Package ‘glmnet’

May 14, 2020

Type Package
Title Lasso and Elastic-Net Regularized Generalized Linear Models
Version 4.0
Date 2020-5-12
Depends R (>= 3.6.0), Matrix (>= 1.0-6)
Imports methods, utils, foreach, shape
Suggests survival, knitr, lars, testthat
Description Extremely efficient procedures for fitting the entire lasso or elastic-net regularization path for linear regression, logistic and multinomial regression models, Poisson regression, Cox model, multiple-response Gaussian, and the grouped multinomial regression. There are two new and important additions. The family argument can be a GLM family object, which opens the door to any programmed family. This comes with a modest computational cost, so when the built-in families suffice, they should be used instead. The other novelty is the relax option, which refits each of the active sets in the path unpenalized. The algorithm uses cyclical coordinate descent in a path-wise fashion, as described in the papers listed in the URL below.

Index  54
Elastic net model paths for some generalized linear models

Description

This package fits lasso and elastic-net model paths for regression, logistic and multinomial regression using coordinate descent. The algorithm is extremely fast, and exploits sparsity in the input x matrix where it exists. A variety of predictions can be made from the fitted models.

Details

Package: glmnet
Type: Package
Version: 1.0
Date: 2008-05-14
License: What license is it under?

Very simple to use. Accepts x, y data for regression models, and produces the regularization path over a grid of values for the tuning parameter lambda. Only 5 functions: glmnet
predict.glmnet
plot.glmnet
print.glmnet
coef.glmnet

Author(s)

Jerome Friedman, Trevor Hastie and Rob Tibshirani
Maintainer: Trevor Hastie hastie@stanford.edu

Glmnet webpage with four vignettes https://glmnet.stanford.edu

Examples
```
x = matrix(rnorm(100 * 20), 100, 20)
y = rnorm(100)
g2 = sample(1:2, 100, replace = TRUE)
g4 = sample(1:4, 100, replace = TRUE)
fit1 = glmnet(x, y)
predict(fit1, newx = x[1:5, ], s = c(0.01, 0.005))
predict(fit1, type = "coef")
plot(fit1, xvar = "lambda")
fit2 = glmnet(x, g2, family = "binomial")
predict(fit2, type = "response", newx = x[2:5, ])
predict(fit2, type = "nonzero")
fit3 = glmnet(x, g4, family = "multinomial")
predict(fit3, newx = x[1:3, ], type = "response", s = 0.01)
```

---

**assess.glmnet**

**assess performance of a 'glmnet' object using test data.**

**Description**

Given a test set, produce summary performance measures for the glmnet model(s).

**Usage**

```r
assess.glmnet(object, newx = NULL, newy, weights = NULL, family = c("gaussian", "binomial", "poisson", "multinomial", "cox", "mgaussian"), ...)
```

```r
confusion.glmnet(object, newx = NULL, newy, family = c("binomial", "multinomial"), ...)
```

```r
roc.glmnet(object, newx = NULL, newy, ...)
```

**Arguments**

- **object**: Fitted "glmnet" or "cv.glmnet", "relaxed" or "cv.relaxed" object, or a matrix of predictions (for roc.glmnet or assess.glmnet). For roc.glmnet the model must be a 'binomial', and for confusion.glmnet must be either 'binomial' or 'multinomial'.
- **newx**: Required argument for all functions; the new 'x' values.
- **newy**: If predictions are to made, these are the 'y' values. Required for confusion.glmnet.
- **weights**: For observation weights for the test observations.
- **family**: The family of the model, in case predictions are passed in as 'object'.
- **...**: additional arguments to predict.glmnet when "object" is a "glmnet" fit, and predictions must be made to produce the statistics.
assess.glmnet

Details

assess.glmnet produces all the different performance measures provided by cv.glmnet for each of the families. A single vector, or a matrix of predictions can be provided, or fitted model objects or CV objects. In the case when the predictions are still to be made, the ... arguments allow, for example, 'offsets' and other prediction parameters such as values for 'gamma' for 'relaxed' fits.

roc.glmnet produces for a single vector a two column matrix with columns TPR and FPR (true positive rate and false positive rate). This object can be plotted to produce an ROC curve. If more than one predictions are called for, then a list of such matrices is produced. confusion.glmnet produces a confusion matrix tabulating the classification results. Again, a single table or a list, with a print method.

Value

assess.glmnet produces a list of vectors of measures. roc.glmnet a list of 'roc' two-column matrices, and confusion.glmnet a list of tables. If a single prediction is provided, or predictions are made from a CV object, the latter two drop the list status and produce a single matrix or table.

data(QuickStartExample)
set.seed(11)
train = sample(seq(length(y)),70,replace=FALSE)
fit1 = glmnet(x[train,], y[train])
assess.glmnet(fit1, newx = x[-train,], newy = y[-train])
preds = predict(fit1, newx = x[-train,], s = c(1, 0.25))
assess.glmnet(preds, newy = y[-train], family = “gaussian”)
fit1c = cv.glmnet(x, y, keep = TRUE)
fit1a = assess.glmnet(fit1c$fit.preval, newy=y,family=“gaussian”)
plot(fit1c$lambda, log=“x”,fit1a$mae,xlab=“Log Lambda”,ylab=“Mean Absolute Error”)
abline(v=fit1c$lambda.min, lty=2, col=“red”)
data(BinomialExample)
fit2 = glmnet(x[train,], y[train], family = “binomial”)
assess.glmnet(fit2,newx = x[-train,], newy=y[-train], s=0.1)
plot(roc.glmnet(fit2, newx = x[-train,], newy=y[-train])[[10]])
fit2c = cv.glmnet(x, y, family = “binomial”, keep=TRUE)
idmin = match(fit2c$lambda.min, fit2c$lambda)
plot(roc.glmnet(fit2c$fit.preval, newy = y)[[idmin]])
data(MultinomialExample)
set.seed(103)
train = sample(seq(length(y)),100,replace=FALSE)
fit3 = glmnet(x[train,], y[train], family = “ multinomial”)
bigGlm

Description

Fit a generalized linear model as in glmnet but unpenalized. This allows all the features of glmnet such as sparse x, bounds on coefficients, offsets, and so on.

Usage

bigGlm(x, ..., path = FALSE)

Arguments

- **x**: input matrix
- **...**: Most other arguments to glmnet that make sense
- **path**: Since glmnet does not do stepsize optimization, the Newton algorithm can get stuck and not converge, especially with unpenalized fits. With path=TRUE, the fit computed with pathwise lasso regularization. The current implementation does this twice: the first time to get the lambda sequence, and the second time with a zero attached to the end). Default is path=FALSE.

---

beta_CVX

**Simulated data for the glmnet vignette**

Description

Simple simulated data, used to demonstrate the features of glmnet

Format

Data objects used to demonstrate features in the glmnet vignette

Details

These datasets are artificial, and are used to test out some of the features of glmnet.

Examples

```r
data(QuickStartExample)
glmnet(x, y)
```

---

confusion.glmnet(fit3, newx = x[-train, ], newy = y[-train], s = 0.01)

fit3c = cv.glmnet(x, y, family = "multinomial", type.measure="class", keep=TRUE)

idmin = match(fit3c$lambda.min, fit3c$lambda)

confusion.glmnet(fit3c$fit.preval, newy = y, family="multinomial")[[idmin]]
Details

This is essentially the same as fitting a "glmnet" model with a single value lambda=0, but it avoids some edge cases. CAVEAT: If the user tries a problem with N smaller than or close to p for some models, it is likely to fail (and maybe not gracefully!) If so, use the path=TRUE argument.

Value

It returns an object of class "bigGlm" that inherits from class "glmnet". That means it can be predicted from, coefficients extracted via coef. It has its own print method.

print, predict, and coef methods.

Examples

```
# Gaussian
x = matrix(rnorm(100 * 20), 100, 20)
y = rnorm(100)
fit1 = bigGlm(x, y)
print(fit1)

fit2=bigGlm(x,y>0,family="binomial")
print(fit2)
fit2p=bigGlm(x,y>0,family="binomial",path=TRUE)
print(fit2p)
```

Cindex

compute C index for a Cox model

Description

Computes Harrel’s C index for predictions from a "coxnet" object.

Usage

Cindex(pred, y, weights = rep(1, nrow(y)))
Arguments

- **pred**: Predictions from a "coxnet" object
- **y**: a survival response object - a matrix with two columns "time" and "status"; see documentation for "glmnet"
- **weights**: optional observation weights

Details

Computes the concordance index, taking into account censoring.

cv.glmnet

Examples

```r
set.seed(10101)
N = 1000
p = 30
nzc = p/3
x = matrix(rnorm(N * p), N, p)
beta = rnorm(nzc)
fx = x[, seq(nzc)] %*% beta/3
hx = exp(fx)
ty = rexp(N, hx)
tcens = rbinom(n = N, prob = 0.3, size = 1) # censoring indicator
y = cbind(time = ty, status = 1 - tcens) # y=Surv(ty,1-tcens) with library(survival)
fit = glmnet(x, y, family = "cox")
pred = predict(fit, newx = x)
Cindex(pred, y)
cv.glmnet(x, y, family = "cox", type.measure = "c")
```
Extract coefficients from a glmnet object

Description

Similar to other predict methods, this functions predicts fitted values, logits, coefficients and more from a fitted "glmnet" object.

