texttt{npcx} and \texttt{npcy} coordinates using a pseudo-aesthetic with a fixed scale. The generation of grobs is done with calls to functions imported from package ’ggplot2’.

Alignment

With textual positions and groups a shift is added to successive labels to avoid overlaps. The shift is based on grouping, however unused levels are not dropped. In plots with faceting, if not all groups appear in each panel, there will be blank spaces in between labels. To solve this pass numeric values for the \texttt{npc} coordinates of each label instead of character strings.

You can modify text alignment with the \texttt{vjust} and \texttt{hjust} aesthetics. These can either be a number between 0 (right/bottom) and 1 (top/left) or a character ("left", "middle", "right", "bottom", "center", "top"). In addition, you can use special alignments for justification including "position", "inward" and "outward". Inward always aligns text towards the center of the plotting area, and outward aligns it away from the center of the plotting area. If tagged with \_\_\_\_mean or \_\_\_\_median (e.g., "outward\_\_\_\_\_\_mean") the mean or median of the data in the panel along the corresponding axis is used as center. If the characters following the underscore represent a number (e.g., "outward\_\_\_\_\_10.5") the reference point will be this value in data units. Position justification is computed based on the direction of the displacement of the position of the label so that each individual text or label is justified outwards from its original position. The default justification is "position".

If no position displacement is applied, or a position function defined in ’ggplot2’ is used, these geometries behave similarly to the corresponding ones from package ’ggplot2’ with a default justification of 0.5 and no segment drawn.
Plot boundaries and clipping

Note that when you change the scale limits for \(x\) and/or \(y\) of a plot, text labels stay the same size, as determined by the size aesthetic, given in millimetres. The actual size as seen in the plotted output is decided during the rendering of the plot to a graphics device. Limits are expanded only to include the anchor point of the labels because the "width" and "height" of a text element are 0 (as seen by ggplot2). Text labels do have height and width, but in grid units, not data units.

geom_label_pairwise

Arguments

mapping Set of aesthetic mappings created by \texttt{aes}. With \texttt{inherit.aes = FALSE} (the default) it is not combined with the default mapping at the top level of the plot. You always need to supply a mapping unless you set \texttt{inherit.aes = TRUE}.

data A data frame. If specified, overrides the default data frame defined at the top level of the plot.

stat The statistical transformation to use on the data for this layer, as a string.

position Position adjustment, either as a string, or the result of a call to a position adjustment function.

... other arguments passed on to \texttt{layer}. There are three types of arguments you can use here:

- Aesthetics: to set an aesthetic to a fixed value, like \texttt{colour = "red"} or \texttt{size = 3}.
- Other arguments to the layer, for example you override the default \texttt{stat} associated with the layer.
- Other arguments passed on to the \texttt{stat}.

parse If \texttt{TRUE}, the labels will be parsed into expressions and displayed as described in \texttt{?plotmath}.

nudge\_x, nudge\_y Horizontal and vertical adjustments to nudge the starting position of each text label. The units for \texttt{nudge\_x} and \texttt{nudge\_y} are the same as for the data units on the x-axis and y-axis.

default.colour, default.color A colour definition to use for elements not targeted by the \texttt{colour} aesthetic.

colour.target, color.target A vector of character strings; \texttt{"all"}, \texttt{"text"}, \texttt{"segment"}, \texttt{"box"}, \texttt{"box.line"}, and \texttt{"box.fill"} or \texttt{"none"}.

default.alpha numeric in [0..1] A transparency value to use for elements not targeted by the \texttt{alpha} aesthetic.

alpha.target A vector of character strings; \texttt{"all"}, \texttt{"text"}, \texttt{"segment"}, \texttt{"box"}, \texttt{"box.line"}, and \texttt{"box.fill"} or \texttt{"none"}.

label.padding Amount of padding around label. Defaults to 0.25 lines.

label.r Radius of rounded corners. Defaults to 0.15 lines.

segment.linewidth numeric Width of the segments or arrows in mm.

arrow specification for arrow heads, as created by \texttt{arrow}

na.rm If \texttt{FALSE} (the default), removes missing values with a warning. If \texttt{TRUE} silently removes missing values.

show.legend logical. Should this layer be included in the legends? \texttt{NA} includes a legend if any aesthetics are mapped. \texttt{FALSE}, the default, never includes it, and \texttt{TRUE} always includes it.

inherit.aes If \texttt{FALSE}, overrides the default aesthetics, rather than combining them.

check.overlap If \texttt{TRUE}, text that overlaps previous text in the same layer will not be plotted. \texttt{check.overlap} takes place at draw time and in the order of the data, thus its action depends of the size at which the plot is drawn.
Details

Geometries `geom_text_pairwise()` and `geom_label_pairwise()` have an interface similar to that of `geom_text` and `geom_label`, but add a segment connecting two values along x. In the most frequent use case they add a segment connecting pairs of levels from a grouping factor mapped to the x or y aesthetic. They can also be used to label ranges of values.

The segment extends from xmin to xmax, and the text label is located at x with a default that positions the label at the centre of the bar. The ends of the bar can be terminated with arrow heads given by parameter `arrow`, with a default of a plain segment without arrow tips. The text label is located slightly above the segment by the default value of `vjust` in `geom_text_pairwise()` and on top of the segment in `geom_label_pairwise()`.

Layer functions `geom_text_pairwise()` and `geom_label_pairwise()` use by default `position_nudge`. Nudging affects both text label and bar, and its default of no displacement will very rarely need to be changed.

Differently to `geom_text_repel()` and `geom_label_repel()`, `geom_text_pairwise()` and `geom_label_pairwise()` do not make use of additional aesthetics for the segments or boxes, but instead allow the choice of which elements are targeted by the usual ‘ggplot2’ aesthetics and which are rendered using a default constant value. In the grammar of graphics using the same aesthetic with multiple meanings is not allowed, thus, the approach used in package ‘ggpp’ attempts to enforce this.

Value

A plot layer instance.

Under development!

This geometry is still under development and its user interface subject to change.

Plot boundaries and clipping

Note that when you change the scale limits for x and/or y of a plot, text labels stay the same size, as determined by the size aesthetic, given in millimetres. The actual size as seen in the plotted output is decided during the rendering of the plot to a graphics device. Limits are expanded only to include the anchor point of the labels because the "width" and "height" of a text element are 0 (as seen by `ggplot2`). Text labels do have height and width, but in grid units, not data units. Either function `expand_limits` or the scale expansion can be used to ensure text labels remain within the plotting area.

Alignment

You can modify text alignment with the `vjust` and `hjust` aesthetics. These can either be a number between 0 (right/bottom) and 1 (top/left) or a character ("left", "middle", "right", "bottom", "center", "top"). Values outside the range 0..1 displace the text label so that the anchor point is outside the text label. In addition, you can use special alignments for justification including "position", "inward" and "outward". Inward always aligns text towards the center of the plotting area, and outward aligns it away from the center of the plotting area. If tagged with `_mean` or `_median` (e.g., "outward_mean") the mean or median of the data in the panel along the corresponding axis is used as center. If the characters following the underscore represent a number (e.g.,
"outward_10.5") the reference point will be this value in data units. Position justification is computed based on the direction of the displacement of the position of the label so that each individual text or label is justified outwards from its original position. The default justification is "identity".

Aesthetics

Layer functions geom_text_pairwise() and geom_label_pairwise() require aesthetics xmin, xmax, x, y and label and support aesthetics: alpha, colour, group, size (of text), family, fontface, linewidth, linetype, hjust and vjust. In addition, geom_text_pairwise supports angle and geom_label_pairwise supports fill. See aes_colour_fill_alpha, aes_linetype_size_shape, aes_position, and aes_group_order.

In 'ggplot2' linewidth when applied to the border of the box drawn by geom_label() is given in points rather than in mm because of a historical error in the code. In other geometries such as geom_segment() linewidth is given in mm. As in geom_label_pairwise() it is important to remain consistent among different linewidth specifications, mm are used both for the box border and linking segment. To imitate the behaviour of geom_label() a correction factor of 0.75 (more exactly 1 pt = 0.7528 mm) can be used for the line width of the border of the box.

Examples

```r
my.cars <- mtcars
my.cars$name <- rownames(my.cars)
p1 <- ggplot(my.cars, aes(factor(cyl), mpg)) +
  geom_boxplot(width = 0.33)

# With a factor mapped to x, highlight pairs

my.pairs <-
data.frame(A = 1:2, B = 2:3, bar.height = c(12, 30),
  p.value = c(0.01, 0.05678))
p1 +
  geom_text_pairwise(data = my.pairs,
    aes(xmin = A, xmax = B,
      y = bar.height,
      label = p.value),
    parse = TRUE)

p1 +
  geom_text_pairwise(data = my.pairs,
    aes(xmin = A, xmax = B,
      y = bar.height,
      label = sprintf("italic(P)~\textbackslashgrave{Var}\%s=\textbackslashgrave{Var}\%s\%\%.2f", p.value)),
    arrow = grid::arrow(angle = 90,
      length = unit(1, "mm"),
      ends = "both"),
    hjust = 0, vjust = 0)
```

"outward_10.5") the reference point will be this value in data units. Position justification is computed based on the direction of the displacement of the position of the label so that each individual text or label is justified outwards from its original position. The default justification is "identity".

Aesthetics

Layer functions geom_text_pairwise() and geom_label_pairwise() require aesthetics xmin, xmax, x, y and label and support aesthetics: alpha, colour, group, size (of text), family, fontface, linewidth, linetype, hjust and vjust. In addition, geom_text_pairwise supports angle and geom_label_pairwise supports fill. See aes_colour_fill_alpha, aes_linetype_size_shape, aes_position, and aes_group_order.

In 'ggplot2' linewidth when applied to the border of the box drawn by geom_label() is given in points rather than in mm because of a historical error in the code. In other geometries such as geom_segment() linewidth is given in mm. As in geom_label_pairwise() it is important to remain consistent among different linewidth specifications, mm are used both for the box border and linking segment. To imitate the behaviour of geom_label() a correction factor of 0.75 (more exactly 1 pt = 0.7528 mm) can be used for the line width of the border of the box.

p2 +
geom_text_pairwise(data = my.ranges,
                   aes(xmin = A, xmax = B,
                        y = bar.height, label = text),
                   arrow = grid::arrow(ends = "both", length = unit(2, "mm")))
```

---

**Description**

Linked text geometries are most useful for adding data labels to plots. `geom_text_s()` and `geom_label_s()` add text to the plot and for nudged positions link the original location to the nudged text with a segment or arrow.

**Usage**

```r
geom_label_s(
             mapping = NULL,
             data = NULL,
             stat = "identity",
             position = "identity",
             ...,
             parse = FALSE,
             nudge_x = 0,
             nudge_y = 0,
             default.colour = "black",
             default.color = default.colour,
             colour.target = c("text", "box"),
             color.target = colour.target,
             default.alpha = 1,
             alpha.target = "all",
             label.padding = grid::unit(0.25, "lines"),
             ...)
```
geom_label_s

label.r = grid::unit(0.15, "lines"),
segment.linewidth = 0.5,
add.segments = TRUE,
box.padding = 1e-06,
point.padding = 1e-06,
min.segment.length = 0,
arrow = NULL,
na.rm = FALSE,
show.legend = NA,
inherit.aes = TRUE
)

geom_text_s(
  mapping = NULL,
data = NULL,
  stat = "identity",
  position = "identity",
  ...
  parse = FALSE,
nudge_x = 0,
nudge_y = 0,
default.colour = "black",
default.color = default.colour,
colour.target = "text",
color.target = colour.target,
default.alpha = 1,
alpha.target = "all",
add.segments = TRUE,
box.padding = 0.25,
point.padding = 1e-06,
segment.linewidth = 0.5,
min.segment.length = 0,
arrow = NULL,
check.overlap = FALSE,
na.rm = FALSE,
show.legend = NA,
inherit.aes = TRUE
)

Arguments

mapping Set of aesthetic mappings created by aes. If specified and with inherit.aes = TRUE (the default), it is combined with the default mapping at the top level of the plot. You only need to supply mapping if there isn’t a mapping defined for the plot.
data A data frame. If specified, overrides the default data frame defined at the top level of the plot.
stat The statistical transformation to use on the data for this layer, as a string.
Position adjustment, either as a string, or the result of a call to a position adjustment function. There are three types of arguments you can use here:

- **Aesthetics**: to set an aesthetic to a fixed value, like `colour = "red"` or `size = 3`.
- **Other arguments to the layer**, for example you override the default stat associated with the layer.
- **Other arguments passed on to the stat**.

If `TRUE`, the labels will be parsed into expressions and displayed as described in `?plotmath`.

Horizontal and vertical adjustments to nudge the starting position of each text label. The units for `nudge_x` and `nudge_y` are the same as for the data units on the x-axis and y-axis.

A colour definition to use for elements not targeted by the colour aesthetic.

A vector of character strings: "all", "text", "segment", "box", "box.line", and "box.fill" or "none".

A vector of character strings: "all", "text", "segment", "box", "box.line", and "box.fill" or "none".

Amount of padding around label. Defaults to 0.25 lines.

Radius of rounded corners. Defaults to 0.15 lines.

numeric Width of the segments or arrows in mm.

logical Display connecting segments or arrows between original positions and displaced ones if both are available.

numeric By how much each end of the segments should shortened in mm.

numeric Segments shorter that the minimum length are not rendered, in mm.

If FALSE (the default), removes missing values with a warning. If TRUE silently removes missing values.

logical. Should this layer be included in the legends? NA, the default, includes a legend if any aesthetics are mapped. FALSE never includes it, and TRUE always includes it.

If FALSE, overrides the default aesthetics, rather than combining them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g., `borders`.

If TRUE, text that overlaps previous text in the same layer will not be plotted. check_overlap takes place at draw time and in the order of the data, thus its action depends of the size at which the plot is drawn.
Details

Geometries `geom_text_s()` and `geom_label_s()` have an interface similar to that of `geom_text` and `geom_label`, but support additional features. Similarly to `geom_text_repel()` and `geom_label_repel()` when used together with position functions defined in package 'ggpp' they draw a segment linking the label at a displaced position to the original position, usually a point corresponding to an observation to which the label refers. Another difference is that they allow control of to which graphical elements the mappings to colour and alpha aesthetics are applied. Differently to `geom_label()`, `geom_label_s()` obeys aesthetic mappings to linewidth and linetype applied to the line at the edge of the label box.

Layer functions `geom_text_s()` and `geom_label_s()` use by default `position_nudge_keep` which is backwards compatible with `position_nudge`. In contrast to `position_nudge, position_nudge_keep` and all other position functions defined in packages 'ggpp' and 'ggrepel' keep the original coordinates, thus allowing the plotting of connecting segments and arrows.

Differently to `geom_text_repel()` and `geom_label_repel()`, `geom_text_s()` and `geom_label_s()` do not make use of additional aesthetics for the segments or boxes, but instead allow the choice of which elements are targeted by the aesthetics and which are rendered in a default colour. In the grammar of graphics using the same aesthetic with multiple meanings is not allowed, thus, the approach used in our geoms attempts to enforce this.

Value

A plot layer instance.

Under development!

These two geometries are still under development and their user interface subject to change. In 'ggpp' (== 0.5.0) support for aesthetics related to segments was removed, and replaced with parameters and a new mechanism for targeting a the usual aesthetics to text, border, and segment was added.

Plot boundaries and clipping

Note that when you change the scale limits for x and/or y of a plot, text labels stay the same size, as determined by the size aesthetic, given in millimetres. The actual size as seen in the plotted output is decided during the rendering of the plot to a graphics device. Limits are expanded only to include the anchor point of the labels because the "width" and "height" of a text element are 0 (as seen by ggplot2). Text labels do have height and width, but in grid units, not data units.

Alignment

You can modify text alignment with the vjust and hjust aesthetics. These can either be a number between 0 (right/bottom) and 1 (top/left) or a character ("left", "middle", "right", "bottom", "center", "top"). In addition, you can use special alignments for justification including "position", "inward" and "outward". Inward always aligns text towards the center of the plotting area, and outward aligns it away from the center of the plotting area. If tagged with _mean or _median (e.g., "outward_mean") the mean or median of the data in the panel along the corresponding axis is used as center. If the characters following the underscore represent a number (e.g., "outward_10.5") the reference point will be this value in data units. Position justification is computed based on the
direction of the displacement of the position of the label so that each individual text or label is justified outwards from its original position. The default justification is "position".

If no position displacement is applied, or a position function defined in 'ggplot2' is used, these geometries behave similarly to the corresponding ones from package 'ggplot2' with a default justification of 0.5 and no segment drawn.

Aesthetics

Layer functions geom_text_s() and geom_label_s() require aesthetics x, y and label and support aesthetics: alpha, colour, group, size (of text), family, fontface, lineheight, hjust and vjust. In addition, geom_text_s supports angle and geom_label_s supports fill, linewight and linetype. See aes_colour_fill_alpha, aes_linetype_size_shape, aes_position, and aes_group_order.

In 'ggplot2' linewight when applied to the border of the box drawn by geom_label() is given in points rather than in mm because of a historical error in the code. In other geometries such as geom_segment() linewight is given in mm. As in geom_label_s() it is important to remain consistent among different linewight specifications, mm are used both for the box border and linking segment. To imitate the behaviour of geom_label() a correction factor of 0.75 (more exactly 1 pt = 0.7528 mm) can be used for the line width of the border of the box.

Position functions

Many layer functions from package 'ggpp' are designed to work seamlessly with position functions that keep, rather than discard, the original x and y positions in data when computing a new displaced position. See position_nudge_keep, position_dodge_keep, position_jitter_keep, position_nudge_center, position_nudge_line, position_nudge_to, position_dodgenudge, position_jitternudge, and position_stacknudge for examples and details of their use.

  scale_radius(range = c(3,6)) + # override scale_area()
  expand_limits(x = c(1.8, 5.5))
```

