Index 20
Compute Confidence Intervals

Description

Compute and display confidence intervals for model estimates. Methods are provided for the mean of a numeric vector `ci.default`, the probability of a binomial vector `ci.binom`, and for `lm`, `lme`, and `mer` objects are provided.

Usage

```r
ci(x, confidence=0.95, alpha=1-confidence, ...) # S3 method for class 'numeric'
ci(x, confidence=0.95, alpha=1-confidence, na.rm=FALSE, ...) # S3 method for class 'binom'
ci(x, confidence=0.95, alpha=1-confidence, ...) # S3 method for class 'lm'
ci(x, confidence=0.95, alpha=1-confidence, ...) # S3 method for class 'lme'
ci(x, confidence=0.95, alpha=1-confidence, ...) # S3 method for class 'estimable'
ci(x, confidence=0.95, alpha=1-confidence, ...) # S3 method for class 'fit_contrast'
```

Arguments

- `x` : object from which to compute confidence intervals.
- `confidence` : confidence level. Defaults to 0.95.
- `alpha` : type one error rate. Defaults to 1.0-confidence
- `na.rm` : boolean indicating whether missing values should be removed. Defaults to FALSE.
- `...` : Arguments for methods

Value

vector or matrix with one row per model parameter and elements/columns `Estimate`, `CI lower`, `CI upper`, `Std. Error`, `DF` (for `lme` objects only), and `p-value`.

Author(s)

Gregory R. Warnes <greg@warnes.net>

# binomial proportion and exact confidence interval
b <- rbinom(prob=0.75, size=1, n=20)
ci.binom(b) # direct call
class(b) <- 'binom'
ci(b) # indirect call

# confidence intervals for regression parameters
data(state)
reg <- lm(Area ~ Population, data=as.data.frame(state.x77))
ci(reg)

---

**coefFrame**

*Return model parameters in a data frame*

Description

Fits a model to each subgroup defined by `by`, then returns a data frame with one row for each fit and one column for each parameter.

Usage

```r
coefFrame(mod, data, by = NULL, fit.on = TRUE, fitfun, keep.unused.levels = TRUE, byvar.sep = "\001", ...)
```

Arguments

- `mod` a model formula, to be passed to `fitfun`.
- `data` a data frame, row subsets of which will be used as the data argument to `fitfun`.
- `by` names of columns in `x` that will be used to define the subgroups.
- `fit.on` a logical vector indicating which rows of `x` are to be used to fit the model (like the subset argument in a lot of other functions). Can be given in terms of variables in `x`
fitfun: a model fitting function (e.g. \texttt{lm}, \texttt{nls}). More specifically, a function that expects at least a formula object (as the first argument) and a data.frame object (passed as an argument named \texttt{data}) and returns a model object for which a \texttt{coef} method has been defined (e.g. \texttt{coef.lm}, \texttt{coef.nls}) to extract fit values of model parameters.

\texttt{keep.unused.levels}: Include rows in output for all unique values of \texttt{by}, even those which were excluded by \texttt{fit.on}. The default value \texttt{TRUE} should be left alone if you are going to go on to pass the result to \texttt{backFit}.

\texttt{byvar.sep}: passed to \texttt{frameApply}, used to form the subsets of the data.

\texttt{...}: other arguments to pass to \texttt{fitfun}.

\textbf{Value}

a data frame with a row for each unique row of \texttt{x[by]}, and column for each model parameter, as well as columns specified in \texttt{by}.

\textbf{Author(s)}

Jim Rogers <james.a.rogers@pfizer.com>

\textbf{Examples}

\begin{verbatim}
# load example data
library(gtools)
data(ELISA)

# Coefficients for four parameter logistic fits:
coefFrame(log(Signal) ~ SSfpl(log(Concentration), A, B, xmid, scal),
data = ELISA, fitfun = nls,
by = c("PlateDay", "Read"),
fit.on = Description == "Standard" & Concentration != 0)

# Coefficients for linear fits:
coefFrame(log(Signal) ~ log(Concentration),
data = ELISA, fitfun = lm,
by = c("PlateDay", "Read"),
fit.on = Description == "Standard" & Concentration != 0 )

# Example passing arguments to fitfun, and example of
# error handling during model fitting:
ELISA$Signal[1] <- NA
coefFrame(log(Signal) ~ log(Concentration),
data = ELISA, fitfun = lm, na.action = na.fail,
by = c("PlateDay", "Read"),
fit.on = Description == "Standard" & Concentration != 0 )
\end{verbatim}
CrossTable

Cross Tabulation with Tests for Factor Independence

Description
An implementation of a cross-tabulation function with output similar to S-Plus crosstabs() and SAS Proc Freq (or SPSS format) with Chi-square, Fisher and McNemar tests of the independence of all table factors.

