Package ‘gt’

May 23, 2020

**Type** Package

**Version** 0.2.1

**Title** Easily Create Presentation-Ready Display Tables

**Description** Build display tables from tabular data with an easy-to-use set of functions. With its progressive approach, we can construct display tables with a cohesive set of table parts. Table values can be formatted using any of the included formatting functions. Footnotes and cell styles can be precisely added through a location targeting system. The way in which 'gt' handles things for you means that you don't often have to worry about the fine details.

**License** MIT + file LICENSE

**URL** [https://github.com/rstudio/gt](https://github.com/rstudio/gt)

**BugReports** [https://github.com/rstudio/gt/issues](https://github.com/rstudio/gt/issues)

**Encoding** UTF-8

**LazyData** true

**ByteCompile** true

**RoxygenNote** 7.1.0

**Depends** R (>= 3.2.0)

**Imports** checkmate (>= 2.0.0), commonmark (>= 1.7), dplyr (>= 0.8.5), fs (>= 1.3.2), ggplot2 (>= 3.3.0), glue (>= 1.3.2), htmltools (>= 0.4.0), magrittr (>= 1.5), rlang (>= 0.4.5), sass (>= 0.1.1), scales (>= 1.1.0), stringr (>= 1.3.1), tibble (>= 3.0.0), tidyselect (>= 1.0.0)

**Suggests** covr, knitr, paletteer, testthat (>= 2.1.0), RColorBrewer, markdown, rvest, shiny, tidyr, webshot, xml2

**Collate** 'as_data_frame.R' 'base64.R' 'build_data.R' 'compile_scss.R' 'data_color.R' 'datasets.R' 'dt__.R' 'dt_body.R' 'dt_boxhead.R' 'dt_cols_merge.R' 'dt_data.R' 'dt_footnotes.R' 'dt_formats.R' 'dt_groups_rows.R' 'dt_has_built.R' 'dt_heading.R' 'dt_options.R' 'dt_row_groups.R' 'dt_source_notes.R' 'dt_spanners.R' 'dt_stub_df.R' 'dt_stub_others.R'

adjust_luminance

`adjust_luminance` Adjust the luminance for a palette of colors

**Description**

This function can brighten or darken a palette of colors by an arbitrary number of steps, which is defined by a real number between -2.0 and 2.0. The transformation of a palette by a fixed step in this function will tend to apply greater darkening or lightening for those colors in the midrange compared to any very dark or very light colors in the input palette.

**Usage**

```r
adjust_luminance(colors, steps)
```

**Arguments**

- **colors** A vector of colors that will undergo an adjustment in luminance. Each color value provided must either be a color name (in the set of colors provided by `grDevices::colors()`) or a hexadecimal string in the form of "#RRGGBB" or "#RRGGBBAA".
- **steps** A positive or negative factor by which the luminance will be adjusted. Must be a number between -2.0 and 2.0.

**Details**

This function can be useful when combined with the `data_color()` function’s palette argument, which can use a vector of colors or any of the `col_*` functions from the `scales` package (all of which have a palette argument).

**Value**

A vector of color values.

**Figures**

**Function ID**

7-18

Other Helper Functions: `cell_borders()`, `cell_fill()`, `cell_text()`, `cells_body()`, `cells_column_labels()`, `cells_column_spanners()`, `cells_grand_summary()`, `cells_row_groups()`, `cells_stubhead()`, `cells_stub()`, `cells_summary()`, `cells_title()`, `currency()`, `escape_latex()`, `gt_latex_dependencies()`, `html()`, `md()`, `pct()`, `px()`, `random_id()`
Examples

# Get a palette of 8 pastel colors from
# the RColorBrewer package
pal <- RColorBrewer::brewer.pal(8, "Pastel2")

# Create lighter and darker variants
# of the base palette (one step lower, one
# step higher)
pal_darker <- pal %>% adjust_luminance(-1.0)
pal_lighter <- pal %>% adjust_luminance(+1.0)

# Create a tibble and make a gt table
# from it; color each column in order of
# increasingly darker palettes (with
# `data_color()`)  
tab_1 <-
dplyr::tibble(a = 1:8, b = 1:8, c = 1:8) %>%
  gt() %>%
data_color(
  columns = vars(a),
  colors = scales::col_numeric(
    palette = pal_lighter,
    domain = c(1, 8)
  )
)
) %>%
data_color(
  columns = vars(b),
  colors = scales::col_numeric(
    palette = pal,
    domain = c(1, 8)
  )
)
) %>%
data_color(
  columns = vars(c),
  colors = scales::col_numeric(
    palette = pal_darker,
    domain = c(1, 8)
  )
)
)

\begin{verbatim}
as_latex

Output a gt object as LaTeX

Description

Get the LaTeX content from a gt_tbl object as a \texttt{knit_asis} object. This object contains the LaTeX code and attributes that serve as LaTeX dependencies (i.e., the LaTeX packages required for the table). Using \texttt{as.character()} on the created object will result in a single-element vector containing the LaTeX code.

\end{verbatim}

Usage

as_latex(data)

Arguments

data A table object that is created using the gt() function.

Function ID

13-3

See Also

Other Export Functions: as_raw_html(), as_rtf(), extract_summary(), gtsave()

Examples

# Use `gtcars` to create a gt table;
# add a header and then export as
# an object with LaTeX code
tab_latex <-
gtcars %>%
dplyr::select(mfr, model, msrp) %>%
dplyr::slice(1:5) %>%
gt() %>%
tab_header(
  title = md("Data listing from **gtcars**"),
  subtitle = md("`gtcars` is an R dataset")
) %>%
as_latex()

# `tab_latex` is a `knit_asis` object,
# which makes it easy to include in
# R Markdown documents that are knit to
# PDF; we can use `as.character()` to
# get just the LaTeX code as a single-
# element vector
tab_latex %>%
as.character() %>%
cat()

as_raw_html

Get the HTML content of a gt table

Description

Get the HTML content from a gt_tbl object as a single-element character vector. By default, the generated HTML will have inlined styles, where CSS styles (that were previously contained in CSS rule sets external to the <table> element) are included as style attributes in the HTML table’s tags. This option is preferable when using the output HTML table in an emailing context.
Usage

as_raw_html(data, inline_css = TRUE)

Arguments

data          A table object that is created using the gt() function.
inline_css    An option to supply styles to table elements as inlined CSS styles. This is useful
               when including the table HTML as part of an HTML email message body, since
               inlined styles are largely supported in email clients over using CSS in a <style>
               block.

Function ID

13-2

See Also

Other Export Functions: as_latex(), as_rtf(), extract_summary(), gtsave()

Examples

# Use `gtcars` to create a gt table;
# add a header and then export as
# HTML code with CSS inlined
tab_html <-
gtcars %>%
dplyr::select(mfr, model, msrp) %>%
dplyr::slice(1:5) %>%
gt() %>%
tab_header(
  title = md("Data listing from **gtcars**"),
  subtitle = md("`gtcars` is an R dataset")
) %>%
as_raw_html()

# `tab_html` is a single-element vector
# containing inlined HTML for the table;
# it has only the `<table>...` part
# so it's not a complete HTML document but
# rather an HTML fragment

tab_html %>%
  substr(1, 700) %>%
cat()
as_rtf  

Output a `gt` object as RTF

---

Description

Get the RTF content from a `gt_tbl` object as a single-element character vector. This object can be used with `writeLines()` to generate a valid .rtf file that can be opened by RTF readers.

Usage

```r
as_rtf(data)
```

Arguments

data  a table object that is created using the `gt()` function.

Function ID

13-4

See Also

Other Export Functions: `as_latex()`, `as_raw_html()`, `extract_summary()`, `gtsave()`

Examples

```r
# Use `gtcars` to create a gt table;
# add a header and then export as
# RTF code

tab_rtf <-
gtcars %>%
dplyr::select(mfr, model) %>%
dplyr::slice(1:2) %>%
gt() %>%
tab_header(
  title = md("Data listing from **gtcars**"),
  subtitle = md("'gtcars' is an R dataset")
) %>%
as_rtf()
```
### cells_body

**Location helper for targeting data cells in the table body**

### Description

The `cells_body()` function is used to target the data cells in the table body. The function can be used to apply a footnote with `tab_footnote()`, to add custom styling with `tab_style()`, or to transform the targeted cells with `text_transform()`. The function is expressly used in each of those functions’ locations argument.

### Usage

```r
cells_body(columns = TRUE, rows = TRUE)
```

### Arguments

- **columns**: The names of the columns that are to be targeted.
- **rows**: The names of the rows that are to be targeted.

### Details

When using any of the location helper functions with an appropriate function that has a `locations` argument, multiple locations can be targeted by enclosing several `cells_*()` helper functions in a `list()`. The following helper functions can be used to target cells (roughly in order from the top to the bottom of a table):

- **`cells_title()`**: targets the table title or the table subtitle depending on the value given to the `groups` argument ("title" or "subtitle").
- **`cells_stubhead()`**: targets the stubhead location, a cell of which is only available when there is a stub; a label in that location can be created by using the `tab_stubhead()` function.
- **`cells_column_spanners()`**: targets the spanner column labels, which appear above the column labels.
- **`cells_column_labels()`**: targets the column labels.
- **`cells_row_groups()`**: targets the row group labels in any available row groups using the `groups` argument.
- **`cells_stub()`**: targets row labels in the table stub using the `rows` argument.
- **`cells_body()`**: targets data cells in the table body using intersections of columns and rows.
- **`cells_summary()`**: targets summary cells in the table body using the `groups` argument and intersections of columns and rows.
- **`cells_grand_summary()`**: targets cells of the table’s grand summary using intersections of columns and rows.

### Value

A list object with the classes `cells_body` and `location_cells`. 

**Description**

The `cells_body()` function is used to target the data cells in the table body. The function can be used to apply a footnote with `tab_footnote()`, to add custom styling with `tab_style()`, or to transform the targeted cells with `text_transform()`. The function is expressly used in each of those functions’ locations argument.

### Usage

```r
cells_body(columns = TRUE, rows = TRUE)
```

### Arguments

- **columns**: The names of the columns that are to be targeted.
- **rows**: The names of the rows that are to be targeted.

### Details

When using any of the location helper functions with an appropriate function that has a `locations` argument, multiple locations can be targeted by enclosing several `cells_*()` helper functions in a `list()`. The following helper functions can be used to target cells (roughly in order from the top to the bottom of a table):

- **`cells_title()`**: targets the table title or the table subtitle depending on the value given to the `groups` argument ("title" or "subtitle").
- **`cells_stubhead()`**: targets the stubhead location, a cell of which is only available when there is a stub; a label in that location can be created by using the `tab_stubhead()` function.
- **`cells_column_spanners()`**: targets the spanner column labels, which appear above the column labels.
- **`cells_column_labels()`**: targets the column labels.
- **`cells_row_groups()`**: targets the row group labels in any available row groups using the `groups` argument.
- **`cells_stub()`**: targets row labels in the table stub using the `rows` argument.
- **`cells_body()`**: targets data cells in the table body using intersections of columns and rows.
- **`cells_summary()`**: targets summary cells in the table body using the `groups` argument and intersections of columns and rows.
- **`cells_grand_summary()`**: targets cells of the table’s grand summary using intersections of columns and rows.

### Value

A list object with the classes `cells_body` and `location_cells`.

Other Helper Functions: adjust_luminance(), cell_borders(), cell_fill(), cell_text(), cells_column_labels(), cells_column_spanners(), cells_grand_summary(), cells_row_groups(), cells_stubhead(), cells_stub(), cells_summary(), cells_title(), currency(), escape_latex(), gt_latex_dependencies(), html(), md(), pct(), px(), random_id()

Examples

# Use `gtcars` to create a gt table; add
# a footnote that targets a single data cell
# with `tab_footnote()` using `cells_body()`
# in `locations` (`rows = hp == max(hp)`) will
# target a single row in the `hp` column

```r
tab_1 <-
  gtcars %>%
  dplyr::filter(ctry_origin == "United Kingdom") %>%
  dplyr::select(mfr, model, year, hp) %>%
  gt() %>%
  tab_footnote(
    footnote = "Highest horsepower.",
    locations = cells_body(
      columns = vars(hp),
      rows = hp == max(hp))
  ) %>%
  opt_footnote_marks(marks = c("*", "+"))
```

---

cells_column_labels  Location helper for targeting the column labels

description

The `cells_column_labels()` function is used to target the table's column labels when applying a footnote with `tab_footnote()` or adding custom style with `tab_style()`. The function is expressly used in each of those functions' locations argument.

Usage

`cells_column_labels(columns)`
**Arguments**

columns  The names of the column labels that are to be targeted.

**Details**

When using any of the location helper functions with an appropriate function that has a locations argument, multiple locations can be targeted by enclosing several cells_*() helper functions in a list(). The following helper functions can be used to target cells (roughly in order from the top to the bottom of a table):

- **cells_title():** targets the table title or the table subtitle depending on the value given to the groups argument ("title" or "subtitle").
- **cells_stubhead():** targets the stubhead location, a cell of which is only available when there is a stub; a label in that location can be created by using the tab_stubhead() function.
- **cells_column_spanners():** targets the spanner column labels, which appear above the column labels.
- **cells_column_labels():** targets the column labels.
- **cells_row_groups():** targets the row group labels in any available row groups using the groups argument.
- **cells_stub():** targets row labels in the table stub using the rows argument.
- **cells_body():** targets data cells in the table body using intersections of columns and rows.
- **cells_summary():** targets summary cells in the table body using the groups argument and intersections of columns and rows.
- **cells_grand_summary():** targets cells of the table’s grand summary using intersections of columns and rows

**Value**

A list object with the classes cells_column_labels and location_cells.

**Figures**

**Function ID**

7-8

Other Helper Functions: adjust_luminance(), cell_borders(), cell_fill(), cell_text(), cells_body(), cells_column_spanners(), cells_grand_summary(), cells_row_groups(), cells_stubhead(), cells_stub(), cells_summary(), cells_title(), currency(), escape_latex(), gt_latex_dependencies(), html(), md(), pct(), px(), random_id()
Examples

```r
# Use `sza` to create a gt table; add a
# header and then add footnotes to the
# column labels with `tab_footnote()` and
# `cells_column_labels()` in `locations`
tab_1 <-
  sza %>%
  dplyr::filter(
    latitude == 20 & month == "jan" &
    !is.na(sza)
  ) %>%
  dplyr::select(-latitude, -month) %>%
  gt() %>%
  tab_footnote(
    footnote = "True solar time.",
    locations = cells_column_labels(
      columns = vars(tst)
    )
  ) %>%
  tab_footnote(
    footnote = "Solar zenith angle.",
    locations = cells_column_labels(
      columns = vars(sza)
    )
  )
```

`cells_column_spanners`  
*Location helper for targeting the column spanners*

Description

The `cells_column_spanners()` function is used to target the cells that contain the table column spanners. This is useful when applying a footnote with `tab_footnote()` or adding custom style with `tab_style()`. The function is expressly used in each of those functions’ `locations` argument.

Usage

`cells_column_spanners(spanners)`

Arguments

- `spanners` The names of the spanners that are to be targeted.

Details

When using any of the location helper functions with an appropriate function that has a `locations` argument, multiple locations can be targeted by enclosing several `cells_~()` helper functions in a `list()`. The following helper functions can be used to target cells (roughly in order from the top to the bottom of a table):
- `cells_title()`: targets the table title or the table subtitle depending on the value given to the `groups` argument ("title" or "subtitle").
- `cells_stubhead()`: targets the stubhead location, a cell of which is only available when there is a stub; a label in that location can be created by using the `tab_stubhead()` function.
- `cells_column_spanners()`: targets the spanner column labels, which appear above the column labels.
- `cells_column_labels()`: targets the column labels.
- `cells_row_groups()`: targets the row group labels in any available row groups using the `groups` argument.
- `cells_stub()`: targets row labels in the table stub using the `rows` argument.
- `cells_body()`: targets data cells in the table body using intersections of columns and rows.
- `cells_summary()`: targets summary cells in the table body using the `groups` argument and intersections of columns and rows.
- `cells_grand_summary()`: targets cells of the table’s grand summary using intersections of columns and rows.

Value

A list object with the classes `cells_column_spanners` and `location_cells`.

Figures

Function ID

7-7

See Also

Other Helper Functions: `adjust_luminance()`, `cell_borders()`, `cell_fill()`, `cell_text()`, `cells_body()`, `cells_column_labels()`, `cells_grand_summary()`, `cells_row_groups()`, `cells_stubhead()`, `cells_stub()`, `cells_summary()`, `cells_title()`, `currency()`, `escape_latex()`, `gt_latex_dependencies()`, `html()`, `md()`, `pct()`, `px()`, `random_id()`

Examples

# Use 'exibble' to create a gt table; add a
# spanner column label over three column
# labels and then use 'tab_style()' to make
# the spanner label text bold

```r
exibble_test <-
dplyr::select(-fctr, -currency, -group) %>%
gt(rowname_col = "row") %>%
tab_spanner(
  label = "dates and times",
  columns = vars(date, time, datetime)
)```
cells_data  

Location helper for targeting data cells in the table body (deprecated)

Description

Location helper for targeting data cells in the table body (deprecated)

Usage

cells_data(columns = TRUE, rows = TRUE)

Arguments

columns  The names of the columns that are to be targeted.
rows     The names of the rows that are to be targeted.

cells_grand_summary  

Location helper for targeting cells in a grand summary

Description

The `cells_grand_summary()` function is used to target the cells in a grand summary and it is useful when applying a footnote with `tab_footnote()` or adding custom styles with `tab_style()`. The function is expressly used in each of those functions’ locations argument.

Usage

cells_grand_summary(columns = TRUE, rows = TRUE)

Arguments

columns  The names of the columns that are to be targeted.
rows     The names of the rows that are to be targeted.
Details

When using any of the location helper functions with an appropriate function that has a locations
argument, multiple locations can be targeted by enclosing several cells_*() helper functions in a
list(). The following helper functions can be used to target cells (roughly in order from the top to
the bottom of a table):

- **cells_title()**: targets the table title or the table subtitle depending on the value given to the
groups argument ("title" or "subtitle").
- **cells_stubhead()**: targets the stubhead location, a cell of which is only available when there
  is a stub; a label in that location can be created by using the `tab_stubhead()` function.
- **cells_column_spanners()**: targets the spanner column labels, which appear above the column
  labels.
- **cells_column_labels()**: targets the column labels.
- **cells_row_groups()**: targets the row group labels in any available row groups using the
groups argument.
- **cells_stub()**: targets row labels in the table stub using the rows argument.
- **cells_body()**: targets data cells in the table body using intersections of columns and rows.
- **cells_summary()**: targets summary cells in the table body using the groups argument and
  intersections of columns and rows.
- **cells_grand_summary()**: targets cells of the table’s grand summary using intersections of
  columns and rows.

Value

A list object with the classes cells_summary and location_cells.

Figures

Function ID

7-13

Other Helper Functions: adjust_luminance(), cell_borders(), cell_fill(), cell_text(),
cells_body(), cells_column_labels(), cells_column_spanners(), cells_row_groups(), cells_stubhead(),
cells_stub(), cells_summary(), cells_title(), currency(), escape_latex(), gt_latex_dependencies(),
html(), md(), pct(), px(), random_id()

Examples

# Use 'countrypops' to create a gt table; add
# some styling to a grand summary cell with
# with 'tab_style()' and 'cells_grand_summary('

```r
tab_1 <-
```
```r
countrypops %>%
dplyr::filter(
  country_name == "Spain",
  year < 1970
) %>%
dplyr::select(-contains("country")) %>%
gt(rowname_col = "year") %>%
fmt_number(
  columns = vars(population),
  decimals = 0
) %>%
grand_summary_rows(
  columns = vars(population),
  fns = list(
    change = ~max(.) - min(.),
  ),
  formatter = fmt_number,
  decimals = 0
) %>%
tab_style(
  style = list(
    cell_text(style = "italic"),
    cell_fill(color = "lightblue"),
  ),
  locations = cells_grand_summary(
    columns = vars(population),
    rows = 1)
)
```

---

**cells_group**

*Location helper for targeting row groups (deprecated)*

**Description**

Location helper for targeting row groups (deprecated)

**Usage**

`cells_group(groups = TRUE)`

**Arguments**

- `groups` The names of the row groups that are to be targeted.
Description

The `cells_row_groups()` function is used to target the table’s row groups when applying a footnote with `tab_footnote()` or adding custom style with `tab_style()`. The function is expressly used in each of those functions’ `locations` argument.

Usage

`cells_row_groups(groups = TRUE)`

Arguments

- `groups` The names of the row groups that are to be targeted.

Details

When using any of the location helper functions with an appropriate function that has a `locations` argument, multiple locations can be targeted by enclosing several `cells_*()` helper functions in a `list()`. The following helper functions can be used to target cells (roughly in order from the top to the bottom of a table):

- `cells_title()`: targets the table title or the table subtitle depending on the value given to the `groups` argument (“title” or "subtitle").
- `cells_stubhead()`: targets the stubhead location, a cell of which is only available when there is a stub; a label in that location can be created by using the `tab_stubhead()` function.
- `cells_column_spanners()`: targets the spanner column labels, which appear above the column labels.
- `cells_column_labels()`: targets the column labels.
- `cells_row_groups()`: targets the row group labels in any available row groups using the `groups` argument.
- `cells_stub()`: targets row labels in the table stub using the `rows` argument.
- `cells_body()`: targets data cells in the table body using intersections of columns and rows.
- `cells_summary()`: targets summary cells in the table body using the `groups` argument and intersections of columns and rows.
- `cells_grand_summary()`: targets cells of the table’s grand summary using intersections of columns and rows.

Value

A list object with the classes `cells_row_groups` and `location_cells`.

cells_body(), cells_column_labels(), cells_column_spanners(), cells_grand_summary(),
cells_stubhead(), cells_stub(), cells_summary(), cells_title(), currency(), escape_latex(),
gt_latex_dependencies(), html(), md(), pct(), px(), random_id()

Examples

# Use `pizzaplace` to create a gt table
# with grouped data; add a summary with the
# `summary_rows()` function and then add a
# footnote to the "peppr_salami" row group
# label with `tab_footnote()` and with
# `cells_row_groups()` in "locations"
tab_1 <-
pizzaplace %>%
dplyr::filter(
  name %in% c("soppressata", "peppr_salami")
) %>%
dplyr::group_by(name, size) %>%
dplyr::summarize(
  'Pizzas Sold' = dplyr::n()
) %>%
gt(rowname_col = "size") %>%
summary_rows(
  groups = TRUE,
  columns = vars("Pizzas Sold"),
  fns = list(TOTAL = "sum"),
  formatter = fmt_number,
  decimals = 0,
  use_seps = TRUE
) %>%
tab_footnote(
  footnote = "The Pepper-Salami.",
  cells_row_groups(groups = "peppr_salami")
)
Description

The `cells_stub()` function is used to target the table’s stub cells and it is useful when applying a footnote with `tab_footnote()` or adding a custom style with `tab_style()`. The function is expressly used in each of those functions’ locations argument.

Usage