---

`geom_label_s`
Descripción

gem_plot y gem_plot_npc añaden objetos ggplot como subimagenes en el objeto del ggplot, utilizando sintaxis similar a la de geom_label y geom_text_s. En la mayoría de los aspectos, se comportan como cualquier otra geometría de ggplot: añaden una capa con uno o más grobs y el agrupamiento y faceting funcionan como de costumbre. La utilización más común de geom_plot es para añadir etiquetas de datos que son ggplots en lugar de texto. geom_plot_npc se utiliza para añadir ggplots como anotaciones a los gráficos, pero en contraste con la función de anotación annotate(), geom_plot_npc es datos impulsores y respecta el agrupamiento y faceting, de modo que las subimagenes pueden diferir entre paneles.

Uso

gem_plot(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  position = "identity",
  ..., 
  nudge_x = 0,
  nudge_y = 0,
  default.colour = "black",
  default.color = default.colour,
  colour.target = "box",
  color.target = colour.target,
  default.alpha = 1,
  alpha.target = "all",
  add.segments = TRUE,
  box.padding = 0.25,
  point.padding = 1e-06,
  segment.linewidth = 0.5,
  min.segment.length = 0,
  arrow = NULL,
  na.rm = FALSE,
  show.legend = FALSE,
  inherit.aes = FALSE
)

gem_plot_npc(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  position = "identity",
  ..., 
  na.rm = FALSE,
```r
show.legend = FALSE,
inherit.aes = FALSE
)
```

### Arguments

- **mapping**
  - The aesthetic mapping, usually constructed with `aes`. Only needs to be set at the layer level if you are overriding the plot defaults.

- **data**
  - A layer specific data set - only needed if you want to override the plot defaults.

- **stat**
  - The statistical transformation to use on the data for this layer, as a string.

- **position**
  - Position adjustment, either as a string, or the result of a call to a position adjustment function.

- **...**
  - other arguments passed on to `layer`. This can include aesthetics whose values you want to set, not map. See `layer` for more details.

- **nudge_x**, **nudge_y**
  - Horizontal and vertical adjustments to nudge the starting position of each text label. The units for `nudge_x` and `nudge_y` are the same as for the data units on the x-axis and y-axis.

- **default.colour**, **default.color**
  - A colour definition to use for elements not targeted by the colour aesthetic.

- **colour.target**, **color.target**
  - A vector of character strings: "all", "text", "box" and "segment".

- **default.alpha**
  - numeric in [0..1] A transparency value to use for elements not targeted by the alpha aesthetic.

- **alpha.target**
  - A vector of character strings: "all", "text", "segment", "box", "box.line", and "box.fill".

- **add.segments**
  - logical Display connecting segments or arrows between original positions and displaced ones if both are available.

- **box.padding**, **point.padding**
  - numeric By how much each end of the segments should shortened in mm.

- **segment.linewidth**
  - numeric Width of the segments or arrows in mm.

- **min.segment.length**
  - numeric Segments shorter that the minimum length are not rendered, in mm.

- **arrow**
  - specification for arrow heads, as created by `arrow`

- **na.rm**
  - If FALSE (the default), removes missing values with a warning. If TRUE silently removes missing values.

- **show.legend**
  - logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

- **inherit.aes**
  - If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. `borders`.
Details

You can modify the size of inset plots with the `vp.width` and `vp.height` aesthetics. These can take a number between 0 (smallest possible inset) and 1 (whole plotting area width or height). The default value for for both of these aesthetics is 1/5. Thus, in contrast to `geom_text` and `geom_text_s` the size of the insets remains the same relative to the size of the plotting area irrespective of how the plot is rendered. The aspect ratio of insets is preserved and size is adjusted until the whole inset fits within the viewport.

By default this geom uses `position_nudge_center` which is backwards compatible with `position_nudge` but provides additional control on the direction of the nudging. In contrast to `position_nudge`, `position_nudge_center` and all other position functions defined in packages 'ggpp' and 'ggrepel' keep the original coordinates thus allowing the plotting of connecting segments and arrows.

This geom works only with tibbles as data, as it expects a list of ggplot objects ("gg" class) to be mapped to the label aesthetic.

The x and y aesthetics determine the position of the whole inset plot, similarly to that of a text label, justification is interpreted as indicating the position of the plot with respect to its x and y coordinates in the data, and angle is used to rotate the plot as a whole.

Of these two geoms only `geom_plot` supports the plotting of segments, as `geom_plot_npc` uses a coordinate system that is unrelated to data units and data. In the case of `geom_plot_npc()`, `npcx` and `npcy` aesthetics determine the position of the inset plot.

Value

A plot layer instance.

Alignment

You can modify text alignment with the `vjust` and `hjust` aesthetics. These can either be a number between 0 (right/bottom) and 1 (top/left) or a character ("left", "middle", "right", "bottom", "center", "top"). In addition, you can use special alignments for justification including "position", "inward" and "outward". Inward always aligns text towards the center of the plotting area, and outward aligns it away from the center of the plotting area. If tagged with `_mean` or `_median` (e.g., "outward_mean") the mean or median of the data in the panel along the corresponding axis is used as center. If the characters following the underscore represent a number (e.g., "outward_10.5") the reference point will be this value in data units. Position justification is computed based on the direction of the displacement of the position of the label so that each individual text or label is justified outwards from its original position. The default justification is "position".

If no position displacement is applied, or a position function defined in 'ggplot2' is used, these geometries behave similarly to the corresponding ones from package 'ggplot2' with a default justification of 0.5 and no segment drawn.

Position functions

Many layer functions from package 'ggpp' are designed to work seamlessly with position functions that keep, rather than discard, the original x and y positions in data when computing a new displaced position. See `position_nudge_keep`, `position_dodge_keep`, `position_jitter_keep`, `position_nudge_center`, `position_nudge_line`, `position_nudge_to`, `position_dodgenudge`, `position_jitternudge`, and `position_stacknudge` for examples and details of their use.
Plot boundaries and clipping

The "width" and "height" of an inset as for a text element are 0, so stacking and dodging inset plots will not work by default, and axis limits are not automatically expanded to include all inset plots. Obviously, insets do have height and width, but they are physical units, not data units. The amount of space they occupy on the main plot is not constant in data units of the base plot: when you modify scale limits, inset plots stay the same size relative to the physical size of the base plot.

Note

The insets are stored nested within the main ggplot object and contain their own copy of the data, and are rendered as grid grobs as normal ggplots at the time the main ggplot is rendered. They can have different themes.

Use annotate as redefined in ‘ggpp’ when adding insets as annotations (automatically available unless ‘ggpp’ is not attached). annotate cannot be used with the npcx and npcy pseudo-aesthetics.

References

The idea of implementing a geom_custom() for grobs has been discussed as an issue at https://github.com/tidyverse/ggplot2/issues/1399.

Examples

```r
# inset plot with enlarged detail from a region of the main plot
library(tibble)
p <-
  ggplot(data = mtcars, mapping = aes(wt, mpg)) +
  geom_point()

df <- tibble(x = 0.01,
  y = 0.01,
  plot = list(p +
    coord_cartesian(xlim = c(3, 4),
    ylim = c(13, 16)) +
    labs(x = NULL, y = NULL) +
    theme_bw(10))))
p +
  geom_plot_npc(data = df,
  aes(npcx = x, npcy = y, label = plot))

p +
  geom_plot_npc(data = df,
    aes(npcx = x, npcy = y, label = plot,
    vp.width = 1/2, vp.height = 1/4))
```
geom_point_s

Points linked by a segment

Description

The geometry "geom_point_s" provides a super set of the capabilities of geom `geom_point` from package 'ggplot2' by allowing plotting of arrows or segments joining the original position of displaced observations to their current position rendered as points or graphic symbols. The most common use is to demonstrate the action of different position functions. It can be also used to highlight observations.

Usage

```r
geom_point_s(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  position = "identity",
  ..., 
  nudge_x = 0,
  nudge_y = 0,
  arrow = grid::arrow(length = unit(1/3, "lines")),
  default.colour = "black",
  default.color = default.colour,
  colour.target = "point",
  color.target = colour.target,
  default.alpha = 1,
  alpha.target = "all",
  add.segments = TRUE,
  box.padding = 0.25,
  point.padding = 1e-06,
  segment.linewidth = 0.5,
  min.segment.length = 0,
)```
geom_point_s

na.rm = FALSE,
show.legend = NA,
inherit.aes = TRUE
)

Arguments

mapping Set of aesthetic mappings created by \texttt{aes}. If specified and \texttt{inherit.aes = TRUE} (the default), is combined with the default mapping at the top level of the plot. You only need to supply \texttt{mapping} if there isn’t a mapping defined for the plot.
data A data frame. If specified, overrides the default data frame defined at the top level of the plot.
stat The statistical transformation to use on the data for this layer, as a string.
position Position adjustment, either as a string, or the result of a call to a position adjustment function.
...
other arguments passed on to \texttt{layer}. There are three types of arguments you can use here:

\begin{itemize}
\item Aesthetics: to set an aesthetic to a fixed value, like \texttt{colour = "red"} or \texttt{size = 3}.
\item Other arguments to the layer, for example you override the default \texttt{stat} associated with the layer.
\item Other arguments passed on to the \texttt{stat}.
\end{itemize}
nudge\_x, nudge\_y Horizontal and vertical adjustments to nudge the starting position of each text label. The units for \texttt{nudge\_x} and \texttt{nudge\_y} are the same as for the data units on the x-axis and y-axis.
arrow specification for arrow heads, as created by \texttt{arrow}
default.colour, default.color A colour definition to use for elements not targeted by the \texttt{colour} aesthetic.
colour.target, color.target A character string, one of "all", "point" and "segment" or "none".
default.alpha numeric in \([0..1]\) A transparency value to use for elements not targeted by the \texttt{alpha} aesthetic.
alpha.target A character string, one of "all", "segment", "point", or "none".
add.segments logical Display connecting segments or arrows between original positions and displaced ones if both are available.
box.padding, point.padding numeric By how much each end of the segments should shortened in mm.
segment.linewidth numeric Width of the segments or arrows in mm.
min.segment.length numeric Segments shorter that the minimum length are not rendered, in mm.
na.rm If \texttt{FALSE} (the default), removes missing values with a warning. If \texttt{TRUE} silently removes missing values.
show.legend logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

inherit.aes If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.

Details

The plotting of segments is similar in idea to that implemented in geom_text_repel and relies on position functions that rename instead of only replacing the original x and y coordinates from the data object.

By default this geom uses position_nudge_center which is backwards compatible with position_nudge but provides additional control on the direction of the nudging.

Value

A plot layer instance.

Position functions

Many layer functions from package 'ggpp' are designed to work seamlessly with position functions that keep, rather than discard, the original x and y positions in data when computing a new displaced position. See position_nudge_keep, position_dodge_keep, position_jitter_keep, position_nudge_center, position_nudge_line, position_nudge_to, position_dodgenudge, position_jitternudge, and position_stacknudge for examples and details of their use.

Note

The insets are stored nested within the main ggplot object and contain their own copy of the data, and are rendered as grid grobs as normal ggplots at the time the main ggplot is rendered. They can have different themes.

Use annotate as redefined in 'ggpp' when adding insets as annotations (automatically available unless 'ggpp' is not attached). annotate cannot be used with thenpcx and npcy pseudo-aesthetics.

Examples

```r
# Same output as with geom_point()
ggplot(mpg[1:20, ],
aes(cyl, hwy)) +
geom_point_s(colour = "blue")

