Package ‘h2o4gpu’

October 13, 2022

Type  Package
Title  Interface to 'H2O4GPU'
Version  0.3.3
Description  Interface to 'H2O4GPU' <https://github.com/h2oai/h2o4gpu>, a collection of 'GPU' solvers for machine learning algorithms.
License  Apache License 2.0
URL  https://github.com/h2oai/h2o4gpu

BugReports  https://github.com/h2oai/h2o4gpu/issues

SystemRequirements  Python (>= 3.6) with header files and shared library; H2O4GPU (https://github.com/h2oai/h2o4gpu)

Encoding  UTF-8
Depends  R (>= 3.1)
Imports  utils, magrittr, reticulate (>= 1.4)
RoxygenNote  6.0.1
Suggests  testthat, knitr, rmarkdown, Matrix
VignetteBuilder  knitr

NeedsCompilation  no

Author  Yuan Tang [aut] (<https://orcid.org/0000-0001-5243-233X>), Navdeep Gill [aut, cre], Erin LeDell [aut], Vladimir Ovsyannikov [aut], H2O.ai [cph, fnd]
Maintainer  Navdeep Gill <navdeep@h2o.ai>
Repository  CRAN

Date/Publication  2021-05-17 22:10:02 UTC

**Description**

Generic Method to Train an H2O4GPU Estimator

Generic Method to Transform a Dataset using Trained H2O4GPU Estimator

**Usage**

```r
fit(object, ...)
```

```r
transform(object, ...)
```

**Arguments**

- **object**
  - The h2o4gpu model object

- **...**
  - Additional arguments (unused for now).
fit.h2o4gpu_model  

Train an H2O4GPU Estimator

Description
This function builds the model using the training data specified.

Usage
## S3 method for class 'h2o4gpu_model'
fit(object, x, y = NULL, ...)

Arguments
- **object**  
The h2o4gpu model object
- **x**  
The training data where each column represents a different predictor variable to be used in building the model.
- **y**  
A vector of numeric values to be used as response variable in building the model. Note that if the vector is character or factor, it will be converted to numeric column (e.g. 0, 1, 2, ...) implicitly. For unsupervised models, this argument can be ignored or specified as NULL.
- **...**  
Additional arguments (unused for now).

Examples
## Not run:
library(h2o4gpu)

# Setup dataset
x <- iris[,1:4]
y <- as.integer(iris$Species) - 1

# Train the classifier
h2o4gpu.random_forest_classifier() %>% fit(x, y)

## End(Not run)
h2o4gpu.elastic_net_classifier

Elastic Net Classifier

Description

Elastic Net Classifier

Usage

h2o4gpu.elastic_net_classifier(alpha = 1, l1_ratio = 0.5, fit_intercept = TRUE, normalize = FALSE, precompute = FALSE, max_iter = 5000L, copy_X = TRUE, tol = 0.01, warm_start = FALSE, positive = FALSE, random_state = NULL, selection = "cyclic", n_gpus = -1L, lambda_stop_early = TRUE, glm_stop_early = TRUE, glm_stop_early_error_fraction = 1, verbose = FALSE, n_threads = NULL, gpu_id = 0L, lambda_min_ratio = 1e-07, n_lambdas = 100L, n_folds = 5L, tol_seek_factor = 0.1, store_full_path = 0L, lambda_max = NULL, lambdas = NULL, double_precision = NULL, order = NULL, backend = "h2o4gpu")

Arguments

alpha

Constant that multiplies the penalty terms. Defaults to 1.0. See the notes for the exact mathematical meaning of this parameter. alpha = 0 is equivalent to an ordinary least square, solved by the :class:LinearRegressionSklearn object. For numerical reasons, using alpha = 0 with the LassoSklearn object is not advised. Given this, you should use the :class:LinearRegressionSklearn object.

Examples

## Not run:

library(h2o4gpu)

# Setup dataset
x <- iris[1:4]
y <- as.integer(iris$Species) - 1

# Initialize and train the classifier
model <- h2o4gpu.random_forest_classifier() %>% fit(x, y)

# Make predictions
predictions <- model %>% predict(x)

## End(Not run)
11_ratio  The ElasticNetSklearn mixing parameter, with $0 \leq l1\_ratio \leq 1$. For $l1\_ratio = 0$ the penalty is an L2 penalty. For $l1\_ratio = 1$ it is an L1 penalty. For $0 < l1\_ratio < 1$, the penalty is a combination of L1 and L2.

fit_intercept  Whether the intercept should be estimated or not. If FALSE, the data is assumed to be already centered.