Usage

## S3 method for class 'glmnet'
coef(object, s = NULL, exact = FALSE, ...)

## S3 method for class 'glmnet'
predict(object, newx, s = NULL, type = c("link", "response", "coefficients", "nonzero", "class"), exact = FALSE, newoffset, ...)

## S3 method for class 'relaxed'
predict(object, newx, s = NULL, gamma = 1, type = c("link", "response", "coefficients", "nonzero", "class"), exact = FALSE, newoffset, ...)

Arguments

object
Fitted "glmnet" model object or a "relaxed" model (which inherits from class "glmnet").

s
Value(s) of the penalty parameter lambda at which predictions are required. Default is the entire sequence used to create the model.

exact
This argument is relevant only when predictions are made at values of s (lambda) different from those used in the fitting of the original model. Not available for "relaxed" objects. If exact=FALSE (default), then the predict function uses linear interpolation to make predictions for values of s (lambda) that do not coincide with those used in the fitting algorithm. While this is often a good approximation, it can sometimes be a bit coarse. With exact=TRUE, these different values of s are merged (and sorted) with object$lambda, and the model is refit before predictions are made. In this case, it is required to supply the original data x= and y= as additional named arguments to predict() or coef(). The workhorse predict.glmnet() needs to update the model, and so needs the data used to create it. The same is true of weights, offset, penalty.factor, lower.limits, upper.limits if these were used in the original call. Failure to do so will result in an error.

... This is the mechanism for passing arguments like x= when exact=TRUE; see exact argument.
newx Matrix of new values for \( x \) at which predictions are to be made. Must be a matrix; can be sparse as in Matrix package. This argument is not used for type=c("coefficients","nonzero")

type Type of prediction required. Type "link" gives the linear predictors for "binomial", "multinomial", "poisson" or "cox" models; for "gaussian" models it gives the fitted values. Type "response" gives the fitted probabilities for "binomial" or "multinomial", fitted mean for "poisson" and the fitted relative-risk for "cox"; for "gaussian" type "response" is equivalent to type "link". Type "coefficients" computes the coefficients at the requested values for \( s \). Note that for "binomial" models, results are returned only for the class corresponding to the second level of the factor response. Type "class" applies only to "binomial" or "multinomial" models, and produces the class label corresponding to the maximum probability. Type "nonzero" returns a list of the indices of the nonzero coefficients for each value of \( s \).

newoffset If an offset is used in the fit, then one must be supplied for making predictions (except for type="coefficients" or type="nonzero")

gamma Single value of gamma at which predictions are required, for "relaxed" objects.

Details

The shape of the objects returned are different for "multinomial" objects. This function actually calls NextMethod(), and the appropriate predict method is invoked for each of the three model types. coef(...) is equivalent to predict(type="coefficients",...)

Value

The object returned depends on type.

predict(fit3, newx = x[1:3,], type = "response", s = 0.01)
```

**coxgrad**

*compute gradient for cox model*

**Description**

Compute the gradient of the partial likelihood at a particular fit

**Usage**

```
coxgrad(f, time, d, w, eps = 1e-05)
```

**Arguments**

- `f` fit vector
- `time` time vector (can have ties)
- `d` death/censoring indicator 1/0
- `w` observation weights (default equal)
- `eps` (default 0.00001) Breaks ties between death and censoring by making death times eps earlier

**Details**

Compute a gradient vector at the fitted vector for the log partial likelihood. This is like a residual vector, and useful for manual screening of predictors for glmnet in applications where p is very large (as in GWAS). Uses the Breslow approach to ties

**Value**

a single gradient vector the same length as `f`

coxnet.deviance

Description

Given a fit or coefficients, compute the deciance (-2 log partial likelihood) for right-censored survival data

Usage

coxnet.deviance(pred = NULL, y, x = 0, offset = NULL, weights = NULL, beta = NULL)

Arguments

pred matrix of predictions
y a survival response matrix, as produced by Surv
x optional x matrix, if pred is NULL
offset optional offset
weights optional observation weights
beta optional coefficient vector/matrix, supplied if pred=NULL

Details

coxnet.deviance computes the deviance for a single prediction, or a matrix of predictions

Value

a single or vector of deviances

coxgrad
cv.glmnet

Cross-validation for glmnet

Description

Does k-fold cross-validation for glmnet, produces a plot, and returns a value for lambda (and gamma if relax=TRUE)

Usage

cv.glmnet(x, y, weights = NULL, offset = NULL, lambda = NULL, type.measure = c("default", "mse", "deviance", "class", "auc", "mae", "C"), nfolds = 10, foldid = NULL, alignment = c("lambda", "fraction"), grouped = TRUE, keep = FALSE, parallel = FALSE, gamma = c(0, 0.25, 0.5, 0.75, 1), relax = FALSE, trace.it = 0, ...)

Arguments

x x matrix as in glmnet.
y response y as in glmnet.
weights Observation weights; defaults to 1 per observation
offset Offset vector (matrix) as in glmnet
lambda Optional user-supplied lambda sequence; default is NULL, and glmnet chooses its own sequence
type.measure loss to use for cross-validation. Currently five options, not all available for all models. The default is type.measure="deviance", which uses squared-error for gaussian models (a.k.a type.measure="mse" there), deviance for logistic and poisson regression, and partial-likelihood for the Cox model. type.measure="class" applies to binomial and multinomial logistic regression only, and gives misclassification error. type.measure="auc" is for two-class logistic regression only, and gives area under the ROC curve. type.measure="mse" or type.measure="mae" (mean absolute error) can be used by all models except the "cox"; they measure the deviation from the fitted mean to the response. type.measure="C" is Harrel's concordance measure, only available for cox models.
nfolds number of folds - default is 10. Although nfolds can be as large as the sample size (leave-one-out CV), it is not recommended for large datasets. Smallest value allowable is nfolds=3
foldid an optional vector of values between 1 and nfold identifying what fold each observation is in. If supplied, nfold can be missing.
alignment This is an experimental argument, designed to fix the problems users were having with CV, with possible values "lambda" (the default) else "fraction". With "lambda" the lambda values from the master fit (on all the data) are used to line up the predictions from each of the folds. In some cases this can give strange values, since the effective lambda values in each fold could be quite different.
With "fraction" we line up the predictions in each fold according to the fraction of progress along the regularization. If in the call a lambda argument is also provided, alignment="fraction" is ignored (with a warning).

**grouped**  This is an experimental argument, with default TRUE, and can be ignored by most users. For all models except the "cox", this refers to computing nfolds separate statistics, and then using their mean and estimated standard error to describe the CV curve. If grouped=FALSE, an error matrix is built up at the observation level from the predictions from the nfold fits, and then summarized (does not apply to type.measure="auc"). For the "cox" family, grouped=TRUE obtains the CV partial likelihood for the Kth fold by subtraction; by subtracting the log partial likelihood evaluated on the full dataset from that evaluated on the on the (K-1)/K dataset. This makes more efficient use of risk sets. With grouped=FALSE the log partial likelihood is computed only on the Kth fold

**keep**  If keep=TRUE, a prevalidated array is returned containing fitted values for each observation and each value of lambda. This means these fits are computed with this observation and the rest of its fold omitted. The foldid vector is also returned. Default is keep=FALSE. If relax=TRUE, then a list of such arrays is returned, one for each value of 'gamma'. Note: if the value 'gamma=1' is omitted, this case is included in the list since it corresponds to the original 'glmnet' fit.

**parallel**  If TRUE, use parallel for each to fit each fold. Must register parallel beforehand, such as doMC or others. See the example below.

**gamma**  The values of the parameter for mixing the relaxed fit with the regularized fit, between 0 and 1; default is gamma = c(0, 0.25, 0.5, 0.75, 1)

**relax**  If TRUE, then CV is done with respect to the mixing parameter gamma as well as lambda. Default is relax=FALSE

**trace.it**  If trace.it=1, then progress bars are displayed; useful for big models that take a long time to fit. Limited tracing if parallel=TRUE

...  Other arguments that can be passed to glmnet

**Details**

The function runs glmnet nfolds+1 times; the first to get the lambda sequence, and then the remainder to compute the fit with each of the folds omitted. The error is accumulated, and the average error and standard deviation over the folds is computed. Note that cv.glmnet does NOT search for values for alpha. A specific value should be supplied, else alpha=1 is assumed by default. If users would like to cross-validate alpha as well, they should call cv.glmnet with a pre-computed vector foldid, and then use this same fold vector in separate calls to cv.glmnet with different values of alpha. Note also that the results of cv.glmnet are random, since the folds are selected at random. Users can reduce this randomness by running cv.glmnet many times, and averaging the error curves.

If relax=TRUE then the values of gamma are used to mix the fits. If \( \eta \) is the fit for lasso/elastic net, and \( \eta_R \) is the relaxed fit (with unpenalized coefficients), then a relaxed fit mixed by \( \gamma \) is

\[
\eta(\gamma) = (1 - \gamma)\eta_R + \gamma\eta
\]

. There is practically no extra cost for having a lot of values for gamma. However, 5 seems sufficient for most purposes. CV then selects both gamma and lambda.
an object of class 'cv.glmnet' is returned, which is a list with the ingredients of the cross-validation fit. If the object was created with relax=TRUE then this class has a prefix class of 'cv.relaxed'.

lambda the values of lambda used in the fits.
cvm The mean cross-validated error - a vector of length length(lambda).
cvsd estimate of standard error of cvm.
cvup upper curve = cvm+cvsd.
cvlo lower curve = cvm-cvsd.
nzero number of non-zero coefficients at each lambda.
name a text string indicating type of measure (for plotting purposes).
glmnet.fit a fitted glmnet object for the full data.
lambda.min value of lambda that gives minimum cvm.
lambda.1se largest value of lambda such that error is within 1 standard error of the minimum.
fit.preval if keep=TRUE, this is the array of prevalidated fits. Some entries can be NA, if that and subsequent values of lambda are not reached for that fold
foldid if keep=TRUE, the fold assignments used
relaxed if relax=TRUE, this additional item has the CV info for each of the mixed fits. In particular it also selects lambda,gamma pairs corresponding to the 1SE rule, as well as the minimum error.