# with segment drawn after nudging
ggplot(mpg[1:20, ],
aes(cyl, hwy, label = drv)) +
geom_point_s(position = position_nudge_keep(x = 0.2),
```

# with segment drawn after nudging
ggplot(mpg[1:20, ],
      aes(cyl, hwy, label = drv)) +
  geom_point_s(position = position_nudge_keep(x = 0.2),
               colour = "red",
               colour.target = "all") +
  geom_point_s(colour = "blue")

# with segment drawn after nudging
  geom_point_s(position = position_nudge_keep(x = 0.2),
               colour = "red",
               colour.target = "segment") +
  geom_point_s(colour = "blue")

  ggplot(mpg[1:20, ],
         aes(cyl, hwy, label = drv)) +
  geom_point_s(position = position_nudgekeep(x = 0.2),
               colour = "red",
               colour.target = "point") +
  geom_point_s(colour = "blue")

  ggplot(mpg[1:50, ],
         aes(cyl, hwy, label = drv)) +
  geom_point_s(position = position_jitternudge(width = 0.66, height = 2,
                                             seed = 456,
                                             nudge.from = "jittered",
                                             kept-origin = "original"),
               colour = "red",
               arrow = grid::arrow(length = grid::unit(0.4, "lines"))) +
  geom_point_s(colour = "blue")

---

**Description**

`geom_vhlines()` adds in a single layer both vertical and horizontal guide lines. Can be thought of as a convenience function that helps with producing consistent vertical and horizontal guide lines. It behaves like `geom_vline()` and `geom_hline()`. `geom_quadrant_lines()` displays the boundaries of four quadrants with an arbitrary origin. The quadrants are specified in the same way as in `stat_quadrant_counts()` and is intended to be used to add guide lines consistent with the counts by quadrant computed by this stat.
geom_quadrant_lines(
mapping = NULL,
data = NULL,
stat = "identity",
position = "identity",
pool.along = c("none", "x", "y", "xy"),
xintercept = 0,
yintercept = 0,
na.rm = FALSE,
show.legend = FALSE,
inherit.aes = FALSE,
...
)

geom_vhlines(
mapping = NULL,
data = NULL,
stat = "identity",
position = "identity",
xintercept = NULL,
yintercept = NULL,
na.rm = FALSE,
show.legend = FALSE,
inherit.aes = FALSE,
...
)

Arguments

mapping The aesthetic mapping, usually constructed with \texttt{aes}. Only needs to be set at
the layer level if you are overriding the plot defaults.
data A layer specific data set - only needed if you want to override the plot defaults.
stat The statistic object to use display the data
position The position adjustment to use for overlapping points on this layer
pool.along character, one of "none", "x", "y", or "xy" indicating whether to plot or not
lines separating quadrants.
xintercept, yintercept numeric vectors the coordinates of the origin of the quadrants.
na.rm a logical indicating whether NA values should be stripped before the computa-
tion proceeds.
show.legend logical. Should this layer be included in the legends? \texttt{NA}, the default, includes if
any aesthetics are mapped. \texttt{FALSE} never includes, and \texttt{TRUE} always includes.
inherit.aes If \texttt{FALSE}, overrides the default aesthetics, rather than combining with them. This
is most useful for helper functions that define both data and aesthetics and should
not inherit behaviour from the default plot specification, e.g. \texttt{borders}.  

other arguments passed on to layer. This can include aesthetics whose values you want to set, not map. See layer for more details.

Details

While geom_vhlines() does not provide defaults for the intercepts and accepts vectors of length > 1, geom_quadrant_lines() sets by default the intercepts to zero producing the natural quadrants and only accepts vectors of length one per panel. That is geom_vhlines() can be used to plot a grid while geom_quadrant_lines() plots at most one vertical and one horizontal line. In the case of geom_quadrant_lines() the pooling along axes can be specified in the same way as in stat_quadrant_counts().

Value

A plot layer instance.

Examples

# generate artificial data
set.seed(4321)
x <- 1:100
y <- rnorm(length(x), mean = 10)
my.data <- data.frame(x, y)

ggplot(my.data, aes(x, y)) +
  geom_quadrant_lines() +
  geom_point()

ggplot(my.data, aes(x, y)) +
  geom_quadrant_lines(linetype = "dotted") +
  geom_point()

ggplot(my.data, aes(x, y)) +
  geom_quadrant_lines(xintercept = 50,
                     yintercept = 10,
                     colour = "blue") +
  geom_point()

ggplot(my.data, aes(x, y)) +
  geom_quadrant_lines(xintercept = 50,
                     pool.along = "y",
                     colour = "blue") +
  geom_point()

ggplot(my.data, aes(x, y)) +
  geom_vhlines(xintercept = c(25, 50, 75),
geom_table and geom_table_npc add data frames as table insets to the base ggplot, using syntax similar to that of \texttt{geom_text} and \texttt{geom_text_s}. In most respects they behave as any other ggplot geometry: they add a layer containing one or more grobs and grouping and faceting works as usual. The most common use of \texttt{geom_table} is to add data labels that are whole tables rather than text. \texttt{geom_table_npc} is used to add tables as annotations to plots, but contrary to layer function \texttt{annotate}, \texttt{geom_table_npc} is data driven and respects grouping and facets, thus plot insets can differ among panels.

**Usage**

\begin{verbatim}
geom_table(
    mapping = NULL,
    data = NULL,
    stat = "identity",
    position = "identity",
    ..., 
    nudge_x = 0, 
    nudge_y = 0, 
    default.colour = "black", 
    default.color = default.colour, 
    colour.target = "box", 
    color.target = colour.target, 
    default.alpha = 1, 
    alpha.target = "all", 
    add.segments = TRUE, 
    box.padding = 0.25, 
    point.padding = 1e-06, 
    segment.linewidth = 0.5,
\end{verbatim}
min.segment.length = 0,
arow = NULL,
table.theme = NULL,
table.rownames = FALSE,
table.colnames = TRUE,
table.hjust = 0.5,
pars = FALSE,
na.rm = FALSE,
show.legend = FALSE,
inherit.aes = FALSE
)

gemn_table_npc(
mapping = NULL,
data = NULL,
stat = "identity",
position = "identity",
...,
table.theme = NULL,
table.rownames = FALSE,
table.colnames = TRUE,
table.hjust = 0.5,
pars = FALSE,
na.rm = FALSE,
show.legend = FALSE,
inherit.aes = FALSE
)

Arguments

mapping The aesthetic mapping, usually constructed with `aes`. Only needs to be set at the layer level if you are overriding the plot defaults.
data A layer specific data set - only needed if you want to override the plot defaults.
stat The statistical transformation to use on the data for this layer, as a string.
position Position adjustment, either as a string, or the result of a ... other arguments passed on to `layer`. This can include aesthetics whose values you want to set, not map. See `layer` for more details.
nudge_x, nudge_y Horizontal and vertical adjustments to nudge the starting position of each text label. The units for nudge_x and nudge_y are the same as for the data units on the x-axis and y-axis.
default.colour, default.color A colour definition to use for elements not targeted by the colour aesthetic.
colour.target, color.target A vector of character strings: "all", "box" and "segment" or "none".
default.alpha numeric in [0..1] A transparency value to use for elements not targeted by the alpha aesthetic.
alpha.target  A vector of character strings; "all", "segment", "box", "box.line", and "box.fill" or "none".

add.segments  logical Display connecting segments or arrows between original positions and displaced ones if both are available.

box.padding, point.padding  numeric By how much each end of the segments should shortened in mm.

segment.linewidth  numeric Width of the segments or arrows in mm.

min.segment.length  numeric Segments shorter that the minimum length are not rendered, in mm.

arrow  specification for arrow heads, as created by arrow

table.theme  NULL, list or function A gridExtra ttheme defintion, or a constructor for a ttheme or NULL for default.

table.rownames, table.colnames  logical flag to enable or disable printing of row names and column names.

table.hjust  numeric Horizontal justification for the core and column headings of the table.

parse  If TRUE, the labels will be parsed into expressions and displayed as described in ?plotmath.

na.rm  If FALSE (the default), removes missing values with a warning. If TRUE silently removes missing values.

show.legend  logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

inherit.aes  If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.

Details

By default geom_table() uses position_nudge_center which is backwards compatible with position_nudge but provides additional control on the direction of the nudging. In contrast to position_nudge, position_nudge_center and all other position functions defined in packages 'ggpp' and 'ggrepel' keep the original coordinates thus allowing the plotting of connecting segments and arrows.

This geom works only with tibbles as data, as its expects a list of data frames (or tibbles) to be mapped to the label aesthetic. A table is built with function gridExtra::gtable for each data frame in the list, and formatted according to a table theme or ttheme. The character strings in the data frame can be parsed into R expressions so the inset tables can include maths.

If the argument passed to table.theme is a constructor function (passing its name without parenthesis), the values mapped to size, colour, fill, alpha, and family aesthetics will the passed to this theme constructor for each individual table. In contrast, if a ready constructed ttheme stored as a list object is passed as argument (e.g., by calling the constructor, using constructor name followed by parenthesis), it will be used as is, i.e., mappings to aesthetics such as colour are ignored if present. By default the constructor ttheme_gtdefault is used and colour and fill, are mapped to NA. Mapping these aesthetics to NA triggers the use of the default base_colour of the ttheme.
As the table is built with function `gridExtra::gtable()`, for formatting details, please, consult `tableGrob`.

The `x` and `y` aesthetics determine the position of the whole inset table, similarly to that of a text label, justification is interpreted as indicating the position of the inset table with respect to its horizontal and vertical axes (rows and columns in the data frame), and `angle` is used to rotate the inset table as a whole.

Of these two geoms only `geom_grob` supports the plotting of segments, as `geom_grob_npc` uses a coordinate system that is unrelated to data units and data. In the case of `geom_table_npc`, `npcx` and `npcy` aesthetics determine the position of the inset table. Justification as described above for `.

Value

A plot layer instance.

Alignment

You can modify text alignment with the `vjust` and `hjust` aesthetics. These can either be a number between 0 (right/bottom) and 1 (top/left) or a character ("left", "middle", "right", "bottom", "center", "top"). In addition, you can use special alignments for justification including "position", "inward" and "outward". Inward always aligns text towards the center of the plotting area, and outward aligns it away from the center of the plotting area. If tagged with `_mean` or `_median` (e.g., "outward_mean") the mean or median of the data in the panel along the corresponding axis is used as center. If the characters following the underscore represent a number (e.g., "outward_10.5") the reference point will be this value in data units. Position justification is computed based on the direction of the displacement of the position of the label so that each individual text or label is justified outwards from its original position. The default justification is "position".

If no position displacement is applied, or a position function defined in 'ggplot2' is used, these geometries behave similarly to the corresponding ones from package 'ggplot2' with a default justification of 0.5 and no segment drawn.

Position functions

Many layer functions from package 'ggpp' are designed to work seamlessly with position functions that keep, rather than discard, the original x and y positions in data when computing a new displaced position. See `position_nudge_keep`, `position_dodge_keep`, `position_jitter_keep`, `position_nudge_center`, `position_nudge_line`, `position_nudge_to`, `position_dodgenudge`, `position_jitternudge`, and `position_stacknudge` for examples and details of their use.

Plot boundaries and clipping

The "width" and "height" of an inset as for a text element are 0, so stacking and dodging inset plots will not work by default, and axis limits are not automatically expanded to include all inset plots. Obviously, insets do have height and width, but they are physical units, not data units. The amount of space they occupy on the main plot is not constant in data units of the base plot: when you modify scale limits, inset plots stay the same size relative to the physical size of the base plot.
Note

Complex tables with annotations or different colouring of rows or cells can be constructed with functions in package ‘gridExtra’ or in any other way as long as they can be saved as grid graphical objects and then added to a ggplot as a new layer with geom_grob.

References

This geometry is inspired on answers to two questions in Stackoverflow. In contrast to these earlier examples, the current geom obeys the grammar of graphics, and attempts to be consistent with the behaviour of ‘ggplot2’ geometries. https://stackoverflow.com/questions/12318120/adding-table-within-the-plotting-region-of-a-ggplot-in-r https://stackoverflow.com/questions/25554548/adding-sub-tables-on-each-panel-of-a-facet-ggplot-in-r?

geom_x_margin_arrow  Reference arrows on the margins

Description

Small arrows on plot margins can supplement a 2d display with annotations. Arrows can be used to highlight specific values along a margin. The geometries `geom_x_margin_arrow()` and `geom_y_margin_arrow()` behave similarly to `geom_vline()` and `geom_hline()` and share their “double personality” as both annotations and geometries.

Usage

```r
geom_x_margin_arrow(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  position = "identity",
  ...
  xintercept,
  sides = "b",
  arrow.length = 0.03,
  na.rm = FALSE,
  show.legend = FALSE,
  inherit.aes = FALSE
)
```

```r
geom_y_margin_arrow(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  position = "identity",
  ...
  yintercept,
  sides = "l",
  arrow.length = 0.03,
  na.rm = FALSE,
  show.legend = FALSE,
  inherit.aes = FALSE
)
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mapping</td>
<td>The aesthetic mapping, usually constructed with <code>aes</code>. Only needs to be set at the layer level if you are overriding the plot defaults.</td>
</tr>
<tr>
<td>data</td>
<td>A layer specific dataset - only needed if you want to override the plot defaults.</td>
</tr>
<tr>
<td>stat</td>
<td>The statistical transformation to use on the data for this layer, as a string.</td>
</tr>
</tbody>
</table>
position

Position adjustment, either as a string, or the result of a call to a position adjust-
ment function.

... other arguments passed on to layer. This can include aesthetics whose values
you want to set, not map. See layer for more details.

xintercept, yintercept

numeric Parameters that control the position of the marginal points. If these are
set, data, mapping and show.legend are overridden.

sides

A string that controls which sides of the plot the rugs appear on. It can be set to
a string containing any combination of "trbl", for top, right, bottom, and left.

arrow.length

numeric value expressed in npc units for the length of the arrows inwards from
the edge of the plotting area.

na.rm

If FALSE (the default), removes missing values with a warning. If TRUE silently
removes missing values.

show.legend

logical. Should this layer be included in the legends? NA, the default, includes if
any aesthetics are mapped. FALSE never includes, and TRUE always includes.

inherit.aes

If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g., borders.

Value

A plot layer instance.

See Also

Other Geometries for marginal annotations in ggplots: geom_x_margin_grob(), geom_x_margin_point()

Examples

```r
p <- ggplot(mtcars, aes(wt, mpg)) +
  geom_point()
p + geom_x_margin_arrow(xintercept = 3.5)
p + geom_y_margin_arrow(yintercept = c(18, 28, 15))
p + geom_x_margin_arrow(data = data.frame(x = c(2.5, 4.5)),
                        mapping = aes(xintercept = x))
p + geom_x_margin_arrow(data = data.frame(x = c(2.5, 4.5)),
                        mapping = aes(xintercept = x),
                        sides="tb")
```
Add Grobs on the margins

Description

Margin grobs can supplement a 2d display with annotations. Margin grobs such as icons or symbols can highlight individual values along a margin. The geometries \texttt{geom\_x\_margin\_grob()} and \texttt{geom\_y\_margin\_grob()} behave similarly to \texttt{geom\_vline()} and \texttt{geom\_hline()} and share their “double personality” as both annotations and geometries.

Usage

\begin{verbatim}
geom\_x\_margin\_grob(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  position = "identity",
  ...
  xintercept,
  sides = "b",
  grob.shift = 0,
  na.rm = FALSE,
  show.legend = FALSE,
  inherit.aes = FALSE
)
\end{verbatim}

\begin{verbatim}
geom\_y\_margin\_grob(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  position = "identity",
  ...
  yintercept,
  sides = "l",
  grob.shift = 0,
  na.rm = FALSE,
  show.legend = FALSE,
  inherit.aes = FALSE
)
\end{verbatim}

Arguments

- \texttt{mapping}  
  The aesthetic mapping, usually constructed with \texttt{aes}. Only needs to be set at the layer level if you are overriding the plot defaults.

- \texttt{data}  
  A layer specific dataset - only needed if you want to override the plot defaults.

- \texttt{stat}  
  The statistical transformation to use on the data for this layer, as a string.
- **position**: Position adjustment, either as a string, or the result of a call to a position adjustment function.
  
  - **xintercept, yintercept**: numeric Parameters that control the position of the marginal points. If these are set, data, mapping and show.legend are overridden.
  
  - **sides**: A character string of length one that controls on which side of the plot the grob annotations appear on. It can be set to a string containing one of "t", "r", "b" or "l", for top, right, bottom, and left.
  
  - **grob.shift**: numeric value expressed innpc units for the shift of the marginal grob inwards from the edge of the plotting area.
  
  - **na.rm**: If FALSE (the default), removes missing values with a warning. If TRUE silently removes missing values.
  
  - **show.legend**: logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.
  
  - **inherit.aes**: If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. `borders`.

**Value**

A plot layer instance.