normalize  This parameter is ignored when fit_intercept is set to FALSE. If TRUE, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use :class:h2o4gpu.preprocessing.StandardScaler before calling fit on an estimator with normalize=FALSE.

precompute  Whether to use a precomputed Gram matrix to speed up calculations. The Gram matrix can also be passed as argument. For sparse input this option is always TRUE to preserve sparsity.

max_iter  The maximum number of iterations

copy_X  If TRUE, X will be copied; else, it may be overwritten.

tol  The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.

warm_start  When set to TRUE, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

positive  When set to TRUE, forces the coefficients to be positive.

random_state  The seed of the pseudo random number generator that selects a random feature to update. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If NULL, the random number generator is the RandomState instance used by np.random. Used when selection == 'random'.

selection  If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when tol is higher than 1e-4.

n_gpus  Number of gpu's to use in GLM solver.

lambda_stop_early  Stop early when there is no more relative improvement on train or validation.

glm_stop_early  Stop early when there is no more relative improvement in the primary and dual residuals for ADMM.

glm_stop_early_error_fraction  Relative tolerance for metric-based stopping criterion (stop if relative improvement is not at least this much).

verbose  Print verbose information to the console if set to > 0.

n_threads  Number of threads to use in the gpu. Each thread is an independent model builder.

gpu_id  ID of the GPU on which the algorithm should run.

lambda_min_ratio  Minimum lambda ratio to maximum lambda, used in lambda search.

n_lambdas  Number of lambdas to be used in a search.
**n_folds**
Number of cross validation folds.

**tol_seek_factor**
Factor of tolerance to seek once below null model accuracy. Default is 1E-1, so seeks tolerance of 1E-3 once below null model accuracy for tol=1E-2.

**store_full_path**
Whether to store full solution for all alphas and lambdas. If 1, then during predict will compute best and full predictions.

**lambda_max**
Maximum Lambda value to use. Default is NULL, and then internally compute standard maximum overrides n_lambdas, lambda_max, and lambda_min_ratio.

**lambdas**
Internally set unless using _ptr methods. Value can either be 0 (float32) or 1(float64)

**order**
Order of data. Default is NULL, and internally determined (unless using _ptr methods) whether row 'r' or column 'c' major order.

**backend**
Which backend to use. Options are 'auto', 'sklearn', 'h2o4gpu'. Saves as attribute for actual backend used.

---

**h2o4gpu.elastic_net_regressor**

_Elastic Net Regressor_

**Description**

Elastic Net Regressor

**Usage**

```r
h2o4gpu.elastic_net_regressor(alpha = 1, l1_ratio = 0.5, fit_intercept = TRUE, normalize = FALSE, precompute = FALSE, max_iter = 5000L, copy_X = TRUE, tol = 0.01, warm_start = FALSE, positive = FALSE, random_state = NULL, selection = "cyclic", n_gpus = -1L, lambda_stop_early = TRUE, glm_stop_early = TRUE, glm_stop_early_error_fraction = 1, verbose = FALSE, n_threads = NULL, gpu_id = 0L, lambda_min_ratio = 1e-07, n_lambdas = 100L, n_folds = 5L, tol_seek_factor = 0.1, store_full_path = 0L, lambda_max = NULL, lambdas = NULL, double_precision = NULL, order = NULL, backend = "h2o4gpu")
```

**Arguments**

**alpha**
Constant that multiplies the penalty terms. Defaults to 1.0. See the notes for the exact mathematical meaning of this parameter. alpha = 0 is equivalent to an ordinary least square, solved by the :class:LinearRegressionSklearn object. For numerical reasons, using alpha = 0 with the LassoSklearn object is not advised. Given this, you should use the :class:LinearRegressionSklearn object.
l1_ratio: The ElasticNetSklearn mixing parameter, with 0 <= l1_ratio <= 1. For l1_ratio = 0 the penalty is an L2 penalty. For l1_ratio = 1 it is an L1 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.

fit_intercept: Whether the intercept should be estimated or not. If FALSE, the data is assumed to be already centered.

normalize: This parameter is ignored when fit_intercept is set to FALSE. If TRUE, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use :class:h2o4gpu.preprocessing.StandardScaler before calling fit on an estimator with normalize=FALSE.

precompute: Whether to use a precomputed Gram matrix to speed up calculations. The Gram matrix can also be passed as argument. For sparse input this option is always TRUE to preserve sparsity.

max_iter: The maximum number of iterations

copy_X: If TRUE, X will be copied; else, it may be overwritten.

tol: The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.

warm_start: When set to TRUE, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

positive: When set to TRUE, forces the coefficients to be positive.

