Index 14
Description
Calculates the zeros and weights needed for Gauss-Hermite quadrature.

Usage
ghq(n.points = 1, modified = TRUE)

Arguments
- n.points: Number of points.
- modified: Multiply by exp(zeros**2)? Default is TRUE.

Details
Based on a Fortran 66 subroutine written by professor Jianming Jin.

Value
A list with components
- zeros: The zeros (abscissas).
- weights: The weights

Note
The code is modified to suit the purpose of glmmML, with the permission of professor Jin.

Author(s)
Jianming Jin, Univ. of Illinois, Urbana-Campaign

References
Gauss-Hermite

See Also
glmmML

Examples
ghq(15, FALSE)
Description

Fits grouped GLMs with fixed group effects. The significance of the grouping is tested by simulation, with a bootstrap approach.

Usage

```r
glmboot(formula, family = binomial, data, cluster, weights, subset, na.action, offset, start.coef = NULL, control = list(epsilon = 1e-08, maxit = 200, trace = FALSE), boot = 0)
```

Arguments

- `formula`: a symbolic description of the model to be fit. The details of model specification are given below.
- `family`: Currently, the only valid values are `binomial` and `poisson`. The binomial family allows for the `logit` and `cloglog` links.
- `data`: an optional data frame containing the variables in the model. By default the variables are taken from `environment(formula)`, typically the environment from which `glmML` is called.
- `cluster`: Factor indicating which items are correlated.
- `weights`: Case weights.
- `subset`: an optional vector specifying a subset of observations to be used in the fitting process.
- `na.action`: See `glm`.
- `offset`: this can be used to specify an a priori known component to be included in the linear predictor during fitting.
- `start.coef`: starting values for the parameters in the linear predictor. Defaults to zero.
- `control`: Controls the convergence criteria. See `glm.control` for details.
- `boot`: number of bootstrap replicates. If equal to zero, no test of significance of the grouping factor is performed.

Details

The simulation is performed by simulating new response vectors from the fitted probabilities without clustering, and comparing the maximized log likelihoods. The maximizations are performed by profiling out the grouping factor. It is a very fast procedure, compared to `glm`, when the grouping factor has many levels.
The return value is a list, an object of class ‘glmmboot’.

- **coefficients**: Estimated regression coefficients
- **loglik**: the max log likelihood
- **cluster.null.deviance**: Deviance without the clustering
- **frail**: The estimated cluster effects
- **bootLog**: The logLik values from the bootstrap samples
- **bootP**: Bootstrap p value
- **variance**: Variance covariance matrix
- **sd**: Standard error of regression parameters
- **boot_rep**: No. of bootstrap replicates
- **mixed**: Logical
- **deviance**: Deviance
- **df.residual**: Its degrees of freedom
- **aic**: AIC
- **boot**: Logical
- **call**: The function call

**Value**

**Note**

There is no overall intercept for this model; each cluster has its own intercept. See frail

- `link{glmmML}`, `optim`, `lmer` in Matrix, and `glmmPQL` in MASS.

**Examples**

```r
## not run:
id <- factor(rep(1:20, rep(5, 20)))
y <- rbinom(100, prob = rep(runif(20), rep(5, 20)), size = 1)
x <- rnorm(100)
dat <- data.frame(y = y, x = x, id = id)
res <- glmmboot(y ~ x, cluster = id, data = dat, boot = 5000)
## End(Not run)
##system.time(res.glm <- glm(y ~ x + id, family = binomial))
```
glmmbootFit

Generalized Linear Models with fixed effects grouping

Description

'glmmbootFit' is the workhorse in the function glmmboot. It is suitable to call instead of 'glmmboot', e.g. in simulations.

Usage

glmmbootfit(x, y, weights = rep(1, NROW(y)),
start.coef = NULL, cluster = rep(1, length(y)),
offset = rep(0, length(y)), family = binomial(),
control = list(epsilon = 1e-8, maxit = 200, trace = FALSE), boot = 0)

Arguments

X
  The design matrix (n * p).
Y
  The response vector of length n.
weights
  Case weights.
start.coef
  start values for the parameters in the linear predictor (except the intercept).
cluster
  Factor indicating which items are correlated.
offset
  this can be used to specify an a priori known component to be included in the linear predictor during fitting.
family
  Currently, the only valid values are binomial and poisson. The binomial family allows for the logit and cloglog links.
control
  A list. Controls the convergence criteria. See glm.control for details.
boot
  number of bootstrap replicates. If equal to zero, no test of significance of the grouping factor is performed. If non-zero, it should be large, at least, say, 2000.