```r
cells_stub(rows = TRUE)
```

Arguments

- **rows**
  
  The names of the rows that are to be targeted.

Details

When using any of the location helper functions with an appropriate function that has a `locations` argument, multiple locations can be targeted by enclosing several `cells_*()` helper functions in a `list()`. The following helper functions can be used to target cells (roughly in order from the top to the bottom of a table):

- **`cells_title()`**: targets the table title or the table subtitle depending on the value given to the `groups` argument (“title” or “subtitle”).
- **`cells_stubhead()`**: targets the stubhead location, a cell of which is only available when there is a stub; a label in that location can be created by using the `tab_stubhead()` function.
- **`cells_column_spanners()`**: targets the spanner column labels, which appear above the column labels.
- **`cells_column_labels()`**: targets the column labels.
- **`cells_row_groups()`**: targets the row group labels in any available row groups using the `groups` argument.
- **`cells_stub()`**: targets row labels in the table stub using the `rows` argument.
- **`cells_body()`**: targets data cells in the table body using intersections of columns and rows.
- **`cells_summary()`**: targets summary cells in the table body using the `groups` argument and intersections of columns and rows.
- **`cells_grand_summary()`**: targets cells of the table’s grand summary using intersections of columns and rows.

Value

A list object with the classes `cells_stub` and `location_cells`.

**Examples**

```
library(tidyr)

# Use `sza` to create a gt table; color
# all of the 'month' values in the table
# stub with `tab_style()`, using `cells_stub()`
# in 'locations' ('rows = TRUE' targets
# all stub rows)

sza %>%
dplyr::filter(latitude == 20 & tst <= "1000") %>%
dplyr::select(-latitude) %>%
dplyr::filter(!is.na(sza)) %>%
tidyr::spread(key = "tst", value = sza) %>%
gt(rownames_col = "month") %>%
fmt_missing(
  columns = TRUE,
  missing_text = ""
) %>%
tab_style(
  style = list(
    cell_fill(color = "darkblue"),
    cell_text(color = "white")
  ),
  locations = cells_stub(rows = TRUE)
)
```
Description

The `cells_stubhead()` function is used to target the table stubhead location when applying a footnote with `tab_footnote()` or adding custom style with `tab_style()`. The function is expressly used in each of those functions’ locations argument.

Usage

`cells_stubhead()`

Details

When using any of the location helper functions with an appropriate function that has a `locations` argument, multiple locations can be targeted by enclosing several `cells_*()` helper functions in a `list()`. The following helper functions can be used to target cells (roughly in order from the top to the bottom of a table):

- `cells_title()`: targets the table title or the table subtitle depending on the value given to the `groups` argument (“title” or “subtitle”).
- `cells_stubhead()`: targets the stubhead location, a cell of which is only available when there is a stub; a label in that location can be created by using the `tab_stubhead()` function.
- `cells_column_spanners()`: targets the spanner column labels, which appear above the column labels.
- `cells_column_labels()`: targets the column labels.
- `cells_row_groups()`: targets the row group labels in any available row groups using the `groups` argument.
- `cells_stub()`: targets row labels in the table stub using the `rows` argument.
- `cells_body()`: targets data cells in the table body using intersections of columns and rows.
- `cells_summary()`: targets summary cells in the table body using the `groups` argument and intersections of columns and rows.
- `cells_grand_summary()`: targets cells of the table’s grand summary using intersections of columns and rows.

### cells_summary

**Location helper for targeting group summary cells**

#### Description

The `cells_summary()` function is used to target the cells in a group summary and it is useful when applying a footnote with `tab_footnote()` or adding a custom style with `tab_style()`. The function is expressly used in each of those functions' `locations` argument.

#### Usage

```r
cells_summary(groups = TRUE, columns = TRUE, rows = TRUE)
```

#### Arguments

- **groups**  The names of the groups that the summary rows reside in.
- **columns**  The names of the columns that are to be targeted.
- **rows**    The names of the rows that are to be targeted.
Details

When using any of the location helper functions with an appropriate function that has a `locations` argument, multiple locations can be targeted by enclosing several `cells_*()` helper functions in a list(). The following helper functions can be used to target cells (roughly in order from the top to the bottom of a table):

- **cells_title()**: targets the table title or the table subtitle depending on the value given to the `groups` argument ("title" or "subtitle").
- **cells_stubhead()**: targets the stubhead location, a cell of which is only available when there is a stub; a label in that location can be created by using the `tab_stubhead()` function.
- **cells_column_spanners()**: targets the spanner column labels, which appear above the column labels.
- **cells_column_labels()**: targets the column labels.
- **cells_row_groups()**: targets the row group labels in any available row groups using the `groups` argument.
- **cells_stub()**: targets row labels in the table stub using the `rows` argument.
- **cells_body()**: targets data cells in the table body using intersections of columns and rows.
- **cells_summary()**: targets summary cells in the table body using the `groups` argument and intersections of columns and rows.
- **cells_grand_summary()**: targets cells of the table’s grand summary using intersections of columns and rows.

Value

A list object with the classes `cells_summary` and `location_cells`.

Examples

```r
# Use `countrypops` to create a gt table; add
# some styling to the summary data cells with
# with `tab_style()`, using `cells_summary()`
# in `locations`
```
tab_1 <-
countrypops %>%
dplyr::filter(
  country_name == "Japan",
  year < 1970)
%>%
dplyr::select(-contains("country"))
%>%
dplyr::mutate(
  decade = paste0(substr(year, 1, 3), "0s")
)
%>%
dplyr::group_by(decade)
%>%
gt(
  rowname_col = "year",
  groupname_col = "decade"
)
%>%
fmt_number(
  columns = vars(population),
  decimals = 0
)
%>%
summary_rows(
  groups = "1960s",
  columns = vars(population),
  fns = list("min", "max"),
  formatter = fmt_number,
  decimals = 0
)
%>%
tab_style(
  style = list(
    cell_text(style = "italic"),
    cell_fill(color = "lightblue")
  ),
  locations = cells_summary(
    groups = "1960s",
    columns = vars(population),
    rows = 1
  )
)
%>%
tab_style(
  style = list(
    cell_text(style = "italic"),
    cell_fill(color = "lightgreen")
  ),
  locations = cells_summary(
    groups = "1960s",
    columns = vars(population),
    rows = 2
  )
)
Description

The `cells_title()` function is used to target the table title or subtitle when applying a footnote with `tab_footnote()` or adding custom style with `tab_style()`. The function is expressly used in each of those functions' `locations` argument.

Usage

```r
cells_title(groups = c("title", "subtitle"))
```

Arguments

groups

We can either specify "title" or "subtitle" to target the title element or the subtitle element.

Details

When using any of the location helper functions with an appropriate function that has a `locations` argument, multiple locations can be targeted by enclosing several `cells_*()` helper functions in a `list()`. The following helper functions can be used to target cells (roughly in order from the top to the bottom of a table):

- **cells_title():** targets the table title or the table subtitle depending on the value given to the `groups` argument ("title" or "subtitle").
- **cells_stubhead():** targets the stubhead location, a cell of which is only available when there is a stub; a label in that location can be created by using the `tab_stubhead()` function.
- **cells_column_spanners():** targets the spanner column labels, which appear above the column labels.
- **cells_column_labels():** targets the column labels.
- **cells_row_groups():** targets the row group labels in any available row groups using the `groups` argument.
- **cells_stub():** targets row labels in the table stub using the `rows` argument.
- **cells_body():** targets data cells in the table body using intersections of columns and rows.
- **cells_summary():** targets summary cells in the table body using the `groups` argument and intersections of columns and rows.
- **cells_grand_summary():** targets cells of the table’s grand summary using intersections of columns and rows.

Value

A list object of classes `cells_title` and `location_cells`.

Examples

# Use `sp500` to create a gt table; add
# a header with a title, and then add a
# footnote to the title with `tab_footnote()`
# and `cells_title()` (in `locations`)

```r
tab_1 <-
  sp500 %>%
  dplyr::filter(
    date >= "2015-01-05" &
    date <= "2015-01-10"
  ) %>%
  dplyr::select(
    -c(adj_close, volume, high, low)
  ) %>%
  gt() %>%
  tab_header(title = "S&P 500") %>%
  tab_footnote(
    footnote = "All values in USD.",
    locations = cells_title(groups = "title")
  )
```

cell_borders

Helper for defining custom borders for table cells

Description

The cell_borders() helper function is to be used with the `tab_style()` function, which itself allows for the setting of custom styles to one or more cells. Specifically, the call to cell_borders() should be bound to the styles argument of `tab_style()`. The selection argument is where we define which borders should be modified (e.g., "left", "right", etc.). With that selection, the color, style, and weight of the selected borders can then be modified.

Usage

cell_borders(sides = "all", color = "#000000", style = "solid", weight = px(1))
Arguments

sides
The border sides to be modified. Options include "left", "right", "top", and "bottom". For all borders surrounding the selected cells, we can use the "all" option.

color, style, weight
The border color, style, and weight. The color can be defined with a color name or with a hexadecimal color code. The default color value is "#000000" (black). The style can be one of either "solid" (the default), "dashed", or "dotted". The weight of the border lines is to be given in pixel values (the \texttt{px()} helper function is useful for this. The default value for weight is "1px". Borders for any defined sides can be removed by supplying NULL to any of color, style, or weight.

Value
A list object of class \texttt{cell_styles}.

Examples

# Add horizontal border lines for
# all table body rows in `exibble`
tab_1 <-
exibble %>%
\texttt{gt()} %>%
tab_options(row.striping.include_table_body = FALSE) %>%
tab_style(    style = \texttt{cell_borders()},
      sides = c("top", "bottom"),
      color = "#BBBBBB",
      weight = \texttt{px}(1.5),
      style = "solid"
    ),
locations = \texttt{cells_body()}
      columns = everything(),
      rows = everything()
cell_fill

Helper for defining custom fills for table cells

Description

The `cell_fill()` helper function is to be used with the `tab_style()` function, which itself allows for the setting of custom styles to one or more cells. Specifically, the call to `cell_fill()` should be bound to the `styles` argument of `tab_style()`.

Usage

```r
cell_fill(color = "#D3D3D3", alpha = NULL)
```
Arguments

- **color**: The fill color. If nothing is provided, then "#D3D3D3" (light gray) will be used as a default.
- **alpha**: An optional alpha transparency value for the color as single value in the range of $0$ (fully transparent) to $1$ (fully opaque). If not provided the fill color will either be fully opaque or use alpha information from the color value if it is supplied in the #RRGGBBAA format.

Value

A list object of class `cell_styles`.

Examples

```r
# Use 'exibble' to create a gt table;
# add styles with 'tab_style()' and
# the 'cell_fill()' helper function

tab_1 <-
  exibble %>%
  dplyr::select(num, currency) %>%
  gt() %>%
  fmt_number(
    columns = vars(num, currency),
    decimals = 1
  ) %>%
  tab_style(
    style = cell_fill(color = "lightblue"),
    locations = cells_body(
      columns = vars(num),
      rows = num >= 5000
    )
  ) %>%
  tab_style(
    style = cell_fill(color = "gray85"),
    locations = cells_body(
      columns = vars(currency),
      rows = currency < 100
    )
  )
```
cell_text

Helper for defining custom text styles for table cells

Description

This helper function is to be used with the `tab_style()` function, which itself allows for the setting of custom styles to one or more cells. We can also define several styles within a single call of `cell_text()` and `tab_style()` will reliably apply those styles to the targeted element.

Usage

```r
cell_text(
  color = NULL,
  font = NULL,
  size = NULL,
  align = NULL,
  v_align = NULL,
  style = NULL,
  weight = NULL,
  stretch = NULL,
  indent = NULL,
  decorate = NULL,
  transform = NULL
)
```

Arguments

- **color** The text color.
- **font** The font or collection of fonts (subsequent font names are) used as fallbacks.
- **size** The size of the font. Can be provided as a number that is assumed to represent px values (or could be wrapped in the `px()` helper function. We can also use one of the following absolute size keywords: "xx-small", "x-small", "small", "medium", "large", "x-large", or "xx-large".
- **align** The text alignment. Can be one of either "center", "left", "right", or "justify".
- **v_align** The vertical alignment of the text in the cell. Options are "middle", "top", or "bottom".
- **style** The text style. Can be one of either "center", "normal", "italic", or "oblique".
- **weight** The weight of the font. Can be a text-based keyword such as "normal", "bold", "lighter", "bolder", or a numeric value between 1 and 1000, inclusive. Note that only variable fonts may support the numeric mapping of weight.
**stretch** Allows for text to either be condensed or expanded. We can use one of the following text-based keywords to describe the degree of condensation/expansion: "ultra-condensed", "extra-condensed", "condensed", "semi-condensed", "normal", "semi-expanded", "expanded", "extra-expanded", or "ultra-expanded". Alternatively, we can supply percentage values from 0% to 200%, inclusive. Negative percentage values are not allowed.

**indent** The indentation of the text. Can be provided as a number that is assumed to represent px values (or could be wrapped in the px() helper function. Alternatively, this can be given as a percentage (easily constructed with pct()).

**decorate** allows for text decoration effect to be applied. Here, we can use "overline", "line-through", or "underline".

**transform** Allows for the transformation of text. Options are "uppercase", "lowercase", or "capitalize".

**Value**

A list object of class cell_styles.

**Examples**

```r
# Use `exibble` to create a gt table;
# add styles with `tab_style()` and
# the `cell_text()` helper function

tab_1 <-
exibble %>%
dplyr::select(num, currency) %>%
gt() %>%
fmt_number(
  columns = vars(num, currency),
  decimals = 1
) %>%
tab_style(
  style = cell_text(weight = "bold"),
  locations = cells_body(
    columns = vars(num),
```
cols_align

```r
rows = num >= 5000
) %>%
tab_style(
  style = cell_text(style = "italic"),
  locations = cells_body(
    columns = vars(currency),
    rows = currency < 100
  )
)
```

---

cols_align  

Set the alignment of columns

Description

The individual alignments of columns (which includes the column labels and all of their data cells) can be modified. We have the option to align text to the left, the center, and the right. In a less explicit manner, we can allow `gt` to automatically choose the alignment of each column based on the data type (with the auto option).

Usage

```r
cols_align(data, align = c("auto", "left", "center", "right"), columns = TRUE)
```

Arguments

- **data**: A table object that is created using the `gt()` function.
- **align**: The alignment type. This can be any of "center", "left", or "right" for center-, left-, or center-alignment. Alternatively, the "auto" option (the default), will automatically align values in columns according to the data type (see the Details section for specifics on which alignments are applied).
- **columns**: An optional vector of column names for which the alignment should be applied. If nothing is supplied, or if columns is TRUE, then the chosen alignment affects all columns.

Details

When you create a `gt` table object using `gt()`, automatic alignment of column labels and their data cells is performed. By default, left-alignment is applied to columns of class character, Date, or POSIXct; center-alignment is for columns of class logical, factor, or list; and right-alignment is used for the numeric and integer columns.

Value

An object of class gt_tbl.
**Function ID**

4-1

**See Also**

Other Modify Columns: `cols_hide()`, `cols_label()`, `cols_merge_range()`, `cols_merge_uncert()`, `cols_merge()`, `cols_move_to_end()`, `cols_move_to_start()`, `cols_move()`, `cols_width()`

**Examples**

```r
# Use `countrypops` to create a gt table;
# align the `population` column data to
# the left
tab_1 <-
countrypops %>%
dplyr::select(-contains("code")) %>%
dplyr::filter(country_name == "Mongolia") %>%
tail(5) %>%
gt() %>%
cols_align(
    align = "left",
    columns = vars(population)
)
```

---

**cols_hide**

*Hide one or more columns*

**Description**

The `cols_hide()` function allows us to hide one or more columns from appearing in the final output table. While it's possible and often desirable to omit columns from the input table data before introduction to the `gt()` function, there can be cases where the data in certain columns is useful (as a column reference during formatting of other columns) but the final display of those columns is not necessary.

**Usage**

`cols_hide(data, columns)`

**Arguments**

- `data` A table object that is created using the `gt()` function.
- `columns` The column names to hide from the output display table. The order of the remaining columns will be preserved. Values provided that do not correspond to column names will be disregarded.
Details

The hiding of columns is internally a rendering directive, so, all columns that are 'hidden' are still accessible and useful in any expression provided to a `rows` argument. Furthermore, the `cols_hide()` function (as with many `gt` functions) can be placed anywhere in a pipeline of `gt` function calls (acting as a promise to hide columns when the timing is right). However there's perhaps greater readability when placing this call closer to the end of such a pipeline.

Value

An object of class `gt_tbl`.

Figures

Function ID

4-7

See Also

Other Modify Columns: `cols_align()`, `cols_label()`, `cols_merge_range()`, `cols_merge_uncert()`, `cols_merge()`, `cols_move_to_end()`, `cols_move_to_start()`, `cols_move()`, `cols_width()`

Examples

```r
# Use `countrypops` to create a `gt` table;
# Hide the columns `country_code_2` and
# `country_code_3`

tab_1 <- countrypops %>%
  dplyr::filter(country_name == "Mongolia") %>%
  tail(5) %>%
  gt() %>%
  cols_hide(
    columns = vars(
      country_code_2, country_code_3)
  )

# Use `countrypops` to create a `gt` table;
# Use the `population` column to provide
# the conditional placement of footnotes,
# then hide that column and one other

tab_2 <- countrypops %>%
  dplyr::filter(country_name == "Mongolia") %>%
  tail(5) %>%
  gt() %>%
  cols_hide(
    columns = vars(country_code_3, population)
  ) %>%
```
Description

Column labels can be modified from their default values (the names of the columns from the input table data). When you create a `gt` table object using `gt()`, column names effectively become the column labels. While this serves as a good first approximation, column names aren’t often appealing as column labels in a `gt` output table. The `cols_label()` function provides the flexibility to relabel one or more columns and we even have the option to use the `md()` or `html()` helper functions for rendering column labels from Markdown or using HTML.

Usage

```r
cols_label(data, ..., .list = list2(...))
```

Arguments

- `data`: A table object that is created using the `gt()` function.
- `...`: One or more named arguments of column names from the input data table along with their labels for display as the column labels. We can optionally wrap the column labels with `md()` (to interpret text as Markdown) or `html()` (to interpret text as HTML).
- `.list`: Allows for the use of a list as an input alternative to `...`.

Details

It’s important to note that while columns can be freely relabeled, we continue to refer to columns by their original column names. Column names in a tibble or data frame must be unique whereas column labels in `gt` have no requirement for uniqueness (which is useful for labeling columns as, say, measurement units that may be repeated several times—usually under different spanner column labels). Thus, we can still easily distinguish between columns in other `gt` function calls (e.g., in all of the `fmt*()` functions) even though we may lose distinguishability in column labels once they have been relabeled.

Value

An object of class `gt_tbl`.

Examples

# Use `countrypops` to create a gt table;
# label all the table's columns to
# present better
tab_1 <-
countrypops %>%
dplyr::select(-contains("code")) %>%
dplyr::filter(country_name == "Mongolia") %>%
tail(5) %>%
gt() %>%
cols_label(
  country_name = "Name",
  year = "Year",
  population = "Population"
)

# Use `countrypops` to create a gt table;
# label columns as before but make them
# bold with markdown formatting
tab_2 <-
countrypops %>%
dplyr::select(-contains("code")) %>%
dplyr::filter(country_name == "Mongolia") %>%
tail(5) %>%
gt() %>%
cols_label(
  country_name = md("**Name**"),
  year = md("**Year**"),
  population = md("**Population**")
)
Description

This function takes input from two or more columns and allows the contents to be merged them into a single column, using a pattern that specifies the formatting. We can specify which columns to merge together in the `columns` argument. The string-combining pattern is given in the `pattern` argument. The first column in the `columns` series operates as the target column (i.e., will undergo mutation) whereas all following columns will be untouched. There is the option to hide the non-target columns (i.e., second and subsequent columns given in `columns`).

Usage

```r
cols_merge(
  data,
  columns,
  hide_columns = columns[-1],
  pattern = paste0("{", seq_along(columns), "}", collapse = " ")
)
```

Arguments

data         A table object that is created using the `gt()` function.
columns      The columns that will participate in the merging process. The first column name provided will be the target column (i.e., undergo mutation) and the other columns will serve to provide input.
hide_columns Any column names provided here will have their state changed to hidden (via internal use of `cols_hide()` if they aren't already hidden. This is convenient if the shared purpose of these specified columns is only to provide string input to the target column.
pattern      A formatting pattern that specifies the arrangement of the `columns` values and any string literals. We need to use column numbers (corresponding to the position of columns provided in `columns`) within the pattern. These indices are to be placed in curly braces (e.g., `{1}`). All characters outside of braces are taken to be string literals.

Details

There are two other column-merging functions that offer specialized behavior that is optimized for common table tasks: `cols_merge_range()` and `cols_merge_uncert()`. These functions operate similarly, where the non-target columns can be optionally hidden from the output table through the `autohide` option.

Value

An object of class `gt_tbl`.

**Examples**

```r
# Use `sp500` to create a gt table;
# merge the `open` & `close` columns
# together, and, the `low` & `high`
# columns (putting an em dash between
# both); rename the columns
	tab_1 <-
	sp500 %>%
	dplyr::slice(50:55) %>%
	dplyr::select(-volume, -adj_close) %>%

gt() %>%
cols_merge(

columns = vars(open, close),
hide_columns = vars(close),
pattern = "{1}&mdash;{2}"
)
%>%
cols_merge(

columns = vars(low, high),
hide_columns = vars(high),
pattern = "{1}&mdash;{2}"
)
%>%
cols_label(

close = "open/close",
low = "low/high"
)
```

---

**Description**

The `cols_merge_range()` function is a specialized variant of the `cols_merge()` function. It operates by taking two columns that constitute a range of values (`col_begin` and `col_end`) and merges them into a single column. What results is a column containing both values separated by a long dash (e.g., 12.0 — 20.0). The column specified in `col_end` is dropped from the output table.

**Usage**