random_state: The seed of the pseudo random number generator that selects a random feature to update. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If NULL, the random number generator is the RandomState instance used by np.random. Used when selection == 'random'.

selection: If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when tol is higher than 1e-4.

n_gpus: Number of gpu’s to use in GLM solver.

lambda_stop_early: Stop early when there is no more relative improvement on train or validation.

glm_stop_early: Stop early when there is no more relative improvement in the primary and dual residuals for ADMM.

glm_stop_early_error_fraction: Relative tolerance for metric-based stopping criterion (stop if relative improvement is not at least this much).

verbose: Print verbose information to the console if set to > 0.

n_threads: Number of threads to use in the gpu. Each thread is an independent model builder.

gpu_id: ID of the GPU on which the algorithm should run.

lambda_min_ratio: Minimum lambda ratio to maximum lambda, used in lambda search.

n_lambdas: Number of lambdas to be used in a search.
h2o4gpu.gradient_boosting_classifier

Gradient Boosting Classifier

Description

Gradient Boosting Classifier

Usage

h2o4gpu.gradient_boosting_classifier(loss = "deviance", learning_rate = 0.1, n_estimators = 100L, subsample = 1, criterion = "friedman_mse", min_samples_split = 2L, min_samples_leaf = 1L, min_weight_fraction_leaf = 0, max_depth = 3L, min_impurity_decrease = 0, min_impurity_split = NULL, init = NULL, random_state = NULL, max_features = "auto", verbose = 0L, max_leaf_nodes = NULL, warm_start = FALSE, presort = "auto", colsample_bytree = 1, num_parallel_tree = 1L, tree_method = "gpu_hist", n_gpus = -1L, predictor = "gpu_predictor", objective = "binary:logistic", booster = "gbtree", n_jobs = 1L, gamma = 0L, min_child_weight = 1L, max_delta_step = 0L, colsample_bylevel = 1L, reg_alpha = 0L, reg_lambda = 1L, scale_pos_weight = 1L, base_score = 0.5, missing = NULL, backend = "h2o4gpu", ...)

n_folds

Number of cross validation folds.

tol_seek_factor

Factor of tolerance to seek once below null model accuracy. Default is 1E-1, so seeks tolerance of 1E-3 once below null model accuracy for tol=1E-2.

store_full_path

Whether to store full solution for all alphas and lambdas. If 1, then during predict will compute best and full predictions.

lambda_max

Maximum Lambda value to use. Default is NULL, and then internally compute standard maximum

lambda_max

overrides n_lambdas, lambda_max, and lambda_min_ratio.

double_precision

Internally set unless using _ptr methods. Value can either be 0 (float32) or 1(float64)

order

Order of data. Default is NULL, and internally determined (unless using _ptr methods) whether row ’r’ or column ’c’ major order.

backend

Which backend to use. Options are ’auto’, ’sklearn’, ’h2o4gpu’. Saves as attribute for actual backend used.
Arguments

loss
loss function to be optimized. 'deviance' refers to deviance (= logistic regression) for classification with probabilistic outputs. For loss 'exponential' gradient boosting recovers the AdaBoost algorithm.

learning_rate
learning rate shrinks the contribution of each tree by learning_rate. There is a trade-off between learning_rate and n_estimators.

n_estimators
The number of boosting stages to perform. Gradient boosting is fairly robust to over-fitting so a large number usually results in better performance.

subsample
The fraction of samples to be used for fitting the individual base learners. If smaller than 1.0 this results in Stochastic Gradient Boosting. subsample interacts with the parameter n_estimators. Choosing subsample < 1.0 leads to a reduction of variance and an increase in bias.

criterion
The function to measure the quality of a split. Supported criteria are "friedman_mse" for the mean squared error with improvement score by Friedman, "mse" for mean squared error, and "mae" for the mean absolute error. The default value of "friedman_mse" is generally the best as it can provide a better approximation in some cases.

min_samples_split
The minimum number of samples required to split an internal node:

min_samples_leaf
The minimum number of samples required to be at a leaf node:

min_weight_fraction_leaf
The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

max_depth
maximum depth of the individual regression estimators. The maximum depth limits the number of nodes in the tree. Tune this parameter for best performance; the best value depends on the interaction of the input variables.

min_impurity_decrease
A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

min_impurity_split
Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

init
An estimator object that is used to compute the initial predictions. init has to provide fit and predict. If NULL it uses loss.init_estimator.

random_state
If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If NULL, the random number generator is the RandomState instance used by np.random.