```
deviance.glmnet

Extract the deviance from a glmnet object

Description

Compute the deviance sequence from the glmnet object

Usage

## S3 method for class 'glmnet'
deviance(object, ...)

Arguments

object                fitted glmnet object
...                   additional print arguments
Details

A glmnet object has components dev.ratio and nulldev. The former is the fraction of (null) deviance explained. The deviance calculations incorporate weights if present in the model. The deviance is defined to be 2*(loglike_sat - loglike), where loglike_sat is the log-likelihood for the saturated model (a model with a free parameter per observation). Null deviance is defined to be 2*(loglike_sat -loglike(Null)); The NULL model refers to the intercept model, except for the Cox, where it is the 0 model. Hence dev.ratio=1-deviance/nulldev, and this deviance method returns (1-dev.ratio)*nulldev.

Value

(1-dev.ratio)*nulldev

dev_function            Elastic net deviance value

Description

Returns the elastic net deviance value.

Usage

dev_function(y, mu, weights, family)
elnet.fit

Arguments

- **y**  
  Quantitative response variable.

- **mu**  
  Model’s predictions for y.

- **weights**  
  Observation weights.

- **family**  
  A description of the error distribution and link function to be used in the model. This is the result of a call to a family function.

elnet.fit  
_Solve weighted least squares (WLS) problem for a single lambda value_

Description

Solves the weighted least squares (WLS) problem for a single lambda value. Internal function that users should not call directly.

Usage

elnet.fit(x, y, weights, lambda, alpha = 1, intercept = TRUE, thresh = 1e-07, maxit = 1e+05, penalty.factor = rep(1, nvars), exclude = c(), lower.limits = -Inf, upper.limits = Inf, warm = NULL, from.glmnet.fit = FALSE, save.fit = FALSE)

Arguments

- **x**  
  Input matrix, of dimension nobs x nvars; each row is an observation vector.

- **y**  
  Quantitative response variable.

- **weights**  
  Observation weights. elnet.fit does NOT standardize these weights.

- **lambda**  
  A single value for the lambda hyperparameter.

- **alpha**  
  The elasticnet mixing parameter, with 0 ≤ α ≤ 1. The penalty is defined as

  \[(1 - α)/2||β||_2^2 + α||β||_1.\]

  alpha=1 is the lasso penalty, and alpha=0 the ridge penalty.

- **intercept**  
  Should intercept be fitted (default=TRUE) or set to zero (FALSE)?

- **thresh**  
  Convergence threshold for coordinate descent. Each inner coordinate-descent loop continues until the maximum change in the objective after any coefficient update is less than thresh times the null deviance. Default value is 1e-7.

- **maxit**  
  Maximum number of passes over the data; default is 10^5. (If a warm start object is provided, the number of passes the warm start object performed is included.)

- **penalty.factor**  
  Separate penalty factors can be applied to each coefficient. This is a number that multiplies lambda to allow differential shrinkage. Can be 0 for some variables, which implies no shrinkage, and that variable is always included in the model. Default is 1 for all variables (and implicitly infinity for variables listed in exclude). Note: the penalty factors are internally rescaled to sum to nvars.
exclude  Indices of variables to be excluded from the model. Default is none. Equivalent to an infinite penalty factor.

lower.limits  Vector of lower limits for each coefficient; default -Inf. Each of these must be non-positive. Can be presented as a single value (which will then be replicated), else a vector of length nvars.

upper.limits  Vector of upper limits for each coefficient; default Inf. See lower.limits.

warm  A glmnetfit object which can be used as a warm start. Default is NULL, indicating no warm start. For internal use only.

from.glmnet.fit  Was elnet.fit() called from glmnet.fit()? Default is FALSE. This has implications for computation of the penalty factors.

save.fit  Return the warm start object? Default is FALSE.

Details

WARNING: Users should not call elnet.fit directly. Higher-level functions in this package call elnet.fit as a subroutine. If a warm start object is provided, some of the other arguments in the function may be overridden.

elnet.fit is essentially a wrapper around a FORTRAN subroutine which minimizes

$$\frac{1}{2} \sum w_i (y_i - X_i^T \beta)^2 + \sum \lambda \gamma_j [(1 - \alpha) \beta^2 + \alpha |\beta|],$$

going over \( \beta \), where \( \gamma_j \) is the relative penalty factor on the \( j \)th variable. If intercept = TRUE, then the term in the first sum is \( w_i (y_i - \beta_0 - X_i^T \beta)^2 \), and we are minimizing over both \( \beta_0 \) and \( \beta \).

None of the inputs are standardized except for penalty.factor, which is standardized so that they sum up to nvars.

Value

An object with class "glmnetfit" and "glmnet". The list returned has the same keys as that of a glmnet object, except that it might have an additional warm_fit key.

get_start

jerr     Error flag, for warnings and errors (largely for internal debugging).
offset   Always FALSE, since offsets do not appear in the WLS problem. Included for
          compatibility with glmnet output.
call     The call that produced this object.
nobs     Number of observations.
warm_fit If save.fit=TRUE, output of FORTRAN routine, used for warm starts. For
          internal use only.

get_start          Get null deviance, starting mu and lambda max

Description

Return the null deviance, starting mu and lambda max values for initialization. For internal use
only.

Usage

get_start(x, y, weights, family, intercept, is.offset, offset, exclude, vp,
alpha, xm = NULL, xs = NULL)

Arguments

x        Input matrix, of dimension nobs x nvars; each row is an observation vector. If
          it is a sparse matrix, it is assumed to be unstandardized and the user must also
          provide the xm and xs arguments. If it is not a sparse matrix, it is assumed to be
          standardized.
y        Quantitative response variable.
weights  Observation weights.
family   A description of the error distribution and link function to be used in the model.
          This is the result of a call to a family function. (See family for details on family
          functions.)
intercept Does the model we are fitting have an intercept term or not?
is.offset Is the model being fit with an offset or not?
offset   Offset for the model. If is.offset=FALSE, this should be a zero vector of the
          same length as y.
exclude  Indices of variables to be excluded from the model.
vp       Separate penalty factors can be applied to each coefficient.
alpha    The elasticnet mixing parameter, with 0 ≤ α ≤ 1.
xm       Vector of length nvars: xm(j) is the centering factor for variable j. User should
          only provide them if x is a sparse matrix.
xs       Vector of length nvars: xs(j) is the scaling factor for variable j. User should
          only provide them if x is a sparse matrix.
glmnet

Details

This function is called by glmnet.path for null deviance, starting mu and lambda max values. It is also called by glmnet.fit and spglmnet.fit when used without warmstart, but they only use the null deviance and starting mu values.

When x is not sparse, the xm and xs arguments are ignored (x is expected to already by centered and scaled). When x is sparse, these arguments represent the centering and scaling factors for x.

Note that whether x is centered & scaled or not, the values of mu and nulldev don’t change. However, the value of lambda.max does change, and we need xm and xs to get the correct value.

Description

Fit a generalized linear model via penalized maximum likelihood. The regularization path is computed for the lasso or elasticnet penalty at a grid of values for the regularization parameter lambda. Can deal with all shapes of data, including very large sparse data matrices. Fits linear, logistic and multinomial, poisson, and Cox regression models.

Usage

```r
glmnet(x, y, family = c("gaussian", "binomial", "poisson", "multinomial", "cox", "mgaussian"), weights = NULL, offset = NULL, alpha = 1, nlambda = 100, lambda.min.ratio = ifelse(nobs < nvars, 0.01, 1e-04), lambda = NULL, standardize = TRUE, intercept = TRUE, thresh = 1e-07, dfmax = nvars + 1, pmax = min(dfmax * 2 + 20, nvars), exclude = NULL, penalty.factor = rep(1, nvars), lower.limits = -Inf, upper.limits = Inf, maxit = 1e+05, type.gaussian = ifelse(nvars < 500, "covariance", "naive"), type.logistic = c("Newton", "modified.Newton"), standardize.response = FALSE, type.multinomial = c("ungrouped", "grouped"), relax = FALSE, trace.it = 0, ...)
```

```r
relax.glmnet(fit, x, ..., maxp = n - 3, path = FALSE, check.args = TRUE)
```