```r
cols_merge_range(data, col_begin, col_end, sep = "--", autohide = TRUE)
```
**Arguments**

- **data** A table object that is created using the `gt()` function.
- **col_begin** A column that contains values for the start of the range.
- **col_end** A column that contains values for the end of the range.
- **sep** The separator text that indicates the values are ranged. The default value of 
  "--" indicates that an en dash will be used for the range separator. Using "---" will
  be taken to mean that an em dash should be used. Should you want these special
  symbols to be taken literally, they can be supplied within the base `I()` function.
- **autohide** An option to automatically hide the column specified as `col_end`. Any columns
  with their state changed to hidden will behave the same as before, they just won’t
  be displayed in the finalized table.

**Details**

This function could be somewhat replicated using `cols_merge()`, however, `cols_merge_range()`
employs the following specialized operations for NA handling:

1. NAs in `col_begin` (but not `col_end`) result in a display of only
2. NAs in `col_end` (but not `col_begin`) result in a display of only the `col_begin` values only for
   the merged column (this is the converse of the previous)
3. NAs both in `col_begin` and `col_end` result in missing values for the merged column

Any resulting NA values in the `col_begin` column following the merge operation can be easily
formatted using the `fmt_missing()` function. Separate calls of `fmt_missing()` can be used for the
`col_begin` and `col_end` columns for finer control of the replacement values.

This function is part of a set of three column-merging functions. The other two are the general
`cols_merge()` function and the specialized `cols_merge_uncert()` function. These functions op-
erate similarly, where the non-target columns can be optionally hidden from the output table through
the `hide_columns` or `autohide` options.

**Value**

An object of class `gt_tbl`.

`cols_merge()`, `cols_move_to_end()`, `cols_move_to_start()`, `cols_move()`, `cols_width()`
Examples

# Use `gtcars` to create a gt table,
# keeping only the `model`, `mpg_c`,
# and `mpg_h` columns; merge the mpg
# columns together as a single range
# column (which is labeled as MPG,
# in italics)

tab_1 <-
gtcars %>%
dplyr::select(model, starts_with("mpg")) %>%
dplyr::slice(1:8) %>%
gt() %>%
cols_merge_range(
  col_begin = vars(mpg_c),
  col_end = vars(mpg_h)
) %>%
cols_label(
  mpg_c = md("*MPG*")
)

---

cols_merge_uncert

Merge two columns to a value & uncertainty column

Description

The `cols_merge_uncert()` function is a specialized variant of the `cols_merge()` function. It operates by taking a base value column (`col_val`) and an uncertainty column (`col_uncert`) and merges them into a single column. What results is a column with values and associated uncertainties (e.g., 12.0 ± 0.1), and, the column specified in `col_uncert` is dropped from the output table.

Usage

cols_merge_uncert(data, col_val, col_uncert, sep = " +/ - ", autohide = TRUE)

Arguments

data A table object that is created using the `gt()` function.
col_val A single column name that contains the base values. This is the column where values will be mutated.
col_uncert A single column name that contains the uncertainty values. These values will be combined with those in `col_val`. We have the option to automatically hide the `col_uncert` column through `autohide`.
sep The separator text that contains the uncertainty mark. The default value of " +/ - " indicates that an appropriate plus/minus mark will be used depending on the output context. Should you want this special symbol to be taken literally, it can be supplied within the base `I()` function.
autohide

An option to automatically hide the column specified as col_uncert. Any columns with their state changed to hidden will behave the same as before, they just won’t be displayed in the finalized table.

Details

This function could be somewhat replicated using cols_merge(), however, cols_merge_uncert() employs the following specialized semantics for NA handling:

1. NAs in col_val result in missing values for the merged column (e.g., NA + 0.1 = NA)
2. NAs in col_uncert (but not col_val) result in base values only for the merged column (e.g., 12.0 + NA = 12.0)
3. NAs both col_val and col_uncert result in missing values for the merged column (e.g., NA + NA = NA)

Any resulting NA values in the col_val column following the merge operation can be easily formatted using the fmt_missing() function.

This function is part of a set of three column-merging functions. The other two are the general cols_merge() function and the specialized cols_merge_range() function. These functions operate similarly, where the non-target columns can be optionally hidden from the output table through the hide_columns or autohide options.

Value

An object of class gt_tbl.

Other Modify Columns: cols_align(), cols_hide(), cols_label(), cols_merge_range(), cols_merge(), cols_move_to_end(), cols_move_to_start(), cols_move(), cols_width()

Examples

# Use `exibble` to create a gt table,
# keeping only the `currency` and `num`
# columns; merge columns into one with
# a base value and uncertainty (after
# formatting the `num` column)

```r
tab_1 <-
exibble %>%
dplyr::select(currency, num) %>%
dplyr::slice(1:7) %>%
```
cols_move

```r
gt() %>%
  fmt_number(
    columns = vars(num),
    decimals = 3,
    use_seps = FALSE
  ) %>%
cols_merge_uncert(
    col_val = vars(currency),
    col_uncert = vars(num)
  ) %>%
cols_label(
    currency = "value + uncert."
  )
```

| cols_move | Move one or more columns |

**Description**

On those occasions where you need to move columns this way or that way, we can make use of the `cols_move()` function. While it’s true that the movement of columns can be done upstream of `gt`, it is much easier and less error prone to use the function provided here. The movement procedure here takes one or more specified columns (in the `columns` argument) and places them to the right of a different column (the `after` argument). The ordering of the `columns` to be moved is preserved, as is the ordering of all other columns in the table.

**Usage**

`cols_move(data, columns, after)`

**Arguments**

- **data** A table object that is created using the `gt()` function.
- **columns** The column names to move to as a group to a different position. The order of the remaining columns will be preserved.
- **after** A column name used to anchor the insertion of the moved columns. All of the moved columns will be placed to the right of this column.

**Details**

The columns supplied in `columns` must all exist in the table and none of them can be in the `after` argument. The `after` column must also exist and only one column should be provided here. If you need to place one or columns at the beginning of the column series, the `cols_move_to_start()` function should be used. Similarly, if those columns to move should be placed at the end of the column series then use `cols_move_to_end()`.
Value

An object of class gt_tbl.

Other Modify Columns: `cols_align()`, `cols_hide()`, `cols_label()`, `cols_merge_range()`, `cols_merge_uncert()`, `cols_merge()`, `cols_move_to_end()`, `cols_move_to_start()`, `cols_width()`

Examples

```r
# Use 'countrypops' to create a gt table;
# With the remaining columns, position
# 'population' after 'country_name'
tab_1 <-
countrypops %>%
dplyr::select(-contains("code")) %>%
dplyr::filter(country_name == "Mongolia") %>%
tail(5) %>%
gt() %>%
cols_move(
    columns = vars(population),
    after = vars(country_name)
)
```

cols_move_to_end | Move one or more columns to the end

Description

It's possible to move a set of columns to the end of the column series, we only need to specify which columns are to be moved. While this can be done upstream of `gt`, this function makes the process much easier and it's less error prone. The ordering of the columns that are moved to the end is preserved (same with the ordering of all other columns in the table).

Usage

```r
cols_move_to_end(data, columns)
```
cols_move_to_end

Arguments

- **data**: A table object that is created using the `gt()` function.
- **columns**: The column names to move to the right-most side of the table. The order in which columns are provided will be preserved (as is the case with the remaining columns).

Details

The columns supplied in `columns` must all exist in the table. If you need to place one or columns at the start of the column series, the `cols_move_to_start()` function should be used. More control is offered with the `cols_move()` function, where columns could be placed after a specific column.

Value

An object of class `gt_tbl`.

Other Modify Columns: `cols_align()`, `cols_hide()`, `cols_label()`, `cols_merge_range()`, `cols_merge_uncert()`, `cols_merge()`, `cols_move_to_start()`, `cols_move()`, `cols_width()`

Examples

```r
# Use 'countrypops' to create a gt table;
# With the remaining columns, move the
# 'year' column to the end
tbl_1 <-
countrypops %>%
dplyr::select(-contains("code")) %>%
dplyr::filter(country_name == "Mongolia") %>%
tail(5) %>%
gt() %>%
cols_move_to_end(  
columns = vars(year)
)
```

```r
# Use 'countrypops' to create a gt table;
# With the remaining columns, move 'year'
# and 'country_name' to the end
tbl_2 <-
countrypops %>%
dplyr::select(-contains("code")) %>%
dplyr::filter(country_name == "Mongolia") %>%
```
cols_move_to_start

Description
We can easily move set of columns to the beginning of the column series and we only need to specify which columns. It's possible to do this upstream of `gt`, however, it is easier with this function and it presents less possibility for error. The ordering of the columns that are moved to the start is preserved (same with the ordering of all other columns in the table).

Usage
```r
cols_move_to_start(data, columns)
```

Arguments

data A table object that is created using the `gt()` function.

columns The column names to move to the left-most side of the table. The order in which columns are provided will be preserved (as is the case with the remaining columns).

Details
The columns supplied in `columns` must all exist in the table. If you need to place one or columns at the end of the column series, the `cols_move_to_end()` function should be used. More control is offered with the `cols_move()` function, where columns could be placed after a specific column.

Examples

```r
# Use `countrypops` to create a gt table;
# With the remaining columns, move the
# `year` column to the start
tabl1 <-
countrypops %>%
dplyr::select(-contains("code")) %>%
dplyr::filter(country_name == "Mongolia") %>%
tail(5) %>%
gt() %>%
cols_move_to_start(
  columns = vars(year)
)

# Use `countrypops` to create a gt table;
# With the remaining columns, move `year`
# and `population` to the start
tabl2 <-
countrypops %>%
dplyr::select(-contains("code")) %>%
dplyr::filter(country_name == "Mongolia") %>%
tail(5) %>%
gt() %>%
cols_move_to_start(
  columns = vars(year, population)
)
```

---

cols_width

Set the widths of columns

Description

Manual specifications of column widths can be performed using the `cols_width()` function. We choose which columns get specific widths (in pixels, usually by use of the `px()` helper function). Width assignments are supplied in ... through two-sided formulas, where the left-hand side defines the target columns and the right-hand side is a single width value in pixels.

Usage

cols_width(data, ..., .list = list2(...))
Arguments

data A table object that is created using the `gt()` function.

Expressions for the assignment of column widths for the table columns in `data`. Two-sided formulas (e.g., `<LHS> ~ <RHS>`) can be used, where the left-hand side corresponds to selections of columns and the right-hand side evaluates to single-length character values in the form `{##}px` (i.e., pixel dimensions); the `px()` helper function is best used for this purpose. Column names should be enclosed in `vars()`. The column-based select helpers `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()` can be used in the LHS. Subsequent expressions that operate on the columns assigned previously will result in overwriting column width values (both in the same `cols_width()` call and across separate calls). All other columns can be assigned a default width value by using `TRUE` or `everything()` on the left-hand side.

.list Allows for the use of a list as an input alternative to `...`.

Details

Normally, column widths are automatically set to span across the width of the container (both table and container widths can be individually modified with the `table.width` and `container.width` options within `tab_options()`). When using `cols_width()` though, the `table.width` option is disregarded in favor of the pixel values set for each column.

Value

An object of class `gt_tbl`.

Other Modify Columns: `cols_align()`, `cols_hide()`, `cols_label()`, `cols_merge_range()`, `cols_merge_uncert()`, `cols_merge()`, `cols_move_to_end()`, `cols_move_to_start()`, `cols_move()`

Examples

```r
# Use `exibble` to create a gt table;
# with named arguments in `...`, we
# can specify the exact widths for
# table columns (using `everything()`
# or `TRUE` at the end will capture
# all remaining columns)

tab_1 <- exibble %>%
```
countrypops

```r
dplyr::select(
  num, char, date,
  datetime, row
) %>%
gt() %>%
cols_width(
  vars(num) ~ px(150),
  ends_with("r") ~ px(100),
  starts_with("date") ~ px(200),
  everything() ~ px(60)
)
```

---

**countrypops**

*Yearly populations of countries from 1960 to 2017*

---

**Description**

A dataset that presents yearly, total populations of countries. Total population is based on counts of all residents regardless of legal status or citizenship. Country identifiers include the English-language country names, and the 2- and 3-letter ISO 3166-1 country codes. Each row contains a population value for a given year (from 1960 to 2017). Any NA values for populations indicate the non-existence of the country during that year.

**Usage**

countrypops

**Format**

A tibble with 12470 rows and 5 variables:

*country_name* Name of the country

*country_code_2* The 2-letter ISO 3166-1 country code

*country_code_3* The 3-letter ISO 3166-1 country code

*year* The year for the population estimate

*population* The population estimate, midway through the year

# Here is a glimpse at the data
# available in `countrypops`
depr::glimpse(countrypops)

---

```r
# Supply a custom currency symbol to `fmt_currency()`
currency
```

Description

The `currency()` helper function makes it easy to specify a context-aware currency symbol to the `currency` argument of `fmt_currency()`. Since `gt` can render tables to several output formats, `currency()` allows for different variations of the custom symbol based on the output context (which are html, latex, rtf, and default). The number of decimal places for the custom currency defaults to 2, however, a value set for the `decimals` argument of `fmt_currency()` will take precedence.

Usage

`currency(..., .list = list2(...))`

Arguments

`...` One or more named arguments using output contexts as the names and currency symbol text as the values.

`.list` Allows for the use of a list as an input alternative to `...`

Details

We can use any combination of html, latex, rtf, and default as named arguments for the currency text in each of the namesake contexts. The default value is used as a fallback when there doesn't exist a dedicated currency text value for a particular output context (e.g., when a table is rendered as HTML and we use `currency(latex = "LTC", default = "ltc"), the currency symbol will be "ltc". For convenience, if we provide only a single string without a name, it will be taken as the default (i.e., `currency("ltc")` is equivalent to `currency(default = "ltc")`). However, if we were to specify currency strings for multiple output contexts, names are required each and every context.

Value

A list object of class `gt_currency`.

Figures
**data_color**

Set data cell colors using a palette or a color function

---

**Description**

It’s possible to add color to data cells according to their values. The `data_color()` function colors all rows of any columns supplied. There are two ways to define how cells are colored: (1) through the use of a supplied color palette, and (2) through use of a color mapping function available from the scales package. The first method colorizes cell data according to whether values are character or numeric. The second method provides more control over how cells are colored since we provide an explicit color function and thus other requirements such as bin counts, cut points, or a numeric domain. Finally, we can choose whether to apply the cell-specific colors to either the cell background or the cell text.

**Usage**

```r
data_color(
  data,
  columns,
  colors,
)```

**Examples**

```r
# Use `exibble` to create a gt table;
# format the `currency` column to have
# currency values in guilder (a defunct
# Dutch currency)

exibble %>%
gt() %>%
fmt_currency(
  columns = vars(currency),
  currency = currency(
    html = "ƒ",
    default = "f"),
  decimals = 2
)```

---

**See Also**

Other Helper Functions: `adjust_luminance()`, `cell_borders()`, `cell_fill()`, `cell_text()`, `cells_body()`, `cells_column_labels()`, `cells_column_spanners()`, `cells_grand_summary()`, `cells_row_groups()`, `cells_stubhead()`, `cells_stub()`, `cells_summary()`, `cells_title()`, `escape_latex()`, `gt_latex_dependencies()`, `html()`, `md()`, `pct()`, `px()`, `random_id()`
```r
alpha = NULL,
apply_to = "fill",
autocolor_text = TRUE
)

Arguments

data  A table object that is created using the `gt()` function.
columns The columns wherein changes to cell data colors should occur.
colors Either a color mapping function from the `scales` package or a vector of colors to use for each distinct value or level in each of the provided columns. The color mapping functions are: `scales::col_numeric()`, `scales::col_bin()`, `scales::col_factor()`, and `scales::col_quantile()`. If providing a vector of colors as a palette, each color value provided must either be a color name (in the set of colors provided by `grDevices::colors()`) or a hexadecimal string in the form of "#RRGGBB" or "#RRGGBBAA".
alpha An optional, fixed alpha transparency value that will be applied to all of the colors provided (regardless of whether a color palette was directly supplied or generated through a color mapping function).
apply_to Which style element should the colors be applied to? Options include the cell background (the default, given as fill) or the cell text (text).
autocolor_text An option to let `gt` modify the coloring of text within cells undergoing background coloring. This will in some cases yield more optimal text-to-background color contrast. By default, this is set to `TRUE`.

Details

The `col_*()` color mapping functions from the scales package can be used in the `colors` argument. These functions map data values (numeric or factor/character) to colors according to the provided palette.

- `scales::col_numeric()`: provides a simple linear mapping from continuous numeric data to an interpolated palette.
- `scales::col_bin()`: provides a mapping of continuous numeric data to value-based bins. This internally uses the `base::cut()` function.
- `scales::col_quantile()`: provides a mapping of continuous numeric data to quantiles. This internally uses the `stats::quantile()` function.
- `scales::col_factor()`: provides a mapping of factors to colors. If the palette is discrete and has a different number of colors than the number of factors, interpolation is used.

By default, `gt` will choose the ideal text color (for maximal contrast) when colorizing the background of data cells. This option can be disabled by setting `autocolor_text` to `FALSE`.

Choosing the right color palette can often be difficult because it’s both hard to discover suitable palettes and then obtain the vector of colors. To make this process easier we can elect to use the `paletteer` package, which makes a wide range of palettes from various R packages readily available. The `info_paletteer()` information table allows us to easily inspect all of the discrete color
palettes available in `paletteer`. We only then need to specify the package and palette when calling the `paletteer::paletteer_d()` function, and, we get the palette as a vector of hexadecimal colors.

**Value**

An object of class `gt_tbl`.

**Examples**

```r
# library(paletteer)

# Use `countrypops` to create a gt table;
# Apply a color scale to the `population` column with `scales::col_numeric`,
# four supplied colors, and a domain

tab_1 <- countrypops %>%
  dplyr::filter(country_name == "Mongolia") %>%
  dplyr::select(-contains("code")) %>%
  tail(10) %>%
  gt() %>%
  data_color(  
    columns = vars(population),
    colors = scales::col_numeric(  
      palette = c("red", "orange", "green", "blue"),
      domain = c(0.2E7, 0.4E7)
    )
  )

# Use `pizzaplace` to create a gt table;
# Apply colors from the `red_material` palette (in the `ggsci` pkg but
# more easily gotten from the `paletteer` package, info at `info_paletteer()`) to
# `sold` and `income` columns; setting
# the `domain` of `scales::col_numeric()` to `NULL` will use the bounds of the
```
# available data as the domain
tab_2 <-
pizzaplace %>%
dplyr::filter(
  type %in% c("chicken", "supreme")
) %>%
dplyr::group_by(type, size) %>%
dplyr::summarize(
  sold = dplyr::n(),
  income = sum(price)
) %>%
getrownames_col = "size") %>%
data_color(
  columns = vars(sold, income),
  colors = scales::col_numeric(
    palette = paletteer::paletteer_d(
      palette = "ggsci::red_material"
    ) %>% as.character(),
    domain = NULL
  )
)

---

### escape_latex

**Perform LaTeX escaping**

**Description**

Text may contain several characters with special meanings in LaTeX. This function will transform a character vector so that it is safe to use within LaTeX tables.

**Usage**

`escape_latex(text)`

**Arguments**

- `text` a character vector containing the text that is to be LaTeX-escaped.

**Value**

A character vector.

**Function ID**

7-20
exibble

extract_summary

### Examples

```r
# Here is a glimpse at the data
# available in `exibble`
dplyr::glimpse(exibble)
```

---

**extract_summary**  
Extract a summary list from a `gt` object

---

**Description**

Get a list of summary row data frames from a `gt_tbl` object where summary rows were added via the `summary_rows()` function. The output data frames contain the `groupname` and `rowname` columns, whereby `rowname` contains descriptive stub labels for the summary rows.

**Usage**

```r
extract_summary(data)
```

**Arguments**

- `data`  
  A table object that is created using the `gt()` function.

**Value**

A list of data frames containing summary data.

---

**Figures**

**Function ID**

13-5

**See Also**

Other Export Functions: `as_latex()`, `as_raw_html()`, `as_rtf()`, `gtsave()`

**Examples**

```r
# Use `sp500` to create a gt table with
# row groups; create summary rows by row
# group (`min`, `max`, `avg`) and then
# extract the summary rows as a list
# object
summary_extracted <-
  sp500 %>%
dplyr::filter(
```
Set a column format with a formatter function

**Description**

The `fmt()` function provides greater control in formatting raw data values than any of the specialized `fmt_*()` functions that are available in `gt`. Along with the `columns` and `rows` arguments that provide some precision in targeting data cells, the `fns` argument allows you to define one or more functions for manipulating the raw data. If providing a single function to `fns`, the recommended format is in the form: `fns = function(x) ...`. This single function will format the targeted data cells the same way regardless of the output format (e.g., HTML, LaTeX, RTF). If you require formatting of `x` that depends on the output format, a list of functions can be provided for the
html, latex, and default contexts. This can be in the form of 
\[
\text{fns = list(html = function(x) ...}, \text{latex = function(x) ...}, \text{default = function(x) ...}).
\]
In this multiple-function case, we recommended including the default function as a fallback if all contexts aren’t provided.

Usage

\[
\text{fmt(data, columns = NULL, rows = NULL, fns)}
\]

Arguments

data A table object that is created using the \texttt{gt()} function.
columns The columns to format. Can either be a series of column names provided in \texttt{vars()}, a vector of column indices, or a helper function focused on selections. The select helper functions are: \texttt{starts_with()}, \texttt{ends_with()}, \texttt{contains()}, \texttt{matches()}, \texttt{one_of()}, and \texttt{everything()}.
rows Optional rows to format. Not providing any value results in all rows in columns being formatted. Can either be a vector of row captions provided \texttt{c()}, a vector of row indices, or a helper function focused on selections. The select helper functions are: \texttt{starts_with()}, \texttt{ends_with()}, \texttt{contains()}, \texttt{matches()}, \texttt{one_of()}, and \texttt{everything()}. We can also use expressions to filter down to the rows we need (e.g., \texttt{[colname_1] > 100 & [colname_2] < 50}).
fns Either a single formatting function or a named list of functions.

Details

As with all of the fmt_*() functions, targeting of values is done through columns and additionally by rows (if nothing is provided for rows then entire columns are selected). A number of helper functions exist to make targeting more effective. Conditional formatting is possible by providing a conditional expression to the rows argument. See the Arguments section for more information on this.

Value

An object of class \texttt{gt_tbl}.