max_features
The number of features to consider when looking for the best split:

verbose
Enable verbose output. If 1 then it prints progress and performance once in a while (the more trees the lower the frequency). If greater than 1 then it prints progress and performance for every tree.
max_leaf_nodes Grow trees with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If NULL then unlimited number of leaf nodes.

warm_start When set to TRUE, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just erase the previous solution.

presort Whether to presort the data to speed up the finding of best splits in fitting. Auto mode by default will use presorting on dense data and default to normal sorting on sparse data. Setting presort to true on sparse data will raise an error.

colsample_bytree Subsample ratio of columns when constructing each tree.

num_parallel_tree Number of trees to grow per round

tree_method The tree construction algorithm used in XGBoost Distributed and external memory version only support approximate algorithm. Choices: ‘auto’, ‘exact’, ‘approx’, ‘hist’, ‘gpu_exact’, ‘gpu_hist’ ‘auto’: Use heuristic to choose faster one. - For small to medium dataset, exact greedy will be used. - For very large dataset, approximate algorithm will be chosen. - Because old behavior is always use exact greedy in single machine, - user will get a message when approximate algorithm is chosen to notify this choice. ‘exact’: Exact greedy algorithm. ‘approx’: Approximate greedy algorithm using sketching and histogram. ‘hist’: Fast histogram optimized approximate greedy algorithm. It uses some performance improvements such as bins caching. ‘gpu_exact’: GPU implementation of exact algorithm. ‘gpu_hist’: GPU implementation of hist algorithm.

n_gpus Number of gpus to use in GradientBoostingClassifier solver. Default is -1.

predictor The type of predictor algorithm to use. Provides the same results but allows the use of GPU or CPU. - ‘cpu_predictor’: Multicore CPU prediction algorithm. - ‘gpu_predictor’: Prediction using GPU. Default for ‘gpu_exact’ and ‘gpu_hist’ tree method.

objective Specify the learning task and the corresponding learning objective or a custom objective function to be used Note: A custom objective function can be provided for the objective parameter. In this case, it should have the signature objective(y_true, y_pred) -> grad, hess:

booster Specify which booster to use: gtree, glinear or dart.

n_jobs Number of parallel threads used to run xgboost.

gamma Minimum loss reduction required to make a further partition on a leaf node of the tree.

min_child_weight Minimum sum of instance weight(hessian) needed in a child.

max_delta_step Maximum delta step we allow each tree’s weight estimation to be.

colsample_bylevel Subsample ratio of columns for each split, in each level.

reg_alpha L1 regularization term on weights

reg_lambda L2 regularization term on weights

scale_pos_weight Balancing of positive and negative weights.
base_score  The initial prediction score of all instances, global bias.
missing  Value in the data which needs to be present as a missing value. If NULL, defaults to np.nan.
backend  Which backend to use. Options are 'auto', 'sklearn', 'h2o4gpu'. Saves as attribute for actual backend used.

Other parameters for XGBoost object. Full documentation of parameters can be found here: https://github.com/dmlc/xgboost/blob/master/doc/parameter.md

**h2o4gpu.gradient_boosting_regressor**

**Description**

Gradient Boosting Regressor

**Usage**

```r
h2o4gpu.gradient_boosting_regressor(loss = "ls", learning_rate = 0.1,
    n_estimators = 100L, subsample = 1, criterion = "friedman_mse",
    min_samples_split = 2L, min_samples_leaf = 1L,
    min_weight_fraction_leaf = 0, max_depth = 3L, min_impurity_decrease = 0,
    min_impurity_split = NULL, init = NULL, random_state = NULL,
    max_features = "auto", alpha = 0.9, verbose = 0L,
    max_leaf_nodes = NULL, warm_start = FALSE, presort = "auto",
    colsample_bytree = 1, num_parallel_tree = 1L, tree_method = "gpu_hist",
    n_gpus = -1L, predictor = "gpu_predictor", objective = "reg:linear",
    booster = "gbtree", n_jobs = 1L, gamma = 0L, min_child_weight = 1L,
    max_delta_step = 0L, colsample_bylevel = 1L, reg_alpha = 0L,
    scale_pos_weight = 1L, base_score = 0.5,
    missing = NULL, backend = "h2o4gpu", ...)
```

**Arguments**

- **loss**: loss function to be optimized. 'ls' refers to least squares regression. 'lad' (least absolute deviation) is a highly robust loss function solely based on order information of the input variables. 'huber' is a combination of the two. 'quantile' allows quantile regression (use alpha to specify the quantile).
- **learning_rate**: learning rate shrinks the contribution of each tree by learning_rate. There is a trade-off between learning_rate and n_estimators.
- **n_estimators**: The number of boosting stages to perform. Gradient boosting is fairly robust to over-fitting so a large number usually results in better performance.
- **subsample**: The fraction of samples to be used for fitting the individual base learners. If smaller than 1.0 this results in Stochastic Gradient Boosting. subsample interacts with the parameter n_estimators. Choosing subsample < 1.0 leads to a reduction of variance and an increase in bias.
The function to measure the quality of a split. Supported criteria are "friedman_mse" for the mean squared error with improvement score by Friedman, "mse" for mean squared error, and "mae" for the mean absolute error. The default value of "friedman_mse" is generally the best as it can provide a better approximation in some cases.