**Alignment**

You can modify text alignment with the `vjust` and `hjust` aesthetics. These can either be a number between 0 (right/bottom) and 1 (top/left) or a character ("left", "middle", "right", "bottom", "center", "top"). In addition, you can use special alignments for justification including "position", "inward" and "outward". Inward always aligns text towards the center of the plotting area, and outward aligns it away from the center of the plotting area. If tagged with `_mean` or `_median` (e.g., "outward_mean") the mean or median of the data in the panel along the corresponding axis is used as center. If the characters following the underscore represent a number (e.g., "outward_10.5") the reference point will be this value in data units. Position justification is computed based on the direction of the displacement of the position of the label so that each individual text or label is justified outwards from its original position. The default justification is "position".

If no position displacement is applied, or a position function defined in ‘ggplot2’ is used, these geometries behave similarly to the corresponding ones from package ‘ggplot2’ with a default justification of 0.5 and no segment drawn.

**Position functions**

Many layer functions from package ‘ggpp’ are designed to work seamlessly with position functions that keep, rather than discard, the original x and y positions in data when computing a new displaced position. See `position_nudge_keep`, `position_dodge_keep`, `position_jitter_keep`, `position_nudge_center`, `position_nudge_line`, `position_nudge_to`, `position_dodgenudge`, `position_jitternudge`, and `position_stacknudge` for examples and details of their use.

Other Geometries for marginal annotations in ggplots: geom_x_margin_arrow(), geom_x_margin_point()

Examples

# We can add icons to the margin of a plot to signal events

geom_x_margin_point

Reference points on the margins

Description

Margin points can supplement a 2d display with annotations. Margin points can highlight individual values along a margin. The geometries geom_x_margin_point() and geom_y_margin_point() behave similarly geom_vline() and geom_hline() and share their "double personality" as both annotations and geometries.

Usage

geom_x_margin_point(
mapping = NULL,
data = NULL,
stat = "identity",
position = "identity",
..., 
xintercept,
sides = "b",
point.shift = 0.017,
na.rm = FALSE,
show.legend = FALSE,
inherit.aes = FALSE
)

gem_y_margin_point(
mapping = NULL,
data = NULL,
stat = "identity",
position = "identity",
..., 
yintercept,
sides = "l",
point.shift = 0.017,
geom_x_margin_point

Arguments

mapping  The aesthetic mapping, usually constructed with `aes`. Only needs to be set at the layer level if you are overriding the plot defaults.
data  A layer specific dataset - only needed if you want to override the plot defaults.
stat  The statistical transformation to use on the data for this layer, as a string.
position  Position adjustment, either as a string, or the result of a call to a position adjustment function.
...  other arguments passed on to `layer`. This can include aesthetics whose values you want to set, not map. See `layer` for more details.
xintercept, yintercept  numeric Parameters that control the position of the marginal points. If these are set, data, mapping and show.legend are overridden.
sides  A string that controls which sides of the plot the rugs appear on. It can be set to a string containing any combination of “trbl”, for top, right, bottom, and left.
point.shift  numeric value expressed innpc units for the shift of the rug points inwards from the edge of the plotting area.
na.rm  If FALSE (the default), removes missing values with a warning. If TRUE silently removes missing values.
show.legend  logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.
inherit.aes  If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. `borders`.

Value

A plot layer instance.

See Also

Other Geometries for marginal annotations in ggplots: `geom_x_margin_arrow()`, `geom_x_margin_grob()`

Examples

```r
p <- ggplot(mtcars, aes(wt, mpg)) +
  geom_point()
p + geom_x_margin_point(xintercept = 3.5)
p + geom_y_margin_point(yintercept = c(18, 28, 15))
p + geom_x_margin_point(data = data.frame(x = c(2.5, 4.5)),
                         mapping = aes(xintercept = x))
```
ggplot\(()\) initializes a ggplot object. It can be used to declare the input spectral object for a graphic and to optionally specify the set of plot aesthetics intended to be common throughout all subsequent layers unless specifically overridden.

Usage

\[
\begin{align*}
\text{ggplot} & \quad \text{## S3 method for class 'ts'} \\
& \quad \text{ggplot} \\
& \quad \quad \text{data, mapping = NULL,} \\
& \quad \quad \text{..., time.resolution = "day",} \\
& \quad \quad \text{as.numeric = TRUE,} \\
& \quad \quad \text{environment = parent.frame()} \\
\end{align*}
\]

\[
\begin{align*}
\text{ggplot} & \quad \text{## S3 method for class 'xts'} \\
& \quad \text{ggplot} \\
& \quad \quad \text{data, mapping = NULL,} \\
& \quad \quad \text{..., time.resolution = "day",} \\
& \quad \quad \text{as.numeric = TRUE,} \\
& \quad \quad \text{environment = parent.frame()} \\
\end{align*}
\]

Arguments

- **data**: Default spectrum dataset to use for plot. If not a spectrum, the methods used will be those defined in package ggplot2. See ggplot. If not specified, must be supplied in each layer added to the plot.
- **mapping**: Default list of aesthetic mappings to use for plot. If not specified, in the case of spectral objects, a default mapping will be used.
- **...**: Other arguments passed on to methods. Not currently used.
- **time.resolution**: character The time unit to which the returned time values will be rounded.
as.numeric  logical If TRUE convert time to numeric, expressed as fractional calendar years.

environment  If an variable defined in the aesthetic mapping is not found in the data, ggplot will look for it in this environment. It defaults to using the environment in which ggplot() is called.

Details

ggplot() is typically used to construct a plot incrementally, using the + operator to add layers to the existing ggplot object. This is advantageous in that the code is explicit about which layers are added and the order in which they are added. For complex graphics with multiple layers, initialization with ggplot is recommended.

There are three common ways to invoke ggplot:

- `ggplot(ts, aes(x, y, <other aesthetics>))`
- `ggplot(ts)`

The first method is recommended if all layers use the same data and the same set of aesthetics, although this method can also be used to add a layer using data from another data frame. See the first example below. The second method specifies the default spectrum object to use for the plot, and the units to be used for y in the plot, but no aesthetics are defined up front. This is useful when one data frame is used predominantly as layers are added, but the aesthetics may vary from one layer to another. The third method specifies the default spectrum object to use for the plot, but no aesthetics are defined up front. This is useful when one spectrum is used predominantly as layers are added, but the aesthetics may vary from one layer to another.

Value

A "ggplot" object.

Note

Current implementation does not merge default mapping with user supplied mapping. If user supplies a mapping, it is used as is. To add to the default mapping, aes() can be used by itself to compose the ggplot.

Examples

ggplot(lynx) + geom_line()
position_dodgenudge  

Combined positions dodge and nudge

Description

position_dodgenudge() combines into one function the action of position_dodge and position_nudge and position_dodge2nudge() combines into one function the action of position_dodge2 and position_nudge. They are useful when labelling plots such as grouped bars, columns, etc. and when adding dodged to text labels linked to observations plotted without dodge. It can replace other position functions as it is backwards compatible. Like all other position functions in 'ggpp' and 'ggrepel' it preserves the initial position to allow drawing of segments or arrow linking the original position to the displaced one.

Usage

```r
position_dodgenudge(
  width = 1,
  preserve = c("total", "single"),
  x = 0,
  y = 0,
  direction = c("none", "split", "split.x", "split.y", "center"),
  kept.origin = c("dodged", "original", "none")
)
```

```r
position_dodge_keep(width = 1, preserve = c("total", "single"))
```

```r
position_dodge2_keep(width = 1, preserve = c("total", "single"))
```

```r
position_dodge2nudge(
  width = 1,
  preserve = c("total", "single"),
  padding = 0.1,
  reverse = FALSE,
  x = 0,
  y = 0,
  direction = c("none", "split", "split.x", "split.y", "center"),
  kept.origin = c("dodged", "original", "none")
)
```

Arguments

- **width**: Dodging width, when different to the width of the individual elements. This is useful when you want to align narrow geoms with wider geoms. See the examples.
- **preserve**: Should dodging preserve the total width of all elements at a position, or the width of a single element?.
position_dodgenudge

- **x, y**: Amount of vertical and horizontal distance to move. A numeric vector of length 1, or of the same length as rows there are in `data`, with nudge values in data rows order.

- **direction**: One of "none", "split", "split.x" or "split.y". A value of "none" replicates the behavior of `position_nudge`. At the moment "split" changes the sign of the nudge at zero, which is suitable for column plots with negative slices.

- **kept.origin**: One of "original" or "none".

- **padding**: Padding between elements at the same position. Elements are shrunk by this proportion to allow space between them. Defaults to 0.1.

- **reverse**: If TRUE, will reverse the default stacking order. This is useful if you’re rotating both the plot and legend.

### Details

The applied dodge is identical to that by `position_dodge` or `position_dodge2` while nudging is similar to that by `position_nudge`.

There are two possible uses for these functions. First they can be used to label dodged bars or boxplots. In this case, it is mandatory to use the same argument to width when passing `position_dodge()` to `geom_col()` and `position_dodgenudge()` to `geom_text()` or `geom_label()` or their repulsive equivalents. Otherwise the arrows or segments will fail to connect to the labels. In other words jittering is computed twice. Jitter should be identical with the same arguments as `position_dodgenudge()` as this last function simply call the same code from package ‘ggplot2’.

The second use is to dodge labels to be connected to elements that have not been jittered. The return of original positions instead of the dodged ones is achieved by passing `origin = "original"` instead of the default of `origin = "dodged"`.

### Value

A "Position" object.

position_jitternudge

Examples

df <- data.frame(x1 = c(1, 2, 1, 3, -1),
                 x2 = c("a", "a", "b", "b", "b"),
                 grp = c("some long name", "other name", "some name",
                          "another name", "some long name"))

# Add labels to a horizontal column plot (stacked by default)
geom_col(aes(group = grp), width = 0.8,
         position = position_dodge()) +
geom_vline(xintercept = 0) +
geom_text(aes(label = grp),
         position = position_dodgenudge(x = 0.09, direction = "split", width = 0.8),
         angle = 90, size = 3) +
theme(legend.position = "none")

# Add labels to a horizontal column plot (stacked by default)
geom_col(aes(group = grp), width = 0.75,
         position = position_dodgenudge(x = 0.09, direction = "split", width = 0.8),
         angle = 90, size = 3) +
theme(legend.position = "none")

deprecated

position_jitternudge

Description

position_jitternudge() combines into one function the action of position_jitter and position_nudge.
It is useful when labels to jittered plots and when adding jitter to text labels linked to points plotted
without jitter. It can replace other position functions as it is backwards compatible. Like all
other position functions in 'ggpp' and 'ggrepel' it preserves the initial position to allow drawing of
segments or arrow linking the original position to the displaced one.

Usage

position_jitternudge(
  width = NULL,
  height = NULL,
  seed = NA,
  x = 0,
  y = 0,
  direction = c("as.is", "alternate", "split"),
)
position_jitternudge

nudge.from = c("original", "original.x", "original.y", "jittered", "jittered.y", "jittered.x"), kept.origin = c("jittered", "original", "none")

position_jitter_keep(width = NULL, height = NULL, seed = NA)

Arguments

width, height  Amount of vertical and horizontal jitter. The jitter is added in both positive and negative directions, so the total spread is twice the value specified here. If omitted, defaults to 40 resolution of the data: this means the jitter values will occupy 80 implied bins. Categorical data is aligned on the integers, so a width or height of 0.5 will spread the data so it’s not possible to see the distinction between the categories.

seed  A random seed to make the jitter reproducible. Useful if you need to apply the same jitter twice, e.g., for a point and a corresponding label. The random seed is reset after jittering. If NA (the default value), the seed is initialised with a random value; this makes sure that two subsequent calls start with a different seed. Use NULL to use the current random seed and also avoid resetting (the behaviour of ggplot 2.2.1 and earlier).

x, y  Amount of vertical and horizontal distance to move. A numeric vector of length 1, or of the same length as rows there are in data, with nudge values in data rows order.

direction  One of "as.is", "alternate", "split", "split.x" or "split.y". A value of "none" replicates the behavior of position_nudge. "split" changes the sign of the nudge depending on the direction of the random jitter applied to each individual observation, which is suitable for nudging labels outward of the jittered data.

nudge.from  One of "original", "jittered", "original.y" (or "jittered.x"), "original.x" (or "jittered.y"). A value of "original" applies the nudge before jittering the observations, while "jittered" applies the nudging after jittering.

kept.origin  One of "original", "jittered" or "none".

Details

Jitter with position_jitternudge() is identical to that with position_jitter while nudging is enhanced compared to position_nudge by taking into use cases specific to the combination of jitter and nudge.

There are two possible uses for this function. First it can be used to label jittered points in a plot. In this case, it is mandatory to use the same arguments to width, height and seed when passing position_jitter() to geom_point() and position_jitternudge() to geom_text() or to geom_label() or their repulsive equivalents. Otherwise the arrows or segments will fail to connect to the labels. In other words jittering is computed twice. Jitter should be identical with the same arguments as position_jitternudge() as this last function calls the same code imported from package 'ggplot2'.
The second use is to jitter labels to be connected to points that have not been jittered. The return of original positions instead of the jittered ones is achieved by passing `origin = "original"` to override the default `origin = "jittered"`.

**Value**

A "Position" object. The layer function within it returns a data frame, with the jittered + nudged values in columns `x` and `y` and by default the jittered values with no nudging as `x_orig` and `y_orig`. With `nudge.from = "original"` the original values with no jitter and no nudge applied are returned as `x_orig` and `y_orig`.

**Note**

When `direction = "split"` is used together with no jitter, the split to left and right, or up and down is done at random.

position_nudge_center  
Nudge labels away from a central point

Description

position_nudge_center() is generally useful for adjusting the position of labels or text, both on a discrete or continuous scale. In contrast to position_nudge, position_nudge_center() returns in data both the original coordinates and the nudged coordinates.

Usage

position_nudge_center(
  x = 0,
  y = 0,
  center_x = NULL,
  center_y = NULL,
  direction = NULL,
position_nudge_centre

Arguments

x, y
Amount of vertical and horizontal distance to move. A numeric vector of length 1, or of the same length as rows there are in data, with nudge values in data rows order.

center_x, center_y
The coordinates of the virtual origin out from which nudging radiates or splits in opposite directions. A numeric vector of length 1 or of the same length as rows there are in data, or a function returning either of these vectors computed from the variables in data mapped to x or y, respectively.

direction
One of "none", "radial", or "split". A value of "none" replicates the behavior of position_nudge. Which of these three values is the default depends on the values passed to the other parameters.

obey_grouping
A logical flag indicating whether to obey or not groupings of the observations. By default, grouping is obeyed when both of the variables mapped to x and y are continuous numeric and ignored otherwise.

kept.origin
One of "original" or "none".

Details

This position function is backwards compatible with position_nudge but extends it by adding support for nudging that varies across the plotting region, either in opposite directions or radially from a virtual center point.

The wrapper position_nudge_keep() with exactly the same signature and behaviour as position_nudge provides an easier to remember name when the desire is only to have access to both the original and nudged coordinates.

Positive values as arguments to x and y are added to the original position along either axis. If no arguments are passed to center_x, center_y or direction, the nudging is applied as is, as is the case if direction = "none". If non-NULL arguments are passed to both center_x and center_y, direction = "radial" is assumed. In this case, if x and/or y positive nudging is applied radially outwards from the center, while if negative, inwards towards the center. When a non-NULL argument
is passed only to one of `center_x` or `center_y`; `direction = "split"` is assumed. In this case when the initial location of the point is to the left of `center_x`, `-x` is used instead of `x` for nudging, and when the initial location of the point is to the below of `center_y`, `-y` is used instead of `y` for nudging. If non-NULL arguments are passed to both `center_x` and `center_y`, and `direction` is passed "split" as argument, then the split as described above is applied to both to `x` and `y` coordinates.