Other Format Data: \texttt{data_color()}, \texttt{fmt_currency()}, \texttt{fmt_datetime()}, \texttt{fmt_date()}, \texttt{fmt_markdown()}, \texttt{fmt_missing()}, \texttt{fmt_number()}, \texttt{fmt_passsthrough()}, \texttt{fmt_percent()}, \texttt{fmt_scientific()}, \texttt{fmt_time()}, \texttt{text_transform()}
Examples

# Use `exibble` to create a gt table;
# format the numeric values in the `num`
# column with a function supplied to
# the `fns` argument

```r
tab_1 <-
exibble %>%
dplyr::select(-row, -group) %>%
gt() %>%
fmt(
     columns = vars(num),
     fns = function(x) {
         paste0('"', x * 1000, '"')
     }
)
```

fmt_currency

Format values as currencies

Description

With numeric values in a `gt` table, we can perform currency-based formatting. This function supports both automatic formatting with a three-letter or numeric currency code. We can also specify a custom currency that is formatted according to the output context with the `currency()` helper function. Numeric formatting facilitated through the use of a locale ID. We have fine control over the conversion from numeric values to currency values, where we could take advantage of the following options:

- the currency: providing a currency code or common currency name will procure the correct currency symbol and number of currency subunits; we could also use the `currency()` helper function to specify a custom currency
- currency symbol placement: the currency symbol can be placed before or after the values
- decimals/subunits: choice of the number of decimal places, and a choice of the decimal symbol, and an option on whether to include or exclude the currency subunits (decimal portion)
- negative values: choice of a negative sign or parentheses for values less than zero
- digit grouping separators: options to enable/disable digit separators and provide a choice of separator symbol
- scaling: we can choose to scale targeted values by a multiplier value
- large-number suffixing: larger figures (thousands, millions, etc.) can be autoscaled and decorated with the appropriate suffixes
- pattern: option to use a text pattern for decoration of the formatted currency values
- locale-based formatting: providing a locale ID will result in currency formatting specific to the chosen locale

We can use the `info_currencies()` function for a useful reference on all of the possible inputs to the `currency` argument.
Usage

```r
fmt_currency(
  data,
  columns,
  rows = NULL,
  currency = "USD",
  use_subunits = TRUE,
  accounting = FALSE,
  decimals = NULL,
  use_seps = TRUE,
  scale_by = 1,
  suffixing = FALSE,
  pattern = "(x)",
  sep_mark = ",",
  dec_mark = ".",
  placement = "left",
  incl_space = FALSE,
  locale = NULL
)
```

Arguments

- **data**: A table object that is created using the `gt()` function.
- **columns**: The columns to format. Can either be a series of column names provided in `vars()`, a vector of column indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`.
- **rows**: Optional rows to format. Not providing any value results in all rows in columns being formatted. Can either be a vector of row captions provided `c()`, a vector of row indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`. We can also use expressions to filter down to the rows we need (e.g., `[colname_1] > 100 & [colname_2] < 50`).
- **currency**: The currency to use for the numeric value. This input can be supplied as a 3-letter currency code (e.g., "USD" for U.S. Dollars, "EUR" for the Euro currency). Use `info_currencies()` to get an information table with all of the valid currency codes and examples of each. Alternatively, we can provide a common currency name (e.g., "dollar", "pound", "yen", etc.) to simplify the process. Use `info_currencies()` with the `type == "symbol"` option to view an information table with all of the supported currency symbol names along with examples. We can also use the `currency()` helper function to specify a custom currency, where the string could vary across output contexts. For example, using `currency(html = "&fnof;", default = "f")` would give us a suitable glyph for the Dutch guilder in an HTML output table, and it would simply be the letter "f" in all other output contexts). Please note that `decimals` will default to 2 when using the `currency()` helper function. If nothing is provided to `currency` then "USD" (U.S. dollars) will be used.
use_subunits  An option for whether the subunits portion of a currency value should be displayed. By default, this is TRUE.

accounting  An option to use accounting style for currency values. With FALSE (the default), negative values will be shown with a minus sign. Using accounting = TRUE will put negative values in parentheses.

decimals  An option to specify the exact number of decimal places to use. The default number of decimal places is 2.

use_seps  An option to use digit group separators. The type of digit group separator is set by sep_mark and overridden if a locale ID is provided to locale. This setting is TRUE by default.
scale_by  A value to scale the input. The default is 1.0. All numeric values will be multiplied by this value first before undergoing formatting. This value will be ignored if using any of the suffixing options (i.e., where suffixing is not set to FALSE).

suffixing  An option to scale and apply suffixes to larger numbers (e.g., 1924000 can be transformed to 1.92M). This option can accept a logical value, where FALSE (the default) will not perform this transformation and TRUE will apply thousands (K), millions (M), billions (B), and trillions (T) suffixes after automatic value scaling. We can also specify which symbols to use for each of the value ranges by using a character vector of the preferred symbols to replace the defaults (e.g., c("k", "M", "B", "T")).

Including NA values in the vector will ensure that the particular range will either not be included in the transformation (e.g., c(NA,"M", "B", "T") won’t modify numbers in the thousands range) or the range will inherit a previous suffix (e.g., with c("K", "M", NA, "T"), all numbers in the range of millions and billions will be in terms of millions).

Any use of suffixing (where it is not set expressly as FALSE) means that any value provided to scale_by will be ignored.

pattern  A formatting pattern that allows for decoration of the formatted value. The value itself is represented by \{x\} and all other characters are taken to be string literals.

sep_mark  The mark to use as a separator between groups of digits (e.g., using sep_mark = ",," with 1000 would result in a formatted value of 1,000).

dec_mark  The character to use as a decimal mark (e.g., using dec_mark = ",," with 0.152 would result in a formatted value of 0.152).

placement  The placement of the currency symbol. This can be either be left (the default) or right.

incl_space  An option for whether to include a space between the value and the currency symbol. The default is to not introduce a space character.

locale  An optional locale ID that can be used for formatting the value according the locale’s rules. Examples include "en_US" for English (United States) and "fr_FR" for French (France). The use of a valid locale ID will override any values provided in sep_mark and dec_mark. We can use the info_locales() function as a useful reference for all of the locales that are supported.
Details

Targeting of values is done through columns and additionally by rows (if nothing is provided for rows then entire columns are selected). A number of helper functions exist to make targeting more effective. Conditional formatting is possible by providing a conditional expression to the `rows` argument. See the Arguments section for more information on this.

Value

An object of class `gt_tbl`.

Examples

```r
# Use `exibble` to create a gt table;
# format the `currency` column to have
# currency values in euros (EUR)
tab_1 <-
exibble %>%
  gt() %>%
  fmt_currency(
    columns = vars(currency),
    currency = "EUR"
  )

# Use `exibble` to create a gt table;
# Keep only the `num` and `currency`
# columns, then, format those columns
# using the "CNY" and "GBP" currencies
tab_2 <-
exibble %>%
dplyr::select(num, currency) %>%
  gt() %>%
  fmt_currency(
    columns = vars(num),
    currency = "CNY"
  ) %>%
  fmt_currency(
    columns = vars(currency),
    currency = "GBP"
  )
```
fmt_date

```r
currency = "GBP"
```

---

**fmt_date**

Format values as dates

---

**Description**

Format input date values that are either of the Date type, or, are character-based and expressed according to the ISO 8601 date format (YYYY-MM-DD). Once the appropriate data cells are targeted with columns (and, optionally, rows), we can simply apply a preset date style to format the dates. The following date styles are available for simpler formatting of ISO dates (all using the input date of 2000-02-29 in the example output dates):

1. iso: 2000-02-29
2. wday_month_day_year: Tuesday, February 29, 2000
3. wd_m_day_year: Tue, Feb 29, 2000
4. wday_day_month_year: Tuesday 29 February 2000
5. month_day_year: February 29, 2000
6. m_day_year: Feb 29, 2000
7. day_m_year: 29 Feb 2000
8. day_month_year: 29 February 2000
9. day_month: February
10. year: 2000
11. month: February
12. day: 29
13. year.mn.day: 2000/02/29
14. y.mn.day: 0/02/29

We can use the *info_date_style()* function for a useful reference on all of the possible inputs to *date_style*.

**Usage**

```r
fmt_date(data, columns, rows = NULL, date_style = 2)
```
Arguments

- **data**: A table object that is created using the `gt()` function.
- **columns**: The columns to format. Can either be a series of column names provided in `vars()`, a vector of column indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`.
- **rows**: Optional rows to format. Not providing any value results in all rows in `columns` being formatted. Can either be a vector of row captions provided `c()`, a vector of row indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`. We can also use expressions to filter down to the rows we need (e.g., `[colname_1] > 100 & [colname_2] < 50`).
- **date_style**: The date style to use. Supply a number (from 1 to 14) that corresponds to the preferred date style. Use `info_date_style()` to see the different numbered and named date presets.

Details

Targeting of values is done through `columns` and additionally by `rows` (if nothing is provided for `rows` then entire columns are selected). A number of helper functions exist to make targeting more effective. Conditional formatting is possible by providing a conditional expression to the `rows` argument. See the Arguments section for more information on this.

Value

An object of class `gt_tbl`.

Examples

```R
# Use `exibble` to create a gt table;
# keep only the `date` and `time` columns;
# format the `date` column to have
# dates formatted as `month_day_year`
# (date style `5`)
tab_1 <-
```
```r
exibble %>%
dplyr::select(date, time) %>%
gt() %>%
fmt_date(
  columns = vars(date),
  date_style = 5
)

# Use `exibble` to create a gt table;
# keep only the `date` and `time` columns;
# format the `date` column to have mixed
date formats (dates after April will
# be different than the others)
tab_2 <-
exibble %>%
dplyr::select(date, time) %>%
gt() %>%
fmt_date(
  columns = vars(date),
  rows =
    as.Date(date) > as.Date("2015-04-01"),
  date_style = 6
) %>%
fmt_date(
  columns = vars(date),
  rows =
    as.Date(date) <= as.Date("2015-04-01"),
  date_style = 7
)
```

---

**fmt_datetime**

Format values as date-times

**Description**

Format input date-time values that are character-based and expressed according to the ISO 8601
date-time format (YYYY-MM-DD HH:MM:SS). Once the appropriate data cells are targeted with
columns (and, optionally, rows), we can simply apply preset date and time styles to format the
date-time values. The following date styles are available for simpler formatting of the date portion
(all using the input date of 2000-02-29 in the example output dates):

1. iso: 2000-02-29
2. wday_month_day_year: Tuesday, February 29, 2000
3. wd_m_day_year: Tue, Feb 29, 2000
4. wday_day_month_year: Tuesday 29 February 2000
5. month_day_year: February 29, 2000
6. m_day_year: Feb 29, 2000
The following time styles are available for simpler formatting of the time portion (all using the input
time of 14:35:00 in the example output times):

1. hms: 14:35:00
2. hm: 14:35
3. hms_p: 2:35:00 PM
4. hm_p: 2:35 PM
5. h_p: 2 PM

We can use the `info_date_style()` and `info_time_style()` functions as useful references for
all of the possible inputs to `date_style` and `time_style`.

**Usage**

```r
fmt_datetime(data, columns, rows = NULL, date_style = 2, time_style = 2)
```

**Arguments**

- `data`: A table object that is created using the `gt()` function.
- `columns`: The columns to format. Can either be a series of column names provided in `vars()`, a vector of column indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`.
- `rows`: Optional rows to format. Not providing any value results in all rows in columns being formatted. Can either be a vector of row captions provided `c()`, a vector of row indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`. We can also use expressions to filter down to the rows we need (e.g., `[colname_1] > 100 & [colname_2] < 50`).
- `date_style`: The date style to use. Supply a number (from 1 to 14) that corresponds to the preferred date style. Use `info_date_style()` to see the different numbered and named date presets.
- `time_style`: The time style to use. Supply a number (from 1 to 5) that corresponds to the preferred time style. Use `info_time_style()` to see the different numbered and named time presets.
Details

Targeting of values is done through columns and additionally by rows (if nothing is provided for rows then entire columns are selected). A number of helper functions exist to make targeting more effective. Conditional formatting is possible by providing a conditional expression to the rows argument. See the Arguments section for more information on this.

   )

fmt_markdown

Format Markdown text

Description

Any Markdown-formatted text in the incoming cells will be transformed to the appropriate output type during render when using fmt_markdown().
Usage

fmt_markdown(data, columns, rows = NULL)

Arguments

data

A table object that is created using the `gt()` function.

columns

The columns to format. Can either be a series of column names provided in `vars()`, a vector of column indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`.

rows

Optional rows to format. Not providing any value results in all rows in columns being formatted. Can either be a vector of row captions provided `c()`, a vector of row indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`. We can also use expressions to filter down to the rows we need (e.g., `[colname_1] > 100 & [colname_2] < 50`).

Details

Targeting of values is done through `columns` and additionally by `rows` (if nothing is provided for `rows` then entire columns are selected). A number of helper functions exist to make targeting more effective. Conditional formatting is possible by providing a conditional expression to the `rows` argument. See the Arguments section for more information on this.

Examples

# Create a few Markdown-based
text_1a <- "### This is Markdown.

```
Markdown's syntax is comprised entirely of punctuation characters, which punctuation characters have been carefully chosen so as to look like what they mean... assuming you've ever used email.

```
text_1b <- "
Info on Markdown syntax can be found [here](https://daringfireball.net/projects/markdown/).
"
```

```
text_2a <- "
The **gt** package has these datasets:
- 'countrypops'
- 'sza'
- 'gtcars'
- 'sp500'
- 'pizzaplace'
- 'exibble'
"
```

```
text_2b <- "
There’s a quick reference [here](https://commonmark.org/help/).
"
```

# Arrange the text snippets as a tibble
# using the `dplyr::tribble()` function;
# then, create a gt table and format
# all columns with `fmt_markdown()`
tab_1 <-
  dplyr::tribble(
    ~Markdown, ~md, text_1a, text_2a, text_1b, text_2b,
  ) %>%
  gt() %>%
  fmt_markdown(columns = TRUE) %>%
  tab_options(table.width = px(400))

---

### fmt_missing

**Format missing values**

**Description**

Wherever there is missing data (i.e., NA values) a customizable mark may present better than the standard NA text that would otherwise appear. The `fmt_missing()` function allows for this replacement through its `missing_text` argument (where an em dash serves as the default).
fmt_missing

Usage

fmt_missing(data, columns, rows = NULL, missing_text = "---")

Arguments

data
A table object that is created using the `gt()` function.
columns
The columns to format. Can either be a series of column names provided in `vars()`, a vector of column indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`.
rows
Optional rows to format. Not providing any value results in all rows in `columns` being formatted. Can either be a vector of row captions provided `c()`, a vector of row indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`. We can also use expressions to filter down to the rows we need (e.g., `[colname_1] > 100 & [colname_2] < 50`).
missing_text
The text to be used in place of `NA` values in the rendered table.

Details

Targeting of values is done through `columns` and additionally by `rows` (if nothing is provided for `rows` then entire columns are selected). A number of helper functions exist to make targeting more effective. Conditional formatting is possible by providing a conditional expression to the `rows` argument. See the Arguments section for more information on this.

Value

An object of class `gt_tbl`.

Other Format Data: `data_color()`, `fmt_currency()`, `fmt_datetime()`, `fmt_date()`, `fmt_markdown()`, `fmt_number()`, `fmt_passthrough()`, `fmt_percent()`, `fmt_scientific()`, `fmt_time()`, `fmt()`, `text_transform()`

Examples

# Use `exibble` to create a gt table;
# NA values in different columns will
# be given replacement text
tab_1 <-
```
exibble %>%
dplyr::select(-row, -group) %>%
gt() %>%
fmt_missing(
  columns = 1:2,
  missing_text = "missing"
) %>%
fmt_missing(
  columns = 4:7,
  missing_text = "nothing"
)
```

### fmt_number

**Format numeric values**

**Description**

With numeric values in a `gt` table, we can perform number-based formatting so that the targeted values are rendered with a higher consideration for tabular presentation. Furthermore, there is finer control over numeric formatting with the following options:

- decimals: choice of the number of decimal places, option to drop trailing zeros, and a choice of the decimal symbol
- digit grouping separators: options to enable/disable digit separators and provide a choice of separator symbol
- scaling: we can choose to scale targeted values by a multiplier value
- large-number suffixing: larger figures (thousands, millions, etc.) can be autoscaled and decorated with the appropriate suffixes
- pattern: option to use a text pattern for decoration of the formatted values
- locale-based formatting: providing a locale ID will result in number formatting specific to the chosen locale

**Usage**

```r
fmt_number(
  data,
  columns,
  rows = NULL,
  decimals = 2,
  drop_trailing_zeros = FALSE,
  use_seps = TRUE,
  scale_by = 1,
  suffixing = FALSE,
  pattern = "{x}";
  sep_mark = ",",
  dec_mark = ",",
  locale = NULL
)
```
Arguments

data  A table object that is created using the `gt()` function.
columns  The columns to format. Can either be a series of column names provided in `vars()`, a vector of column indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`.
rows  Optional rows to format. Not providing any value results in all rows in `columns` being formatted. Can either be a vector of row captions provided `c()`, a vector of row indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`. We can also use expressions to filter down to the rows we need (e.g., `[colname_1] > 100 & [colname_2] < 50`).
decimals  An option to specify the exact number of decimal places to use. The default number of decimal places is 2.
drop_trailing_zeros  A logical value that allows for removal of trailing zeros (those redundant zeros after the decimal mark).
use_seps  An option to use digit group separators. The type of digit group separator is set by `sep_mark` and overridden if a locale ID is provided to `locale`. This setting is `TRUE` by default.
scale_by  A value to scale the input. The default is `1.0`. All numeric values will be multiplied by this value first before undergoing formatting. This value will be ignored if using any of the `suffixing` options (i.e., where `suffixing` is not set to `FALSE`).
suffixing  An option to scale and apply suffixes to larger numbers (e.g., 1924000 can be transformed to 1.92M). This option can accept a logical value, where `FALSE` (the default) will not perform this transformation and `TRUE` will apply thousands (K), millions (M), billions (B), and trillions (T) suffixes after automatic value scaling. We can also specify which symbols to use for each of the value ranges by using a character vector of the preferred symbols to replace the defaults (e.g., `c("k","M","B","T")`). Including `NA` values in the vector will ensure that the particular range will either not be included in the transformation (e.g, `c(NA,"M","B","T")`) won’t modify numbers in the thousands range) or the range will inherit a previous suffix (e.g., with `c("K","M",NA,"T")`, all numbers in the range of millions and billions will be in terms of millions). Any use of `suffixing` (where it is not set expressly as `FALSE`) means that any value provided to `scale_by` will be ignored.
pattern  A formatting pattern that allows for decoration of the formatted value. The value itself is represented by `{x}` and all other characters are taken to be string literals.
sep_mark  The mark to use as a separator between groups of digits (e.g., using `sep_mark = ","` with 1000 would result in a formatted value of 1,000).
dec_mark  The character to use as a decimal mark (e.g., using `dec_mark = ","` with 0.152 would result in a formatted value of 0,152).
locale

An optional locale ID that can be used for formatting the value according the locale’s rules. Examples include "en_US" for English (United States) and "fr_FR" for French (France). The use of a valid locale ID will override any values provided in sep_mark and dec_mark. We can use the info_locales() function as a useful reference for all of the locales that are supported.

Details

Targeting of values is done through columns and additionally by rows (if nothing is provided for rows then entire columns are selected). A number of helper functions exist to make targeting more effective. Conditional formatting is possible by providing a conditional expression to the rows argument. See the Arguments section for more information on this.

Value

An object of class gt_tbl.

Examples

library(tidyr)

# Use `exibble` to create a gt table;
# format the `num` column as numeric
# with three decimal places and with no
# use of digit separators
tab_1 <-
exibble %>%
  gt() %>%
  fmt_number(
    columns = vars(num),
    decimals = 3,
    use_seps = FALSE
  )

# Use `countrypops` to create a gt
# table; format all numeric columns
# to use large-number suffixing
tab_2 <-
countrypops %>%
dplyr::select(country_code_3, year, population) %>%
dplyr::filter(
  country_code_3 %in% c(
    "CHN", "IND", "USA", "PAK", "IDN"
  )
) %>%
dplyr::filter(year > 1975 & year %% 5 == 0) %>%
tidyr::spread(year, population) %>%
gt(rowname_col = "country_code_3") %>%
fmt_number(
  columns = 2:9,
  decimals = 2,
  suffixing = TRUE
)

fmt_passthrough  Format by simply passing data through

Description

Format by passing data through no other transformation other than: (1) coercing to character (as all the fmt_*() functions do), and (2) applying text via the pattern argument (the default is to apply nothing). All of this is useful when don’t want to modify the input data other than to decorate it within a pattern. Also, this function is useful when used as the formatter function in the summary_rows() function, where the output may be text or useful as is.

Usage

fmt_passthrough(data, columns, rows = NULL, escape = TRUE, pattern = "{x}")

Arguments

data  A table object that is created using the gt() function.

columns  The columns to format. Can either be a series of column names provided in vars(), a vector of column indices, or a helper function focused on selections. The select helper functions are: starts_with(), ends_with(), contains(), matches(), one_of(), and everything().

rows  Optional rows to format. Not providing any value results in all rows in columns being formatted. Can either be a vector of row captions provided c(), a vector of row indices, or a helper function focused on selections. The select helper functions are: starts_with(), ends_with(), contains(), matches(), one_of(), and everything(). We can also use expressions to filter down to the rows we need (e.g., [colname_1] > 100 & [colname_2] < 50).
fmt_passthrough

**escape**
An option to escape text according to the final output format of the table. For example, if a LaTeX table is to be generated then LaTeX escaping would be performed during rendering. By default this is set to TRUE and setting to FALSE is useful in the case where LaTeX-formatted text should be passed through to the output LaTeX table unchanged.

**pattern**
A formatting pattern that allows for decoration of the formatted value. The value itself is represented by \( \{x\} \) and all other characters are taken to be string literals.

**Details**
Targeting of values is done through columns and additionally by rows (if nothing is provided for rows then entire columns are selected). A number of helper functions exist to make targeting more effective. Conditional formatting is possible by providing a conditional expression to the rows argument. See the Arguments section for more information on this.

**Value**
An object of class gt_tbl.

3-9

**See Also**
Other Format Data: data_color(), fmt_currency(), fmt_datetime(), fmt_date(), fmt_markdown(), fmt_missing(), fmt_number(), fmt_percent(), fmt_scientific(), fmt_time(), fmt(), text_transform()

**Examples**

```r
# Use `exibble` to create a gt table;
# keep only the `char` column;
# pass the data in that column through
# but apply a simple pattern that adds
# an 's' to the non-NA values

tab_1 <-
exibble %>%
dplyr::select(char) %>%
gt() %>%
fmt_passthrough(
  columns = vars(char),
  rows = !is.na(char),
  pattern = "{x}s"
)
```
**fmt_percent**  
*Format values as a percentage*

**Description**

With numeric values in a `gt` table, we can perform percentage-based formatting. It is assumed the input numeric values are in a fractional format since the numbers will be automatically multiplied by 100 before decorating with a percent sign. For more control over percentage formatting, we can use the following options:

- percent sign placement: the percent sign can be placed after or before the values and a space can be inserted between the symbol and the value.
- decimals: choice of the number of decimal places, option to drop trailing zeros, and a choice of the decimal symbol
- digit grouping separators: options to enable/disable digit separators and provide a choice of separator symbol
- pattern: option to use a text pattern for decoration of the formatted values
- locale-based formatting: providing a locale ID will result in number formatting specific to the chosen locale

**Usage**