The minimum number of samples required to split an internal node:

The minimum number of samples required to be at a leaf node:

The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

maximum depth of the individual regression estimators. The maximum depth limits the number of nodes in the tree. Tune this parameter for best performance; the best value depends on the interaction of the input variables.

A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

An estimator object that is used to compute the initial predictions. init has to provide fit and predict. If NULL it uses loss.init_estimator.

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If NULL, the random number generator is the RandomState instance used by np.random.

The number of features to consider when looking for the best split:

The alpha-quantile of the huber loss function and the quantile loss function. Only if loss='huber' or loss='quantile'.

Enable verbose output. If 1 then it prints progress and performance once in a while (the more trees the lower the frequency). If greater than 1 then it prints progress and performance for every tree.

Grow trees with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If NULL then unlimited number of leaf nodes.

When set to TRUE, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just reuse the previous solution.

Whether to presort the data to speed up the finding of best splits in fitting. Auto mode by default will use presorting on dense data and default to normal sorting on sparse data. Setting presort to true on sparse data will raise an error.

Subsample ratio of columns when constructing each tree.

Number of trees to grow per round
h2o4gpu.gradient_boosting_regressor

- **tree_method**  The tree construction algorithm used in XGBoost Distributed and external memory version only support approximate algorithm. Choices: 'auto', 'exact', 'approx', 'hist', 'gpu_exact', 'gpu_hist' 'auto': Use heuristic to choose faster one. - For small to medium dataset, exact greedy will be used. - For very large dataset, approximate algorithm will be chosen. - Because old behavior is always use exact greedy in single machine, - user will get a message when approximate algorithm is chosen to notify this choice. 'exact': Exact greedy algorithm. 'approx': Approximate greedy algorithm using sketching and histogram. 'hist': Fast histogram optimized approximate greedy algorithm. It uses some performance improvements such as bins caching. 'gpu_exact': GPU implementation of exact algorithm. 'gpu_hist': GPU implementation of hist algorithm.

- **n_gpus**  Number of gpu’s to use in GradientBoostingRegressor solver. Default is -1.

- **predictor**  The type of predictor algorithm to use. Provides the same results but allows the use of GPU or CPU. - 'cpu_predictor': Multicore CPU prediction algorithm. - 'gpu_predictor': Prediction using GPU. Default for 'gpu_exact' and 'gpu_hist' tree method.

- **objective**  Specify the learning task and the corresponding learning objective or a custom objective function to be used Note: A custom objective function can be provided for the objective parameter. In this case, it should have the signature objective(y_true, y_pred) -> grad, hess:

- **booster**  Specify which booster to use: gbtree, gblinear or dart.

- **n_jobs**  Number of parallel threads used to run xgboost.

- **gamma**  Minimum loss reduction required to make a further partition on a leaf node of the tree.

- **min_child_weight**  Minimum sum of instance weight(hessian) needed in a child.

- **max_delta_step**  Maximum delta step we allow each tree’s weight estimation to be.

- **reg_lambda**  L2 regularization term on weights

- **scale_pos_weight**  Balancing of positive and negative weights.

- **base_score**  The initial prediction score of all instances, global bias.

- **missing**  Value in the data which needs to be present as a missing value. If NULL, defaults to np.nan.

- **backend**  Which backend to use. Options are 'auto', 'sklearn', 'h2o4gpu'. Saves as attribute for actual backend used.