**Value**

A "Position" object.

**Note**

Some situations are handled as special cases. When `direction = "split"` or `direction = "radial"`, observations at exactly the _center_ are nudged using `x` and `y` unchanged. When `direction = "split"`, and both `center_x` and `center_y` have been supplied, segments are drawn at eight different possible angles. When segments are exactly horizontal or vertical they would be shorter than when drawn at the other four angles, in which case `x` or `y` are adjusted to ensure these segments are of the same lengths as those at other angles.

This position is most useful when labeling points forming a cloud or grouped along vertical or horizontal lines or "divides".

position_nudge_line

Nudge labels away from a line

Description

position_nudge_line() is generally useful for adjusting the starting position of labels or text to be repelled while preserving the original position as the start of the segments. The difference compared to position_nudge_center is that the nudging is away from a line or curve fitted to the data points or supplied as coefficients. While position_nudge_center() is most useful for “round-shaped”, vertically- or horizontally elongated clouds of points, position_nudge_line() is most suitable when observations follow a linear or curvilinear relationship between x and y values. In contrast to position_nudge, position_nudge_line() returns in ‘data’ both the original coordinates and the nudged coordinates.

Usage

position_nudge_line(
  x = NA_real_,
  y = NA_real_,
  xy_relative = c(0.03, 0.03),
  abline = NULL,
  method = NULL,
  formula = y ~ x,
  direction = c("automatic", "none", "split"),
  line_nudge = 1,
  kept.origin = c("original", "none")
)

Arguments

x, y  Amount of vertical and horizontal distance to move. A numeric vector of length 1, or of the same length as rows there are in data, with nudge values in data rows order.
xy_relative  Nudge relative to x and y data expanse, ignored unless x and y are both NAs.
abline   a vector of length two giving the intercept and slope.
mетод One of "spline", "lm" or "auto".
formula A model formula for lm when method = "lm". Ignored otherwise.
direction One of "automatic", "none", or "split".
line_nudge A positive multiplier >= 1, increasing nudging away from the curve or line compared to nudging from points.
kept.origin One of "original" or "none".

Details

The default amount of nudging is 3 x and y axes, which in most cases is good. In most cases it is best to apply nudging along a direction perpendicular to the line or curve, if this is the aim, passing an argument to only one of x, y or xy_relative will be enough. When direction = "split" nudging is away from an implicit line or curve on either side with positive nudging. The line or curve can be smooth spline or linear regression fitted on-the-fly to the data points, or a straight line defined by its coefficients passed to abline. The fitting is well defined only if the observations fall roughly on a curve or straight line that is monotonic in y. By means of line_nudge one can increment nudging away from the line or curve compared to away from the points, which is useful for example to keep labels outside of a confidence band. Direction defaults to "split" when line_nudge > 1, and otherwise to "none".

Value

A "Position" object.

Note

For method = "lm" only model formulas corresponding to polynomials with no missing terms are supported. If using poly in the model formula, raw = TRUE is required.

In practice, x and y should have the same sign for nudging to work correctly.

This position is most useful when labeling points conforming a cloud along an arbitrary curve or line.

See Also

position_nudge, position_nudge_repel.

Other position adjustments: position_dodgenudge(), position_jitternudge(), position_nudge_center(), position_nudge_to(), position_stacknudge()

Examples

```r
set.seed(16532)
df <- data.frame(
  x = -10:10,
  y = (-10:10)^2,
```
\[
\begin{align*}
yy &= (-10:10)^2 + \text{rnorm}(21, 0, 4), \\
yyy &= (-10:10) + \text{rnorm}(21, 0, 4), \\
l &= \text{letters}[1:21]
\end{align*}
\]

# Setting the nudging distance

ggplot(subset(df, x >= 0), aes(y, sqrt(y), label = l)) +  
  geom_line(linetype = "dotted") +  
  geom_point() +  
  geom_text(position = position_nudge_line())

# Points scattered near a curve or line, we use 'direction = "split"'

ggplot(df, aes(x)) +  
  geom_line(aes(y = y), linetype = "dotted") +  
  geom_point(aes(y = yy)) +  
  geom_text(aes(y = yy, label = l),  
            position = position_nudge_line(direction = "split"))

ggplot(subset(df, x >= 0), aes(y, yy)) +
position_nudge_to

Description

position_nudge_to() is generally useful for adjusting the position of labels or text, both on a
discrete or continuous scale. position_nudge_to() differs from position_nudge in that the co-
ordinates of the new position are given directly, rather than as a displacement from the original
location. It optionally sets an even distance among positions. As other position functions in this
package, it preserves the original position to allow the text to be linked back to its original position
with a segment or arrow.

Usage

position_nudge_to(
  x = NULL,
  y = NULL,
  x.action = c("none", "spread"),
  y.action = c("none", "spread"),
  direction = c("horizontal", "vertical"),
  line_nudge = 0,
  method = c("lm", "spline"),
  formula = NULL
)
Arguments

x, y  Coordinates of the destination position. A vector of mode numeric, that is extended if needed, to the same length as rows there are in data. The values are applied in the order of the observations in data. The default, NULL, leaves the original coordinates unchanged.

x.action, y.action  character string, one of "none", or "spread". With "spread" evenly distributing the positions within the range of argument x or y, if non-null, or the range the variable mapped to x or y, otherwise.

kept.origin  One of "original" or "none".

Details

The nudged x or y replace the original ones in data, while the original coordinates are returned in x_orig and y_orig. Values supported are those of mode numeric, thus including dates and times.

Value

A "Position" object.

Note

Irrespective of the action, the ordering of rows in data is preserved.

See Also

position_nudge, position_nudge_repel.

Other position adjustments: position_dodgenudge(), position_jitternudge(), position_nudge_center(), position_nudge_line(), position_stacknudge()

Examples

df <- data.frame(
  x = c(1,3,2,5,4,2.5),
  y = c(2, 1, 2.5, 1.8, 2.8, 1.5),
  label = c("abc","cd","d","c","bcd","a")
)

ggplot(df, aes(x, y, label = label)) +
  geom_point() +
  geom_text(position = position_nudge_to(y = 3))

ggplot(df, aes(x, y, label = label)) +
  geom_point() +
  geom_text_s(position = position_nudge_to(y = 3))
ggplot(df, aes(x, y, label = label)) +
geom_point() +
geom_text_s(position =
  position_nudge_to(y = 3, x.action = "spread"))

ggplot(df, aes(x, y, label = label)) +
geom_point() +
geom_text_s(position =
  position_nudge_to(y = 3, x = c(2,4), x.action = "spread"),
  hjust = "center")
Arguments

vjust
Vertical adjustment for geoms that have a position (like points or lines), not a
dimension (like bars or areas). Set to 0 to align with the bottom, 0.5 for the
middle, and 1 (the default) for the top.

reverse
If TRUE, will reverse the default stacking order. This is useful if you’re rotating
both the plot and legend.

x, y
Amount of vertical and horizontal distance to move. A numeric vector of length
1, or of the same length as rows there are in data, with nudge values in data
rows order.

direction
One of "none", "split", "split.x" or "split.y". A value of "none" replicates the behavior of \texttt{position_nudge}. At the moment "split" changes the
sign of the nudge at zero, which is suitable for column plots with negative slices.

kept.origin
One of "original", "stacked" or "none".

Details

This position function is backwards compatible with \texttt{position_nudge} but extends it by adding
support for stacking and for geometries that make use of the original position to draw connecting
segments or arrows.

The wrapper \texttt{position_nudge\_keep()} with exactly the same signature and behaviour as \texttt{position_nudge}
provides an easier to remember name when the desire is only to have access to both the original and
nudged coordinates.

Value

A "Position" object.

scale_continuous_npc  Position scales for continuous data (npcx & npcy)

Description

scale_npcx_continuous() and scale_npcy_continuous() are scales for continuous npcx and npcy aesthetics expressed in "npc" units. There are no variants. Obviously limits are always the full range of "npc" units and transformations meaningless. These scales are used by the newly defined aesthetics npcx and npcy.

Usage

scale_npcx_continuous(...)

scale_npcy_continuous(...)

Arguments

... Other arguments passed on to continuous_scale()

Value

A "Scale" object.

stat_apply_group  Apply a function to x or y values

Description

stat_summary_xy() and stat_centroid() are similar to ggplot2::stat_summary() but summarize both x and y values in the same plot layer. Differently to stat_summary() no grouping based on data values is done; the grouping respected is that already present based on mappings to aesthetics. This makes it possible to highlight the actual location of the centroid with geom_point(), geom_text(), and similar geometries. Instead, if we use geom_rug() they are only a convenience avoiding the need to add two separate layers and flipping one of them using orientation = "y".

Usage

stat_apply_group(
  mapping = NULL,
  data = NULL,
  geom = "line",
  .fun.x = NULL,
  .fun.x.args = list(),
  .fun.y = NULL,
  .fun.y.args = list(),
)
\begin{verbatim}
stat_apply_group(
    position = "identity", 
    na.rm = FALSE, 
    show.legend = FALSE, 
    inherit.aes = TRUE, 
    ...
)

stat_summary_xy(
    mapping = NULL, 
    data = NULL, 
    geom = "point", 
    .fun.x = NULL, 
    .fun.x.args = list(), 
    .fun.y = NULL, 
    .fun.y.args = list(), 
    position = "identity", 
    na.rm = FALSE, 
    show.legend = FALSE, 
    inherit.aes = TRUE, 
    ...
)

stat_centroid(
    mapping = NULL, 
    data = NULL, 
    geom = "point", 
    .fun = NULL, 
    .fun.args = list(), 
    position = "identity", 
    na.rm = FALSE, 
    show.legend = FALSE, 
    inherit.aes = TRUE, 
    ...
)
\end{verbatim}

**Arguments**

- **mapping**  
  The aesthetic mapping, usually constructed with \texttt{aes}. Only needs to be set at the layer level if you are overriding the plot defaults.

- **data**  
  A layer specific dataset - only needed if you want to override the plot defaults.

- **geom**  
  The geometric object to use display the data

- **.fun.x, .fun.y, .fun**  
  Function to be applied or the name of the function to be applied as a character string.

- **.fun.x.args, .fun.y.args, .fun.args**  
  Additional arguments to be passed to the function as a named list.

- **position**  
  The position adjustment to use for overlapping points on this layer
stat_apply_group

na.rm a logical value indicating whether NA values should be stripped before the computation proceeds.

show.legend logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

inherit.aes If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.

... other arguments passed on to layer. This can include aesthetics whose values you want to set, not map. See layer for more details.

Details

stat_apply_group applies functions to data. When possible it is preferable to use transformations through scales or summary functions such as ggplot2::stat_summary(), stat_summary_xy() or stat_centroid(). There are some computations that are not scale transformations but are not usual summaries either, as the number of data values does not decrease all the way to one row per group. A typical case for a summary is the computation of quantiles. For transformations are cumulative ones, e.g., using cumsum(), runmed() and similar functions. Obviously, it is always possible to apply such functions to the data before plotting and passing them to a single layer function. However, it can be useful to apply such functions on-the-fly to ensure that grouping is consistent between computations and aesthetics. One particularity of these statistics is that they can apply simultaneously different functions to x values and to y values when needed. In contrast to these statistics, geom_smooth applies a function that takes both x and y values as arguments.

These four statistics are similar. They differ on whether they return a single or multiple rows of data per group.

Value

A data frame with the same variables as the data input, with either a single or multiple rows, with the values of x and y variables replaced by the values returned by the applied functions, or possibly filled with NA if no function was supplied or available by default. If the applied function returns a named vector, the names are copied into columns x.names and/or y.names. If the summary function applied returns a one row data frame, it will be column bound keeping the column names, but overwriting columns x and/or y with y from the summary data frame. In the names returned by .fun.x the letter "y" is replaced by "x". These allows the use of the same functions as in ggplot2::stat_summary().

- x x-value as returned by .fun.x, with names removed
- y y-value as returned by .fun.y, with names removed
- x.names if the x-value returned by .fun.x is named, these names
- y.names if the y-value returned by .fun.y is named, these names
- xmin, xmax values returned by .fun.x under these names, if present
- ymin, ymax values returned by .fun.y under these names, if present
- <other> additional values as returned by .fun.y under other names
Note

The applied function(s) must accept as first argument a vector that matches the variables mapped to \( x \) or \( y \) aesthetics. For `stat_summary_xy()` and `stat_centroid()` the function(s) to be applied is(are) expected to return a vector of length 1 or a data frame with only one row, as `mean_se()`, `mean_cl_normal()` `mean_cl_boot()`, `mean_sdl()` and `median_hilow()` from `ggplot2` do.

For `stat_apply_group` the vectors returned by the the functions applied to \( x \) and \( y \) must be of exactly the same length. When only one of `.fun.x` or `.fun.y` are passed a function as argument, the other variable in the returned data is filled with `NA_real_`. If other values are desired, they can be set by means of a user-defined function.

stat_dens1d_filter

Filter observations by local 1D density

Description

*stat_dens1d_filter* Filters-out/filters-in observations in regions of a plot panel with high density of observations, based on the values mapped to one of x and y aesthetics. *stat_dens1d_filter_g* does the same filtering by group instead of by panel. This second stat is useful for highlighting observations, while the first one tends to be most useful when the aim is to prevent clashes among text labels. By default the data are handled all together, but it is also possible to control labeling separately in each tail.