```r
definition
fmt_percent(
data,
columns,
rows = NULL,
decimals = 2,
drop_trailing_zeros = FALSE,
use_seps = TRUE,
pattern = "\{x\}",
sep_mark = ",",
dec_mark = ".",
incl_space = FALSE,
placement = "right",
locale = NULL
)
```

**Arguments**

- **data**: A table object that is created using the `gt()` function.
- **columns**: The columns to format. Can either be a series of column names provided in `vars()`, a vector of column indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`.
**fmt_percent**

rows Optional rows to format. Not providing any value results in all rows in columns being formatted. Can either be a vector of row captions provided `c()`, a vector of row indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`. We can also use expressions to filter down to the rows we need (e.g., `colname_1 > 100 & colname_2 < 50`).

decimals An option to specify the exact number of decimal places to use. The default number of decimal places is 2.

drop_trailing_zeros A logical value that allows for removal of trailing zeros (those redundant zeros after the decimal mark).

use_seps An option to use digit group separators. The type of digit group separator is set by `sep_mark` and overridden if a locale ID is provided to `locale`. This setting is `TRUE` by default.

pattern A formatting pattern that allows for decoration of the formatted value. The value itself is represented by `{x}` and all other characters are taken to be string literals.

sep_mark The mark to use as a separator between groups of digits (e.g., using `sep_mark = "","` with 1000 would result in a formatted value of 1,000).

dec_mark The character to use as a decimal mark (e.g., using `dec_mark = ","` with 0.152 would result in a formatted value of 0,152).

incl_space An option for whether to include a space between the value and the percent sign. The default is to not introduce a space character.

placement The placement of the percent sign. This can be either be `right` (the default) or `left`.

locale An optional locale ID that can be used for formatting the value according to the locale's rules. Examples include "en_US" for English (United States) and "fr_FR" for French (France). The use of a valid locale ID will override any values provided in `sep_mark` and `dec_mark`. We can use the `info_locales()` function as a useful reference for all of the locales that are supported.

**Details**

Targeting of values is done through `columns` and additionally by `rows` (if nothing is provided for `rows` then entire columns are selected). A number of helper functions exist to make targeting more effective. Conditional formatting is possible by providing a conditional expression to the `rows` argument. See the Arguments section for more information on this.

**Value**

An object of class `gt_tbl`.

Other Format Data: data_color(), fmt_currency(), fmt_datetime(), fmt_date(), fmt_markdown(), fmt_missing(), fmt_number(), fmt Passthrough(), fmt_scientific(), fmt_time(), fmt(), text_transform()

Examples

# Use `pizzaplace` to create a gt table;
# format the `frac_of_quota` column to
# display values as percentages

```r
tab_1 <-
pizzaplace %>%
dplyr::mutate(month = as.numeric(substr(date, 6, 7))) %>%
dplyr::group_by(month) %>%
dplyr::summarize(pizzas_sold = dplyr::n()) %>%
dplyr::ungroup() %>%
dplyr::mutate(frac_of_quota = pizzas_sold / 4000) %>%
gt(rownames_col = "month") %>%
fmt_percent(
  columns = vars(frac_of_quota),
  decimals = 1
)
```

fmt_scientific

Format values to scientific notation

Description

With numeric values in a gt table, we can perform formatting so that the targeted values are rendered in scientific notation. Furthermore, there is fine control with the following options:

- decimals: choice of the number of decimal places, option to drop trailing zeros, and a choice of the decimal symbol
- scaling: we can choose to scale targeted values by a multiplier value
- pattern: option to use a text pattern for decoration of the formatted values
- locale-based formatting: providing a locale ID will result in formatting specific to the chosen locale

Usage

```r
fmt_scientific(
  data,
  columns,
  rows = NULL,
  decimals = 2,
  drop_trailing_zeros = FALSE,
)```
scale_by = 1,
pattern = "(x)",
sep_mark = ",",
dec_mark = ".",
locale = NULL
)

Arguments

data A table object that is created using the `gt()` function.
columns The columns to format. Can either be a series of column names provided in `vars()`, a vector of column indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`.
rows Optional rows to format. Not providing any value results in all rows in columns being formatted. Can either be a vector of row captions provided `c()`, a vector of row indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`. We can also use expressions to filter down to the rows we need (e.g., `[colname_1] > 100 & [colname_2] < 50`).
decimals An option to specify the exact number of decimal places to use. The default number of decimal places is 2.
drop_trailing_zeros A logical value that allows for removal of trailing zeros (those redundant zeros after the decimal mark).
scale_by A value to scale the input. The default is 1.0. All numeric values will be multiplied by this value first before undergoing formatting. This value will be ignored if using any of the suffixing options (i.e., where suffixing is not set to FALSE).
pattern A formatting pattern that allows for decoration of the formatted value. The value itself is represented by `{x}` and all other characters are taken to be string literals.
sep_mark The mark to use as a separator between groups of digits (e.g., using `sep_mark = ","` with 1000 would result in a formatted value of 1,000).
dec_mark The character to use as a decimal mark (e.g., using `dec_mark = ","` with 0.152 would result in a formatted value of 0,152).
locale An optional locale ID that can be used for formatting the value according the locale’s rules. Examples include "en_US" for English (United States) and "fr_FR" for French (France). The use of a valid locale ID will override any values provided in `sep_mark` and `dec_mark`. We can use the `info_locales()` function as a useful reference for all of the locales that are supported.

Details

Targeting of values is done through columns and additionally by rows (if nothing is provided for rows then entire columns are selected). A number of helper functions exist to make targeting more effective. Conditional formatting is possible by providing a conditional expression to the `rows` argument. See the Arguments section for more information on this.
Value

An object of class `gt_tbl`.

Other Format Data: `data_color()`, `fmt_currency()`, `fmt_datetime()`, `fmt_date()`, `fmt_markdown()`, `fmt_missing()`, `fmt_number()`, `fmt_passthrough()`, `fmt_percent()`, `fmt_time()`., `fmt()`, `text_transform()`

Examples

```r
# Use `exibble` to create a gt table;
# format the `num` column as partially
# numeric and partially in scientific
# notation

tab_1 <-
exibble %>%
  gt() %>%
  fmt_number(
    columns = vars(num),
    rows = num > 500,
    decimals = 1,
    scale_by = 1/1000,
    pattern = "{x}K"
  ) %>%
  fmt_scientific(
    columns = vars(num),
    rows = num <= 500,
    decimals = 1
  )
```

fmt_time

Format values as times

Description

Format input time values that are character-based and expressed according to the ISO 8601 time format (HH:MM:SS). Once the appropriate data cells are targeted with `columns` (and, optionally, `rows`), we can simply apply a preset time style to format the times. The following time styles are available for simpler formatting of ISO times (all using the input time of `14:35:00` in the example output times):
```r
1. hms: 14:35:00
2. hm: 14:35
3. hms_p: 2:35:00 PM
4. hm_p: 2:35 PM
5. h_p: 2 PM

We can use the `info_time_style()` function for a useful reference on all of the possible inputs to `time_style`.

**Usage**

```r
fmt_time(data, columns, rows = NULL, time_style = 2)
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>A table object that is created using the <code>gt()</code> function.</td>
</tr>
<tr>
<td>columns</td>
<td>The columns to format. Can either be a series of column names provided in <code>vars()</code>, a vector of column indices, or a helper function focused on selections. The select helper functions are: <code>starts_with()</code>, <code>ends_with()</code>, <code>contains()</code>, <code>matches()</code>, <code>one_of()</code>, and <code>everything()</code>.</td>
</tr>
<tr>
<td>rows</td>
<td>Optional rows to format. Not providing any value results in all rows in <code>columns</code> being formatted. Can either be a vector of row captions provided <code>c()</code>, a vector of row indices, or a helper function focused on selections. The select helper functions are: <code>starts_with()</code>, <code>ends_with()</code>, <code>contains()</code>, <code>matches()</code>, <code>one_of()</code>, and <code>everything()</code>. We can also use expressions to filter down to the rows we need (e.g., <code>[colname_1] &gt; 100 &amp; [colname_2] &lt; 50</code>).</td>
</tr>
<tr>
<td>time_style</td>
<td>The time style to use. Supply a number (from 1 to 5) that corresponds to the preferred time style. Use <code>info_time_style()</code> to see the different numbered and named time presets.</td>
</tr>
</tbody>
</table>

**Details**

Targeting of values is done through `columns` and additionally by `rows` (if nothing is provided for `rows` then entire columns are selected). A number of helper functions exist to make targeting more effective. Conditional formatting is possible by providing a conditional expression to the `rows` argument. See the Arguments section for more information on this.

  columns = vars(time),
  rows =
    time <= "16:00",
    time_style = 4
)
```

**ggplot_image**

Helper function for adding a ggplot
Description

We can add a ggplot2 plot inside of a table with the help of the ggplot_image() function. The function provides a convenient way to generate an HTML fragment with a ggplot object. Because this function is currently HTML-based, it is only useful for HTML table output. To use this function inside of data cells, it is recommended that the text_transform() function is used. With that function, we can specify which data cells to target and then include a call to ggplot_image() within the required user-defined function (for the fn argument). If we want to include a plot in other places (e.g., in the header, within footnote text, etc.) we need to use ggplot_image() within the html() helper function.

Usage

ggplot_image(plot_object, height = 100, aspect_ratio = 1)

Arguments

- **plot_object**: A ggplot plot object.
- **height**: The absolute height (px) of the image in the table cell.
- **aspect_ratio**: The plot’s final aspect ratio. Where the height of the plot is fixed using the height argument, the aspect_ratio will either compress (aspect_ratio < 1.0) or expand (aspect_ratio > 1.0) the plot horizontally. The default value of 1.0 will neither compress nor expand the plot.

Details

By itself, the function creates an HTML image tag with an image URI embedded within (a 100 dpi PNG). We can easily experiment with any ggplot2 plot object, and using it within ggplot_image(plot_object = <plot object>) evaluates to:

```
<img cid=<random CID> src=<data URI> style="height:100px;">
```

where a height of 100px is a default height chosen to work well within the heights of most table rows. There is the option to modify the aspect ratio of the plot (the default aspect_ratio is 1.0) and this is useful for elongating any given plot to fit better within the table construct.

Value

A character object with an HTML fragment that can be placed inside of a cell.

Other Image Addition Functions: local_image(), test_image(), web_image()
Examples

```r
library(ggplot2)

# Create a ggplot plot
plot_object <-
ggplot(
data = gtcars,
aes(x = hp, y = trq,
    size = msrp)) +
geom_point(color = "blue") +
theme(legend.position = "none")

# Create a tibble that contains two
# cells (where one is a placeholder for
# an image), then, create a gt table;
# use the `text_transform()` function
# to insert the plot using by calling
# `ggplot_object()` within the user-
# defined function
tab_1 <-
dplyr::tibble(
    text = "Here is a ggplot:",
    ggplot = NA
  ) %>%
  gt() %>%
text_transform(
    locations = cells_body(vars(ggplot)),
    fn = function(x) {
      plot_object %>%
      ggplot_image(height = px(200))
    }
  )
```

---

### grand_summary_rows

Add grand summary rows to the gt table by using applying aggregation functions to the table data. The summary rows incorporate all of the available data, regardless of whether some of the data are part of row groups. You choose how to format the values in the resulting summary cells by use of a formatter function (e.g., `fmt_number`) and any relevant options.

**Description**

Add grand summary rows to the gt table by using applying aggregation functions to the table data.

**Usage**

```r
grand_summary_rows(
data,
columns = TRUE,
```
Arguments

- **data**
  
  A table object that is created using the `gt()` function.

- **columns**
  
  The columns for which the summaries should be calculated.

- **fns**
  
  Functions used for aggregations. This can include base functions like `mean`, `min`, `max`, `median`, `sd`, or `sum` or any other user-defined aggregation function. The function(s) should be supplied within a `list()`. Within that list, we can specify the functions by use of function names in quotes (e.g., "sum"), as bare functions (e.g., `sum`), or as one-sided R formulas using a leading ~. In the formula representation, a . serves as the data to be summarized (e.g., `sum(., na.rm = TRUE)`). The use of named arguments is recommended as the names will serve as summary row labels for the corresponding summary rows data (the labels can derived from the function names but only when not providing bare function names).

- **missing_text**
  
  The text to be used in place of NA values in summary cells with no data outputs.

- **formatter**
  
  A formatter function name. These can be any of the fmt_*() functions available in the package (e.g., `fmt_number()`, `fmt_percent()`, etc.), or a custom function using `fmt()`. The default function is `fmt_number()` and its options can be accessed through ....

- **...**
  
  Values passed to the formatter function, where the provided values are to be in the form of named vectors. For example, when using the default formatter function, `fmt_number()`, options such as `decimals`, `use_seps`, and `locale` can be used.

Details

Should we need to obtain the summary data for external purposes, the `extract_summary()` function can be used with a `gt_tbl` object where grand summary rows were added via `grand_summary_rows()`.

Value

An object of class `gt_tbl`.

Other Add Rows: summary_rows()

Examples

# Use 'sp500' to create a gt table with
# row groups; create grand summary rows
# ('min', 'max', 'avg') for the table

tab_1 <-
  sp500 %>%
  dplyr::filter(
    date >= "2015-01-05" &
    date <= "2015-01-16"
  ) %>%
  dplyr::arrange(date) %>%
  dplyr::mutate(
    week = paste0(
      "W", strftime(date, format = "%V"))
  ) %>%
  dplyr::select(-adj_close, -volume) %>%
  gt(
    rowname_col = "date",
    groupname_col = "week"
  ) %>%
  grand_summary_rows(
    columns = vars(open, high, low, close),
    fns = list(
      min = ~min(.),
      max = ~max(.),
      avg = ~mean(.)),
    formatter = fmt_number,
    use_seps = FALSE
  )

---

**gt**

*Create a gt table object*

Description

The gt() function creates a gt table object when provided with table data. Using this function is the first step in a typical gt workflow. Once we have the gt table object, we can perform styling transformations before rendering to a display table of various formats.

Usage

```r
gt(
  data,
  rowname_col = "rowname",
```
gt

```r
groupname_col = dplyr::group_vars(data),
rownames_to_stub = FALSE,
auto_align = TRUE,
id = NULL,
row_group.sep = getOption("gt.row_group.sep", " - ")
```

**Arguments**

- `data` A `data.frame` object or a tibble.
- `rownames_col` The column name in the input data table to use as row captions to be placed in the display table stub. If the `rownames_to_stub` option is `TRUE` then any column name provided to `rownames_col` will be ignored.
- `groupname_col` The column name in the input data table to use as group labels for generation of stub row groups. If the input data table has the `grouped_df` class (through use of the `dplyr::group_by()` function or associated group_by*() functions) then any input here is ignored.
- `rownames_to_stub` An option to take rownames from the input data table as row captions in the display table stub.
- `auto_align` Optionally have column data be aligned depending on the content contained in each column of the input data. Internally, this calls `cols_align(align = "auto")` for all columns.
- `id` The table ID. By default, with `NULL`, this will be a random, ten-letter ID as generated by using the `random_id()` function. A custom table ID can be used with any single-length character vector.
- `row_group.sep` The separator to use between consecutive group names (a possibility when providing data as a grouped_df with multiple groups) in the displayed stub row group label.

**Details**

There are a few data ingest options we can consider at this stage. We can choose to create a table stub with rowname captions using the `rownames_col` argument. Further to this, stub row groups can be created with the `groupname_col`. Both arguments take the name of a column in the input table data. Typically, the data in the `groupname_col` will consist of categories of data in a table and the data in the `rownames_col` are unique labels (perhaps unique across the entire table or unique within groups).

Row groups can also be created by passing a grouped_df to `gt()` by using the `dplyr::group_by()` function on the table data. In this way, two or more columns of categorical data can be used to make row groups. The `row_group.sep` argument allows for control in how the row group label will appear in the display table.

**Value**

An object of class `gt_tbl`.

Other Create Table: \code{gt_preview()}

Examples

```r
# Create a table object using the
# `exibble` dataset; use the `row`
# and `group` columns to add a stub
# and row groups
tabl <-
exibble %>%
gt(
  rowname_col = "row",
  groupname_col = "group"
)

# The resulting object can be used
# in transformations (with `tab_*()`,
# `fmt_*()`, `cols_*()` functions)
tab2 <-
tabl %>%
  tab_header(
    title = "Table Title",
    subtitle = "Subtitle"
  ) %>%
  fmt_number(
    columns = vars(num),
    decimals = 2
  ) %>%
  cols_label(num = "number")
```

---

\textbf{gt-package options}

**Description**

\texttt{gt} package options
Package options

`gt` uses the following `options()` to configure behavior:

- `gt.row_group.sep`: a separator between groups for the row group label.

Description

Expensive and fast cars. Not your father's `mtcars`. Each row describes a car of a certain make, model, year, and trim. Basic specifications such as horsepower, torque, EPA MPG ratings, type of drivetrain, and transmission characteristics are provided. The country of origin for the car manufacturer is also given.

Usage

`gtcars`

Format

A tibble with 47 rows and 15 variables:

- `mfr`: The name of the car manufacturer
- `model`: The car's model name
- `year`: The car's model year
- `trim`: A short description of the car model’s trim
- `bdy_style`: An identifier of the car’s body style, which is either coupe, convertible, sedan, or hatchback
- `hp, hp_rpm`: The car’s horsepower and the associated RPM level
- `trq, trq_rpm`: The car’s torque and the associated RPM level
- `mpg_c, mpg_h`: The miles per gallon fuel efficiency rating for city and highway driving
- `drivetrain`: The car’s drivetrain which, for this dataset is either rwd (Rear Wheel Drive) or awd (All Wheel Drive)
- `trsmn`: The codified transmission type, where the number part is the number of gears; the car could have automatic transmission (a), manual transmission (m), an option to switch between both types (am), or, direct drive (dd)
- `ctry_origin`: The country name for where the vehicle manufacturer is headquartered

Details

All of the `gtcars` have something else in common (aside from the high asking prices): they are all grand tourer vehicles. These are proper GT cars that blend pure driving thrills with a level of comfort that is more expected from a fine limousine (e.g., a Rolls-Royce Phantom EWB). You’ll find that, with these cars, comfort is emphasized over all-out performance. Nevertheless, the driving experience should also mean motoring at speed, doing so in style and safety.
Function ID
11-3

See Also
Other Datasets: countrypops, exibble, pizzaplace, sp500, sza

Examples
# Here is a glimpse at the data
# available in 'gtcars'
dplyr::glimpse(gtcars)

gtsave(data, filename, path = NULL, ...)

Arguments
data A table object that is created using the \texttt{gt()} function.
filename The file name to create on disk. Ensure that an extension compatible with the output types is provided (.html, .tex, .ltx, .rtf). If a custom save function is provided then the file extension is disregarded.
path An optional path to which the file should be saved (combined with filename).
... All other options passed to the appropriate internal saving function.

Details
Output filenames with either the .html or .htm extensions will produce an HTML document. In this case, we can pass a \texttt{TRUE} or \texttt{FALSE} value to the \texttt{inline_css} option to obtain an HTML document with inlined CSS styles (the default is \texttt{FALSE}). More details on CSS inlining are available at \texttt{as_raw_html()}. We can pass values to arguments in \texttt{htmltools::save_html()} through the \texttt{...}. Those arguments are either \texttt{background} or \texttt{libdir}, please refer to the \texttt{htmltools} documentation for more details on the use of these arguments.

We can create an image file based on the HTML version of the \texttt{gt} table. With the filename extension .png, we get a PNG image file. A PDF document can be generated by using the .pdf extension.
This process is facilitated by the `webshot` package, so, this package needs to be installed before attempting to save any table as an image file. There is the option of passing values to the underlying `webshot::webshot()` function though . . . . Some of the more useful arguments for PNG saving are `zoom` (defaults to a scale level of 2) and `expand` (adds whitespace pixels around the cropped table image, and has a default value of 5). There are several more options available so have a look at the `webshot` documentation for further details.

If the output filename extension is either of `.tex`, `.ltx`, or `.rnw`, a LaTeX document is produced. An output filename of `.rtf` will generate an RTF document. The LaTeX and RTF saving functions don’t have any options to pass to . . . .

Function ID

Other Export Functions: `as_latex()`, `as_raw_html()`, `as_rtf()`, `extract_summary()`

Examples

```r
if (interactive()) {
  # Use `gtcars` to create a gt table; add
  # a stubhead label to describe what is
  # in the stub
  tab_1 <-
    gcars %>%
    dplyr::select(model, year, hp, trq) %>%
    dplyr::slice(1:5) %>%
    gt(rownames_col = "model") %>%
    tab_stubhead(label = "car")

  # Get an HTML file with inlined CSS
  # (which is necessary for including the
  # table as part of an HTML email)
  tab_1 %>%
    gtsave(
      "tab_1.html", inline_css = TRUE,
      path = tempdir()
    )

  # By leaving out the `inline_css` option,
  # we get a more conventional HTML file
  # with embedded CSS styles
  tab_1 %>%
    gtsave("tab_1.html", path = tempdir())

  # Saving as PNG file results in a cropped
  # image of an HTML table; the amount of
  # whitespace can be set
  tab_1 %>%
    gtsave("tab_1.png", zoom = 2, expand = 5)
}
```

gtsave(
    "tab_1.png", expand = 10,
    path = tempdir()
)

# Any use of the `.tex`, `.ltx`, or `.rnw`
# will result in the output of a LaTeX
# document
tab_1 %>%
    gtsave("tab_1.tex", path = tempdir())
}

---

**gt_latex_dependencies** *Get the LaTeX dependencies required for a gt table*

**Description**

When working with Rnw (Sweave) files or otherwise writing LaTeX code, including a gt table can be problematic if we don’t have knowledge of the LaTeX dependencies. For the most part, these dependencies are the LaTeX packages that are required for rendering a gt table. The \texttt{gt_latex_dependencies()} function provides an object that can be used to provide the LaTeX in an Rnw file, allowing gt tables to work and not yield errors due to missing packages.

**Usage**

\texttt{gt_latex_dependencies()}

**Details**

Here is an example Rnw document that shows how the \texttt{gt_latex_dependencies()} can be used in conjunction with a gt table:

```latex
\documentclass{article}

<<echo=FALSE>>=
library(gt)
@

<<results='asis', echo=FALSE>>=
gt_latex_dependencies()
@

\begin{document}
```
gt_output

Create a \texttt{gt} display table output element for \textsc{Shiny}

Description

Using \texttt{gt_output()} we can render a reactive \texttt{gt} table, a process initiated by using the \texttt{render_gt()} function in the \texttt{server} component of a \textsc{Shiny} app. The \texttt{gt_output()} call is to be used in the \textsc{Shiny} \texttt{ui} component, the position and context wherein this call is made determines the where the \texttt{gt} table is rendered on the app page. It's important to note that the ID given during the \texttt{render_gt()} call is needed as the \texttt{outputId} in \texttt{gt_output()} (e.g., \texttt{server: output$<id> <- render_gt(...); ui: gt_output(outputId = "<id>")}.

Usage

\texttt{gt_output(outputId)}

Arguments

\begin{itemize}
  \item \texttt{outputId} An output variable from which to read the table.
\end{itemize}

Details

We need to ensure that we have the \texttt{shiny} package installed first. This is easily by using \texttt{install.packages("shiny")}. More information on creating \textsc{Shiny} apps can be found at the \texttt{Shiny Site}.

Function ID

Other Shiny functions: render_gt()

Examples