Arguments

- **x**: input matrix, of dimension nobx nvars; each row is an observation vector. Can be in sparse matrix format (inherit from class "sparseMatrix" as in package Matrix; not yet available for family="cox")
- **y**: response variable. Quantitative for family="gaussian", or family="poisson" (non-negative counts). For family="binomial" should be either a factor with two levels, or a two-column matrix of counts or proportions (the second column is treated as the target class; for a factor, the last level in alphabetical order is the target class). For family="multinomial", can be a nc>=2 level factor, or
a matrix with nc columns of counts or proportions. For either "binomial" or
"multinomial", if y is presented as a vector, it will be coerced into a factor. For
family="cox", y should be a two-column matrix with columns named 'time'
and 'status'. The latter is a binary variable, with '1' indicating death, and '0' in-
dicating right censored. The function Surv() in package survival produces such
a matrix. For family="mgaussian", y is a matrix of quantitative responses.

family   Response type (see above). Either a character string representing one of the
built-in families, or else a glm() family object.

weights  observation weights. Can be total counts if responses are proportion matrices.
Default is 1 for each observation

offset   A vector of length nobss that is included in the linear predictor (a nobss x nc
matrix for the "multinomial" family). Useful for the "poisson" family (e.g.
log of exposure time), or for refining a model by starting at a current fit. Default
is NULL. If supplied, then values must also be supplied to the predict function.

alpha    The elasticnet mixing parameter, with 0 ≤ α ≤ 1. The penalty is defined as

        (1 − α)/2||β||^2_2 + α||β||_1.

alpha=1 is the lasso penalty, and alpha=0 the ridge penalty.

nlambda  The number of lambda values - default is 100.

lambda.min.ratio Smallest value for Lambda, as a fraction of lambda.max, the (data derived) entry
value (i.e. the smallest value for which all coefficients are zero). The default
depends on the sample size nobss relative to the number of variables nvars. If
nobss > nvars, the default is 0.0001, close to zero. If nobss < nvars, the default
is 0.01. A very small value of lambda.min.ratio will lead to a saturated fit in
the nobss < nvars case. This is undefined for "binomial" and "multinomial"
models, and glmnet will exit gracefully when the percentage deviance explained
is almost 1.

lambda   A user supplied lambda sequence. Typical usage is to have the program compute
its own lambda sequence based on nlambda and lambda.min.ratio. Supplying
a value of lambda overrides this. WARNING: use with care. Avoid supplying
a single value for lambda (for predictions after CV use predict() instead).
Supply instead a decreasing sequence of lambda values. glmnet relies on its
warms starts for speed, and its often faster to fit a whole path than compute a
single fit.

standardize Logical flag for x variable standardization, prior to fitting the model sequence.
The coefficients are always returned on the original scale. Default is standardize=TRUE.
If variables are in the same units already, you might not wish to standardize. See
details below for y standardization with family="gaussian".

intercept Should intercept(s) be fitted (default=TRUE) or set to zero (FALSE)

thresh   Convergence threshold for coordinate descent. Each inner coordinate-descent
loop continues until the maximum change in the objective after any coefficient
update is less than thresh times the null deviance. Defaults value is 1E-7.

dfmax    Limit the maximum number of variables in the model. Useful for very large
nvars, if a partial path is desired.
pmmax
exclude
penalty.factor
lower.limits
upper.limits
maxit
type.gaussian
type.logistic
standardize.response
type.multinomial
relax
trace.it
...
fit
maxp
path

Limit the maximum number of variables ever to be nonzero
Indices of variables to be excluded from the model. Default is none. Equivalent to an infinite penalty factor (next item).
Separate penalty factors can be applied to each coefficient. This is a number that multiplies lambda to allow differential shrinkage. Can be 0 for some variables, which implies no shrinkage, and that variable is always included in the model. Default is 1 for all variables (and implicitly infinity for variables listed in exclude). Note: the penalty factors are internally rescaled to sum to nvars, and the lambda sequence will reflect this change.
Vector of lower limits for each coefficient; default -Inf. Each of these must be non-positive. Can be presented as a single value (which will then be replicated), else a vector of length nvars
Vector of upper limits for each coefficient; default Inf. See lower.limits
Maximum number of passes over the data for all lambda values; default is 10^5.
Two algorithm types are supported for (only) family="gaussian". The default when nvar<500 is type.gaussian="covariance", and saves all inner-products ever computed. This can be much faster than type.gaussian="naive", which loops through nobs every time an inner-product is computed. The latter can be far more efficient for nvar >> nobs situations, or when nvar > 500.
If "Newton" then the exact hessian is used (default), while "modified.Newton" uses an upper-bound on the hessian, and can be faster.
This is for the family="mgaussian" family, and allows the user to standardize the response variables
If "grouped" then a grouped lasso penalty is used on the multinomial coefficients for a variable. This ensures they are all in our out together. The default is "ungrouped"
If TRUE then for each active set in the path of solutions, the model is refit without any regularization. See details for more information. This argument is new, and users may experience convergence issues with small datasets, especially with non-gaussian families. Limiting the value of 'maxp' can alleviate these issues in some cases.
If trace.it=1, then a progress bar is displayed; useful for big models that take a long time to fit.
Additional argument used in relax.glmnet. These include some of the original arguments to `glmnet`, and each must be named if used.
For relax.glmnet a fitted `glmnet` object
a limit on how many relaxed coefficients are allowed. Default is 'n-3', where 'n' is the sample size. This may not be sufficient for non-gaussian families, in which case users should supply a smaller value. This argument can be supplied directly to `glmnet`.
Since glmnet does not do stepsize optimization, the Newton algorithm can get stuck and not converge, especially with relaxed fits. With path=TRUE, each
relaxed fit on a particular set of variables is computed pathwise using the original sequence of lambda values (with a zero attached to the end). Not needed for Gaussian models, and should not be used unless needed, since will lead to longer compute times. Default is `path=FALSE`. appropriate subset of variables

**Details**

The sequence of models implied by `lambda` is fit by coordinate descent. For `family="gaussian"` this is the lasso sequence if `alpha=1`, else it is the elasticnet sequence.

From version 4.0 onwards, glmnet supports both the original built-in families, as well as any family object as used by `stats:glm()`. The built in families are specified via a character string. For all families, the object produced is a lasso or elasticnet regularization path for fitting the generalized linear regression paths, by maximizing the appropriate penalized log-likelihood (partial likelihood for the "cox" model). Sometimes the sequence is truncated before `nlambda` values of `lambda` have been used, because of instabilities in the inverse link functions near a saturated fit.

glmnet(...,family="binomial") fits a traditional logistic regression model for the log-odds.
glmnet(...,family="multinomial") fits a symmetric multinomial model, where each class is represented by a linear model (on the log-scale). The penalties take care of redundancies. A two-class "multinomial" model will produce the same fit as the corresponding "binomial" model, except the pair of coefficient matrices will be equal in magnitude and opposite in sign, and half the "binomial" values. Note that the objective function for "gaussian" is

\[ \frac{1}{2} \text{RSS}/\text{nobs} + \lambda \ast \text{penalty}, \]

and for the other models it is

\[ -\frac{\text{loglik}}{\text{nobs}} + \lambda \ast \text{penalty}. \]

Note also that for "gaussian", glmnet standardizes y to have unit variance (using 1/n rather than 1/(n-1) formula) before computing its lambda sequence (and then unstandardizes the resulting coefficients); if you wish to reproduce/compare results with other software, best to supply a standardized y. The coefficients for any predictor variables with zero variance are set to zero for all values of lambda. Two useful additional families are the `family="mgaussian"` family and the `type.multinomial="grouped"` option for multinomial fitting. The former allows a multi-response gaussian model to be fit, using a "group -lasso" penalty on the coefficients for each variable. Tying the responses together like this is called "multi-task" learning in some domains. The grouped multinomial allows the same penalty for the `family="multinomial"` model, which is also multi-responded. For both of these the penalty on the coefficient vector for variable j is

\[ (1 - \alpha)/2 ||\beta_j||_2^2 + \alpha ||\beta_j||_2. \]

When `alpha=1` this is a group-lasso penalty, and otherwise it mixes with quadratic just like elasticnet. A small detail in the Cox model: if death times are tied with censored times, we assume the censored times occurred just before the death times in computing the Breslow approximation; if users prefer the usual convention of after, they can add a small number to all censoring times to achieve this effect.

Version 4.0 and later allows for the family argument to be a S3 class "family" object (a list of functions and expressions). This opens the door to a wide variety of additional models. For example `family=binomial(link=cloglog)` or `family=negative.binomial(theta=1.5)` (from the MASS library). Note that the code runs faster for the built-in families.
If `relax=TRUE` a duplicate sequence of models is produced, where each active set in the elastic-net path is refit without regularization. The result of this is a matching "glmnet" object which is stored on the original object in a component named "relaxed", and is part of the glmnet output. Generally users will not call `relax.glmnet` directly, unless the original 'glmnet' object took a long time to fit. But if they do, they must supply the fit, and all the original arguments used to create that fit. They can limit the length of the relaxed path via 'maxp'.