Usage

```r
stat_dens1d_filter(
  mapping = NULL,
  data = NULL,
  geom = "point",
  position = "identity",
  ..., 
  keep.fraction = 0.1,
  keep.number = Inf,
  keep.sparse = TRUE,
  exclude.these = FALSE,
  these.target = "label",
  pool.along = c("x", "none"),
  xintercept = 0,
  invert.selection = FALSE,
  bw = "SJ",
  kernel = "gaussian",
  adjust = 1,
  n = 512,
  return.density = FALSE,
  orientation = c("x", "y"),
  na.rm = TRUE,
  show.legend = FALSE,
  inherit.aes = TRUE
)
```

```r
geom_point() +
stat_apply_group(geom = "debug",
  .fun.x = quantile,
  .fun.x.args = list(probs = my.probs),
  .fun.y = quantile,
  .fun.y.args = list(probs = my.probs))
```
stat_dens1d_filter_g(
  mapping = NULL,
  data = NULL,
  geom = "point",
  position = "identity",
  keep.fraction = 0.1,
  keep.number = Inf,
  keep.sparse = TRUE,
  keep.these = FALSE,
  exclude.these = FALSE,
  these.target = "label",
  pool.along = c("x", "none"),
  xintercept = 0,
  invert.selection = FALSE,
  na.rm = TRUE,
  show.legend = FALSE,
  inherit.aes = TRUE,
  bw = "SJ",
  adjust = 1,
  kernel = "gaussian",
  n = 512,
  return.density = FALSE,
  orientation = c("x", "y"),
  ...
)

Arguments

mapping The aesthetic mapping, usually constructed with \texttt{aes} or \texttt{aes}_. Only needs to be set at the layer level if you are overriding the plot defaults.
data A layer specific dataset - only needed if you want to override the plot defaults.
geom The geometric object to use display the data.
position The position adjustment to use for overlapping points on this layer
... other arguments passed on to \texttt{layer}. This can include aesthetics whose values you want to set, not map. See \texttt{layer} for more details.
keep.fraction numeric vector of length 1 or 2 \([0..1]\). The fraction of the observations (or rows) in data to be retained.
keep.number integer vector of length 1 or 2. Set the maximum number of observations to retain, effective only if obeying keep.fraction would result in a larger number.
keep.sparse logical If TRUE, the default, observations from the more sparse regions are retained, if FALSE those from the densest regions.
keep.these, exclude.these character vector, integer vector, logical vector or function that takes one or more variables in data selected by these.target. Negative integers behave as in R’s extraction methods. The rows from data indicated by keep.these and exclude.these are kept or excluded irrespective of the local density.
these.target character, numeric or logical selecting one or more column(s) of data. If TRUE the whole data object is passed.

pool.along character, one of "none" or "x", indicating if selection should be done pooling the observations along the x aesthetic, or separately on either side of xintercept.

xintercept numeric The split point for the data filtering. If NA the data are not split.

invert.selection logical If TRUE, the complement of the selected rows are returned.

bw numeric or character The smoothing bandwidth to be used. If numeric, the standard deviation of the smoothing kernel. If character, a rule to choose the bandwidth, as listed in \texttt{bw.nrd}.

kernel character See \texttt{density} for details.

adjust numeric A multiplicative bandwidth adjustment. This makes it possible to adjust the bandwidth while still using the a bandwidth estimator through an argument passed to bw. The larger the value passed to adjust the stronger the smoothing, hence decreasing sensitivity to local changes in density.

n numeric Number of equally spaced points at which the density is to be estimated for applying the cut point. See \texttt{density} for details.

return.density logical vector of length 1. If TRUE add columns "density" and "keep.obs" to the returned data frame.

orientation character The aesthetic along which density is computed. Given explicitly by setting orientation to either "x" or "y".

na.rm a logical value indicating whether NA values should be stripped before the computation proceeds.

show.legend logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

inherit.aes If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. \texttt{borders}.

Details

The 1D density of observations of \texttt{x} or \texttt{y} is computed with function \texttt{density} and used to select observations, passing to the geom a subset of the rows in its data input. The default is to select observations in sparse regions of the plot, but the selection can be inverted so that only observations in the densest regions are returned. Specific observations can be protected from being deselected and "kept" by passing a suitable argument to keep.these. Logical and integer vectors work as indexes to rows in data, while a values in a character vector are compared to the character values mapped to the label aesthetic. A function passed as argument to keep.these will receive as argument the values in the variable mapped to label and should return a character, logical or numeric vector as described above. If no variable has been mapped to label, row names are used in its place.

How many rows are retained in addition to those in keep.these is controlled with arguments passed to keep.number and keep.fraction. keep.number sets the maximum number of observations selected, whenever keep.fraction results in fewer observations selected, it is obeyed. If ‘xintercept’ is a finite value within the x range of the data and pool.along is passed "none" the data as are split.
into two groups and keep.number and keep.fraction are applied separately to each tail with density still computed jointly from all observations. If the length of keep.number and keep.fraction is one, this value is used for both tails, if their length is two, the first value is use for the left tail and the second value for the right tail.

Computation of density and of the default bandwidth require at least two observations with different values. If data do not fulfill this condition, they are kept only if keep.fraction = 1. This is correct behavior for a single observation, but can be surprising in the case of multiple observations.

Parameters keep.these and exclude.these make it possible to force inclusion or exclusion of observations after the density is computed. In case of conflict, exclude.these overrides keep.these.

Value

A plot layer instance. Using as output data a subset of the rows in input data retained based on a 1D filtering criterion.

Note

Which points are kept and which not depends on how dense and flexible is the density curve estimate. This depends on the values passed as arguments to parameters n, bw and kernel. It is also important to be aware that both geom_text() and geom_text_repel() can avoid over plotting by discarding labels at the plot rendering stage, i.e., what is plotted may differ from what is returned by this statistic.

  stat_dens1d_filter(geom = "debug", return.density = TRUE)
}

stat_dens1d_labels

Replace labels in data based on 1D density

**Description**

*stat_dens1d_labels()* Sets values mapped to the label aesthetic to "" or a user provided character string based on the local density in regions of a plot panel. Its main use is together with repulsive geoms from package *ggrepel* to restrict labeling to the low density tails of a distribution. By default the data are handled all together, but it is also possible to control labeling separately in each tail.

If there is no mapping to label in data, the mapping is set to *rownames(data)*, with a message.

**Usage**

```r
stat_dens1d_labels(
  mapping = NULL,
  data = NULL,
  geom = "text",
  position = "identity",
  ..., 
  keep.fraction = 0.1,
  keep.number = Inf,
  keep.sparse = TRUE,
  keep.these = FALSE,
)```
```r
exclude.these = FALSE,
these.target = "label",
pool.along = c("x", "none"),
xintercept = 0,
invert.selection = FALSE,
bw = "SJ",
kernel = "gaussian",
adjust = 1,
n = 512,
orIENTATION = c("x", "y"),
label.fill = "",
return.density = FALSE,
na.rm = TRUE,
show.legend = FALSE,
inherit.aes = TRUE
)
```

**Arguments**

- **mapping**: The aesthetic mapping, usually constructed with `aes` or `aes_`. Only needs to be set at the layer level if you are overriding the plot defaults.
- **data**: A layer specific dataset - only needed if you want to override the plot defaults.
- **geom**: The geometric object to use display the data.
- **position**: The position adjustment to use for overlapping points on this layer
- **...**: other arguments passed on to `layer`. This can include aesthetics whose values you want to set, not map. See `layer` for more details.
- **keep.fraction**: numeric vector of length 1 or 2 [0..1]. The fraction of the observations (or rows) in `data` to be retained.
- **keep.number**: integer vector of length 1 or 2. Set the maximum number of observations to retain, effective only if obeying `keep.fraction` would result in a larger number.
- **keep.sparse**: logical If TRUE, the default, observations from the more sparse regions are retained, if FALSE those from the densest regions.
- **keep.these, exclude.these**: character vector, integer vector, logical vector or function that takes one or more variables in data selected by `these.target`. Negative integers behave as in R's extraction methods. The rows from `data` indicated by `keep.these` and `exclude.these` are kept or excluded irrespective of the local density.
- **these.target**: character, numeric or logical selecting one or more column(s) of data. If TRUE the whole `data` object is passed.
- **pool.along**: character, one of "none" or "x", indicating if selection should be done pooling the observations along the x aesthetic, or separately on either side of xintercept.
- **xintercept**: numeric The split point for the data filtering.
- **invert.selection**: logical If TRUE, the complement of the selected rows are returned.
bw  numeric or character The smoothing bandwidth to be used. If numeric, the
standard deviation of the smoothing kernel. If character, a rule to choose the
bandwidth, as listed in bw.nrd.

kernel character See density for details.

adjust numeric A multiplicative bandwidth adjustment. This makes it possible to adjust
the bandwidth while still using the a bandwidth estimator through an argument
passed to bw. The larger the value passed to adjust the stronger the smoothing,
and decreasing sensitivity to local changes in density.

n numeric Number of equally spaced points at which the density is to be estimated
for applying the cut point. See density for details.

orientation character The aesthetic along which density is computed. Given explicitly by
setting orientation to either "x" or "y".

label.fill character vector of length 1 or a function.

return.density logical vector of length 1. If TRUE add columns "density" and "keep.obs" to
the returned data frame.

na.rm a logical value indicating whether NA values should be stripped before the com-
putation proceeds.

show.legend logical. Should this layer be included in the legends? NA, the default, includes if
any aesthetics are mapped. FALSE never includes, and TRUE always includes.

inherit.aes If FALSE, overrides the default aesthetics, rather than combining with them.
This is most useful for helper functions that define both data and aesthetics and
shouldn’t inherit behaviour from the default plot specification, e.g. borders.

Details

stat_dens1d_labels() is designed to work together with geometries from package ‘ggrepel’. To
avoid text labels being plotted over unlabelled points the corresponding rows in data need to be
retained but labels replaced with the empty character string, "". Function stat_dens1d_filter
cannot be used with the repulsive geoms from ‘ggrepel’ because it drops the observations.
stat_dens1d_labels() can be useful also in other situations, as the substitution character string
can be set by the user by passing an argument to label.fill. If this argument is NULL the un-
selected rows are filtered out.

The local density of observations along x or y is computed with function density and used to select
observations, passing to the geom all the rows in its data input but with with the text of labels
replaced in those "not kept". The default is to select observations in sparse regions of the plot, but
the selection can be inverted so that only observations in the densest regions are returned. Specific
observations can be protected from having the label replaced by passing a suitable argument to
tkeep.these. Logical and integer vectors function as indexes to rows in data, while a character
vector is compared to values in the variable mapped to the label aesthetic. A function passed as
argument to keep.these will receive as argument the values in the variable mapped to label
and should return a character, logical or numeric vector as described above.

How many labels are retained intact in addition to those in keep.these is controlled with arguments
passed to keep.number and keep.fraction. keep.number sets the maximum number of observ-
ations selected, whenever keep.fraction results in fewer observations selected, it is obeyed. If
xintercept is a finite value within the x range of the data and pool.along is passed "none" the
data are split into two groups and `keep.number` and `keep.fraction` are applied separately to each tail with density still computed jointly from all observations. If the length of `keep.number` and `keep.fraction` is one, half this value is used each tail, if their length is two, the first value is used for the left tail and the second value for the right tail (or if using orientation = "y" the lower and upper tails, respectively).

Computation of density and of the default bandwidth require at least two observations with different values. If data do not fulfill this condition, they are kept only if `keep.fraction = 1`. This is correct behavior for a single observation, but can be surprising in the case of multiple observations.

Parameters `keep.these` and `exclude.these` make it possible to force inclusion or exclusion of labels after the density is computed. In case of conflict, `exclude.these` overrides `keep.these`.

Value

A plot layer instance. Using as output data the input data after value substitution based on a 1D the filtering criterion.

Note

Which points are kept and which not depends on how dense and flexible is the density curve estimate. This depends on the values passed as arguments to parameters `n`, `bw` and `kernel`. It is also important to be aware that both `geom_text()` and `geom_text_repel()` can avoid overplotting by discarding labels at the plot rendering stage, i.e., what is plotted may differ from what is returned by this statistic.

**stat_dens2d_filter**

*Filter observations by local 2D density*

**Description**

*stat_dens2d_filter* Filters-out/filters-in observations in regions of a plot panel with high density of observations, based on the values mapped to both \textit{x} and \textit{y} aesthetics. *stat_dens2d_filter_g* does the filtering by group instead of by panel. This second stat is useful for highlighting observations, while the first one tends to be most useful when the aim is to prevent clashes among text labels. If there is no mapping to \textit{label} in \textit{data}, the mapping is silently set to \texttt{rownames(data)}.

**Usage**

```r
stat_dens2d_filter(
  mapping = NULL,
  data = NULL,
  .
```
stat_dens2d_filter

geom = "point",
position = "identity",
...
keep.fraction = 0.1,
keep.number = Inf,
keep.sparse = TRUE,
keep.these = FALSE,
exclude.these = FALSE,
these.target = "label",
pool.along = c("xy", "x", "y", "none"),
xintercept = 0,
yintercept = 0,
invert.selection = FALSE,
na.rm = TRUE,
show.legend = FALSE,
inherit.aes = TRUE,
h = NULL,
n = NULL,
return.density = FALSE

stat_dens2d_filter_g(
  mapping = NULL,
data = NULL,
geom = "point",
position = "identity",
...
keep.fraction = 0.1,
keep.number = Inf,
keep.sparse = TRUE,
keep.these = FALSE,
exclude.these = FALSE,
these.target = "label",
pool.along = c("xy", "x", "y", "none"),
xintercept = 0,
yintercept = 0,
invert.selection = FALSE,
na.rm = TRUE,
show.legend = FALSE,
inherit.aes = TRUE,
h = NULL,
n = NULL,
return.density = FALSE
)

Arguments

mapping The aesthetic mapping, usually constructed with \texttt{aes} or \texttt{aes_}. Only needs to be set at the layer level if you are overriding the plot defaults.
data A layer specific dataset - only needed if you want to override the plot defaults.
geom The geometric object to use display the data.
position The position adjustment to use for overlapping points on this layer
... other arguments passed on to layer. This can include aesthetics whose values you want to set, not map. See layer for more details.
keep.fraction numeric [0..1]. The fraction of the observations (or rows) in data to be retained.
keep.number integer Set the maximum number of observations to retain, effective only if obeying keep.fraction would result in a larger number.
keep.sparse logical If TRUE, the default, observations from the more sparse regions are retained, if FALSE those from the densest regions.
keep.these, exclude.these character vector, integer vector, logical vector or function that takes one or more variables in data selected by these.target. Negative integers behave as in R’s extraction methods. The rows from data indicated by keep.these and exclude.these are kept or excluded irrespective of the local density.
these.target character, numeric or logical selecting one or more column(s) of data. If TRUE the whole data object is passed.
pool.along character, one of "none", "x", "y", or "xy" indicating if selection should be done pooling the observations along the x, y, both axes or none based on quadrants given by xintercept and yintercept.
xintercept, yintercept numeric The center point of the quadrants.
invert.selection logical If TRUE, the complement of the selected rows are returned.
na.rm a logical value indicating whether NA values should be stripped before the computation proceeds.
show.legend logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.
inherit.aes If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.
h vector of bandwidths for x and y directions. Defaults to normal reference bandwidth (see bandwidth.nrd). A scalar value will be taken to apply to both directions.
n Number of grid points in each direction. Can be scalar or a length-2 integer vector
return.density logical vector of length 1. If TRUE add columns "density" and "keep.obs" to the returned data frame.

Details
The local density of observations in 2D (x and y) is computed with function kde2d and used to select observations, passing to the geom a subset of the rows in its data input. The default is to select observations in sparse regions of the plot, but the selection can be inverted so that only
observations in the densest regions are returned. Specific observations can be protected from being
deselected and "kept" by passing a suitable argument to keep.these. Logical and integer vectors
work as indexes to rows in data, while a character vector values are compared to the character
values mapped to the label aesthetic. A function passed as argument to keep.these will receive
as argument the values in the variable mapped to label and should return a character, logical or
numeric vector as described above. If no variable has been mapped to label, row names are used
in its place.

How many rows are retained in addition to those in keep.these is controlled with arguments passed
to keep.number and keep.fraction. keep.number sets the maximum number of observations
selected, whenever keep.fraction results in fewer observations selected, it is obeyed.

Computation of density and of the default bandwidth require at least two observations with different
values. If data do not fulfill this condition, they are kept only if keep.fraction = 1. This is correct
behavior for a single observation, but can be surprising in the case of multiple observations.

Parameters keep.these and exclude.these make it possible to force inclusion or exclusion of ob-
servations after the density is computed. In case of conflict, exclude.these overrides keep.these.

Value

A plot layer instance. Using as output data a subset of the rows in input data retained based on a
2D-density-based filtering criterion.

Note

Which points are kept and which not depends on how dense a grid is used and how flexible the
density surface estimate is. This depends on the values passed as arguments to parameters n, bw
and kernel. It is also important to be aware that both geom_text() and geom_text_repel() can
avoid overplotting by discarding labels at the plot rendering stage, i.e., what is plotted may differ
from what is returned by this statistic.

See Also

stat_dens2d_labels and kde2d used internally. Parameters n, h in these statistics correspond to
the parameters with the same name in this imported function. Limits are set to the limits of the plot
scales.

Other statistics returning a subset of data: stat_dens1d_filter(), stat_dens1d_labels(), stat_dens2d_labels()

Examples