- **...**  Other parameters for XGBoost object. Full documentation of parameters can be found here: https://github.com/dmlc/xgboost/blob/master/doc/parameter.md
**Description**

K-means Clustering

**Usage**

```r
h2o4gpu.kmeans(n_clusters = 8L, init = "k-means++", n_init = 1L,
max_iter = 300L, tol = 1e-04, precompute_distances = "auto",
verbose = 0L, random_state = NULL, copy_x = TRUE, n_jobs = 1L,
algorithm = "auto", gpu_id = 0L, n_gpus = -1L, do_checks = 1L,
backend = "h2o4gpu")
```

**Arguments**

- `n_clusters`: The number of clusters to form as well as the number of centroids to generate.
- `init`: Method for initialization, defaults to `random`: 'k-means++': selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. Not supported yet - if chosen we will use SKLearn’s methods. 'random': choose k observations (rows) at random from data for the initial centroids. If an ndarray is passed, it should be of shape (n_clusters, n_features) and gives the initial centers. Not supported yet - if chosen we will use SKLearn’s methods.
- `n_init`: Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia. Not supported yet - always runs 1.
- `max_iter`: Maximum number of iterations of the algorithm.
- `tol`: Relative tolerance to declare convergence.
- `precompute_distances`: Precompute distances (faster but takes more memory). 'auto': do not precompute distances if n_samples * n_clusters > 12 million. This corresponds to about 100MB overhead per job using double precision. TRUE: always precompute distances FALSE: never precompute distances Not supported yet - always uses auto if running h2o4gpu version.
- `verbose`: Logger verbosity level.
- `random_state`: random_state for RandomState. Must be convertible to 32 bit unsigned integers.
- `copy_x`: When pre-computing distances it is more numerically accurate to center the data first. If copy_x is TRUE, then the original data is not modified. If FALSE, the original data is modified, and put back before the function returns, but small numerical differences may be introduced by subtracting and then adding the data mean. Not supported yet - always uses TRUE if running h2o4gpu version.
The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel. If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used. Not supported yet - CPU backend not yet implemented.

K-means algorithm to use. The classical EM-style algorithm is "full". The "elkan" variation is more efficient by using the triangle inequality, but currently doesn’t support sparse data. "auto" chooses "elkan" for dense data and "full" for sparse data. Not supported yet - always uses full if running h2o4gpu version.

ID of the GPU on which the algorithm should run.

Number of GPUs on which the algorithm should run. < 0 means all possible GPUs on the machine. 0 means no GPUs, run on CPU.

If set to 0 GPU error check will not be performed.

Which backend to use. Options are 'auto', 'sklearn', 'h2o4gpu'. Saves as attribute for actual backend used.

---

**h2o4gpu.pca**

*Principal Component Analysis (PCA)*

**Description**

Principal Component Analysis (PCA)

**Usage**

```r
h2o4gpu.pca(n_components = 2L, copy = TRUE, whiten = FALSE,
svd_solver = "arpack", tol = 0, iterated_power = "auto",
random_state = NULL, verbose = FALSE, backend = "h2o4gpu",
gpu_id = 0L)
```

**Arguments**

- **n_components**: Desired dimensionality of output data
- **copy**: If FALSE, data passed to fit are overwritten and running fit(X).transform(X) will not yield the expected results, use fit_transform(X) instead.
- **whiten**: When TRUE (FALSE by default) the components_ vectors are multiplied by the square root of (n_samples) and divided by the singular values to ensure uncorrelated outputs with unit component-wise variances.
- **svd_solver**: 'auto' is selected by a default policy based on X.shape and n_components: if the input data is larger than 500x500 and the number of components to extract is lower than 80 percent of the smallest dimension of the data, then the more efficient 'randomized' method is enabled. Otherwise the exact full SVD is computed and optionally truncated afterwards. 'full' runs exact full SVD calling the standard LAPACK solver via scipy.linalg.svd and select the components by postprocessing 'arpack' runs SVD truncated to n_components calling ARPACK solver via scipy.sparse.linalg.svds. It requires strictly 0 < n_components < columns. 'randomized' runs randomized SVD by the method of Halko et al.
tol
iterated_power
random_state
verbose
backend
gpu_id

tol
Tolerance for singular values computed by svd_solver == 'arpack'.

iterated_power
Number of iterations for the power method computed by svd_solver == 'randomized'.

random_state
If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If NULL, the random number generator is the RandomState instance used by np.random. Used when svd_solver == 'arpack' or 'randomized'.

verbose
Verbose or not

backend
Which backend to use. Options are 'auto', 'sklearn', 'h2o4gpu'. Saves as attribute for actual backend used.

gpu_id
ID of the GPU on which the algorithm should run. Only used by h2o4gpu backend.

h2o4gpu.random_forest_classifier

Description

Random Forest Classifier

Usage

h2o4gpu.random_forest_classifier(n_estimators = 100L, criterion = "gini",
max_depth = 3L, min_samples_split = 2L, min_samples_leaf = 1L,
min_weight_fraction_leaf = 0, max_features = "auto",
max_leaf_nodes = NULL, min_impurity_decrease = 0,
min_impurity_split = NULL, bootstrap = TRUE, oob_score = FALSE,
n_jobs = 1L, random_state = NULL, verbose = 0L, warm_start = FALSE,
class_weight = NULL, subsample = 1, colsample_bytree = 1,
num_parallel_tree = 1L, tree_method = "gpu_hist", n_gpus = -1L,
predictor = "gpu_predictor", backend = "h2o4gpu")