**Value**

An object with S3 class "glmnet", "*", where "*" is "elnet", "lognet", "multnet", "fishnet" (poisson), "coxnet" or "mrelnet" for the various types of models. If the model was created with `relax=TRUE` then this class has a prefix class of "relaxed".

call the call that produced this object

a0 Intercept sequence of length `length(lambda)`

beta For "elnet", "lognet", "fishnet" and "coxnet" models, an `nvars x length(lambda)` matrix of coefficients, stored in sparse column format ("CsparseMatrix"). For "multnet" and "mgaussian", a list of nc such matrices, one for each class.

lambda The actual sequence of `lambda` values used. When `alpha=0`, the largest `lambda` reported does not quite give the zero coefficients reported (`lambda=inf` would in principle). Instead, the largest `lambda` for `alpha=0.001` is used, and the sequence of `lambda` values is derived from this.

dev.ratio The fraction of (null) deviance explained (for "elnet", this is the R-square). The deviance calculations incorporate weights if present in the model. The deviance is defined to be 2*(loglike_sat - loglike), where loglike_sat is the log-likelihood for the saturated model (a model with a free parameter per observation). Hence dev.ratio=1-dev/nulldev.

nulldev Null deviance (per observation). This is defined to be 2*(loglike_sat -loglike(Null)); The NULL model refers to the intercept model, except for the Cox, where it is the 0 model.

df The number of nonzero coefficients for each value of `lambda`. For "multnet", this is the number of variables with a nonzero coefficient for any class.

dfmat For "multnet" and "mrelnet" only. A matrix consisting of the number of nonzero coefficients per class

dim dimension of coefficient matrix (ices)

nobs number of observations

npasses total passes over the data summed over all `lambda` values

offset a logical variable indicating whether an offset was included in the model

jerr error flag, for warnings and errors (largely for internal debugging).

relaxed If `relax=TRUE`, this additional item is another glmnet object with different values for beta and dev.ratio

system.time(fit2n <- glmnet(x, y))
glmnet.control

Description

View and/or change the factory default parameters in glmnet

Usage

glmnet.control(fdev = 1e-05, devmax = 0.999, eps = 1e-06,
big = 9.9e+35, mnlam = 5, pmin = 1e-09, exmx = 250,
prec = 1e-10, mxit = 100, itrace = 0, epsnr = 1e-08,
mxitnr = 25, factory = FALSE)

Arguments

fdev  minimum fractional change in deviance for stopping path; factory default = 1.0e-5
devmax  maximum fraction of explained deviance for stopping path; factory default = 0.999
eps  minimum value of lambda.min.ratio (see glmnet); factory default = 1.0e-6
big  large floating point number; factory default = 9.9e35. Inf in definition of upper.limit is set to big
mnlam  minimum number of path points (lambda values) allowed; factory default = 5
pmin  minimum probability for any class. factory default = 1.0e-9. Note that this implies a pmax of 1-pmin.
exmx  maximum allowed exponent. factory default = 250.0
prec  convergence threshold for multi response bounds adjustment solution. factory default = 1.0e-10
mxit  maximum iterations for multiresponse bounds adjustment solution. factory default = 100
itrace  If I then progress bar is displayed when running glmnet and cv.glmnet. factory default = 0
epsnr  convergence threshold for glmnet.fit. factory default = 1.0e-8
mxitnr  maximum iterations for the IRLS loop in glmnet.fit. factory default = 25
factory  If TRUE, reset all the parameters to the factory default; default is FALSE

Details

If called with no arguments, glmnet.control() returns a list with the current settings of these parameters. Any arguments included in the call sets those parameters to the new values, and then silently returns. The values set are persistent for the duration of the R session.

Value

A list with named elements as in the argument list

### glmnet.fit

*Fit a GLM with elastic net regularization for a single value of lambda*

#### Description

Fit a generalized linear model via penalized maximum likelihood for a single value of lambda. Can deal with any GLM family.

#### Usage

```r
glmnet.fit(x, y, weights, lambda, alpha = 1, offset = rep(0, nobs),
family = gaussian(), intercept = TRUE, thresh = 1e-10,
maxit = 1e+05, penalty.factor = rep(1, nvars), exclude = c(),
lower.limits = -Inf, upper.limits = Inf, warm = NULL,
from.glmnet.path = FALSE, save.fit = FALSE, trace.it = 0)
```

#### Arguments

- **x**: Input matrix, of dimension `nobs x nvars`; each row is an observation vector.
- **y**: Quantitative response variable.
- **weights**: Observation weights. `glmnet.fit` does NOT standardize these weights.
- **lambda**: A single value for the `lambda` hyperparameter.
- **alpha**: The elasticnet mixing parameter, with `0 ≤ α ≤ 1`. The penalty is defined as
  
  $$(1 - α)/2||β||_2^2 + α||β||_1.$$

  `alpha=1` is the lasso penalty, and `alpha=0` the ridge penalty.
- **offset**: A vector of length `nobs` that is included in the linear predictor. Useful for the "poisson" family (e.g. log of exposure time), or for refining a model by starting at a current fit. Default is NULL. If supplied, then values must also be supplied to the `predict` function.
family
A description of the error distribution and link function to be used in the model. This is the result of a call to a family function. Default is gaussian(). (See family for details on family functions.)

intercept
Should intercept be fitted (default=TRUE) or set to zero (FALSE)?

thresh
Convergence threshold for coordinate descent. Each inner coordinate-descent loop continues until the maximum change in the objective after any coefficient update is less than thresh times the null deviance. Default value is 1e-10.

maxit
Maximum number of passes over the data; default is 10^5. (If a warm start object is provided, the number of passes the warm start object performed is included.)

penalty.factor
Separate penalty factors can be applied to each coefficient. This is a number that multiplies lambda to allow differential shrinkage. Can be 0 for some variables, which implies no shrinkage, and that variable is always included in the model. Default is 1 for all variables (and implicitly infinity for variables listed in exclude). Note: the penalty factors are internally rescaled to sum to nvars.

exclude
Indices of variables to be excluded from the model. Default is none. Equivalent to an infinite penalty factor.

lower.limits
Vector of lower limits for each coefficient; default -Inf. Each of these must be non-positive. Can be presented as a single value (which will then be replicated), else a vector of length nvars.

upper.limits
Vector of upper limits for each coefficient; default Inf. See lower.limits.

warm
A glmnetfit object which can be used as a warm start. Default is NULL, indicating no warm start. For internal use only.

from glmnet.path
Was glmnet.fit() called from glmnet.path()? Default is FALSE. This has implications for computation of the penalty factors.

save.fit
Return the warm start object? Default is FALSE.

trace.it
Controls how much information is printed to screen. If trace.it=2, some information about the fitting procedure is printed to the console as the model is being fitted. Default is trace.it=0 (no information printed). (trace.it=1 not used for compatibility with glmnet.path.)

Details

WARNING: Users should not call glmnet.fit directly. Higher-level functions in this package call glmnet.fit as a subroutine. If a warm start object is provided, some of the other arguments in the function may be overriden.

glmnet.fit solves the elastic net problem for a single, user-specified value of lambda. glmnet.fit works for any GLM family. It solves the problem using iteratively reweighted least squares (IRLS). For each IRLS iteration, glmnet.fit makes a quadratic (Newton) approximation of the log-likelihood, then calls elnet.fit to minimize the resulting approximation.

In terms of standardization: glmnet.fit does not standardize x and weights. penalty.factor is standardized so that they sum up to nvars.
glmnet.measures

Value

An object with class "glmnetfit" and "glmnet". The list returned contains more keys than that of a "glmnet" object.

- **a0**: Intercept value.
- **beta**: A `nvars x 1` matrix of coefficients, stored in sparse matrix format.
- **df**: The number of nonzero coefficients.
- **dim**: Dimension of coefficient matrix.
- **lambda**: Lambda value used.
- **dev.ratio**: The fraction of (null) deviance explained. The deviance calculations incorporate weights if present in the model. The deviance is defined to be 2*(loglike_sat - loglike), where loglike_sat is the log-likelihood for the saturated model (a model with a free parameter per observation). Hence dev.ratio=1-dev/nulldev.
- **nulldev**: Null deviance (per observation). This is defined to be 2*(loglike_sat-loglike(Null)). The null model refers to the intercept model.
- **npasses**: Total passes over the data.
- **jerr**: Error flag, for warnings and errors (largely for internal debugging).
- **offset**: A logical variable indicating whether an offset was included in the model.
- **call**: The call that produced this object.
- **nobs**: Number of observations.
- **warm_fit**: If `save.fit=TRUE`, output of FORTRAN routine, used for warm starts. For internal use only.
- **family**: Family used for the model.
- **converged**: A logical variable: was the algorithm judged to have converged?
- **boundary**: A logical variable: is the fitted value on the boundary of the attainable values?
- **obj_function**: Objective function value at the solution.

---

### Description

Produces a list of names of measures

### Usage

```r
glmnet.measures(family = c("all", "gaussian", "binomial", "poisson", "multinomial", "cox", "mgaussian", "GLM"))
```
Arguments

family If a "glmnet" family is supplied, a list of the names of measures available for that family are produced. Default is "all", in which case the names of measures for all families are produced.

Details

Try it and see. A very simple function to provide information

Author(s)

Trevor Hastie
Maintainer: Trevor Hastie <hastie@stanford.edu>

See Also
cv.glmnet and assess.glmnet.

Description

Fit a generalized linear model via penalized maximum likelihood for a path of lambda values. Can deal with any GLM family.