```r
random_string <-
  function(len = 6) {
    paste(sample(letters, len, replace = TRUE), collapse = "")
  }

# Make random data.
set.seed(1001)
d <- tibble::tibble(
x = rnorm(100),
y = rnorm(100),
```
```r
stat_dens2d_filter

group = rep(c("A", "B"), c(50, 50)),
lab = replicate(100, { random_string() })
)

# filter (and here highlight) 1/10 observations in sparsest regions
ggplot(data = d, aes(x, y)) +
  geom_point() +
  stat_dens2d_filter(colour = "red")

# filter observations not in the sparsest regions
ggplot(data = d, aes(x, y)) +
  geom_point() +
  stat_dens2d_filter(colour = "blue", invert.selection = TRUE)

# filter observations in dense regions of the plot
ggplot(data = d, aes(x, y)) +
  geom_point() +
  stat_dens2d_filter(colour = "blue", keep.sparse = FALSE)

# filter 1/2 the observations
ggplot(data = d, aes(x, y)) +
  geom_point() +
  stat_dens2d_filter(colour = "red", keep.fraction = 0.5)

# filter 1/2 the observations but cap their number to maximum 12 observations
ggplot(data = d, aes(x, y)) +
  geom_point() +
  stat_dens2d_filter(colour = "red",
                    keep.fraction = 0.5,
                    keep.number = 12)

# density filtering done jointly across groups
ggplot(data = d, aes(x, y, colour = group)) +
  geom_point() +
  stat_dens2d_filter(shape = 1, size = 3, keep.fraction = 1/4)

# density filtering done independently for each group
ggplot(data = d, aes(x, y, colour = group)) +
  geom_point() +
  stat_dens2d_filter_g(shape = 1, size = 3, keep.fraction = 1/4)

# density filtering done jointly across groups by overriding grouping
ggplot(data = d, aes(x, y, colour = group)) +
  geom_point() +
  stat_dens2d_filter_g(colour = "black",
                      shape = 1, size = 3, keep.fraction = 1/4)

# label observations
ggplot(data = d, aes(x, y, label = lab, colour = group)) +
  geom_point() +
  stat_dens2d_filter(geom = "text")
```

stat_dens2d_labels

Replace labels in data based on 2D density

**Description**

`stat_dens2d_labels()` Sets values mapped to the `label` aesthetic to "" or a user provided character string based on the local density in regions of a plot panel. Its main use is together with repulsive geoms from package `ggrepel`. If there is no mapping to `label` in `data`, the mapping is set to `rownames(data)`, with a message.

**Usage**

```r
stat_dens2d_labels(
  mapping = NULL,
  data = NULL,
  geom = "text",
  position = "identity",
  ..., 
  keep.fraction = 0.1,
  keep.number = Inf,
  keep.sparse = TRUE,
)```
Arguments

mapping
The aesthetic mapping, usually constructed with `aes` or `aes_`. Only needs to be set at the layer level if you are overriding the plot defaults.

data
A layer specific dataset - only needed if you want to override the plot defaults.

geom
The geometric object to use display the data.

position
The position adjustment to use for overlapping points on this layer

... other arguments passed on to `layer`. This can include aesthetics whose values you want to set, not map. See `layer` for more details.

keep.fraction numeric [0..1]. The fraction of the observations (or rows) in data to be retained.

keep.number integer Set the maximum number of observations to retain, effective only if obeying keep.fraction would result in a larger number.

keep.sparse logical If TRUE, the default, observations from the more sparse regions are retained, if FALSE those from the densest regions.

keep.these, exclude.these character vector, integer vector, logical vector or function that takes one or more variables in data selected by `these.target`. Negative integers behave as in R’s extraction methods. The rows from data indicated by `keep.these` and `exclude.these` are kept or excluded irrespective of the local density.

these.target character, numeric or logical selecting one or more column(s) of data. If TRUE the whole data object is passed.

pool.along character, one of "none" or "x", indicating if selection should be done pooling the observations along the x aesthetic, or separately on either side of `xintercept`.

xintercept, yintercept numeric The split points for the data filtering.

invert.selection logical If TRUE, the complement of the selected rows are returned.

h vector of bandwidths for x and y directions. Defaults to normal reference bandwidth (see bandwidth.nrd). A scalar value will be taken to apply to both directions.
Number of grid points in each direction. Can be scalar or a length-2 integer vector.

Character vector of length 1, a function or NULL.

Logical vector of length 1. If TRUE add columns "density" and "keep.obs" to the returned data frame.

A logical value indicating whether NA values should be stripped before the computation proceeds.

Logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.

**Details**

`stat_dens2d_labels()` is designed to work together with geometries from package `ggrepel`. To avoid text labels being plotted over unlabelled points all the rows in data need to be retained but labels replaced with the empty character string, "". Function `stat_dens2d_filter` cannot be used with the repulsive geoms from ‘ggrepel’ because it drops observations.

`stat_dens2d_labels()` can be useful also in other situations, as the substitution character string can be set by the user by passing an argument to `label.fill`. If this argument is NULL the unselected rows are filtered out identically as by `stat_dens2d_filter`.

The local density of observations in 2D (x and y) is computed with function `kde2d` and used to select observations, passing to the geom all the rows in its data input but with with the text of labels replaced in those "not kept". The default is to select observations in sparse regions of the plot, but the selection can be inverted so that only observations in the densest regions are returned. Specific observations can be protected from having the label replaced by passing a suitable argument to keep.these. Logical and integer vectors function as indexes to rows in data, while a character vector is compared to values in the variable mapped to the label aesthetic. A function passed as argument to keep.these will receive as its first argument the values in the variable mapped to label and should return a character, logical or numeric vector as described above.

How many labels are retained intact in addition to those in keep.these is controlled with arguments passed to keep.number and keep.fraction. keep.number sets the maximum number of observations selected, whenever keep.fraction results in fewer observations selected, it is obeyed.

Computation of density and of the default bandwidth require at least two observations with different values. If data do not fulfill this condition, they are kept only if keep.fraction = 1. This is correct behavior for a single observation, but can be surprising in the case of multiple observations.

Parameters keep.these and exclude.these make it possible to force inclusion or exclusion of observations after the density is computed. In case of conflict, exclude.these overrides keep.these.

**Value**

A plot layer instance. Using as output data the input data after value substitution based on a 2D the filtering criterion.
stat_dens2d_labels

Note

Which points are kept and which not depends on how dense a grid is used and how flexible the density surface estimate is. This depends on the values passed as arguments to parameters \( n \), \( bw \) and \( kernel \). It is also important to be aware that both \texttt{geom_text()} and \texttt{geom_text_repel()} can avoid overplotting by discarding labels at the plot rendering stage, i.e., what is plotted may differ from what is returned by this statistic.

See Also

\texttt{stat_dens2d_filter} and \texttt{kde2d} used internally. Parameters \( n \), \( h \) in this statistic correspond to the parameters with the same name in this imported function. Limits are set to the limits of the plot scales.

Other statistics returning a subset of data: \texttt{stat_dens1d_filter()}, \texttt{stat_dens1d_labels()}, \texttt{stat_dens2d_filter()}

Examples

  geom_point() +
  stat_dens2d_labels(geom = "debug")
}
stat_fmt_tb

Select and slice a tibble nested in data

**Description**

`stat_fmt_tb` selects, reorders and/or renames columns and or rows of a tibble nested in `data`. This stat is intended to be used to pre-process tibble objects mapped to the `label` aesthetic before adding them to a plot with `geom_table`.

**Usage**

```r
stat_fmt_tb(
  mapping = NULL,
  data = NULL,
  geom = "table",
  tb.vars = NULL,
  tb.rows = NULL,
  digits = 3,
  position = "identity",
  table.theme = NULL,
  table.rownames = FALSE,
  table.colnames = TRUE,
  table.hjust = 0.5,
  parse = FALSE,
  na.rm = FALSE,
  show.legend = FALSE,
  inherit.aes = TRUE,
  ...
)
```

**Arguments**

- `mapping`: The aesthetic mapping, usually constructed with `aes` or `aes_`. Only needs to be set at the layer level if you are overriding the plot defaults.
- `data`: A layer specific dataset - only needed if you want to override the plot defaults.
- `geom`: The geometric object to use display the data.
- `tb.vars`, `tb.rows`: character or numeric vectors, optionally named, used to select and/or rename the columns or rows in the table returned.
- `digits`: integer indicating the number of significant digits to be retained in data.
- `position`: The position adjustment to use for overlapping points on this layer.
- `table.theme`: NULL, list or function A `gridExtra` `ttheme` definition, or a constructor for a `ttheme` or NULL for default.
table.rownames, table.colnames logical flag to enable or disabling printing of row names and column names.

table.hjust numeric Horizontal justification for the core and column headings of the table.

parse If TRUE, the labels will be parsed into expressions and displayed as described in ?plotmath.

na.rm a logical indicating whether NA values should be stripped before the computation proceeds.

show.legend logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

inherit.aes If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn’t inherit behaviour from the default plot specification, e.g. borders.

... other arguments passed on to layer. This can include aesthetics whose values you want to set, not map. See layer for more details.

Value
A plot layer instance. Using as output data a copy of the input data in which the data frames mapped to label have been modified.

Computed variables
The output of sequentially applying slice with tb.rows as argument and select with tb.vars to a list variable list mapped to label and containing a single tibble per row in data.

See Also
See geom_table for details on how tables respond to mapped aesthetics and table themes. For details on predefined table themes see ttheme_gtdefault.

Examples

```r
my.df <-
tibble::tibble(
  x = c(1, 2),
  y = c(0, 4),
  group = c("A", "B"),
  tbs = list(a = tibble::tibble(Xa = 1:6, Y = rep(c("x", "y"), 3)),
            b = tibble::tibble(Xb = 1:3, Y = "x"))
)

ggplot(my.df, aes(x, y, label = tbs)) +
  stat_fmt_tb() +
  expand_limits(x = c(0,3), y = c(-2, 6))

# Hide column names, display row names
ggplot(my.df, aes(x, y, label = tbs)) +
  stat_fmt_tb(table.colnames = FALSE,
              table.rownames = TRUE) +
```

```r
# Use a theme for the table
ggplot(my.df, aes(x, y, label = tbs)) +
    stat_fmt_tb(table.theme = ttheme_gtlight) +
    expand_limits(x = c(0,3), y = c(-2, 6))

# selection and renaming by column position
ggplot(my.df, aes(x, y, label = tbs)) +
    stat_fmt_tb(tb.vars = c(value = 1, group = 2),
               tb.rows = 1:3) +
    expand_limits(x = c(0,3), y = c(-2, 6))

# selection, reordering and renaming by column position
ggplot(my.df, aes(x, y, label = tbs)) +
    stat_fmt_tb(tb.vars = c(group = 2, value = 1),
               tb.rows = 1:3) +
    expand_limits(x = c(0,3), y = c(-2, 6))

# selection and renaming, using partial matching to column name
ggplot(my.df, aes(x, y, label = tbs)) +
    stat_fmt_tb(tb.vars = c(value = "X", group = "Y"),
               tb.rows = 1:3) +
    expand_limits(x = c(0,3), y = c(-2, 6))
```

---

**stat_functions**  
*Draw functions as curves*

**Description**  
stat_functions() computes values from functions and returns new data containing numeric vectors for x and y. As function definitions are passed through data this statistic follows the grammar of graphics in its behaviour.

**Usage**  
```r
stat_functions(
    mapping = NULL,
    data = NULL,
    n = 101,
    geom = "line",
    position = "identity",
    na.rm = FALSE,
    show.legend = NA,
    inherit.aes = TRUE,
    ...
)```
Arguments

- **mapping**: The aesthetic mapping, usually constructed with `aes` or `aes_`. Only needs to be set at the layer level if you are overriding the plot defaults.

- **data**: A layer specific dataset. Useful if the function curve is to be overlaid on other layers.

- **n**: Integer Number of points to interpolate along the x axis.

- **geom**: The geometric object to use display the data

- **position**: The position adjustment to use on this layer

- **na.rm**: A logical indicating whether NA values should be stripped before the computation proceeds.

- **show.legend**: Logical. Should this layer be included in the legends? NA, the default, includes it if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

- **inherit.aes**: If FALSE, overrides the default aesthetics, rather than combining with them.

- **...**: Other arguments passed on to `layer`. This can include aesthetics whose values you want to set, not map. See `layer` for more details.

Details

This statistic can be used to plot values computed by functions. As it follows the grammar of graphics, grouping and facets are supported. In this it differs from `geom_function` which behaves like a plot annotation.

Aesthetics `xmin` and `xmax` should be mapped to numeric values defining the range of the vector to be created and passed as argument to the function to compute the y values, and returned as `x` in `data`. `n` is the length of this `x` vector.

Value

A plot layer instance.

Computed variables

- `x` numeric vector
- `y` numeric vector
- `idx` integer vector, with values corresponding to rows in the input `data`, i.e., for each function

As shown in one example below `geom_debug` can be used to print the computed values returned by any statistic. The output shown includes also values mapped to aesthetics.

Examples

```r
# one function
df1 <- data.frame(min = 0, max = pi, fun = I(list(sin)))
```
ggplot(df1, aes(xmin = min, xmax = max, y = fun)) +
  stat_functions()

---

stat_panel_counts

Number of observations in a plot panel
Description

`stat_panel_counts()` counts the number of observations in each panel. `stat_group_counts()` counts the number of observations in each group. By default they add one or more text labels to the top right corner of each panel. Grouping is ignored by `stat_panel_counts()`. If no grouping exists, the two statistics behave similarly.

Usage

```r
stat_panel_counts(
    mapping = NULL,
    data = NULL,
    geom = "text_npc",
    position = "identity",
    label.x = "right",
    label.y = "top",
    na.rm = FALSE,
    show.legend = FALSE,
    inherit.aes = TRUE,
    ...
)
```

```r
stat_group_counts(
    mapping = NULL,
    data = NULL,
    geom = "text_npc",
    position = "identity",
    label.x = "right",
    label.y = "top",
    hstep = 0,
    vstep = NULL,
    digits = 2,
    na.rm = FALSE,
    show.legend = FALSE,
    inherit.aes = TRUE,
    ...
)
```

Arguments

- `mapping` The aesthetic mapping, usually constructed with `aes` or `aes_`. Only needs to be set at the layer level if you are overriding the plot defaults.
- `data` A layer specific dataset. Rarely used, as you will not want to override the plot defaults.
- `geom` The geometric object to use display the data
- `position` The position adjustment to use on this layer
- `label.x`, `label.y` numeric Coordinates (in npc units) to be used for absolute positioning of the labels.
na.rm

a logical indicating whether NA values should be stripped before the computation proceeds.

show.legend

logical. Should this layer be included in the legends? NA, the default, includes it if any aesthetics are mapped. FALSE never includes, and TRUE always includes.

inherit.aes

If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and should not inherit behaviour from the default plot specification, e.g., borders.

...

other arguments passed on to layer. This can include aesthetics whose values you want to set, not map. See layer for more details.

hstep, vstep

numeric in npc units, the horizontal and vertical step used between labels for different groups.

digits

integer Number of digits for fraction and percent labels.

Details

These statistics can be used to automatically count observations in each panel of a plot, and by default add these counts as text labels. These statistics, unlike stat_quadrant_counts() requires only one of x or y aesthetics and can be used together with statistics that have the same requirement, like stat_density().

The default position of the label is in the top right corner. When using facets even with free limits for x and y axes, the location of the labels is consistent across panels. This is achieved by use of geom = "text_npc" or geom = "label_npc". To pass the positions in native data units to label.x and label.y, pass also explicitly geom = "text", geom = "label" or some other geometry that use the x and/or y aesthetics. A vector with the same length as the number of panels in the figure can be used if needed.

Value

A plot layer instance. Using as output data the counts of observations in each plot panel or per group in each plot panel.

Computed variables

Data frame with one or more rows, one for each group of observations for which counts are counted in data.

x,npcx  x value of label position in data- or npc units, respectively

y,npcy  y value of label position in data- or npc units, respectively

count  number of observations as an integer

count.label  number of observations as character

As shown in one example below geom_debug can be used to print the computed values returned by any statistic. The output shown includes also values mapped to aesthetics, like label in the example. x and y are included in the output only if mapped.
Note

If a factor is mapped to x or to y aesthetics each level of the factor constitutes a group, in this case the default positioning and geom using NPC pseudo aesthetics will have to be overriden by passing `geom = "text"` and data coordinates used. The default for factors may change in the future.

Examples