Value

A list with components

coefficients
  Estimated regression coefficients (note: No intercept).
logLik
  The maximised log likelihood.
cluster.null.deviance
  deviance from a model without cluster.
frail
  The estimated cluster effects.
bootlog
  The maximised bootstrap log likelihood values. A vector of length boot.
bootP
  The bootstrap p value.
variance
  The variance-covariance matrix of the fixed effects (no intercept).
sd
  The standard errors of the coefficients.
boot_rep
  The number of bootstrap replicates.
Note

A profiling approach is used to estimate the cluster effects.

Examples

```r
## not run
x <- matrix(rnorm(1000), ncol = 1)
id <- rep(1:100, rep(10, 100))
y <- rbinom(1000, size = 1, prob = 0.4)
fit <- glmmbootFit(x, y, cluster = id, boot = 200)
summary(fit)
## end(not run)
## should show no effects and boot too small.
```

---

### glmmML

*Generalized Linear Models with random intercept*

**Description**

Fits GLMs with random intercept by Maximum Likelihood and numerical integration via Gauss-Hermite quadrature.

**Usage**

```r
glmmML(formula, family = binomial, data, cluster, weights,
cluster.weights, subset, na.action,
offset, prior = c("gaussian", "logistic", "cauchy"),
start.coef = NULL, start.sigma = NULL, fix.sigma = FALSE, x = FALSE,
control = list(epsilon = 1e-08, maxit = 200, trace = FALSE),
method = c("Laplace", "ghq"), n.points = 8, boot = 0)
```

**Arguments**

- **formula**: a symbolic description of the model to be fit. The details of model specification are given below.
- **family**: Currently, the only valid values are binomial and poisson. The binomial family allows for the logit and cloglog links.
- **data**: an optional data frame containing the variables in the model. By default the variables are taken from 'environment(formula)', typically the environment from which 'glmmML' is called.
cluster Factor indicating which items are correlated.
weights Case weights. Defaults to one.
cluster.weights Cluster weights. Defaults to one.
subset an optional vector specifying a subset of observations to be used in the fitting process.
na.action See glm.
start.coef starting values for the parameters in the linear predictor. Defaults to zero.
start.sigma starting value for the mixing standard deviation. Defaults to 0.5.
fix.sigma Should sigma be fixed at start.sigma?
x If TRUE, the design matrix is returned (as x).
offset this can be used to specify an a priori known component to be included in the linear predictor during fitting.
prior Which "prior" distribution (for the random effects)? Possible choices are "gaussian" (default), "logistic", and "cauchy".
control Controls the convergence criteria. See glm.control for details.
method There are two choices "Laplace" (default) and "ghq" (Gauss-Hermite).
n.points Number of points in the Gauss-Hermite quadrature. If n.points == 1, the Gauss-Hermite is the same as Laplace approximation. If method is set to "Laplace", this parameter is ignored.
boot Do you want a bootstrap estimate of cluster effect? The default is No (boot = 0). If you want to say yes, enter a positive integer here. It should be equal to the number of bootstrap samples you want to draw. A recommended absolute minimum value is boot = 2000.

Details
The integrals in the log likelihood function are evaluated by the Laplace approximation (default) or Gauss-Hermite quadrature. The latter is now fully adaptive; however, only approximate estimates of variances are available for the Gauss-Hermite (n.points > 1) method.

For the binomial families, the response can be a two-column matrix, see the help page for glm for details.

Value
The return value is a list, an object of class 'glmmML'. The components are:

boot No. of boot replicates
converged Logical
coefficients Estimated regression coefficients
coeff.sd Their standard errors
sigma The estimated random effects' standard deviation
sigma.sd Its standard error
The estimated variance-covariance matrix. The last column/row corresponds to the standard deviation of the random effects (sigma)

AIC

Bootstrap p value from testing the null hypothesis of no random effect (sigma = 0)

Deviance

Logical

Degrees of freedom

Deviance from a glm with no clustering. Subtracting deviance gives a test statistic for the null hypothesis of no clustering. Its asymptotic distribution is a symmetric mixture a constant at zero and a chi-squared distribution with one df. The printed p-value is based on this.