Usage

glmnet.path(x, y, weights = NULL, lambda = NULL, nlambda = 100, lambda.min.ratio = ifelse(nobs < nvars, 0.01, 1e-04), alpha = 1, offset = NULL, family = gaussian(), standardize = TRUE, intercept = TRUE, thresh = 1e-10, maxit = 1e+05, penalty.factor = rep(1, nvars), exclude = integer(0), lower.limits = -Inf, upper.limits = Inf, trace.it = 0)

Arguments

x Input matrix, of dimension nobs x nvars; each row is an observation vector.
y Quantitative response variable.
weights Observation weights. Default is 1 for each observation.
lambda A user supplied lambda sequence. Typical usage is to have the program compute its own lambda sequence based on nlambda and lambda.min.ratio. Supplying a value of lambda overrides this.
nlambda The number of lambda values, default is 100.
lambda.min.ratio
Smallest value for lambda as a fraction of lambda.max, the (data derived) entry value (i.e. the smallest value for which all coefficients are zero). The default depends on the sample size nobs relative to the number of variables nvars. If nobs \( \geq \) nvars, the default is 0.0001, close to zero. If nobs < nvars, the default is 0.01. A very small value of lambda.min.ratio will lead to a saturated fit in the nobs < nvars case. This is undefined for some families of models, and the function will exit gracefully when the percentage deviance explained is almost 1.

alpha
The elasticnet mixing parameter, with \( 0 \leq \alpha \leq 1 \). The penalty is defined as
\[
(1 - \alpha)/2||\beta||_2^2 + \alpha||\beta||_1.
\]
alpha=1 is the lasso penalty, and alpha=0 the ridge penalty.

theresh
A vector of length nobs that is included in the linear predictor. Useful for the "poisson" family (e.g. log of exposure time), or for refining a model by starting at a current fit. Default is NULL. If supplied, then values must also be supplied to the predict function.

family
A description of the error distribution and link function to be used in the model. This is the result of a call to a family function. Default is gaussian(). (See family for details on family functions.)

standardize
Logical flag for x variable standardization, prior to fitting the model sequence. The coefficients are always returned on the original scale. Default is standardize=TRUE. If variables are in the same units already, you might not wish to standardize.

intercept
Should intercept be fitted (default=TRUE) or set to zero (FALSE)?

maxit
Maximum number of passes over the data; default is 10^5.

penalty.factor
Separate penalty factors can be applied to each coefficient. This is a number that multiplies lambda to allow differential shrinkage. Can be 0 for some variables, which implies no shrinkage, and that variable is always included in the model. Default is 1 for all variables (and implicitly infinity for variables listed in exclude). Note: the penalty factors are internally rescaled to sum to nvars.

exclude
Indices of variables to be excluded from the model. Default is none. Equivalent to an infinite penalty factor.

lower.limits
Vector of lower limits for each coefficient; default -Inf. Each of these must be non-positive. Can be presented as a single value (which will then be replicated), else a vector of length nvars.

upper.limits
Vector of upper limits for each coefficient; default Inf. See lower.limits.

trace.it
Controls how much information is printed to screen. Default is trace.it=0 (no information printed). If trace.it=1, a progress bar is displayed. If trace.it=2, some information about the fitting procedure is printed to the console as the model is being fitted.
**Details**

glmnet.path solves the elastic net problem for a path of lambda values. It generalizes glmnet::glmnet in that it works for any GLM family.

Sometimes the sequence is truncated before nlambda values of lambda have been used. This happens when glmnet.path detects that the decrease in deviance is marginal (i.e. we are near a saturated fit).

**Value**

An object with class "glmnetfit" and "glmnet".

- **a0**: Intercept sequence of length length(lambda).
- **beta**: A nvars x length(lambda) matrix of coefficients, stored in sparse matrix format.
- **df**: The number of nonzero coefficients for each value of lambda.
- **dim**: Dimension of coefficient matrix.
- **lambda**: The actual sequence of lambda values used. When alpha=0, the largest lambda reported does not quite give the zero coefficients reported (lambda=inf would in principle). Instead, the largest lambda for alpha=0.001 is used, and the sequence of lambda values is derived from this.
- **dev.ratio**: The fraction of (null) deviance explained. The deviance calculations incorporate weights if present in the model. The deviance is defined to be 2*(loglike_sat - loglike), where loglike_sat is the log-likelihood for the saturated model (a model with a free parameter per observation). Hence dev.ratio=1-dev/nulldev.
- **nulldev**: Null deviance (per observation). This is defined to be 2*(loglike_sat -loglike(Null)). The null model refers to the intercept model.
- **npasses**: Total passes over the data summed over all lambda values.
- **jerr**: Error flag, for warnings and errors (largely for internal debugging).
- **offset**: A logical variable indicating whether an offset was included in the model.
- **call**: The call that produced this object.
- **family**: Family used for the model.
- **nobs**: Number of observations.

**Examples**

```r
set.seed(1)
x <- matrix(rnorm(100 * 20), nrow = 100)
y <- ifelse(rnorm(100) > 0, 1, 0)

# binomial with probit link
fit1 <- glmnet.path(x, y, family = binomial(link = "probit"))
```
makeX

convert a data frame to a data matrix with one-hot encoding

Description

Converts a data frame to a data matrix suitable for input to glmnet. Factors are converted to dummy matrices via "one-hot" encoding. Options deal with missing values and sparsity.

Usage

makeX(train, test = NULL, na.impute = FALSE, sparse = FALSE, ...)

Arguments

- train: Required argument. A dataframe consisting of vectors, matrices and factors
- test: Optional argument. A dataframe matching 'train' for use as testing data
- na.impute: Logical, default FALSE. If TRUE, missing values for any column in the resultant 'x' matrix are replaced by the means of the nonmissing values derived from 'train'
- sparse: Logical, default FALSE. If TRUE then the returned matrices are converted to matrices of class "CsparseMatrix". Useful if some factors have a large number of levels, resulting in very big matrices, mostly zero
- ...: additional arguments, currently unused

Details

The main function is to convert factors to dummy matrices via "one-hot" encoding. Having the 'train' and 'test' data present is useful if some factor levels are missing in either. Since a factor with k levels leads to a submatrix with 1/k entries zero, with large k the sparse=TRUE option can be helpful; a large matrix will be returned, but stored in sparse matrix format. Finally, the function can deal with missing data. The current version has the option to replace missing observations with the mean from the training data. For dummy submatrices, these are the mean proportions at each level.

Value

If only 'train' was provided, the function returns a matrix 'x'. If missing values were imputed, this matrix has an attribute containing its column means (before imputation). If 'test' was provided as well, a list with two components is returned: 'x' and 'xtest'.

X4 = sample(LETTERS[1:3], 10, replace = TRUE)
df = data.frame(X, X3, X4)
makeX(df)
makeX(df, sparse = TRUE)

### Single data frame with missing values
Xn = X
Xn[3, 1] = NA
Xn[5, 2] = NA
X3n = X3
X3n[6] = NA
X4n = X4
X4n[9] = NA
dfn = data.frame(Xn, X3n, X4n)

makeX(dfn)
makeX(dfn, sparse = TRUE)
makeX(dfn, na.impute = TRUE)
makeX(dfn, na.impute = TRUE, sparse = TRUE)

### Test data as well
X = matrix(rnorm(10), 5, 2)
X3 = sample(letters[1:3], 5, replace = TRUE)
X4 = sample(LETTERS[1:3], 5, replace = TRUE)
dft = data.frame(X, X3, X4)

makeX(df, dft)
makeX(df, dft, sparse = TRUE)

### Missing data in test as well
Xn = X
Xn[3, 1] = NA
Xn[5, 2] = NA
X3n = X3
X3n[1] = NA
X4n = X4
X4n[2] = NA
dftn = data.frame(Xn, X3n, X4n)

makeX(dfn, dftn)
makeX(dfn, dftn, sparse = TRUE)
makeX(dfn, dftn, na.impute = TRUE)
makeX(dfn, dftn, sparse = TRUE, na.impute = TRUE)
na.replace

Replace the missing entries in a matrix columnwise with the entries in a supplied vector

Description

Missing entries in any given column of the matrix are replaced by the column means or the values in a supplied vector.

Usage

na.replace(x, m = rowSums(x, na.rm = TRUE))

Arguments

x

A matrix with potentially missing values, and also potentially in sparse matrix format (i.e. inherits from "sparseMatrix")

m

Optional argument. A vector of values used to replace the missing entries, columnwise. If missing, the column means of 'x' are used

Details

This is a simple imputation scheme. This function is called by makeX if the na.impute=TRUE option is used, but of course can be used on its own. If 'x' is sparse, the result is sparse, and the replacements are done so as to maintain sparsity.

Value

A version of 'x' is returned with the missing values replaced.

---

**obj_function**  
*Elastic net objective function value*

**Description**

Returns the elastic net objective function value.

**Usage**

```
obj_function(y, mu, weights, family, lambda, alpha, coefficients, vp)
```

**Arguments**

- `y`: Quantitative response variable.
- `mu`: Model’s predictions for `y`.
- `weights`: Observation weights.
- `family`: A description of the error distribution and link function to be used in the model. This is the result of a call to a family function.
- `lambda`: A single value for the lambda hyperparameter.
- `alpha`: The elasticnet mixing parameter, with $0 \leq \alpha \leq 1$.
- `coefficients`: The model’s coefficients (excluding intercept).
- `vp`: Penalty factors for each of the coefficients.
pen_function

Returns the elastic net penalty value without the lambda factor.

Usage

pen_function(coefficients, alpha = 1, vp = 1)

Arguments

coefficients The model’s coefficients (excluding intercept).
alpha The elasticnet mixing parameter, with 0 ≤ α ≤ 1.
v The penalty factors for each of the coefficients.