Arguments

n_estimators
The number of trees in the forest.

criterion
The function to measure the quality of a split. Supported criteria are "gini" for the Gini impurity and "entropy" for the information gain. Note: this parameter is tree-specific.

max_depth
The maximum depth of the tree. If NULL, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.

min_samples_split
The minimum number of samples required to split an internal node:

min_samples_leaf
The minimum number of samples required to be at a leaf node:
The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

The number of features to consider when looking for the best split.

Grow trees with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If NULL then unlimited number of leaf nodes.

A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Whether bootstrap samples are used when building trees.

Whether to use out-of-bag samples to estimate the $R^2$ on unseen data.

The number of jobs to run in parallel for both fit and predict. If -1, then the number of jobs is set to the number of cores.

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If NULL, the random number generator is the RandomState instance used by np.random.

Controls the verbosity of the tree building process.

When set to TRUE, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest.

"balanced_subsample" or NULL, optional (default=NULL) Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of y.

Subsample ratio of the training instance.

Subsample ratio of columns when constructing each tree.

Number of trees to grow per round

The tree construction algorithm used in XGBoost Distributed and external memory version only support approximate algorithm. Choices: ‘auto’, ‘exact’, ‘approx’, ‘hist’, ‘gpu_exact’, ‘gpu_hist’ ‘auto’: Use heuristic to choose faster one. - For small to medium dataset, exact greedy will be used. - For very large-dataset, approximate algorithm will be chosen. - Because old behavior is always use exact greedy in single machine, - user will get a message when approximate algorithm is chosen to notify this choice. ‘exact’: Exact greedy algorithm. ‘approx’: Approximate greedy algorithm using sketching and histogram. ‘hist’: Fast histogram optimized approximate greedy algorithm. It uses some performance improvements such as bins caching. ‘gpu_exact’: GPU implementation of exact algorithm. ‘gpu_hist’: GPU implementation of hist algorithm.

Number of gpu’s to use in RandomForestClassifier solver. Default is -1.
predictor  The type of predictor algorithm to use. Provides the same results but allows the use of GPU or CPU. - 'cpu_predictor': Multicore CPU prediction algorithm. - 'gpu_predictor': Prediction using GPU. Default for 'gpu_exact' and 'gpu_hist' tree method.

backend  Which backend to use. Options are 'auto', 'sklearn', 'h2o4gpu'. Saves as attribute for actual backend used.

h2o4gpu.random_forest_regressor

Description

Random Forest Regressor

Usage

h2o4gpu.random_forest_regressor(n_estimators = 100L, criterion = "mse", max_depth = 3L, min_samples_split = 2L, min_samples_leaf = 1L, min_weight_fraction_leaf = 0, max_features = "auto", max_leaf_nodes = NULL, min_impurity_decrease = 0, min_impurity_split = NULL, bootstrap = TRUE, oob_score = FALSE, n_jobs = 1L, random_state = NULL, verbose = 0L, warm_start = FALSE, subsample = 1, colsample_bytree = 1, num_parallel_tree = 1L, tree_method = "gpu_hist", n_gpus = -1L, predictor = "gpu_predictor", backend = "h2o4gpu")

Arguments

n_estimators  The number of trees in the forest.

criterion  The function to measure the quality of a split. Supported criteria are "mse" for the mean squared error, which is equal to variance reduction as feature selection criterion, and "mae" for the mean absolute error.

max_depth  The maximum depth of the tree. If NULL, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.

min_samples_split  The minimum number of samples required to split an internal node:

min_samples_leaf  The minimum number of samples required to be at a leaf node:

min_weight_fraction_leaf  The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

max_features  The number of features to consider when looking for the best split:
max_leaf_nodes  Grow trees with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If NULL, then unlimited number of leaf nodes.

min_impurity_decrease  A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

min_impurity_split  Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

bootstrap  Whether bootstrap samples are used when building trees.

oob_score  Whether to use out-of-bag samples to estimate the R^2 on unseen data.

n_jobs  The number of jobs to run in parallel for both fit and predict. If -1, then the number of jobs is set to the number of cores.

random_state  If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If NULL, the random number generator is the RandomState instance used by np.random.

verbose  Controls the verbosity of the tree building process.

warm_start  When set to TRUE, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest.

subsample  Subsample ratio of the training instance.

colsample_bytree  Subsample ratio of columns when constructing each tree.