Its degrees of freedom

Estimated posterior modes of the random effects

The terms object

From hessian inversion. Should be 0. If not, no variances could be estimated. You could try fixing sigma at the estimated value and rerun.

Which prior was used?

The function call

The design matrix if asked for, otherwise not present

The optimization may not converge with the default value of start.sigma. In that case, try different start values for sigma. If still no convergence, consider the possibility to fix the value of sigma at several values and study the profile likelihood.

Göran Broström

glmmboot, glm, optim, lmer in Matrix and glmmPQL in MASS.
Examples

```r
id <- factor(rep(1:20, rep(5, 20)))
y <- rbinom(100, prob = rep(runif(20), rep(5, 20)), size = 1)
x <- rnorm(100)
dat <- data.frame(y = y, x = x, id = id)
glmmML(y ~ x, data = dat, cluster = id)
```

Description

This function is called by glmmML, but it can also be called directly by the user.

Usage

```r
glmmML.fit(X, Y, weights = rep(1, NROW(Y)), cluster.weights = rep(1, NROW(Y)),
start.coef = NULL, start.sigma = NULL,
fix.sigma = FALSE,
cluster = NULL, offset = rep(0, nobs), family = binomial(),
method = 1, n.points = 1,
control = list(epsilon = 1.e-8, maxit = 200, trace = FALSE),
intercept = TRUE, boot = 0, prior = 0)
```

Arguments

- **X**: Design matrix of covariates.
- **Y**: Response vector. Or two-column matrix.
- **weights**: Case weights. Defaults to one.
- **cluster.weights**: Cluster weights. Defaults to one.
- **start.coef**: Starting values for the coefficients.
- **start.sigma**: Starting value for the mixing standard deviation.
- **fix.sigma**: Should sigma be fixed at start.sigma?
- **cluster**: The clustering variable.
- **offset**: The offset in the model.
- **family**: Family of distributions. Defaults to binomial with logit link. Other possibilities are binomial with cloglog link and poisson with log link.
- **method**: Laplace (1) or Gauss-hermite (0)?
- **n.points**: Number of points in the Gauss-Hermite quadrature. Default is n.points = 1, which is equivalent to Laplace approximation.
- **control**: Control of the iterations. See `glm.control`.
- **intercept**: Logical. If TRUE, an intercept is fitted.
- **boot**: Integer. If > 0, bootstrapping with boot replicates.
- **prior**: Which prior distribution? 0 for "gaussian", 1 for "logistic", 2 for "cauchy".
print.glmmboot

Details
In the optimisation, "vmmin" (in C code) is used.

Value
A list. For details, see the code, and glmmML.

Author(s)
Göran Broström

References
Broström (2003)

See Also
glmmML, glmmPQL, and lmer.

Examples
x <- cbind(rep(1, 14), rnorm(14))
y <- rbinom(14, prob = 0.5, size = 1)
id <- rep(1:7, 2)
glmmML.fit(x, y, cluster = id)

print.glmmboot

Prints a 'glmmML' object.

Description
A glmmboot object is the output of glmmboot.

Usage
## S3 method for class 'glmmboot'
print(x, digits = max(3,getOption("digits") - 3), na.print = ",", ...)

Arguments
x The glmmboot object
digits Number of printed digits.
na.print How to print NAs
... Additional parameters, which are ignored.
Details

Nothing in particular.

Value

A short summary of the object is printed.

Note

This is the only summary method available for the moment.

glmmboot

print.glmmML

Prints a 'glmmML' object.

Description

A glmmML object is the output of glmmML.

Usage

```r
## S3 method for class 'glmmML'
print(x, digits = max(3, getOption("digits") - 3), na.print = "", ...)
```

Arguments

- `x` The glmmML object
- `digits` Number of printed digits.
- `na.print` How to print NAs
- `...` Additional parameters, which are ignored.

Details

Nothing in particular.

Value

A short summary of the object is printed.
Summary of a glmmboot object

Description

It simply calls print.glmmboot

Usage

```r
## S3 method for class 'glmmboot'
summary(object, ...)
```

Arguments

- `object` A glmmboot object
- `...` Additional arguments

Details

A summary method will be written soon.

Value

Nothing is returned.