Usage
CrossTable(x, y, digits=3, max.width = 5, expected=FALSE, prop.r=TRUE, prop.c=TRUE, prop.t=TRUE, prop.chisq=TRUE, chisq = FALSE, fisher=FALSE, mcnemar=FALSE, resid=FALSE, sresid=FALSE, asresid=FALSE, missing.include=FALSE, format=c("SAS","SPSS"), dnn = NULL, ...)

Arguments
- **x**: A vector or a matrix. If y is specified, x must be a vector
- **y**: A vector in a matrix or a dataframe
- **digits**: Number of digits after the decimal point for cell proportions
- **max.width**: In the case of a 1 x n table, the default will be to print the output horizontally. If the number of columns exceeds max.width, the table will be wrapped for each successive increment of max.width columns. If you want a single column vertical table, set max.width to 1
- **expected**: If TRUE, chisq will be set to TRUE and expected cell counts from the \( \chi^2 \) will be included
- **prop.r**: If TRUE, row proportions will be included
- **prop.c**: If TRUE, column proportions will be included
- **prop.t**: If TRUE, table proportions will be included
- **prop.chisq**: If TRUE, chi-square contribution of each cell will be included
- **chisq**: If TRUE, the results of a chi-square test will be included
- **fisher**: If TRUE, the results of a Fisher Exact test will be included
- **mcnemar**: If TRUE, the results of a McNemar test will be included
- **resid**: If TRUE, residual (Pearson) will be included
- **sresid**: If TRUE, standardized residual will be included
- **asresid**: If TRUE, adjusted standardized residual will be included
- **missing.include**: If TRUE, then remove any unused factor levels
- **format**: Either SAS (default) or SPSS, depending on the type of output desired.
- **dnn**: the names to be given to the dimensions in the result (the dimnames names).
- **...**: optional arguments
Details

A summary table will be generated with cell row, column and table proportions and marginal totals and proportions. Expected cell counts can be printed if desired (if `chisq = TRUE`). In the case of a 2 x 2 table, both corrected and uncorrected values will be included for appropriate tests. In the case of tabulating a single vector, cell counts and table proportions will be printed.

Note: If `x` is a vector and `y` is not specified, no statistical tests will be performed, even if any are set to TRUE.

Value

A list with multiple components including key table data and statistical test results, where performed.

t: An n by m matrix containing table cell counts
prop.col: An n by m matrix containing cell column proportions
prop.row: An n by m matrix containing cell row proportions
prop.tbl: An n by m matrix containing cell table proportions
chisq: Results from the Chi-Square test. A list with class `htest`. See ?chisq.test for details
chisq.corr: Results from the corrected Chi-Square test. A list with class `htest`. See ?chisq.test for details. ONLY included in the case of a 2 x 2 table.
fisher.ts: Results from the two-sided Fisher Exact test. A list with class `htest`. See ?fisher.test for details. ONLY included if `fisher` = TRUE.
fisher.lt: Results from the Fisher Exact test with HA = "less". A list with class `htest`. See ?fisher.test for details. ONLY included if `fisher` = TRUE and in the case of a 2 x 2 table.
fisher.gt: Results from the Fisher Exact test with HA = "greater". A list with class `htest`. See ?fisher.test for details. ONLY included if `fisher` = TRUE and in the case of a 2 x 2 table.
mcnemar: Results from the McNemar test. A list with class `htest`. See ?mcnemar.test for details. ONLY included if `mcnemar` = TRUE.
mcnemar.corr: Results from the corrected McNemar test. A list with class `htest`. See ?mcnemar.test for details. ONLY included if `mcnemar` = TRUE and in the case of a 2 x 2 table.
resid/sresid/asresid: Pearson Residuals (from chi-square tests).

CrossTable(warpbreaks$wool, warpbreaks$tension, dnn = c("Wool", "Tension"))

estimable

Contrasts and estimable linear functions of model coefficients

Description

Compute and test contrasts and other estimable linear functions of model coefficients for for lm, glm, lme, mer, and geese objects

Usage

estimable(obj, cm, beta0, conf.int=NULL, show.beta0, ...)
## Default S3 method:
estimable(obj, cm, beta0, conf.int=NULL, show.beta0, joint.test=FALSE, ...)