```r
# generate artificial data with numeric x and y
set.seed(67821)
x <- 1:100
y <- rnorm(length(x), mean = 10)
group <- factor(rep(c("A", "B"), times = 50))
my.data <- data.frame(x, y, group)

# using automatically generated text labels
ggplot(my.data, aes(x, y)) +
  geom_point() +
  stat_panel_counts()

ggplot(my.data, aes(x, y, colour = group)) +
  geom_point() +
  stat_panel_counts()

ggplot(my.data, aes(x, y, colour = group)) +
  geom_point() +
  stat_group_counts(label.x = "left", hstep = 0.06, vstep = 0)

ggplot(my.data, aes(x, y, colour = group)) +
  geom_point() +
  stat_group_counts(aes(label = after_stat(pc.label)), digits = 3)

ggplot(my.data, aes(x, y, colour = group)) +
  geom_point() +
  stat_group_counts(aes(label = after_stat(fr.label)))

ggplot(my.data, aes(x, y, colour = group)) +
  geom_point() +
  stat_group_counts(aes(label = after_stat(dec.label)))
```
# one of x or y can be a factor
# label.x or label.y along the factor can be set to “factor” together
# with the use of geom_text()

ggplot(mpg,
       aes(factor(cyl), hwy)) +
  stat_boxplot() +
  stat_group_counts(geom = "text",
                   label.y = 10,
                   label.x = "factor") +
  stat_panel_counts()

# Numeric values can be used to build labels with alternative formats
# Here with sprintf(), but paste() and format() also work.

ggplot(my.data, aes(x, y)) +
  geom_point() +
  stat_panel_counts(aes(label = sprintf("n\[%i\] ~ \text{Var} ~ %i",
                               after_stat(count))),
                   label.y = 10,
                   label.x = "factor")

  # label position

ggplot(my.data, aes(y)) +
  stat_panel_counts(label.x = "left") +
  stat_density(alpha = 0.5)

ggplot(my.data, aes(y, colour = group)) +
  stat_group_counts(label.y = "top") +
  stat_density(aes(fill = group), alpha = 0.3)
The numeric value can be used as a label as is

```r
ggplot(mpg,
    aes(factor(cyl), hwy)) +
stat_boxplot() +
stat_group_counts(geom = "text",
    aes(label = after_stat(count)),
    label.x = "factor",
    label.y = 10) +
annotate(geom = "text", x = 0.55, y = 10, label = "n[i]-\text{Var}\Var", parse = TRUE)
```

# We use geom_debug() to see the computed values

```r
gginnards.installed <- requireNamespace("gginnards", quietly = TRUE)
if (gginnards.installed) {
  library(gginnards)

  ggplot(my.data, aes(x, y)) +
    geom_point() +
    stat_panel_counts(geom = "debug")
}
if (gginnards.installed) {
  ggplot(my.data, aes(x, y, colour = group)) +
    geom_point() +
    stat_group_counts(geom = "debug")
}
```

---

**stat_quadrant_counts**  
Number of observations in quadrants

**Description**

`stat_quadrant_counts()` counts the number of observations in each quadrant of a plot panel. By default it adds a text label to the far corner of each quadrant. It can also be used to obtain the total number of observations in each of two pairs of quadrants or in the whole panel. Grouping is ignored, so in every case a single count is computed for each quadrant in a plot panel.

**Usage**

```r
stat_quadrant_counts(
    mapping = NULL,
    data = NULL,
    geom = "text_npc",
    position = "identity",
    quadrants = NULL,
    pool.along = c("none", "x", "y", "xy"),
    xintercept = 0,
```
```r
yintercept = 0,
label.x = NULL,
label.y = NULL,
digits = 2,
na.rm = FALSE,
show.legend = FALSE,
inherit.aes = TRUE,
...
```

**Arguments**

- `mapping` The aesthetic mapping, usually constructed with `aes` or `aes_`. Only needs to be set at the layer level if you are overriding the plot defaults.
- `data` A layer specific dataset - only needed if you want to override the plot defaults.
- `geom` The geometric object to use display the data
- `position` The position adjustment to use on this layer
- `quadrants` integer vector indicating which quadrants are of interest, with a 0L indicating the whole plot.
- `pool.along` character, one of "none", "x" or "y", indicating which quadrants to pool to calculate counts by pair of quadrants.
- `xintercept`, `yintercept` numeric the coordinates of the origin of the quadrants.
- `label.x`, `label.y` numeric Coordinates (in npc units) to be used for absolute positioning of the labels.
- `digits` integer Number of digits for fraction and percent labels.
- `na.rm` a logical indicating whether NA values should be stripped before the computation proceeds.
- `show.legend` logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes.
- `inherit.aes` If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and should not inherit behaviour from the default plot specification, e.g., `borders`.
- `...` other arguments passed on to `layer`. This can include aesthetics whose values you want to set, not map. See `layer` for more details.

**Details**

This statistic can be used to automatically count observations in each of the four quadrants of a plot, and by default add these counts as text labels. Values exactly equal to `xintercept` or `yintercept` are counted together with those larger than the intercepts. An argument value of zero, passed to formal parameter `quadrants` is interpreted as a request for the count of all observations in each plot panel.

The default origin of quadrants is at `xintercept = 0, yintercept = 0`. Also by default, counts are computed for all quadrants within the `x` and `y` scale limits, but ignoring any marginal scale
expansion. The default positions of the labels is in the farthest corner or edge of each quadrant using npc coordinates. Consequently, when using facets even with free limits for x and y axes, the location of the labels is consistent across panels. This is achieved by use of geom = "text_npc” or geom = "label_npc”. To pass the positions in native data units, pass geom = “text” explicitly as argument.

Value

A plot layer instance. Using as output data the counts of observations per plot quadrant.

Computed variables

Data frame with one to four rows, one for each quadrant for which counts are counted in data.

- quadrant integer, one of 0:4
- x x value of label position in data units
- y y value of label position in data units
-_npcx x value of label position in npc units
- npcy y value of label position in npc units
- count number of observations in the quadrant(s)
- total number of observations in data
- count.label number of observations as character
- pc.label percent of observations as character
- fr.label fraction of observations as character

As shown in one example below geom_debug can be used to print the computed values returned by any statistic. The output shown includes also values mapped to aesthetics, like label in the example.

  stat_quadrant_counts(geom = "debug", xintercept = 50)
```
try_data_frame

Convert an R object into a tibble

Description

This function tries to convert any R object into a data.frame object. If `x` is already a data.frame, it is returned as is. If it is a list or a vector it is converted by means of `as.data.frame()`. If of any other type, a conversion into an object of class `xts` is attempted by means of `try.xts()` and if successful the `xts` object is converted into a data frame with a variable `time` containing times as `POSIXct` and the remaining data columns with the time series data. In this conversion row names are stripped.

Usage

```r
try_data_frame(
  x,
  time.resolution = "month",
  as.numeric = FALSE,
  col.names = NULL
)
```

```r
try_tibble(x, time.resolution = "month", as.numeric = FALSE, col.names = NULL)
```

Arguments

- `x` An R object
- `time.resolution` character The time unit to which the returned time values will be rounded.
- `as.numeric` logical If TRUE convert time to numeric, expressed as fractional calendar years.
- `col.names` character vector

Value

A `tidyverse::tibble` object, derived from `data.frame`.

Warning!

The time zone was set to "UTC" by `try.xts()` in the test cases I used. Setting `TZ` to "UTC" can cause some trouble as several frequently used functions have as default the local or system `TZ` and will apply a conversion before printing or plotting time data, which in addition is affected by summer/winter time transitions. This should be taken into account as even for yearly data when conversion is to `POSIXct` a day (1st of January) will be set, but then shifted some hours if printed on a `TZ` different from "UTC". I recommend reading the documentation of package `lubridate-package` where the irregularities of time data and the difficulties they cause are very well described. In many cases when working with time series with yearly observations it is best to work with numeric values for years.
**Note**

This function can be used to easily convert time series data into a format that can be easily plotted with package ggplot2. `try_tibble` is another name for `try_data_frame` which tracks the separation and re-naming of `data_frame` into `tibble::tibble` in the imported packages.

**Examples**

```r
class(lynx)
try_tibble(lynx)
try_tibble(lynx, as.numeric = TRUE)
try_tibble(lynx, "year")

class(austres)
try_tibble(austres)
try_tibble(austres, as.numeric = TRUE)
try_tibble(austres, "quarter")
class(cars)
try_tibble(cars)
```

---

**ttheme_gtdefault**  
*Table themes*

**Description**

Additional theme constructors for use with `geom_table`.

**Usage**

```r
ttheme_gtdefault(
  base_size = 10,
  base_colour = "black",
  base_family = "",
  parse = FALSE,
  padding = unit(c(0.8, 0.6), "char"),
  ...
)

ttheme_gtminimal(
  base_size = 10,
  base_colour = "black",
  base_family = "",
  parse = FALSE,
  padding = unit(c(0.5, 0.4), "char"),
  ...
)

ttheme_gtbw(
  base_size = 10,
```

ttheme_gtdefault

  ```r
  base_colour = "black",
  base_family = "",
  parse = FALSE,
  padding = unit(c(1, 0.6), "char"),
  ...
  )

ttheme_gtplain

  ```r
  base_size = 10,
  base_colour = "black",
  base_family = "",
  parse = FALSE,
  padding = unit(c(0.8, 0.6), "char"),
  ...
  )

ttheme_gtdark

  ```r
  base_size = 10,
  base_colour = "grey90",
  base_family = "",
  parse = FALSE,
  padding = unit(c(0.8, 0.6), "char"),
  ...
  )

ttheme_gtsimple

  ```r
  base_size = 10,
  base_colour = "grey10",
  base_family = "",
  parse = FALSE,
  padding = unit(c(0.5, 0.4), "char"),
  ...
  )

ttheme_gtstripes

  ```r
  base_size = 10,
  base_colour = "grey10",
  base_family = "",
  parse = FALSE,
padding = unit(c(0.8, 0.6), "char"),
...)

Arguments

base_size numeric, default font size.
base_colour default font colour.
base_family default font family.
parse logical, default behaviour for parsing text as plotmath.
padding length-2 unit vector specifying the horizontal and vertical padding of text within each cell.
... further arguments to control the gtable.

Details

Depending on the theme, the base_colour, which is mapped to the colour aesthetic if present, is applied to only the text elements, or to the text elements and rules. The difference is exemplified below.

Value

A list object that can be used as ttheme in the construction of tables with functions from package 'gridExtra'.

Note

These theme constructors are wrappers on gridExtra::ttheme_default() and gridExtra::ttheme_minimal(). They can also be used with grid.table if desired.

Examples

library(dplyr)
library(tibble)

mtcars %>%
  group_by(cyl) %>%
  summarize(wt = mean(wt), mpg = mean(mpg)) %>%
  ungroup() %>%
  mutate(wt = sprintf("%.2f", wt),
         mpg = sprintf("%.1f", mpg)) -> tb

df <- tibble(x = 5.45, y = 34, tb = list(tb))

# Same as the default theme constructor
ggplot(mtcars, aes(wt, mpg, colour = factor(cyl))) +
  geom_point() +
  geom_table(data = df, aes(x = x, y = y, label = tb),
             table.theme = ttheme_gtdefault) +
  theme_classic()
# Minimal theme constructor
ggplot(mtcars, aes(wt, mpg, colour = factor(cyl))) +
  geom_point() +
  geom_table(data = df, aes(x = x, y = y, label = tb),
    table.theme = ttheme_gtminimal) +
  theme_classic()

# A theme with white background
ggplot(mtcars, aes(wt, mpg, colour = factor(cyl))) +
  geom_point() +
  geom_table(data = df, aes(x = x, y = y, label = tb),
    table.theme = ttheme_gtbw) +
  theme_bw()

# Default colour of theme superceded by aesthetic constant
ggplot(mtcars, aes(wt, mpg, colour = factor(cyl))) +
  geom_point() +
  geom_table(data = df, aes(x = x, y = y, label = tb),
    table.theme = ttheme_gtbw, colour = "darkblue") +
  theme_bw()

# A theme with dark background
ggplot(mtcars, aes(wt, mpg, colour = factor(cyl))) +
  geom_point() +
  geom_table(data = df, aes(x = x, y = y, label = tb),
    table.theme = ttheme_gtdark) +
  theme_dark()

# Default colour of theme superceded by aesthetic constant
ggplot(mtcars, aes(wt, mpg, colour = factor(cyl))) +
  geom_point() +
  geom_table(data = df, aes(x = x, y = y, label = tb),
    table.theme = ttheme_gtdark, colour = "yellow") +
  theme_dark()

# A theme with light background
ggplot(mtcars, aes(wt, mpg, colour = factor(cyl))) +
  geom_point() +
  geom_table(data = df, aes(x = x, y = y, label = tb),
    table.theme = ttheme_gtlight)

# Default colour of theme superceded by aesthetic constant
ggplot(mtcars, aes(wt, mpg, colour = factor(cyl))) +
  geom_point() +
  geom_table(data = df, aes(x = x, y = y, label = tb),
    table.theme = ttheme_gtlight, colour = "darkred")

# Default colour of theme superceded by aesthetic constant
ggplot(mtcars, aes(wt, mpg, colour = factor(cyl))) +
  geom_point() +
  geom_table(data = df, aes(x = x, y = y, label = tb),
    table.theme = ttheme_gtsimple)
ttheme_set

Set default table theme

Description

Set R option to the theme to use as current default. This function is implemented differently but is used in the same way as ggplot2::theme_set() but affects the default table-theme instead of the plot theme.

Usage

ttheme_set(table.theme = NULL)

Arguments

- table.theme: NULL, list or function A gridExtra theme definition, or a constructor for a theme or NULL for default.

Value

A named list with the previous value of the option.

Note

The ttheme is set when a plot object is constructed, and consequently the option setting does not affect rendering of ready built plot objects.

Examples

library(dplyr)
library(tibble)

mtcars %>%
  group_by(cyl) %>%
  summarize(wt = mean(wt), mpg = mean(mpg)) %>%
  ungroup() %>%
  mutate(wt = sprintf("%.2f", wt),
         mpg = sprintf("%.1f", mpg)) -> tb

df <- tibble(x = 5.45, y = 34, tb = list(tb))
# Same as the default theme constructor