```r
library(shiny)

gtcars <- ggplot2::ggplot(gtcars, aes(x = Species, y = Sepal.Length)) +
  geom_boxplot() +
  labs(x = "Species", y = "Sepal.Length")

ui <- appLenses

ui <- fluidPage(
  gt_output(outputId = "table")
)

server <- function(input, output, session) {
  output$table <- render_gt(
    expr = gtcars,
    height = px(600),
    width = px(600)
  )
}

if (interactive()) {
  shinyApp(ui, server)
}
```

**gt_preview**

_preview a _gt_ table object_

Description

Sometimes you may want to see just a small portion of your input data. We can use `gt_preview()` in place of `gt()` to get the first x rows of data and the last y rows of data (which can be set by the `top_n` and `bottom_n` arguments). It's not advised to use additional `gt` functions to further modify the output of `gt_preview()`. Furthermore, you cannot pass a `gt` object to `gt_preview()`.
Usage

gt_preview(data, top_n = 5, bottom_n = 1, incl_rownums = TRUE)

Arguments

data A data.frame object or a tibble.
top_n This value will be used as the number of rows from the top of the table to display. The default, 5, will show the first five rows of the table.
bottom_n The value will be used as the number of rows from the bottom of the table to display. The default, 1, will show the final row of the table.
incl_rownums An option to include the row numbers for data in the table stub. By default, this is TRUE.

Details

Any grouped data or magic columns such as rowname and groupname will be ignored by gt_preview() and, as such, one cannot add a stub or group rows in the output table. By default, the output table will include row numbers in a stub (including a range of row numbers for the omitted rows). This row numbering option can be deactivated by setting incl_rownums to FALSE.

Value

An object of class gt_tbl.

Other Create Table: gt()

Examples

# Use `gtcars` to create a gt table
# preview (with only a few of its columns); you'll see the first five rows and the last row
tab_1 <-
gtcars %>%
dplyr::select(mfr, model, year) %>%
gt_preview()
html

Interpret input text as HTML-formatted text

Description

For certain pieces of text (like in column labels or table headings) we may want to express them as raw HTML. In fact, with HTML, anything goes so it can be much more than just text. The `html()` function will guard the input HTML against escaping, so, your HTML tags will come through as HTML when rendered... to HTML.

Usage

```r
html(text, ...)
```

Arguments

text, ... The text that is understood to be HTML text, which is to be preserved.

Value

A character object of class `html`. It’s tagged as an HTML fragment that is not to be sanitized.

Figures

Function ID

7-2

Other Helper Functions: `adjust_luminance()`, `cell_borders()`, `cell_fill()`, `cell_text()`, `cells_body()`, `cells_column_labels()`, `cells_column_spanners()`, `cells_grand_summary()`, `cells_row_groups()`, `cells_stubhead()`, `cells_stub()`, `cells_summary()`, `cells_title()`, `currency()`, `escape_latex()`, `gt_latex_dependencies()`, `md()`, `pct()`, `px()`, `random_id()`

Examples

```r
# Use `exibble` to create a gt table;
# when adding a title, use the `html()`
# helper to use html formatting

exibble <-
  dplyr::select(currency, char) %>%
  gt() %>%
  tab_header(
    title = html("<em>HTML</em>"))
```
info_currencies

View a table with info on supported currencies

Description

The `fmt_currency()` function lets us format numeric values as currencies. The table generated by the `info_currencies()` function provides a quick reference to all the available currencies. The currency identifiers are provided (name, 3-letter currency code, and 3-digit currency code) along with the each currency’s exponent value (number of digits of the currency subunits). A formatted example is provided (based on the value of 49.95) to demonstrate the default formatting of each currency.

Usage

```r
info_currencies(type = c("code", "symbol"), begins_with = NULL)
```

Arguments

- **type**
  - The type of currency information provided. Can either be code where currency information corresponding to 3-letter currency codes is provided, or symbol where currency info for common currency names (e.g., dollar, pound, yen, etc.) is returned.

- **begins_with**
  - Providing a single letter will filter currencies to only those that begin with that letter in their currency code. The default (NULL) will produce a table with all currencies displayed. This option only constrains the information table where type == "code".

Details

There are 172 currencies, which can lead to a verbose display table. To make this presentation more focused on retrieval, we can provide an initial letter corresponding to the 3-letter currency code to begins_with. This will filter currencies in the info table to just the set beginning with the supplied letter.

Figures

Function ID

Other Information Functions: `info_date_style()`, `info_locales()`, `info_paletteer()`, `info_time_style()`
Examples

# Get a table of info on all of the currencies where the three-letter code begins with a "h"
```r
tab_1 <- info_currencies(begins_with = "h")
```

# Get a table of info on all of the common currency name/symbols that can be used with `fmt_currency()`
```r
tab_2 <- info_currencies(type = "symbol")
```

```
info_date_style  View a table with info on date styles
```

Description

The `fmt_date()` function lets us format date-based values in a convenient manner using preset styles. The table generated by the `info_date_style()` function provides a quick reference to all 14 styles, with associated number codes, the format names, and example outputs using a fixed date (2000-02-29).

Usage

```r
info_date_style()
```

Figures

Function ID

Other Information Functions: `info_currencies()`, `info_locales()`, `info_paletteer()`, `info_time_style()`

Examples

# Get a table of info on the different date-formatting styles (which are used by supplying a number code to the `fmt_date()` function)
```r
tab_1 <- info_date_style()
```
Description

Many of the fmt_*( ) functions have a locale argument that makes locale-based formatting easier. The table generated by the info_locales( ) function provides a quick reference to all the available locales. The locale identifiers are provided (base locale ID, common display name) along with the each locale’s group and decimal separator marks. A formatted numeric example is provided (based on the value of 11027) to demonstrate the default formatting of each locale.

Usage

info_locales(begins_with = NULL)

Arguments

begins_with Providing a single letter will filter locales to only those that begin with that letter in their base locale ID. The default (NULL) will produce a table with all locales displayed.

Details

There are 712 locales, which means that a very long display table is provided by default. To trim down the output table size, we can provide an initial letter corresponding to the base locale ID to begins_with. This will filter locales in the info table to just the set that begins with the supplied letter.

Function ID

10-4

Examples

# Get a table of info on all of
# the locales where the base
# locale ID begins with a "v"

# Get a table of info on all of
# the locales where the base
# locale ID begins with a "v"

tab_1 <- info_locales(begins_with = "v")
Description

While the `data_color()` function allows us to flexibly color data cells in our `gt` table, the harder part of this process is discovering and choosing color palettes that are suitable for the table output. We can make this process much easier in two ways: (1) by using the `paletteer` package, which makes a wide range of palettes from various R packages readily available, and (2) calling the `info_paletteer()` function to give us an information table that serves as a quick reference for all of the discrete color palettes available in `paletteer`.

Usage

`info_paletteer(color_pkgs = NULL)`

Arguments

color_pkgs A vector of color packages that determines which sets of palettes should be displayed in the information table. If this is `NULL` (the default) then all of the discrete palettes from all of the color packages represented in `paletteer` will be displayed.

Details

The palettes displayed are organized by package and by palette name. These values are required when obtaining a palette (as a vector of hexadecimal colors), from the the `paletteer::paletteer_d()` function. Once we are familiar with the names of the color palette packages (e.g., `RColorBrewer`, `ggthemes`, `wesanderson`), we can narrow down the content of this information table by supplying a vector of such package names to `color_pkgs`.

Colors from the following color packages (all supported by `paletteer`) are shown by default with `info_paletteer()`:

- `awtools`, 5 palettes
- `dichromat`, 17 palettes
- `dutchmasters`, 6 palettes
- `gppomological`, 2 palettes
- `ggsci`, 42 palettes
- `ggthemes`, 31 palettes
- `ghibli`, 27 palettes
- `grDevices`, 1 palette
- `jcolors`, 13 palettes
- `LaCroixColoR`, 21 palettes
- `NineteenEightyR`, 12 palettes
- nord, 16 palettes
- ochRe, 16 palettes
- palettetown, 389 palettes
- pals, 8 palettes
- Polychrome, 7 palettes
- quickpalette, 17 palettes
- rcartocolor, 34 palettes
- RColorBrewer, 35 palettes
- Redmonder, 41 palettes
- wesanderson, 19 palettes
- yarr, 21 palettes

Other Information Functions: info_currencies(), info_date_style(), info_locales(), info_time_style()

Examples

```r
# Get a table of info on just the
# `ggthemes` color palette (easily
# accessible from the paletteer pkg)
tab_1 <-
  info_paletteer(
    color_pkgs = "ggthemes")
```

Description

The fmt_time() function lets us format time-based values in a convenient manner using preset styles. The table generated by the info_time_style() function provides a quick reference to all five styles, with associated number codes, the format names, and example outputs using a fixed time (14:35).
Usage

info_time_style()

Figures

Function ID

10-2

Other Information Functions: info_currencies(), info_date_style(), info_locales(), info_paletter()

Examples

# Get a table of info on the different
# time-formatting styles (which are used
# by supplying a number code to the
# `fmt_time()` function)
tab_1 <- info_time_style()

---

local_image(filename, height = 30)

Arguments

filename A path to an image file.
height The absolute height (px) of the image in the table cell.

Description

We can flexibly add a local image (i.e., an image residing on disk) inside of a table with local_image() function. The function provides a convenient way to generate an HTML fragment using an on-disk PNG or SVG. Because this function is currently HTML-based, it is only useful for HTML table output. To use this function inside of data cells, it is recommended that the text_transform() function is used. With that function, we can specify which data cells to target and then include a local_image() call within the required user-defined function (for the fn argument). If we want to include an image in other places (e.g., in the header, within footnote text, etc.) we need to use local_image() within the html() helper function.

Usage

local_image(filename, height = 30)
Details

By itself, the function creates an HTML image tag with an image URI embedded within. We can easily experiment with a local PNG or SVG image that’s available in the `gt` package using the `test_image()` function. Using that, the call `local_image(file = test_image(type = "png"))` evaluates to:

```html
<img cid=<random CID> src=<data URI> style="height:30px;">
```

where a height of 30px is a default height chosen to work well within the heights of most table rows.

Value

A character object with an HTML fragment that can be placed inside of a cell.

Figures

Function ID

8-2

See Also

Other Image Addition Functions: `ggplot_image()`, `test_image()`, `web_image()`

Examples

```r
# Create a tibble that contains heights
# of an image in pixels (one column as a
# string, the other as numerical values),
# then, create a gt table; use the
# `text_transform()` function to insert
# a local test image (PNG) image with the
# various sizes

tab_1 <-
  dplyr::tibble(
    pixels = px(seq(10, 35, 5)),
    image = seq(10, 35, 5)
  ) %>%
  gt()

%>%
  text_transform(
    locations = cells_body(vars(image)),
    fn = function(x) {
      local_image(
        filename = test_image(type = "png"),
        height = as.numeric(x)
      )
    }
  )
```
**Description**

Markdown! It’s a wonderful thing. We can use it in certain places (e.g., footnotes, source notes, the table title, etc.) and expect it to render to HTML as Markdown does. There is the `html()` helper that allows you to ferry in HTML but this function `md()`... it’s almost like a two-for-one deal (you get to use Markdown plus any HTML fragments *at the same time*).

**Usage**

`md(text)`

**Arguments**

- **text**
  The text that is understood to contain Markdown formatting.

**Value**

A character object of class `from_markdown`. It’s tagged as being Markdown text and it will undergo conversion to HTML.

**Figures**

**Function ID**

7-1

**See Also**

Other Helper Functions: `adjust_luminance()`, `cell_borders()`, `cell_fill()`, `cell_text()`, `cells_body()`, `cells_column_labels()`, `cells_column_spanners()`, `cells_grand_summary()`, `cells_row_groups()`, `cells_stubhead()`, `cells_stub()`, `cells_summary()`, `cells_title()`, `currency()`, `escape_latex()`, `gt_latex_dependencies()`, `html()`, `pct()`, `px()`, `random_id()`

**Examples**

```r
# Use 'exibble' to create a gt table;
# when adding a title, use the 'md()' helper to use Markdown formatting
tab_1 <-
exibble %>%
dplyr::select(currency, char) %>%
gt() %>%
tab_header(
  title = md("Using *Markdown*"))
```
**opt_align_table_header**

*Option to align the table header*

**Description**

By default, a table header added to a `gt` table has center alignment for both the title and the subtitle elements. This function allows us to easily set the horizontal alignment of the title and subtitle to the left or right by using the "align" argument. This function serves as a convenient shortcut for `<gt_tbl> %>% tab_options(heading.align = <align>).`

**Usage**

```r
opt_align_table_header(data, align = c("left", "center", "right"))
```

**Arguments**

- `data` A table object that is created using the `gt()` function.
- `align` The alignment of the title and subtitle elements in the table header. Options are "left" (the default), "center", or "right".

**Value**

An object of class `gt_tbl`.

**Figures**

**Function ID**

9.3

**See Also**

Other Table Option Functions: `opt_all_caps()`, `opt_footnote_marks()`, `opt_row_striping()`, `opt_table_lines()`, `opt_table_outline()`

**Examples**

```r
# Use `exibble` to create a `gt` table with
# a number of table parts added; the header
# (consisting of the title and the subtitle)
# are to be aligned to the left with the
# `opt_align_table_header()`' function

# `exibble` function

exibble <-
    exibble %>%
    gt(rowname_col = "row", groupname_col = "group") %>%
```
summary_rows(
  groups = "grp_a",
  columns = vars(num, currency),
  fns = list(
    min = ~min(., na.rm = TRUE),
    max = ~max(., na.rm = TRUE)
  )) %>%
grand_summary_rows(
  columns = vars(currency),
  fns = list(
    total = ~sum(., na.rm = TRUE)
  )) %>%
tab_source_note(source_note = "This is a source note.") %>%
tab_footnote(
  footnote = "This is a footnote.",
  locations = cells_body(columns = 1, rows = 1)
) %>%
tab_header(
  title = "The title of the table",
  subtitle = "The table's subtitle"
) %>%
opt_align_table_header(align = "left")

---

**opt_all_caps**  
*Option to use all caps in select table locations*

**Description**

Sometimes an all-capitalized look is suitable for a table. With the `opt_all_caps()` function, we can transform characters in the column labels, the stub, and in all row groups in this way (and there's control over which of these locations are transformed).

**Usage**

```r
opt_all_caps(
  data,
  all_caps = TRUE,
  locations = c("column_labels", "stub", "row_group")
)
```

**Arguments**

- `data` A table object that is created using the `gt()` function.
- `all_caps` A logical value to indicate whether the text transformation to all caps should be performed (TRUE, the default) or reset to default values (FALSE) for the locations targeted.
- `locations` Which locations should undergo this text transformation? By default it includes all of the "column_labels", the "stub", and the "row_group" locations. However, we could just choose one or two of those.
Details

This function serves as a convenient shortcut for `gt_tbl %>% tab_options(location).text_transform = "uppercase", location.font.size = pct(80), location.font.weight = "bolder") (for all locations selected).

Value

An object of class `gt_tbl`.

Other Table Option Functions: `opt_align_table_header()`, `opt_footnote_marks()`, `opt_row_striping()`, `opt_table_lines()`, `opt_table_outline()`

Examples

```r
# Use `exibble` to create a gt table with
# a number of table parts added; all text
# in the column labels, the stub, and in
# all row groups is to be transformed to
# all caps using `opt_all_caps`

tab_1 <-
  exibble %>%
    gt(rownames_col = "row", groupnames_col = "group") %>%
    summary_rows(
      groups = "grp_a",
      columns = vars(num, currency),
      fns = list(
        min = ~min(., na.rm = TRUE),
        max = ~max(., na.rm = TRUE)
      )) %>%
    grand_summary_rows(
      columns = vars(currency),
      fns = list(
        total = ~sum(., na.rm = TRUE)
      )) %>%
    tab_source_note(source_note = "This is a source note.") %>%
    tab_footnote(
      footnote = "This is a footnote.",
      locations = cells_body(columns = 1, rows = 1)
    ) %>%
    tab_header(
      title = "The title of the table",
```
opt_footnote_marks

Option to modify the set of footnote marks

Description
Alter the footnote marks for any footnotes that may be present in the table. Either a vector of marks can be provided (including Unicode characters), or, a specific keyword could be used to signify a preset sequence. This function serves as a shortcut for using `tab_options(footnotes.marks = {marks})`

Usage
`opt_footnote_marks(data, marks)`

Arguments
- `data`: A table object that is created using the `gt()` function.
- `marks`: Either a character vector of length greater than 1 (that will represent the series of marks) or a single keyword that represents a preset sequence of marks. The valid keywords are: "numbers" (for numeric marks), "letters" and "LETTERS" (for lowercase and uppercase alphabetic marks), "standard" (for a traditional set of four symbol marks), and "extended" (which adds two more symbols to the standard set).

Details
We can supply a vector of that will represent the series of marks. The series of footnote marks is recycled when its usage goes beyond the length of the set. At each cycle, the marks are simply doubled, tripled, and so on (e.g., * -> ** -> ***). The option exists for providing keywords for certain types of footnote marks. The keywords are:

- "numbers": numeric marks, they begin from 1 and these marks are not subject to recycling behavior
- "letters": miniscule alphabetic marks, internally uses the `letters` vector which contains 26 lowercase letters of the Roman alphabet
- "LETTERS": majuscule alphabetic marks, using the `LETTERS` vector which has 26 uppercase letters of the Roman alphabet
- "standard": symbolic marks, four symbols in total
- "extended": symbolic marks, extends the standard set by adding two more symbols, making six
Value

An object of class `gt_tbl`.

Other Table Option Functions: `opt_align_table_header()`, `opt_all_caps()`, `opt_row_striping()`, `opt_table_lines()`, `opt_table_outline()`

Examples

# Use `sza` to create a gt table,
# adding three footnotes; call
# `opt_footnote_marks()` to specify
# which footnote marks to use

```r
tab_1 <-
  sza %>%
  dplyr::group_by(latitude, tst) %>%
  dplyr::summarize(
    SZA.Max = max(sza),
    SZA.Min = min(sza, na.rm = TRUE)
  ) %>%
  dplyr::ungroup() %>%
  dplyr::filter(latitude == 30, !is.infinite(SZA.Min)) %>%
  dplyr::select(-latitude) %>%
  gt(rownname_col = "tst") %>%
  tab_spanner_delim(delim = ".") %>%
  fmt_missing(
    columns = everything(),
    missing_text = "90+"
  ) %>%
  tab_stubhead("TST") %>%
  tab_footnote(
    footnote = "True solar time. ",
    locations = cells_stubhead()
  ) %>%
  tab_footnote(
    footnote = "Solar zenith angle. ",
    locations = cells_column_spanners(spanners = "SZA")
  ) %>%
  tab_footnote(
    footnote = "The Lowest SZA. ",
    locations = cells_stub(rows = "1200")
  ) %>%
  opt_footnote_marks(marks = "standard")
```
opt_row_striping

Option to add or remove row striping

Description

By default, a gt table does not have row striping enabled. However, this function allows us to easily enable or disable striped rows in the table body. This function serves as a convenient shortcut for `<gt_tbl> %>% tab_options(row.striping.include_table_body = TRUE|FALSE).

Usage

`opt_row_striping(data, row_striping = TRUE)`

Arguments

- `data`: A table object that is created using the `gt()` function.
- `row_striping`: A logical value to indicate whether row striping should be added or removed.

Value

An object of class `gt_tbl`.

Examples

```r
# Use 'exibble' to create a gt table with
# a number of table parts added; next, we
# add row striping to every second row with
# the `opt_row_striping()` function

tab_1 <-
  exibble %>%
  gt(rowname_col = "row", groupname_col = "group") %>%
  summary_rows(
    groups = "grp_a",
    columns = vars(num, currency),
```
```r
fns = list(
  min = ~min(., na.rm = TRUE),
  max = ~max(., na.rm = TRUE)
)) %>%
grand_summary_rows(
  columns = vars(currency),
  fns = list(
    total = ~sum(., na.rm = TRUE)
  )
)

tab_source_note(source_note = "This is a source note.") %>%
tab_footnote(
  footnote = "This is a footnote.",
  locations = cells_body(columns = 1, rows = 1)
)

opt_row_striping()
```

---

**opt_table_lines**  
*Option to set table lines to different extents*

**Description**

The `opt_table_lines()` function sets table lines in one of three possible ways: (1) all possible table lines drawn ("all"), (2) no table lines at all ("none"), and (3) resetting to the default line styles ("default"). This is great if you want to start off with lots of lines and subtract just a few of them with `tab_options()` or `tab_style()`. Or, use it to start with a completely lineless table, adding individual lines as needed.

**Usage**

```r
opt_table_lines(data, extent = c("all", "none", "default"))
```

**Arguments**

- **data**  
  A table object that is created using the `gt()` function.

- **extent**  
  The extent to which lines will be visible in the table. Options are "all", "none", or "default".

**Value**

An object of class `gt_tbl`.

**Figures**
Function ID

9-5

Other Table Option Functions: opt_align_table_header(), opt_all_caps(), opt_footnote_marks(), opt_row_striping(), opt_table_outline()

Examples

# Use 'exibble' to create a gt table with
# a number of table parts added; then, use
# the `opt_table_lines()` function to
# have lines everywhere there can possibly
# be lines

```r
exibble <-
  exibble %>%
  gt(rowname_col = "row", groupname_col = "group") %>%
  summary_rows(
    groups = "grp_a",
    columns = vars(num, currency),
    fns = list(
      min = ~min(., na.rm = TRUE),
      max = ~max(., na.rm = TRUE)
    )) %>%
  grand_summary_rows(
    columns = vars(currency),
    fns = list(
      total = ~sum(., na.rm = TRUE)
    )) %>%
  tab_source_note(source_note = "This is a source note.") %>%
  tab_footnote(
    footnote = "This is a footnote.",
    locations = cells_body(columns = 1, rows = 1)
  ) %>%
  tab_header(
    title = "The title of the table",
    subtitle = "The table's subtitle"
  ) %>%
  opt_table_lines()
```
default value of style ("solid") will draw a solid outline, whereas a value of "none" will remove any present outline.

Usage

opt_table_outline(data, style = "solid", width = px(3), color = "#D3D3D3")

Arguments

data A table object that is created using the `gt()` function.

style, width, color
The style, width, and color properties for the table outline. By default, these are "solid", px(3) (or, "3px"), and "#D3D3D3". If "none" is used then the outline is removed and any values provided for width and color will be ignored (i.e., not set).

Value

An object of class `gt_tbl`.

Other Table Option Functions: `opt_align_table_header()`, `opt_all_caps()`, `opt_footnote_marks()`, `opt_row_striping()`, `opt_table_lines()`

Examples