Details

The penalty is defined as

\[(1 - \alpha)/2 \sum vp_j \beta_j^2 + \alpha \sum vp_j |\beta_j|,\]

Note the omission of the multiplicative lambda factor.

plot.cv.glmnet

Plots the cross-validation curve, and upper and lower standard deviation curves, as a function of the lambda values used. If the object has class "cv.relaxed" a different plot is produced, showing both lambda and gamma

Usage

## S3 method for class 'cv.glmnet'
plot(x, sign.lambda = 1, ...)

## S3 method for class 'cv.relaxed'
plot(x, se.bands = TRUE, ...)

Arguments

x fitted "cv.glmnet" object
sign.lambda Either plot against log(lambda) (default) or its negative if sign.lambda=-1.
... Other graphical parameters to plot
se.bands Should shading be produced to show standard-error bands; default is TRUE
Details

A plot is produced, and nothing is returned.

set.seed(1010)
n = 1000
p = 100
nc = trunc(p/10)
x = matrix(rnorm(n * p), n, p)
beta = rnorm(nc)
fx = (x[, seq(nc)] %*% beta)
eps = rnorm(n) * 5
y = drop(fx + eps)
px = exp(fx)
px = px/(1 + px)
ly = rbinom(n = length(px), prob = px, size = 1)
cvob1 = cv.glmnet(x, y)
plot(cvob1)
title("Gaussian Family", line = 2.5)
cvob1r = cv.glmnet(x, y, relax = TRUE)
plot(cvob1r)
frame()
set.seed(1011)
par(mfrow = c(2, 2), mar = c(4.5, 4.5, 4, 1))
cvob2 = cv.glmnet(x, ly, family = "binomial")
plot(cvob2)
title("Binomial Family", line = 2.5)
## set.seed(1011)
## cvob3 = cv.glmnet(x, ly, family = "binomial", type = "class")
## plot(cvob3)
## title("Binomial Family", line = 2.5)
```
plot.glmnet

plot coefficients from a "glmnet" object

Description

Produces a coefficient profile plot of the coefficient paths for a fitted "glmnet" object.

Usage

## S3 method for class 'glmnet'
plot(x, xvar = c("norm", "lambda", "dev"),
     label = FALSE, ...)

## S3 method for class 'mrelnet'
plot(x, xvar = c("norm", "lambda", "dev"),
     label = FALSE, type.coef = c("coef", "2norm"), ...)

## S3 method for class 'multnet'
plot(x, xvar = c("norm", "lambda", "dev"),
     label = FALSE, type.coef = c("coef", "2norm"), ...)

## S3 method for class 'relaxed'
plot(x, xvar = c("lambda", "dev"), label = FALSE,
     gamma = 1, ...)

Arguments

x fitted "glmnet" model
xvar What is on the X-axis. "norm" plots against the L1-norm of the coefficients,
"lambda" against the log-lambda sequence, and "dev" against the percent de-
viance explained.
label If TRUE, label the curves with variable sequence numbers.
... Other graphical parameters to plot
type.coef If type.coef="2norm" then a single curve per variable, else if type.coef="coef",
a coefficient plot per response
gamma Value of the mixing parameter for a "relaxed" fit

Details

A coefficient profile plot is produced. If x is a multinomial model, a coefficient plot is produced for
each class.

predict.cv.glmnet make predictions from a "cv.glmnet" object.

Description
This function makes predictions from a cross-validated glmnet model, using the stored "glmnet.fit" object, and the optimal value chosen for lambda (and gamma for a 'relaxed' fit).

Usage
## S3 method for class 'cv.glmnet'
predict(object, newx, s = c("lambda.1se", "lambda.min"), ...)
## S3 method for class 'cv.relaxed'
predict(object, newx, s = c("lambda.1se", "lambda.min"), gamma = c("gamma.1se", "gamma.min"), ...)

Arguments
object Fitted "cv.glmnet" or "cv.relaxed" object.
newx Matrix of new values for x at which predictions are to be made. Must be a matrix; can be sparse as in Matrix package. See documentation for predict.glmnet.
s Value(s) of the penalty parameter lambda at which predictions are required. Default is the value s="lambda.1se" stored on the CV object. Alternatively s="lambda.min" can be used. If s is numeric, it is taken as the value(s) of lambda to be used. (For historical reasons we use the symbol 's' rather than 'lambda' to reference this parameter)
predict.cv.glmnet

... Not used. Other arguments to predict.

gamma Value (single) of 'gamma' at which predictions are to be made

Details
This function makes it easier to use the results of cross-validation to make a prediction.

Value
The object returned depends on the ...argument which is passed on to the predict method for glmnet objects.

glmnet, and print, and coef methods, and cv.glmnet.

Examples

```r
x = matrix(rnorm(100 * 20), 100, 20)
y = rnorm(100)
cv.fit = cv.glmnet(x, y)
predict(cv.fit, newx = x[1:5, ])
coef(cv.fit)
coef(cv.fit, s = "lambda.min")
predict(cv.fit, newx = x[1:5, ], s = c(0.001, 0.002))
cv.fitr = cv.glmnet(x, y, relax = TRUE)
predict(cv.fit, newx = x[1:5, ])
coef(cv.fit)
coef(cv.fit, s = "lambda.min", gamma = "gamma.min")
predict(cv.fit, newx = x[1:5, ], s = c(0.001, 0.002), gamma = "gamma.min")
```
**predict.glmnetfit**  

Get predictions from a glmnetfit fit object

---

**Description**

Gives fitted values, linear predictors, coefficients and number of non-zero coefficients from a fitted glmnetfit object.

**Usage**

```r
## S3 method for class 'glmnetfit'
predict(object, newx, s = NULL, type = c("link", 
   "response", "coefficients", "nonzero"), exact = FALSE, newoffset, ...)
```

**Arguments**

- **object**
  Fitted "glmnetfit" object.
- **newx**
  Matrix of new values for x at which predictions are to be made. Must be a matrix. This argument is not used for type = c("coefficients", "nonzero").
- **s**
  Value(s) of the penalty parameter lambda at which predictions are required. Default is the entire sequence used to create the model.
- **type**
  Type of prediction required. Type "link" gives the linear predictors (eta scale); Type "response" gives the fitted values (mu scale). Type "coefficients" computes the coefficients at the requested values for s. Type "nonzero" returns a list of the indices of the nonzero coefficients for each value of s.
- **exact**
  This argument is relevant only when predictions are made at values of s (lambda) different from those used in the fitting of the original model. If exact=FALSE (default), then the predict function uses linear interpolation to make predictions for values of s (lambda) that do not coincide with those used in the fitting algorithm. While this is often a good approximation, it can sometimes be a bit coarse. With exact=TRUE, these different values of s are merged (and sorted) with object$lambda, and the model is refit before predictions are made. In this case, it is required to supply the original data x= and y= as additional named arguments to predict() or coef(). The workhorse predict.glmnet() needs to update the model, and so needs the data used to create it. The same is true of weights, offset, penalty.factor, lower.limits, upper.limits if these were used in the original call. Failure to do so will result in an error.
- **newoffset**
  If an offset is used in the fit, then one must be supplied for making predictions (except for type="coefficients" or type="nonzero").
- **...**
  This is the mechanism for passing arguments like x= when exact=TRUE; see exact argument.

**Value**

The object returned depends on type.
print.cv.glmnet

print a cross-validated glmnet object

Description

Print a summary of the results of cross-validation for a glmnet model.

Usage

## S3 method for class 'cv.glmnet'
print(x, digits = max(3, getOption("digits") - 3),
      ...)  

Arguments

x           fitted 'cv.glmnet' object
digits      significant digits in printout
...         additional print arguments

Details

A summary of the cross-validated fit is produced, slightly different for a 'cv.relaxed' object than for a 'cv.glmnet' object. Note that a 'cv.relaxed' object inherits from class 'cv.glmnet', so by directly invoking print.cv.glmnet(object) will print the summary as if relax=TRUE had not been used.

glmnet, predict and coef methods.
Examples

```r
x = matrix(rnorm(100 * 20), 100, 20)
y = rnorm(100)
fit1 = cv.glmnet(x, y)
print(fit1)
fit1r = cv.glmnet(x, y, relax = TRUE)
print(fit1r)
## print.cv.glmnet(fit1r) ## CHECK WITH TREVOR
```

Description

Print a summary of the glmnet path at each step along the path.

Usage

```r
## S3 method for class 'glmnet'
print(x, digits = max(3, getOption("digits") - 3), ...)
```

Arguments

- `x`: fitted glmnet object
- `digits`: significant digits in printout
- `...`: additional print arguments

Details

The call that produced the object `x` is printed, followed by a three-column matrix with columns `Df`, `%Dev` and `Lambda`. The `Df` column is the number of nonzero coefficients (Df is a reasonable name only for lasso fits). `%Dev` is the percent deviance explained (relative to the null deviance). In the case of a 'relaxed' fit, an additional column is inserted, `%Dev R` which gives the percent deviance explained by the relaxed model. For a "bigGlm" model, a simpler summary is printed.

Value

The matrix above is silently returned

x = matrix(rnorm(100 * 20), 100, 20)
y = rnorm(100)
fit1 = glmnet(x, y)
print(fit1)
```

**rmult**

*Generate multinomial samples from a probability matrix*

**Description**

Generate multinomial samples

**Usage**

```r
rmult(p)
```

**Arguments**

- `p` matrix of probabilities, with number of columns the number of classes

**Details**

Simple function that calls the `rmultinom` function. It generates a class label for each row of its input matrix of class probabilities.