## S3 method for class 'mlm'
estimable(obj, cm, beta0, conf.int=NULL, show.beta0, ...)

Arguments

obj Regression (lm, glm, lme, mer, mlm) object.

cm Vector, List, or Matrix specifying estimable linear functions or contrasts. See below for details.

beta0 Vector of null hypothesis values

conf.int Confidence level. If provided, confidence intervals will be computed.

joint.test Logical value. If TRUE a 'joint' Wald test for the hypothesis $L\beta = \beta_0$ is performed. Otherwise 'row-wise' tests are performed, i.e. $(L\beta)_i = \beta_{0i}$

show.beta0 Logical value. If TRUE a column for beta0 will be included in the output table. Defaults to TRUE when beta0 is specified, FALSE otherwise.

... ignored
Details

`estimable` computes an estimate, test statistic, significance test, and (optional) confidence interval for each linear functions of the model coefficients specified by `cm`.

The estimable function(s) may be specified via a vector, list, or matrix. If `cm` is a vector, it should contained named elements each of which gives the coefficient to be applied to the corresponding parameter. These coefficients will be used to construct the contrast matrix, with unspecified model parameters assigned zero coefficients. If `cm` is a list, it should contain one or more coefficient vectors, which will be used to construct rows of the contrast matrix. If `cm` is a matrix, column names must match (a subset of) the model parameters, and each row should contain the corresponding coefficient to be applied. Model parameters which are not present in the set of column names of `cm` will be set to zero.

The estimates and their variances are obtained by applying the contrast matrix (generated from) `cm` to the model estimates variance-covariance matrix. Degrees of freedom are obtained from the appropriate model terms.

The user is responsible for ensuring that the specified linear functions are meaningful.

For computing contrasts among levels of a single factor, `fit.contrast` may be more convenient. For computing contrasts between two specific combinations of model parameters, the `contrast` function in Frank Harrell’s `rms` library (formerly ‘Design’) may be more convenient.

Value

Returns a matrix with one row per linear function. Columns contain the beta0 value (optional, see `show.beta0` above), estimated coefficients, standard errors, t values, degrees of freedom, two-sided p-values, and the lower and upper endpoints of the 1-alpha confidence intervals.

Note

The estimated fixed effect parameters of `lme` objects may have different degrees of freedom. If a specified contrast includes nonzero coefficients for parameters with differing degrees of freedom, the smallest number of degrees of freedom is used and a warning message is issued.

   family=quasipoisson("identity"))

   cm <- rbind(
      'Setosa vs. Versicolor'  = c(0, 0, 1, 0, 1, 0),
      'Setosa vs. Virginica'  = c(0, 0, 0, 1, 0, 1),
      'Versicolor vs. Virginica'= c(0, 0, 1,-1, 1,-1)
   )
estimable(lm1, cm)
estimable(glm1, cm)

---

fast.prcomp  

Efficient computation of principal components and singular value decompositions.

Description

The standard prcomp and svd function are very inefficient for wide matrixes. fast.prcomp and  
fast.svd are modified versions which are efficient even for matrixes that are very wide.
Usage

```r
fast.prcomp(x, retx = TRUE, center = TRUE, scale. = FALSE, tol = NULL)
fast.svd( x, nu = min(n, p), nv = min(n, p), ...)
```

Arguments

- **x**: data matrix
- **retx**, **center**, **scale.**, **tol**: See documentation for `prcomp`
- **nu**, **nv**, **...**: See documentation for `svd`

Details

The current implementation of the function `svd` in S-Plus and R is much slower when operating on a matrix with a large number of columns than on the transpose of this matrix, which has a large number of rows. As a consequence, `prcomp`, which uses `svd`, is also very slow when applied to matrices with a large number of rows.

For R, the simple solution is to use `La.svd` instead of `svd`. A suitable patch to `prcomp` has been submitted. In the mean time, the function `fast.prcomp` has been provided as a short-term workaround.

For S-Plus the solution is to replace the standard `svd` with a version that checks the dimensions of the matrix, and performs the computation on the transposed the matrix if it is wider than tall.

For R:

- `fast.prcomp` is a modified version of `prcomp` that calls `La.svd` instead of `svd`
- `fast.svd` is simply a wrapper around `La.svd`.