```r
# Use `exibble` to create a gt table with
# a number of table parts added; have an
# outline wrap around the entire table by
# using `opt_table_outline()`

tab_1 <-
exibble %>%
  gt(rowname_col = "row", groupname_col = "group") %>%
  summary_rows(
    groups = "grp_a",
    columns = vars(num, currency),
    fns = list(
      min = ~min(., na.rm = TRUE),
      max = ~max(., na.rm = TRUE)
    )) %>%
  grand_summary_rows(
    columns = vars(currency),
```
pct

Helper for providing a numeric value as percentage

**Description**

A percentage value acts as a length value that is relative to an initial state. For instance an 80 percent value for something will size the target to 80 percent the size of its 'previous' value. This type of sizing is useful for sizing up or down a length value with an intuitive measure. This helper function can be used for the setting of font sizes (e.g., in `cell_text()`) and altering the thicknesses of lines (e.g., in `cell_borders()`). Should a more exact definition of size be required, the analogous helper function `pct()` will be more useful.

**Usage**

```r
pct(x)
```

**Arguments**

- `x`  
  the numeric value to format as a string percentage for some `tab_options()` arguments that can take percentage values (e.g., `table.width`).

**Value**

A character vector with a single value in percentage units.

**Figures**
Function ID

7-4

Examples

```r
# Use 'exibble' to create a gt table;
# use the 'pct()' helper to define the
# font size for the column labels
tab_1 <-
exibble %>%
gt() %>%
tab_style(  
  style = cell_text(size = pct(75)),  
  locations = cells_column_labels(columns = TRUE)  
)
```

pizzaplace

A year of pizza sales from a pizza place

Description

A synthetic dataset that describes pizza sales for a pizza place somewhere in the US. While the contents are artificial, the ingredients used to make the pizzas are far from it. There are 32 different pizzas that fall into 4 different categories: classic (classic pizzas: 'You probably had one like it before, but never like this!'), chicken (pizzas with chicken as a major ingredient: 'Try the Southwest Chicken Pizza! You'll love it!'), supreme (pizzas that try a little harder: 'My Soppressata pizza uses only the finest salami from my personal salumist!'), and, veggie (pizzas without any meats whatsoever: 'My Five Cheese pizza has so many cheeses, I can only offer it in Large Size!').

Usage

   pizzaplace

Format

A tibble with 49574 rows and 7 variables:

  id The ID for the order, which consists of one or more pizzas at a give date and time
  date A character representation of the order date, expressed in the ISO 8601 date format (YYYY-MM-DD)
**time**  A character representation of the order time, expressed as a 24-hour time the ISO 8601 extended time format (hh:mm:ss)

**name**  The short name for the pizza

**size**  The size of the pizza, which can either be S, M, L, XL (rare!), or XXL (even rarer!); most pizzas are available in the S, M, and L sizes but exceptions apply

**type**  The category or type of pizza, which can either be *classic*, *chicken*, *supreme*, or *veggie*

**price**  The price of the pizza and the amount that it sold for (in USD)

---

**Details**

Each pizza in the dataset is identified by a short name. The following listings provide the full names of each pizza and their main ingredients.

**Classic Pizzas:**

- **classic_dlx**: The Classic Deluxe Pizza (Pepperoni, Mushrooms, Red Onions, Red Peppers, Bacon)
- **big_meat**: The Big Meat Pizza (Bacon, Pepperoni, Italian Sausage, Chorizo Sausage)
- **pepperoni**: The Pepperoni Pizza (Mozzarella Cheese, Pepperoni)
- **hawaiian**: The Hawaiian Pizza (Sliced Ham, Pineapple, Mozzarella Cheese)
- **pep_msh_pep**: The Pepperoni, Mushroom, and Peppers Pizza (Pepperoni, Mushrooms, and Green Peppers)
- **ital_cpcllo**: The Italian Capocollo Pizza (Capocollo, Red Peppers, Tomatoes, Goat Cheese, Garlic, Oregano)
- **napolitana**: The Napolitana Pizza (Tomatoes, Anchovies, Green Olives, Red Onions, Garlic)
- **the_greek**: The Greek Pizza (Kalamata Olives, Feta Cheese, Tomatoes, Garlic, Beef Chuck Roast, Red Onions)

**Chicken Pizzas:**

- **thai_ckn**: The Thai Chicken Pizza (Chicken, Pineapple, Tomatoes, Red Peppers, Thai Sweet Chilli Sauce)
- **bbq_ckn**: The Barbecue Chicken Pizza (Barbecued Chicken, Red Peppers, Green Peppers, Tomatoes, Red Onions, Barbecue Sauce)
- **southw_ckn**: The Southwest Chicken Pizza (Chicken, Tomatoes, Red Peppers, Red Onions, Jalapeno Peppers, Corn, Cilantro, Chipotle Sauce)
- **cali_ckn**: The California Chicken Pizza (Chicken, Artichoke, Spinach, Garlic, Jalapeno Peppers, Fontina Cheese, Gouda Cheese)
- **ckn_pesto**: The Chicken Pesto Pizza (Chicken, Tomatoes, Red Peppers, Spinach, Garlic, Pesto Sauce)
- **ckn_alfredo**: The Chicken Alfredo Pizza (Chicken, Red Onions, Red Peppers, Mushrooms, Asiago Cheese, Alfredo Sauce)

**Supreme Pizzas:**

- **brie_carre**: The Brie Carre Pizza (Brie Carre Cheese, Prosciutto, Caramelized Onions, Pears, Thyme, Garlic)
• **calabrese**: The Calabrese Pizza (‘Nduja Salami, Pancetta, Tomatoes, Red Onions, Friggitello Peppers, Garlic)

• **soppressata**: The Soppressata Pizza (Soppressata Salami, Fontina Cheese, Mozzarella Cheese, Mushrooms, Garlic)

• **sicilian**: The Sicilian Pizza (Coarse Sicilian Salami, Tomatoes, Green Olives, Luganega Sausage, Onions, Garlic)

• **ital_supr**: The Italian Supreme Pizza (Calabrese Salami, Capocollo, Tomatoes, Red Onions, Green Olives, Garlic)

• **peppr_salami**: The Pepper Salami Pizza (Genoa Salami, Capocollo, Pepperoni, Tomatoes, Asiago Cheese, Garlic)

• **prsc_argla**: The Prosciutto and Arugula Pizza (Prosciutto di San Daniele, Arugula, Mozzarella Cheese)

• **spinach_supr**: The Spinach Supreme Pizza (Spinach, Red Onions, Pepperoni, Tomatoes, Artichokes, Kalamata Olives, Garlic, Asiago Cheese)

• **spicy_ital**: The Spicy Italian Pizza (Capocollo, Tomatoes, Goat Cheese, Artichokes, Peperoncini verdi, Garlic)

**Vegetable Pizzas**

• **mexicana**: The Mexicana Pizza (Tomatoes, Red Peppers, Jalapeno Peppers, Red Onions, Cilantro, Corn, Chipotle Sauce, Garlic)

• **four_cheese**: The Four Cheese Pizza (Ricotta Cheese, Gorgonzola Piccante Cheese, Mozzarella Cheese, Parmigiano Reggiano Cheese, Garlic)

• **five_cheese**: The Five Cheese Pizza (Mozzarella Cheese, Provolone Cheese, Smoked Gouda Cheese, Romano Cheese, Blue Cheese, Garlic)

• **spin_pesto**: The Spinach Pesto Pizza (Spinach, Artichokes, Tomatoes, Sun-dried Tomatoes, Garlic, Pesto Sauce)

• **veggie_veg**: The Vegetables + Vegetables Pizza (Mushrooms, Tomatoes, Red Peppers, Green Peppers, Red Onions, Zucchini, Spinach, Garlic)

• **green_garden**: The Green Garden Pizza (Spinach, Mushrooms, Tomatoes, Green Olives, Feta Cheese)

• **mediterraneo**: The Mediterranean Pizza (Spinach, Artichokes, Kalamata Olives, Sun-dried Tomatoes, Feta Cheese, Plum Tomatoes, Red Onions)

• **spinach_fet**: The Spinach and Feta Pizza (Spinach, Mushrooms, Red Onions, Feta Cheese, Garlic)

• **ital_veggie**: The Italian Vegetables Pizza (Eggplant, Artichokes, Tomatoes, Zucchini, Red Peppers, Garlic, Pesto Sauce)

```

---

**px**  
*Helper for providing a numeric value as pixels value*

---

**Description**

For certain parameters, a length value is required. Examples include the setting of font sizes (e.g., in `cell_text()`) and thicknesses of lines (e.g., in `cell_borders()`). Setting a length in pixels with `px()` allows for an absolute definition of size as opposed to the analogous helper function `pct()`.

**Usage**

```r
px(x)
```

**Arguments**

- `x`  
  the numeric value to format as a string (e.g., "12px") for some `tab_options()` arguments that can take values as units of pixels (e.g., `table.font.size`).

**Value**

A character vector with a single value in pixel units.

random_id

Examples

```r
# Use `exibble` to create a gt table;
# use the `px()` helper to define the
# font size for the column labels
tab_1 <-
exibble %>%
  gt() %>%
  tab_style(
    style = cell_text(size = px(20)),
    locations = cells_column_labels(columns = TRUE)
  )
```

random_id  Helper for creating a random id for a gt table

Description

This helper function can be used to create a random, character-based ID value argument of variable length (the default is 10 letters).

Usage

```r
random_id(n = 10)
```

Arguments

- `n` The number of lowercase letters to use for the random ID.

Value

A character vector containing a single, random ID.

Function ID

7.19

render_gt

A `gt` display table render function for use in Shiny

Description

With `render_gt()` we can create a reactive `gt` table that works wonderfully once assigned to an output slot (with `gt_output()`). This function is to be used within Shiny's `server()` component. We have some options for controlling the size of the container holding the `gt` table. The `width` and `height` arguments allow for sizing the container, and the `align` argument allows us to align the table within the container (some other fine-grained options for positioning are available in the `tab_options()` function).

Usage

```r
render_gt(
  expr, 
  width = NULL, 
  height = NULL, 
  align = NULL, 
  env = parent.frame(), 
  quoted = FALSE, 
  outputArgs = list()
)
```

Arguments

- `expr` An expression that creates a `gt` table object. For sake of convenience, a data frame or tibble can be used here (it will be automatically introduced to `gt()` with its default options).
- `width, height` The width and height of the table's container. Either can be specified as a single-length character with units of pixels or as a percentage. If provided as a single-length numeric vector, it is assumed that the value is given in units of pixels. The `px()` and `pct()` helper functions can also be used to pass in numeric values and obtain values as pixel or percent units.
- `align` The alignment of the table in its container. By default, this is "center". Other options are "left" and "right".
- `env` The environment in which to evaluate the `expr`.
- `quoted` Is `expr` a quoted expression (with `quote()`)? This is useful if you want to save an expression in a variable.
- `outputArgs` A list of arguments to be passed through to the implicit call to `gt_output()` when `render_gt` is used in an interactive R Markdown document.

Details

We need to ensure that we have the `shiny` package installed first. This is easily by using `install.packages("shiny")`. More information on creating Shiny apps can be found at the [Shiny Site](#).
Function ID

12-1

Other Shiny functions: `gt_output()`

Examples

```r
library(shiny)

# Here is a Shiny app (contained within
# a single file) that (1) prepares a
# gt table, (2) sets up the `ui` with
# `gt_output()`, and (3) sets up the
# `server` with a `render_gt()` that
# uses the `gt_tbl` object as the input
# expression

gt_tbl <-
gtcars %>%
  gt() %>%
  cols_hide(contains("_"))

ui <- fluidPage(
  gt_output(outputId = "table")
)

server <- function(input, output, session) {
  output$table <-
    render_gt(
      expr = gt_tbl,
      height = px(600),
      width = px(600)
    )
}

if (interactive()) {
  shinyApp(ui, server)
}
```

*row_group_order*  Modify the ordering of any row groups
Description

We can modify the display order of any row groups in a gt object with the `row_group_order()` function. The `groups` argument can either take a vector of row group names or a numeric vector of row group indices; whichever is provided, the row groups will adhere to this revised ordering. It isn’t necessary to provide all row group names in `groups`, rather, what is provided will assume the specified ordering at the top of the table and the remaining row groups will follow in their original ordering.

Usage

`row_group_order(data, groups)`

Arguments

data A table object that is created using the `gt()` function.

groups A vector of row group names, or, a numeric vector of indices corresponding to the new ordering. Either vector must correspond to assigned group names or the index positions. Also, either type of vector is not required to have all of the row group names or available index positions within it; any omitted values will be added to the end while preserving the original ordering.

Value

An object of class `gt_tbl`.

Figures

Function ID

5-1

Examples

```r
# Use `exibble` to create a gt table
# with a stub and with row groups;
# modify the order of the row groups
# with `row_group_order()`, specifying
# the new ordering in `groups`

tab_1 <-
exibble %>%
dplyr::select(char, currency, row, group) %>%
  gt(
    rowname_col = "row",
    groupname_col = "group"
  ) %>%
  row_group_order(
    groups = c("grp_b", "grp_a")
  )
```
Description

This dataset provides daily price indicators for the S&P 500 index from the beginning of 1950 to the end of 2015. The index includes 500 leading companies and captures about 80%

Usage

sp500

Format

A tibble with 16607 rows and 7 variables:

date  The date expressed as Date values
open, high, low, close  The day’s opening, high, low, and closing prices in USD; the close price is adjusted for splits
volume  the number of trades for the given date
adj_close  The close price adjusted for both dividends and splits

Function ID

11-4

Examples

# Here is a glimpse at the data
# available in `sp500`
dplyr::glimpse(sp500)
summary_rows  Add groupwise summary rows using aggregation functions

Description

Add summary rows to one or more row groups by using the table data and any suitable aggregation functions. You choose how to format the values in the resulting summary cells by use of a formatter function (e.g., `fmt_number`, etc.) and any relevant options.

Usage

```r
summary_rows(
  data,
  groups = NULL,
  columns = TRUE,
  fns,
  missing_text = "---",
  formatter = fmt_number,
  ...
)
```

Arguments

data  A table object that is created using the `gt()` function.

groups  The groups to consider for generation of groupwise summary rows. By default this is set to `NULL`, which results in the formation of grand summary rows (a grand summary operates on all table data). Providing the names of row groups in `c()` will create a groupwise summary and generate summary rows for the specified groups. Setting this to `TRUE` indicates that all available groups will receive groupwise summary rows.

columns  The columns for which the summaries should be calculated.
fns  Functions used for aggregations. This can include base functions like `mean`, `min`, `max`, `median`, `sd`, or `sum` or any other user-defined aggregation function. The function(s) should be supplied within a `list()`. Within that list, we can specify the functions by use of function names in quotes (e.g., "sum"), as bare functions (e.g., `sum`), or as one-sided R formulas using a leading `~`. In the formula representation, a `.serves as the data to be summarized (e.g., `sum(. , na.rm = TRUE)`). The use of named arguments is recommended as the names will serve as summary row labels for the corresponding summary rows data (the labels can derived from the function names but only when not providing bare function names).

missing_text  The text to be used in place of NA values in summary cells with no data outputs.

formatter  A formatter function name. These can be any of the `fmt_*()` functions available in the package (e.g., `fmt_number()`, `fmt_percent()`, etc.), or a custom function using `fmt()`. The default function is `fmt_number()` and its options can be accessed through . . .
Summary Rows

Values passed to the formatter function, where the provided values are to be in the form of named vectors. For example, when using the default formatter function, `fmt_number()`, options such as `decimals`, `use_seps`, and `locale` can be used.

Details

Should we need to obtain the summary data for external purposes, the `extract_summary()` function can be used with a `gt_tbl` object where summary rows were added via `summary_rows()`.

Value

An object of class `gt_tbl`.

Figures

Function ID

6-1

Other Add Rows: `grand_summary_rows()`

Examples

```r
# Use `sp500` to create a gt table with # row groups; create summary rows (`min`, # `max`, `avg`) by row group, where each # each row group is a week number

tab_1 <-
  sp500 %>%
  dplyr::filter(
    date >= "2015-01-05" &
    date <= "2015-01-16"
  ) %>%
  dplyr::arrange(date) %>%
  dplyr::mutate(
    week = paste0(
      "W", strftime(date, format = "%V")
    )
  ) %>%
  dplyr::select(-adj_close, -volume) %>%
  gt(
    rowname_col = "date",
    groupname_col = "week"
  ) %>%
  summary_rows(
    groups = TRUE,
    columns = vars(open, high, low, close),
    fns = list(
```
min = ~min(.),
max = ~max(.),
avg = ~mean(.)),
formatter = fmt_number,
use_seps = FALSE
)

sza

Twice hourly solar zenith angles by month & latitude

Description
This dataset contains solar zenith angles (in degrees, with the range of 0-90) every half hour from 04:00 to 12:00, true solar time. This set of values is calculated on the first of every month for 4 different northern hemisphere latitudes. For determination of afternoon values, the presented tabulated values are symmetric about noon.

Usage
sza

Format
A tibble with 816 rows and 4 variables:

latitude The latitude in decimal degrees for the observations
month The measurement month; all calculations where conducted for the first day of each month
tst The true solar time at the given latitude and date (first of month) for which the solar zenith angle is calculated
sza The solar zenith angle in degrees, where NAs indicate that sunrise hadn’t yet occurred by the tst value

Details
The solar zenith angle (SZA) is one measure that helps to describe the sun’s path across the sky. It’s defined as the angle of the sun relative to a line perpendicular to the earth’s surface. It is useful to calculate the SZA in relation to the true solar time. True solar time relates to the position of the sun with respect to the observer, which is different depending on the exact longitude. For example, two hours before the sun crosses the meridian (the highest point it would reach that day) corresponds to a true solar time of 10 a.m. The SZA has a strong dependence on the observer’s latitude. For example, at a latitude of 50 degrees N at the start of January, the noontime SZA is 73.0 but a different observer at 20 degrees N would measure the noontime SZA to be 43.0 degrees.

---

**Description**

The `tab_footnote()` function can make it a painless process to add a footnote to a `gt` table. There are two components to a footnote: (1) a footnote mark that is attached to the targeted cell text, and (2) the footnote text (that starts with the corresponding footnote mark) that is placed in the table’s footer area. Each call of `tab_footnote()` will add a different note, and one or more cells can be targeted via the location helper functions (e.g., `cells_body()`, `cells_column_labels()`, etc.).

**Usage**

`tab_footnote(data, footnote, locations)`

**Arguments**

data: A table object that is created using the `gt()` function.

footnote: The text to be used in the footnote. We can optionally use the `md()` and `html()` functions to style the text as Markdown or to retain HTML elements in the footnote text.

locations: The cell or set of cells to be associated with the footnote. Supplying any of the `cells_*()` helper functions is a useful way to target the location cells that are associated with the footnote text. These helper functions are: `cells_title()`, `cells_stubhead()`, `cells_column_spanners()`, `cells_column_labels()`, `cells_row_groups()`, `cells_stub()`, `cells_body()`, `cells_summary()`, and `cells_grand_summary()`. Additionally, we can enclose several `cells_*()` calls within a `list()` if we wish to link the footnote text to different types of locations (e.g., body cells, row group labels, the table title, etc.).
Details

The formatting of the footnotes can be controlled through the use of various parameters in the `tab_options()` function:

- `footnotes.sep`: allows for a choice of the separator between consecutive footnotes in the table footer. By default, this is set to a linebreak.
- `footnotes.marks`: the set of sequential characters or numbers used to identify the footnotes.
- `footnotes.font.size`: the size of the font used in the footnote section.
- `footnotes.padding`: the amount of padding to apply between the footnote and source note sections in the table footer.

Value

An object of class `gt_tbl`.

Other Create or Modify Parts: `tab_header()`, `tab_options()`, `tab_row_group()`, `tab_source_note()`, `tab_spanner_delim()`, `tab_spanner()`, `tab_stubhead()`, `tab_style()`

Examples

# Use 'sza' to create a gt table; color
# the 'sza' column using the 'data_color()' function, then, add a footnote to the
# 'sza' column label explaining what the
# color scale signifies

```r
sza <-
  sza %>%
  dplyr::filter(
    latitude == 20 &
    month == "jan" &
    !is.na(sza)
  ) %>%
  dplyr::select(-latitude, -month) %>%
  gt() %>%
  data_color(
    columns = vars(sza),
    colors = scales::col_numeric(
      palette = c("white", "yellow", "navyblue"),
      domain = c(0, 90))
  ) %>%
```
**tab_header**

```
    tab_footnote(
        footnote = "Color indicates height of sun.",
        locations = cells_column_labels(
            columns = vars(sza))
    )
```

---

**tab_header**  
*Add a table header*

**Description**

We can add a table header to the **gt** table with a title and even a subtitle. A table header is an optional table part that is positioned above the column labels. We have the flexibility to use Markdown formatting for the header’s title and subtitle. Furthermore, if the table is intended for HTML output, we can use HTML in either of the title or subtitle.

**Usage**

```
tab_header(data, title, subtitle = NULL)
```

**Arguments**

- **data**  
  A table object that is created using the `gt()` function.

- **title, subtitle**  
  Text to be used in the table title and, optionally, for the table subtitle. We can elect to use the `md()` and `html()` helper functions to style the text as Markdown or to retain HTML elements in the text.

**Value**

An object of class `gt_tbl`.

Examples

# Use `gtcars` to create a gt table;
# add a header part to contain a title
# and subtitle

```r
tab_1 <-
  gtcars %>%
  dplyr::select(mfr, model, msrp) %>%
  dplyr::slice(1:5) %>%
  gt() %>%
  tab_header(
    title = md("Data listing from **gtcars**"),
    subtitle = md("gtcars is an R dataset")
  )
```

---

**tab_options**

Modify the table output options

Description

Modify the options available in a table. These options are named by the components, the subcomponents, and the element that can be adjusted.