**Value**

a vector of class memberships

Trevor Hastie
Maintainer: Trevor Hastie hastie@stanford.edu
spelnet.fit Solve weighted least squares (WLS) problem for a single lambda value

Description
Solves the weighted least squares (WLS) problem for a single lambda value. Internal function that users should not call directly. This version should be called if `x` is a sparse matrix.

Usage
```r
spelnet.fit(x, xm, xs, y, weights, lambda, alpha = 1, intercept = TRUE, 
thresh = 1e-07, maxit = 1e+05, penalty.factor = rep(1, nvars), 
exclude = c(), lower.limits = -Inf, upper.limits = Inf, 
warm = NULL, from.spglmnet.fit = FALSE, save.fit = FALSE)
```

Arguments
- `x` Input matrix, of dimension `nobs x nvars`; each row is an observation vector.
- `xm` Vector of length `nvars`: `xm(j)` is the centering factor for variable `j`.
- `xs` Vector of length `nvars`: `xs(j)` is the scaling factor for variable `j`.
- `y` Quantitative response variable.
- `weights` Observation weights. `spelnet.fit` does NOT standardize these weights.
- `lambda` A single value for the `lambda` hyperparameter.
- `alpha` The elasticnet mixing parameter, with `0 \leq \alpha \leq 1`. The penalty is defined as

\[
(1 - \alpha)/2||\beta||^2_2 + \alpha||\beta||_1.
\]

`alpha=1` is the lasso penalty, and `alpha=0` the ridge penalty.
- `intercept` Should intercept be fitted (default=TRUE) or set to zero (FALSE)?
- `thresh` Convergence threshold for coordinate descent. Each inner coordinate-descent loop continues until the maximum change in the objective after any coefficient update is less than `thresh` times the null deviance. Default value is `1e-7`.
- `maxit` Maximum number of passes over the data; default is `10^5`. (If a warm start object is provided, the number of passes the warm start object performed is included.)
- `penalty.factor` Separate penalty factors can be applied to each coefficient. This is a number that multiplies `lambda` to allow differential shrinkage. Can be 0 for some variables, which implies no shrinkage, and that variable is always included in the model. Default is 1 for all variables (and implicitly infinity for variables listed in `exclude`). Note: the penalty factors are internally rescaled to sum to `nvars`.
- `exclude` Indices of variables to be excluded from the model. Default is none. Equivalent to an infinite penalty factor.
lower.limits Vector of lower limits for each coefficient; default -Inf. Each of these must be non-positive. Can be presented as a single value (which will then be replicated), else a vector of length nvars.

upper.limits Vector of upper limits for each coefficient; default Inf. See lower.limits.

warm A glmnetfit object which can be used as a warm start. Default is NULL, indicating no warm start. For internal use only.

from.spglmnet.fit Was spelnet.fit() called from spglmnet.fit()? Default is FALSE. This has implications for computation of the penalty factors.

save.fit Return the warm start object? Default is FALSE.

Details

WARNING: Users should not call spelnet.fit directly. Higher-level functions in this package call spelnet.fit as a subroutine. If a warm start object is provided, some of the other arguments in the function may be overridden.

spelnet.fit is essentially a wrapper around a FORTRAN subroutine which minimizes

\[ \frac{1}{2} \sum w_i (y_i - X^T \beta)^2 + \sum \lambda \gamma_j [(1 - \alpha)/2 \beta^2 + \alpha |\beta|], \]

over \( \beta \), where \( \gamma_j \) is the relative penalty factor on the \( j \)th variable. If intercept = TRUE, then the term in the first sum is \( w_i (y_i - \beta_0 - X^T \beta)^2 \), and we are minimizing over both \( \beta_0 \) and \( \beta \).

None of the inputs are standardized except for penalty.factor, which is standardized so that they sum up to nvars.

Value

An object with class "glmnetfit" and "glmnet". The list returned has the same keys as that of a glmnet object, except that it might have an additional warm_fit key.

a0 Intercept value.

beta A nvars x 1 matrix of coefficients, stored in sparse matrix format.

df The number of nonzero coefficients.

dim Dimension of coefficient matrix.

lambda Lambda value used.

dev.ratio The fraction of (null) deviance explained. The deviance calculations incorporate weights if present in the model. The deviance is defined to be \( 2*(\text{loglike}_{\text{sat}} - \text{loglike}) \), where \( \text{loglike}_{\text{sat}} \) is the log-likelihood for the saturated model (a model with a free parameter per observation). Hence dev.ratio=1-dev/nulldev.

nulldev Null deviance (per observation). This is defined to be \( 2*(\text{loglike}_{\text{sat}} - \text{loglike}({\text{Null}})) \). The null model refers to the intercept model.

npasses Total passes over the data.

jerr Error flag, for warnings and errors (largely for internal debugging).

offset Always FALSE, since offsets do not appear in the WLS problem. Included for compatibility with glmnet output.
**spglmnet.fit**

The call that produced this object.

nobs

Number of observations.

warm_fit

If save.fit=TRUE, output of FORTRAN routine, used for warm starts. For internal use only.

---

**spglmnet.fit**

*Fit a GLM with elastic net regularization for a single value of lambda*

---

**Description**

Fit a generalized linear model via penalized maximum likelihood for a single value of lambda. Can deal with any GLM family. This version should be called if x is a sparse matrix.

**Usage**

```r
spglmnet.fit(x, xm, xs, y, weights, lambda, alpha = 1, offset = rep(0, nobs), family = gaussian(), intercept = TRUE, thresh = 1e-10, maxit = 1e+05, penalty.factor = rep(1, nvars), exclude = c(), lower.limits = -Inf, upper.limits = Inf, warm = NULL, from.glmnet.path = FALSE, save.fit = FALSE, trace.it = 0)
```

**Arguments**

- `x`: Input matrix, of dimension nobs x nvars; each row is an observation vector.
- `xm`: Vector of length nvars: xm(j) is the centering factor for variable j.
- `xs`: Vector of length nvars: xs(j) is the scaling factor for variable j.
- `y`: Quantitative response variable.
- `weights`: Observation weights. spglmnet.fit does NOT standardize these weights.
- `lambda`: A single value for the lambda hyperparameter.
- `alpha`: The elasticnet mixing parameter, with 0 ≤ α ≤ 1. The penalty is defined as
  \[
  (1 - \alpha)/2||\beta||^2_2 + \alpha||\beta||_1.\]

alpha=1 is the lasso penalty, and alpha=0 the ridge penalty.
- `offset`: A vector of length nobs that is included in the linear predictor. Useful for the "poisson" family (e.g. log of exposure time), or for refining a model by starting at a current fit. Default is NULL. If supplied, then values must also be supplied to the predict function.
- `family`: A description of the error distribution and link function to be used in the model. This is the result of a call to a family function. Default is gaussian(). (See family for details on family functions.)
- `intercept`: Should intercept be fitted (default=TRUE) or set to zero (FALSE)?
- `thresh`: Convergence threshold for coordinate descent. Each inner coordinate-descent loop continues until the maximum change in the objective after any coefficient update is less than thresh times the null deviance. Default value is 1e-10.
spglmnet.fit

maxit
Maximum number of passes over the data; default is 10^5. (If a warm start object is provided, the number of passes the warm start object performed is included.)

penalty.factor
Separate penalty factors can be applied to each coefficient. This is a number that multiplies lambda to allow differential shrinkage. Can be 0 for some variables, which implies no shrinkage, and that variable is always included in the model. Default is 1 for all variables (and implicitly infinity for variables listed in exclude). Note: the penalty factors are internally rescaled to sum to nvars.

exclude
Indices of variables to be excluded from the model. Default is none. Equivalent to an infinite penalty factor.

lower.limits
Vector of lower limits for each coefficient; default -Inf. Each of these must be non-positive. Can be presented as a single value (which will then be replicated), else a vector of length nvars.

upper.limits
Vector of upper limits for each coefficient; default Inf. See lower.limits.

warm
A glmnetfit object which can be used as a warm start. Default is NULL, indicating no warm start. For internal use only.

from.glmnet.path
Was spglmnet.fit() called from glmnet.path()? Default is FALSE. This has implications for computation of the penalty factors.

save.fit
Return the warm start object? Default is FALSE.

trace.it
Controls how much information is printed to screen. If trace.it=2, some information about the fitting procedure is printed to the console as the model is being fitted. Default is trace.it=0 (no information printed). (trace.it=1 not used for compatibility with glmnet.path.)

Details

WARNING: Users should not call spglmnet.fit directly. Higher-level functions in this package call spglmnet.fit as a subroutine. If a warm start object is provided, some of the other arguments in the function may be overriden.

spglmnet.fit solves the elastic net problem for a single, user-specified value of lambda. spglmnet.fit works for any GLM family. It solves the problem using iteratively reweighted least squares (IRLS). For each IRLS iteration, spglmnet.fit makes a quadratic (Newton) approximation of the log-likelihood, then calls spelnet.fit to minimize the resulting approximation.

In terms of standardization: spglmnet.fit does not standardize x and weights. penalty.factor is standardized so that they sum up to nvars.

Value

An object with class "glmnetfit" and "glmnet". The list returned contains more keys than that of an "glmnet" object.

a0
Intercept value.

beta
A nvars x 1 matrix of coefficients, stored in sparse matrix format.

df
The number of nonzero coefficients.