For S-Plus:

- `fast.prcomp` is a modified version of `prcomp` that calls `fast.svd` instead of `svd`
- `fast.svd` checks the dimensions of the matrix. When it is wider than tall, it transposes the input matrix and calls `svd`. It then swaps u and v and returns the result. Otherwise, it just calls `svd` and returns the results unchanged.

Value

See the documentation for `prcomp` or `svd`.

Author(s)

Modifications by Gregory R. Warnes <greg@warne.net>

See Also

- `prcomp`, `svd`, `La.svd`
Examples

```r
# create test matrix
set.seed(4943546)
nr <- 50
nc <- 2000
x <- matrix( rnorm( nr*nc), nrow=nr, ncol=nc )
tx <- t(x)

# SVD directly on matrix is SLOW:
system.time( val.x <- svd(x)$u )

# SVD on t(matrix) is FAST:
system.time( val.tx <- svd(tx)$v )

# and the results are equivalent:
max( abs(val.x) - abs(val.tx) )

# Time gap dissapears using fast.svd:
system.time( val.x <- fast.svd(x)$u )
system.time( val.tx <- fast.svd(tx)$v )
max( abs(val.x) - abs(val.tx) )

library(stats)

# prcomp directly on matrix is SLOW:
system.time( pr.x <- prcomp(x) )

# prcomp.fast is much faster
system.time( fast.pr.x <- fast.prcomp(x) )

# and the results are equivalent
max( pr.x$sdev - fast.pr.x$sdev )
max( abs(pr.x$rotation[,1:49]) - abs(fast.pr.x$rotation[,1:49]) )
max( abs(pr.x$x) - abs(fast.pr.x$x) )

# (except for the last and least significant component):
max( abs(pr.x$rotation[,50]) - abs(fast.pr.x$rotation[,50]) )
```

**Description**

Compute and test arbitrary contrasts for regression objects.
Usage

fit.contrast(model, varname, coeff, ...)
## S3 method for class 'lm'
fit.contrast(model, varname, coeff, showall=FALSE,
conf.int=NULL, df=FALSE, ...)
## S3 method for class 'lme'
fit.contrast(model, varname, coeff, showall=FALSE,
conf.int=NULL, df=FALSE, ...)

Arguments

model regression (lm, glm, aov, lme) object for which the contrast(s) will be computed.
varname variable name
coeff vector or matrix specifying contrasts (one per row).
showall return all regression coefficients. If TRUE, all model coefficients will be returned. If FALSE (the default), only the coefficients corresponding to the specified contrast will be returned.
conf.int numeric value on (0,1) or NULL. If a numeric value is specified, confidence intervals with nominal coverage probability conf.int will be computed. If NULL, confidence intervals will not be computed.
df boolean indicating whether to return a column containing the degrees of freedom.
...
optional arguments provided by methods.

Details

Computes the specified contrast(s) by re-fitting the model with the appropriate arguments. A contrast of the form \(c(1,0,0,-1)\) would compare the mean of the first group with the mean of the fourth group.

Value

Returns a matrix containing estimated coefficients, standard errors, t values, two-sided p-values. If df is TRUE, an additional column containing the degrees of freedom is included. If conf.int is specified lower and upper confidence limits are also returned.

fm2 <- lme(distance ~ Sex + AgeGroup, data = Orthodont,random=~1|Subject)

# fit.contrast(fm2, "AgeGroup", rbind("Linear"=c(-2,-1,1,2),
    "U-Shaped"=c(-1,1,1,-1),
    "Change-Point at 11"=c(-1,-1,1,1)),
    conf.int=0.95)
Test a General Linear Hypothesis for a Regression Model

Description
Test, print, or summarize a general linear hypothesis for a regression model

Usage

```r
glh.test(reg, cm, d=rep(0, nrow(cm)))
# S3 method for class 'glh.test'
print(x, digits=4,...)
# S3 method for class 'glh.test'
summary(object, digits=4,...)
```

Arguments

- `reg`: Regression model
- `cm`: matrix. Each row specifies a linear combination of the coefficients
- `d`: vector specifying the null hypothesis values for each linear combination
- `x, object`: `glh.test` object
- `digits`: number of digits
- `...`: optional parameters (ignored)

Details
Test the general linear hypothesis $C\hat{\beta} = d$ for the regression model `reg`.
The test statistic is obtained from the formula:

$$f = \frac{(C\hat{\beta} - d)'(C(X'X)^{-1}C')(C\hat{\beta} - d)}{SSE/(n - p)}$$

Under the null hypothesis, $f$ will follow a F-distribution with $r$ and $n-p$ degrees of freedom.