num_parallel_tree  Number of trees to grow per round

tree_method  The tree construction algorithm used in XGBoost Distributed and external memory version only support approximate algorithm. Choices: ‘auto’, ‘exact’, ‘approx’, ‘hist’, ‘gpu_exact’, ‘gpu_hist’ ‘auto’: Use heuristic to choose faster one.  - For small to medium dataset, exact greedy will be used. - For very large dataset, approximate algorithm will be chosen. - Because old behavior is always use exact greedy in single machine, - user will get a message when approximate algorithm is chosen to notify this choice. ‘exact’: Exact greedy algorithm. ‘approx’: Approximate greedy algorithm using sketching and histogram. ‘hist’: Fast histogram optimized approximate greedy algorithm. It uses some performance improvements such as bins caching. ‘gpu_exact’: GPU implementation of exact algorithm. ‘gpu_hist’: GPU implementation of hist algorithm.

n_gpus  Number of gpus’s to use in RandomForestRegressor solver. Default is -1.

predictor  The type of predictor algorithm to use. Provides the same results but allows the use of GPU or CPU. - ‘cpu_predictor’: Multicore CPU prediction algorithm. - ‘gpu_predictor’: Prediction using GPU. Default for ‘gpu_exact’ and ‘gpu_hist’ tree method.

backend  Which backend to use. Options are ‘auto’, ‘sklearn’, ‘h2o4gpu’. Saves as attribute for actual backend used.
h2o4gpu.truncated_svd  
Truncated Singular Value Decomposition (TruncatedSVD)

Description

Truncated Singular Value Decomposition (TruncatedSVD)

Usage

h2o4gpu.truncated_svd(n_components = 2L, algorithm = "power",
                      n_iter = 100L, random_state = NULL, tol = 1e-05, verbose = FALSE,
                      backend = "h2o4gpu", n_gpus = 1L, gpu_id = 0L)

Arguments

n_components  Desired dimensionality of output data
algorithm     SVD solver to use. H2O4GPU options: Either "cusolver" (similar to ARPACK)
              or "power" for the power method. SKlearn options: Either "arpack" for the
              ARPACK wrapper in SciPy (scipy.sparse.linalg.svds), or "randomized" for the
              randomized algorithm due to Halko (2009).
n_iter        number of iterations (only relevant for power method) Should be at most 2147483647
              due to INT_MAX in C++ backend.
random_state  seed (NULL for auto-generated)
tol           Tolerance for "power" method. Ignored by "cusolver". Should be > 0.0 to ensure
              convergence. Should be 0.0 to effectively ignore and only base convergence
              upon n_iter
verbose       Verbose or not
backend       Which backend to use. Options are 'auto', 'sklearn', 'h2o4gpu'. Saves as attribute
              for actual backend used.
n_gpus        How many gpus to use. If 0, use CPU backup method. Currently SVD only uses
              1 GPU, so >1 has no effect compared to 1.
gpu_id        ID of the GPU on which the algorithm should run.

predict.h2o4gpu_model  
Make Predictions using Trained H2O4GPU Estimator

Description

This function makes predictions from new data using a trained H2O4GPU model and returns class
predictions for classification and predicted values for regression.
Usage

## S3 method for class 'h2o4gpu_model'
predict(object, x, type = "raw", ...)

Arguments

object
The h2o4gpu model object

x
The new data where each column represents a different predictor variable to be used in generating predictions.

type
One of "raw" or "prob", indicating the type of output: predicted values or probabilities

...
Additional arguments (unused for now).

Examples

## Not run:

library(h2o4gpu)

# Setup dataset
x <- iris[1:4]
y <- as.integer(iris$Species) - 1

# Initialize and train the classifier
model <- h2o4gpu.random_forest_classifier() %>% fit(x, y)

# Make predictions
predictions <- model %>% predict(x)

## End(Not run)
Arguments

- **object**: The h2o4gpu model object
- **x**: The new data where each column represents a different predictor variable to be used in generating predictions.
- **...**: Additional arguments (unused for now).

Examples

```r
## Not run:

library(h2o4gpu)

# Prepare data
iris$Species <- as.integer(iris$Species) # convert to numeric data

# Randomly sample 80% of the rows for the training set
set.seed(1)
train_idx <- sample(1:nrow(iris), 0.8*nrow(iris))
train <- iris[train_idx, ]
 test <- iris[-train_idx, ]

# Train a K-Means model
model_km <- h2o4gpu.kmeans(n_clusters = 3L) %>% fit(train)

# Transform test data
test_dist <- model_km %>% transform(test)

## End(Not run)
```