Usage

```r
tab_options(
  data,
  container.width = NULL,
  container.height = NULL,
  container.overflow.x = NULL,
  container.overflow.y = NULL,

)

Arguments

data
A table object that is created using the `gt()` function.

container.width, container.height
The width and height of the table’s container. Can be specified as a single-length character with units of pixels or as a percentage. If provided as a single-length numeric vector, it is assumed that the value is given in units of pixels. The `px()` and `pct()` helper functions can also be used to pass in numeric values and obtain values as pixel or percent units.

container.overflow.x, container.overflow.y
Options to enable scrolling in the horizontal and vertical directions when the table content overflows the container dimensions. Using `TRUE` (the default for both) means that horizontal or vertical scrolling is enabled to view the entire table in those directions. With `FALSE`, the table may be clipped if the table width or height exceeds the `container.width` or `container.height`.

table.width
The width of the table. Can be specified as a single-length character with units of pixels or as a percentage. If provided as a single-length numeric vector, it is assumed that the value is given in units of pixels. The `px()` and `pct()` helper functions can also be used to pass in numeric values and obtain values as pixel or percent units.

table.align
The horizontal alignment of the table in its container. By default, this is "center". Other options are "left" and "right". This will automatically set `table.margin.left` and `table.margin.right` to the appropriate values.

table.margin.left, table.margin.right
The size of the margins on the left and right of the table within the container. Can be specified as a single-length character with units of pixels or as a percentage. If provided as a single-length numeric vector, it is assumed that the value is given in units of pixels. The `px()` and `pct()` helper functions can also be used to pass in numeric values and obtain values as pixel or percent units. Using `table.margin.left` or `table.margin.right` will overwrite any values set by `table.align`.

table.background.color, heading.background.color, column_labels.background.color, row_group.background.color, ... grand_summary_row.background.color, footnotes.background.color, source_notes.background.color
Background colors for the parent element `table` and the following child elements: `heading`, `column_labels`, `row_group`, `stub`, `summary_row`, `grand_summary_row`, `footnotes`, and `source_notes`. A color name or a hexadecimal color code should be provided.
```
**tab_options**

- **table.font.color**, **table.font.color.light**
  - The text color used throughout the table. There are two variants: `table.font.color` is for text overlaid on lighter background colors, and `table.font.color.light` is automatically used when text needs to be overlaid on darker background colors. A color name or a hexadecimal color code should be provided.

  - The font sizes for the parent text element `table` and the following child elements: `heading.title`, `heading.subtitle`, `column_labels`, `row_group`, `footnotes`, and `source_notes`. Can be specified as a single-length character vector with units of pixels (e.g., 12px) or as a percentage (e.g., 80%). If provided as a single-length numeric vector, it is assumed that the value is given in units of pixels. The `px()` and `pct()` helper functions can also be used to pass in numeric values and obtain values as pixel or percentage units.

  - The style, width, and color properties of the table's absolute top and absolute bottom borders.

- **heading.align**
  - Controls the horizontal alignment of the heading title and subtitle. We can either use "center", "left", or "right".

- **heading.title.font.weight**, **heading.subtitle.font.weight**, **column_labels.font.weight**, **row_group.font.weight**, **stub.font.weight**
  - The font weights of the `heading.title`, `heading.subtitle`, `column_labels`, `row_group`, and `stub` text elements. Can be a text-based keyword such as "normal", "bold", "lighter", "bolder", or a numeric value between 1 and 1000, inclusive. Note that only variable fonts may support the numeric mapping of weight.

- **heading.border.bottom.style**, **heading.border.bottom.width**, **heading.border.bottom.color**
  - The style, width, and color properties of the header's bottom border. This border shares space with that of the `column_labels` location. If the width of this border is larger, then it will be the visible border.

- **heading.border.lr.style**, **heading.border.lr.width**, **heading.border.lr.color**
  - The style, width, and color properties for the left and right borders of the heading location.

- **column_labels.text_transform**, **row_group.text_transform**, **stub.text_transform**, **summary_row.text_transform**, **grand_summary_row.text_transform**
  - Options to apply text transformations to the `column_labels`, `row_group`, `stub`, `summary_row`, and `grand_summary_row` text elements. Either of the "uppercase", "lowercase", or "capitalize" keywords can be used.

- **column_labels.vlines.style**, **column_labels.vlines.width**, **column_labels.vlines.color**
  - The style, width, and color properties for all vertical lines ('vlines') of the the `column_labels`.

- **column_labels.border.top.style**, **column_labels.border.top.width**, **column_labels.border.top.color**
  - The style, width, and color properties for the top border of the `column_labels` location. This border shares space with that of the heading location. If the width of this border is larger, then it will be the visible border.

- **column_labels.border.bottom.style**, **column_labels.border.bottom.width**, **column_labels.border.bottom.color**
  - The style, width, and color properties for the bottom border of the `column_labels` location.

- **column_labels.border.lr.style**, **column_labels.border.lr.width**, **column_labels.border.lr.color**
  - The style, width, and color properties for the left and right borders of the `column_labels` location.
**tab_options**

*column_labels.hidden*

An option to hide the column labels. If providing `TRUE` then the entire `column_labels` location won't be seen and the table header (if present) will collapse downward.

*row_group.border.top.style*, *row_group.border.top.width*, *row_group.border.top.color*, *row_group.border.right.style*, *row_group.border.right.width*, *row_group.border.right.color*

The style, width, and color properties for all top, bottom, left, and right borders of the `row_group` location.

*table_body.hlines.style*, *table_body.hlines.width*, *table_body.hlines.color*, *table_body.vlines.style*, *table_body.vlines.width*, *table_body.vlines.color*

The style, width, and color properties for all horizontal lines (‘hlines’) and vertical lines (‘vlines’) in the `table_body`.

*table_body.border.top.style*, *table_body.border.top.width*, *table_body.border.top.color*, *table_body.border.bottom.style*, *table_body.border.bottom.width*, *table_body.border.bottom.color*

The style, width, and color properties for all top and bottom borders of the `table_body` location.

*stub.border.style*, *stub.border.width*, *stub.border.color*

The style, width, and color properties for the vertical border of the table stub.

*data_row.padding*, *row_group.padding*, *summary_row.padding*, *grand_summary_row.padding*, *footnotes.padding*

The amount of vertical padding to incorporate in the `data_row`, `row_group`, `summary_row`, `grand_summary_row`, `footnotes` locations.

*summary_row.border.style*, *summary_row.border.width*, *summary_row.border.color*

The style, width, and color properties for all horizontal borders of the `summary_row` location.

*grand_summary_row.border.style*, *grand_summary_row.border.width*, *grand_summary_row.border.color*

The style, width, and color properties for the top borders of the `grand_summary_row` location.

*footnotes.border.bottom.style*, *footnotes.border.bottom.width*, *footnotes.border.bottom.color*

The style, width, and color properties for the bottom border of the `footnotes` location.

*footnotes.border.lr.style*, *footnotes.border.lr.width*, *footnotes.border.lr.color*

The style, width, and color properties for the left and right borders of the `footnotes` location.

*footnotes.sep*

The separating characters between adjacent footnotes in the `footnotes` section.
The default value produces a linebreak.

*footnotes.marks*

The set of sequential marks used to reference and identify each of the footnotes (same input as the `opt_footnote_marks()` function). We can supply a vector that represents the series of footnote marks. This vector is recycled when its usage goes beyond the length of the set. At each cycle, the marks are simply combined (e.g., * -> ** -> ***). The option exists for providing keywords for certain types of footnote marks. The keyword “numbers” (the default, indicating that we want to use numeric marks). We can use lowercase “letters” or uppercase “LETTERS”. There is the option for using a traditional symbol set where “standard” provides four symbols, and, “extended” adds two more symbols, making six.

*source_notes.border.bottom.style*, *source_notes.border.bottom.width*, *source_notes.border.bottom.color*

The style, width, and color properties for the bottom border of the `source_notes` location.

*source_notes.border.lr.style*, *source_notes.border.lr.width*, *source_notes.border.lr.color*

The style, width, and color properties for the left and right borders of the `source_notes` location.
row.striping.background_color
The background color for striped table body rows. A color name or a hexadecimal color code should be provided.

row.striping.include_stub
An option for whether to include the stub when striping rows.

row.striping.include_table_body
An option for whether to include the table body when striping rows.

Value
An object of class `gt_tbl`.

# Reduce the size of the title and the subtitle text
tab_6 <-
  tab_1 %>%
  tab_options(
    heading.title.font.size = "small",
    heading.subtitle.font.size = "small"
  )
**Description**

Create a row group with a collection of rows. This requires specification of the rows to be included, either by supplying row labels, row indices, or through use of a select helper function like `starts_with()`.

**Usage**

```r
tab_row_group(data, group = NULL, rows = NULL, others = NULL)
```

**Arguments**

- `data` A table object that is created using the `gt()` function.
- `group` The name of the row group. This text will also serve as the row group label.
- `rows` The rows to be made components of the row group. Can either be a vector of row captions provided in `c()`, a vector of row indices, or a helper function focused on selections. The select helper functions are: `starts_with()`, `ends_with()`, `contains()`, `matches()`, `one_of()`, and `everything()`.
- `others` An option to set a default row group label for any rows not formally placed in a row group named by `group` in any call of `tab_row_group()`. A separate call to `tab_row_group()` with only a value to `others` is possible and makes explicit that the call is meant to provide a default row group label. If this is not set and there are rows that haven’t been placed into a row group (where one or more row groups already exist), those rows will be automatically placed into a row group without a label.

**Value**

An object of class `gt_tbl`.

Other Create or Modify Parts: `tab_footnote()`, `tab_header()`, `tab_options()`, `tab_source_note()`, `tab_spanner_delim()`, `tab_spanner()`, `tab_stubhead()`, `tab_style()`
Examples

# Use `gtcars` to create a gt table and
# add two row groups with the labels:
# `numbered` and `NA` (a group without
# a title, or, the rest)
tab_1 <-
gtcars %>%
dplyr::select(model, year, hp, trq) %>%
dplyr::slice(1:8) %>%
gt(rowname_col = "model") %>%
tab_row_group(
  group = "numbered",
  rows = matches("^[0-9]")
)

# Use `gtcars` to create a gt table;
# add two row groups with the labels
# `powerful` and `super powerful`: the
# distinction being `hp` lesser or
# greater than `600`
tab_2 <-
gtcars %>%
dplyr::select(model, year, hp, trq) %>%
dplyr::slice(1:8) %>%
gt(rowname_col = "model") %>%
tab_row_group(
  group = "powerful",
  rows = hp <= 600
) %>%
tab_row_group(
  group = "super powerful",
  rows = hp > 600
)

---

**tab_source_note**  
*Add a source note citation*

Description

Add a source note to the footer part of the gt table. A source note is useful for citing the data included in the table. Several can be added to the footer, simply use multiple calls of `tab_source_note()` and they will be inserted in the order provided. We can use Markdown formatting for the note, or, if the table is intended for HTML output, we can include HTML formatting.

Usage

```
  tab_source_note(data, source_note)
```
Arguments

- **data**: A table object that is created using the `gt()` function.
- **source_note**: Text to be used in the source note. We can optionally use the `md()` and `html()` functions to style the text as Markdown or to retain HTML elements in the text.

Value

An object of class `gt_tbl`.

# Use `gtcars` to create a gt table;
# add a source note to the table
# footer that cites the data source

tab_1 <-
gtcars %>%
dplyr::select(mfr, model, msrp) %>%
dplyr::slice(1:5) %>%
gt() %>%
tab_source_note(
  source_note = "From edmunds.com"
)
```

---

**tab_spanner**  Add a spanner column label

Description

Set a spanner column label by mapping it to columns already in the table. This label is placed above one or more column labels, spanning the width of those columns and column labels.

Usage

```
tab_spanner(data, label, columns, gather = TRUE)
```
Arguments

- **data**: A table object that is created using the `gt()` function.
- **label**: The text to use for the spanner column label.
- **columns**: The columns to be components of the spanner heading.
- **gather**: An option to move the specified columns such that they are unified under the spanner column label. Ordering of the moved-into-place columns will be preserved in all cases.

Value

An object of class `gt_tbl`.

Figures

Function ID

Other Create or Modify Parts: `tab_footnote()`, `tab_header()`, `tab_options()`, `tab_row_group()`, `tab_source_note()`, `tab_spanner_delim()`, `tab_stubhead()`, `tab_style()`

Examples

```r
# Use 'gtcars' to create a gt table;
# Group several columns related to car
# performance under a spanner column
# with the label 'performance'

tab_1 <-
gtcars %>%
dplyr::select(
  -mfr, -trim, bdy_style, drivetrain,
  -drivetrain, -trsmn, -ctry_origin
) %>%
dplyr::slice(1:8) %>%
gt(rownames_col = "model") %>%
tab_spanner(
  label = "performance",
  columns = vars(
    hp, hp_rpm, trq, trq_rpm,
    mpg_c, mpg_h
  )
)
```
Description

This function will split selected delimited column names such that the first components (LHS) are promoted to being spanner column labels, and the secondary components (RHS) will become the column labels. Please note that reference to individual columns must continue to be the column names from the input table data (which are unique by necessity).

Usage

```r
tab_spanner_delim(data, delim, columns = NULL, gather = TRUE)
```

Arguments

- **data**: A table object that is created using the `gt()` function.
- **delim**: The delimiter to use to split an input column name. The delimiter supplied will be autoescaped for the internal splitting procedure. The first component of the split will become the group name and the second component will be the column label.
- **columns**: An optional vector of column names that this operation should be limited to. The default is to consider all columns in the table.
- **gather**: An option to move the specified columns such that they are unified under the spanner column label. Ordering of the moved-into-place columns will be preserved in all cases.

Details

If we look to the column names in the `iris` dataset as an example of how `tab_spanner_delim()` might be useful, we find the names `Sepal.Length`, `Sepal.Width`, `Petal.Length`, `Petal.Width`. From this naming system, it's easy to see that the `Sepal` and `Petal` can group together the repeated `Length` and `Width` values. In your own datasets, we can avoid a lengthy relabeling with `cols_label()` if column names can be fashioned beforehand to contain both the spanner column label and the column label. An additional advantage is that the column names in the input table data remain unique even though there may eventually be repeated column labels in the rendered output table.

Value

An object of class `gt_tbl`.

Figures
Add label text to the stubhead

**Description**

Add a label to the stubhead of a **gt** table. The stubhead is the lone element that is positioned left of the column labels, and above the stub. If a stub does not exist, then there is no stubhead (so no change will be made when using this function in that case). We have the flexibility to use Markdown formatting for the stubhead label. Furthermore, if the table is intended for HTML output, we can use HTML for the stubhead label.

**Usage**

```r
tab_stubhead(data, label)
```

**Arguments**

- `data`: A table object that is created using the **gt()** function.
- `label`: The text to be used as the stubhead label. We can optionally use the **md()** and **html()** functions to style the text as Markdown or to retain HTML elements in the text.

**Value**

An object of class **gt_tbl**.

Other Create or Modify Parts: `tab_footnote()`, `tab_header()`, `tab_options()`, `tab_row_group()`, `tab_source_note()`, `tab_spanner_delim()`, `tab_spanner()`, `tab_style()`

Examples

```r
# Use 'gtcars' to create a gt table; add
# a stubhead label to describe what is
# in the stub
tab_1 <-
gtcars %>%
dplyr::select(model, year, hp, trq) %>%
dplyr::slice(1:5) %>%
gt(rowname_col = "model") %>%
tab_stubhead(label = "car")
```

Description

With the `tab_style()` function we can target specific cells and apply styles to them. This is best done in conjunction with the helper functions `cell_text()`, `cell_fill()`, and `cell_borders()`. At present this function is focused on the application of styles for HTML output only (as such, other output formats will ignore all `tab_style()` calls). Using the aforementioned helper functions, here are some of the styles we can apply:

- the background color of the cell (`cell_fill()`: color)
- the cell’s text color, font, and size (`cell_text()`: color, font, size)
- the text style (`cell_text()`: style), enabling the use of italics or oblique text.
- the text weight (`cell_text()`: weight), allowing the use of thin to bold text (the degree of choice is greater with variable fonts)
- the alignment and indentation of text (`cell_text()`: align and indent)
- the cell borders (`cellBorders()`)

Usage

```r
tab_style(data, style, locations)
```
Arguments

data A table object that is created using the `gt()` function.

style a vector of styles to use. The `cell_text()`, `cell_fill()`, and `cell_borders()` helper functions can be used here to more easily generate valid styles. If using more than one helper function to define styles, all calls must be enclosed in a `list()`.

locations the cell or set of cells to be associated with the style. Supplying any of the `cells_*( )` helper functions is a useful way to target the location cells that are associated with the styling. These helper functions are: `cells_title()`, `cells_stubhead()`, `cells_column_spanners()`, `cells_column_labels()`, `cells_row_groups()`, `cells_stub()`, `cells_body()`, `cells_summary()`, and `cells_grand_summary()`. Additionally, we can enclose several `cells_*( )` calls within a `list()` if we wish to apply styling to different types of locations (e.g., body cells, row group labels, the table title, etc.).

Value

An object of class `gt_tbl`.

`cell_text()`, `cell_fill()`, and `cell_borders()` as helpers for defining custom styles and `cells_body()` as one of many useful helper functions for targeting the locations to be styled.

Other Create or Modify Parts: `tab_footnote()`, `tab_header()`, `tab_options()`, `tab_row_group()`, `tab_source_note()`, `tab_spanner_delim()`, `tab_spanner()`, `tab_stubhead()`

Examples

```r
# Use `exibble` to create a gt table;
# add styles that are to be applied
# to data cells that satisfy a
# condition (using `tab_style()`)

tab_1 <-
exibble %>%
dplyr::select(num, currency) %>%
gt() %>%
fmt_number(
  columns = vars(num, currency),
  decimals = 1
) %>%
tab_style(
```
style = list(
    cell_fill(color = "lightcyan"),
    cell_text(weight = "bold")
),
locations = cells_body(
    columns = vars(num),
    rows = num >= 5000
)
) %>%
tab_style(
    style = list(
        cell_fill(color = "#F9E3D6"),
        cell_text(style = "italic")
    ),
    locations = cells_body(
        columns = vars(currency),
        rows = currency < 100
    )
)

# Use `sp500` to create a gt table;
# color entire rows of cells based
# on values in a particular column
tab_2 <-
sp500 %>%
dplyr::filter(
    date >= "2015-12-01" &
    date <= "2015-12-15"
) %>%
dplyr::select(-c(adj_close, volume)) %>%
_gt() %>%
tab_style(
    style = cell_fill(color = "lightgreen"),
    locations = cells_body(
        rows = close > open
    )
) %>%
tab_style(
    style = list(
        cell_fill(color = "red"),
        cell_text(color = "white")
    ),
    locations = cells_body(
        rows = open > close
    )
)

---
test_image

**Generate a path to a test image**

**Description**

Two test images are available within the gt package. Both contain the same imagery (sized at 200px by 200px) but one is a PNG file while the other is an SVG file. This function is most useful when
text_transform

paired with `local_image()` since we test various sizes of the test image within that function.

Usage

test_image(type = c("png", "svg"))

Arguments

type The type of the image, which can either be `png` (the default) or `svg`.

Value

A character vector with a single path to an image file.

Function ID

8-4

See Also

Other Image Addition Functions: `ggplot_image()`, `local_image()`, `web_image()`

---

text_transform Perform targeted text transformation with a function

Description

Perform targeted text transformation with a function

Usage

text_transform(data, locations, fn)

Arguments

data A table object that is created using the `gt()` function.

locations The cell or set of cells to be associated with the transformation. Only the `cells_body()`, `cells_stub()`, and `cells_column_labels()` helper functions can be used here. We can enclose several of these calls within a `list()` if we wish to make the transformation happen at different locations.

fn The function to use for text transformation.

Value

An object of class `gt_tbl`.

Figures

Other Format Data: data_color(), fmt_currency(), fmt_datetime(), fmt_date(), fmt_markdown(), fmt_missing(), fmt_number(), fmt_passthrough(), fmt_percent(), fmt_scientific(), fmt_time(), fmt()

Examples

# Use `exibble` to create a gt table;
# transform the formatted text in the
# `num` and `currency` columns using
# a function within `text_transform()`,
# where `\'x\'` is a formatted vector of
# column values

```r
tab_1 <-
exibble %>%
dplyr::select(num, char, currency) %>%
dplyr::slice(1:4) %>%
gt() %>%
fmt_number(columns = vars(num)) %>%
fmt_currency(columns = vars(currency)) %>%
text_transform(
  locations = cells_body(
    columns = vars(num)),
  fn = function(x) {
    paste0(
      x, " (",
      dplyr::case_when(
        x > 20 ~ "large",
        x <= 20 ~ "small"),
      ")")
  })
```

---

**web_image**

*Helper function for adding an image from the web*

**Description**

We can flexibly add a web image inside of a table with `web_image()` function. The function provides a convenient way to generate an HTML fragment with an image URL. Because this function is currently HTML-based, it is only useful for HTML table output. To use this function inside of data cells, it is recommended that the `text_transform()` function is used. With that function, we can specify which data cells to target and then include a `web_image()` call within the required user-defined function (for the `fn` argument). If we want to include an image in other places (e.g., in the header, within footnote text, etc.) we need to use `web_image()` within the `html()` helper function.
**web_image**

**Usage**

```
web_image(url, height = 30)
```

**Arguments**

- `url` A url that resolves to an image file.
- `height` The absolute height (px) of the image in the table cell.

**Details**

By itself, the function creates an HTML image tag, so, the call `web_image("http://some.web.site/image.png")` evaluates to:

```
<img src="http://some.web.site/image.png" style="height:30px;">
```

where a height of 30px is a default height chosen to work well within the heights of most table rows.

**Value**

A character object with an HTML fragment that can be placed inside of a cell.

Other Image Addition Functions: `ggplot_image()`, `local_image()`, `test_image()`

**Examples**

```r
# Get the PNG-based logo for the R Project from an image URL
r_png_url <-
  "https://www.r-project.org/logo/Rlogo.png"

# Create a tibble that contains heights
# of an image in pixels (one column as a
# string, the other as numerical values),
# then, create a gt table; use the
# `text_transform()` function to insert
# the R logo PNG image with the various
# sizes

tab_1 <-
  dplyr::tibble(
    pixels = px(seq(10, 35, 5)),
    image = seq(10, 35, 5)
  ) %>%
```
gt() %>%
text_transform(
  locations = cells_body(vars(image)),
  fn = function(x) {
    web_image(
      url = r_png_url,
      height = as.numeric(x)
    )
  }
)

# Get the SVG-based logo for the R
# Project from an image URL
r_svg_url <-
  "https://www.r-project.org/logo/Rlogo.svg"

# Create a tibble that contains heights
# of an image in pixels (one column as a
# string, the other as numerical values),
# then, create a gt table; use the
# `tab_header()` function to insert
# the R logo SVG image once in the title
# and five times in the subtitle
tab_2 <-
dplyr::tibble(
  pixels = px(seq(10, 35, 5)),
  image = seq(10, 35, 5)
) %>%
  gt() %>%
  tab_header(
    title = html(
      "<strong>R Logo</strong>",
      web_image(
        url = r_svg_url,
        height = px(50)
      )
    ),
    subtitle = html(
      web_image(
        url = r_svg_url,
        height = px(12)
      ) %>%