Value
Object of class c("glh.test", "htest") with elements:

- `call`: Function call that created the object
- `statistic`: F statistic
- `parameter`: vector containing the numerator ($r$) and denominator ($n-p$) degrees of freedom
- `p.value`: p-value
estimate      computed estimate for each row of cm
null.value    d
method        description of the method
data.name      name of the model given for reg
matrix        matrix specifying the general linear hypothesis (cm)

Note
When using treatment contrasts (the default) the first level of the factors are subsumed into the intercept term. The estimated model coefficients are then contrasts versus the first level. This should be taken into account when forming contrast matrixes, particularly when computing contrasts that include 'baseline' level of factors.
See the comparison with fit.contrast in the examples below.

**make.contrasts**  
*Construct a User-Specified Contrast Matrix*

**Description**

Construct a user-specified contrast matrix.

**Usage**

make.contrasts(contr, how.many = ncol(contr))

**Arguments**

- **contr**: vector or matrix specifying contrasts (one per row).
- **how.many**: dimensions of the desired contrast matrix. This must equal the number of levels of the target factor variable.

**Details**

This function converts human-readable contrasts into the form that R requires for computation.

Specifying a contrast row of the form \( c(1, 0, 0, -1) \) creates a contrast that will compare the mean of the first group with the mean of the fourth group.

**Value**

make.contrasts returns a matrix with dimensions (how.many, how.many) containing the specified contrasts augmented (if necessary) with orthogonal "filler" contrasts.

This matrix can then be used as the argument to `contrasts` or to the `contrasts` argument of model functions (eg, `lm`).

**Author(s)**

Gregory R. Warnes <greg@warnes.net>

Examples

```r
set.seed(4684)
y <- rnorm(100)
x.true <- rnorm(100, mean=y, sd=0.25)
x <- factor(cut(x.true,c(-4,-1.5,0,1.5,4)))
reg <- lm(y ~ x)
summary(reg)

# Mirror default treatment contrasts
test <- make.contrasts(rbind( c(-1,1,0,0), c(-1,0,1,0), c(-1,0,0,1) ))
lm( y ~ x, contrasts=list(x = test ) )

# Specify some more complicated contrasts
# - mean of 1st group vs mean of 4th group
# - mean of 1st and 2nd groups vs mean of 3rd and 4th groups
# - mean of 1st group vs mean of 2nd, 3rd and 4th groups
cmat <- rbind( "1 vs 4"=c(-1,0,0,1),
               "1+2 vs 3+4"=c(-1/2,-1/2,1/2,1/2),
               "1 vs 2+3+4"=c(-3/3,1/3,1/3,1/3) )

summary(lm( y ~ x, contrasts=list(x=make.contrasts(cmat) )))
# or
contrasts(x) <- make.contrasts(cmat)
summary(lm( y ~ x ) )

# or use contrasts.lm
reg <- lm(y ~ x)
fit.contrast( reg, "x", cmat )

# compare with values computed directly using group means
gm <- sapply(split(y,x),mean)
gm
```

# Example for Analysis of Variance

```r
set.seed(03215)
Genotype <- sample(c("WT","KO"), 1000, replace=TRUE)
Time <- factor(sample(1:3, 1000, replace=TRUE))
data <- data.frame(y, Genotype, Time)
y <- rnorm(1000)
data <- data.frame(y, Genotype, as.factor(Time))

# Compute Contrasts & obtain 95% confidence intervals
model <- aov( y ~ Genotype + Time + Genotype:Time, data=data )
fit.contrast( model, "Genotype", rbind("KO vs WT"=c(-1,1) ), conf=0.95 )
```
```r
# Compute contrasts and show SSQ decompositions

model <- aov( y ~ Genotype + Time + Genotype:Time, data=data,
              contrasts=list(Genotype=make.contrasts(cm.G),
                             Time=make.contrasts(cm.T))
)

summary(model, split=list( Genotype=list("KO vs WT"=1 ),
                            Time = list( "1 vs 2" = 1,
                                         "2 vs 3" = 2 ) ) )
```

```
fit.contrast( model, "Time",
             rbind("1 vs 2"=c(-1,1,0),
                   "2 vs 3"=c(0,-1,1) ),
             conf=0.95 )

cm.G <- rbind("KO vs WT"=c(-1,1) )
cm.T <- rbind("1 vs 2"=c(-1,1,0),
               "2 vs 3"=c(0,-1,1) )
```
