Maintainer  Hadley Wickham <hadley@rstudio.com>

Repository  CRAN

Date/Publication  2021-08-04 04:50:23 UTC
as_factor

Convert input to a factor.

Description

The base function `as.factor()` is not a generic, but this variant is. Methods are provided for factors, character vectors, labelled vectors, and data frames. By default, when applied to a data frame, it only affects labelled columns.

Usage

```r
## S3 method for class 'data.frame'
as_factor(x, ..., only_labelled = TRUE)

## S3 method for class 'haven_labelled'
as_factor(
  x,
  levels = c("default", "labels", "values", "both"),
  ordered = FALSE,
  ...)

## S3 method for class 'labelled'
as_factor(
  x,
  levels = c("default", "labels", "values", "both"),
  ordered = FALSE,
  ...
)
```
Arguments

x  Object to coerce to a factor.

... Other arguments passed down to method.

only_labelled Only apply to labelled columns?

levels How to create the levels of the generated factor:
  • "default": uses labels where available, otherwise the values. Labels are sorted by value.
  • "both": like "default", but pastes together the level and value
  • "label": use only the labels; unlabelled values become NA
  • "values": use only the values

ordered If TRUE create an ordered (ordinal) factor, if FALSE (the default) create a regular (nominal) factor.

Details

Includes methods for both class haven_labelled and labelled for backward compatibility.

Examples

x <- labelled(sample(5, 10, replace = TRUE), c(Bad = 1, Good = 5))

# Default method uses values where available
as_factor(x)

# You can also extract just the labels
as_factor(x, levels = "labels")

# Or just the values
as_factor(x, levels = "values")

# Or combine value and label
as_factor(x, levels = "both")

# as_factor() will preserve SPSS missing values from values and ranges
y <- labelled_spss(1:10, na_values = c(2, 4), na_range = c(8, 10))
as_factor(y)

# use zap_missing() first to convert to NAs
zap_missing(y)
as_factor(zap_missing(y))

labelled Create a labelled vector.

Description

A labelled vector is a common data structure in other statistical environments, allowing you to assign text labels to specific values. This class makes it possible to import such labelled vectors in to R without loss of fidelity. This class provides few methods, as I expect you’ll coerce to a standard R class (e.g. a factor()) soon after importing.
Usage

```
labelled(x = double(), labels = NULL, label = NULL)
```

```
is.labelled(x)
```

Arguments

- **x** A vector to label. Must be either numeric (integer or double) or character.
- **labels** A named vector or `NULL`. The vector should be the same type as `x`. Unlike factors, labels don’t need to be exhaustive: only a fraction of the values might be labelled.
- **label** A short, human-readable description of the vector.

Examples

```
s1 <- labelled(c("M", "M", "F"), c(Male = "M", Female = "F"))
s2 <- labelled(c(1, 1, 2), c(Male = 1, Female = 2))
s3 <- labelled(c(1, 1, 2), c(Male = 1, Female = 2),
               label="Assigned sex at birth")

# Unfortunately it's not possible to make as.factor work for labelled objects
# so instead use as_factor. This works for all types of labelled vectors.
as_factor(s1)
as_factor(s1, levels = "values")
as_factor(s2)

# Other statistical software supports multiple types of missing values
s3 <- labelled(c("M", "M", "F", "X", "N/A"),
               c(Male = "M", Female = "F", Refused = "X", "Not applicable" = "N/A")
)
s3
as_factor(s3)

# Often when you have a partially labelled numeric vector, labelled values
# are special types of missing. Use zap_labels to replace labels with missing
# values
x <- labelled(c(1, 2, 1, 2, 10, 9), c(Unknown = 9, Refused = 10))
zap_labels(x)
```

Description

This class is only used when `user_na = TRUE` in `read_sav()`. It is similar to the `labelled()` class but it also models SPSS’s user-defined missings, which can be up to three distinct values, or for numeric vectors a range.
Usage

```r
labelled_spss(
  x = double(),
  labels = NULL,
  na_values = NULL,
  na_range = NULL,
  label = NULL
)
```

Arguments

- **x**: A vector to label. Must be either numeric (integer or double) or character.
- **labels**: A named vector or `NULL`. The vector should be the same type as `x`. Unlike factors, labels don’t need to be exhaustive: only a fraction of the values might be labelled.
- **na_values**: A vector of values that should also be considered as missing.
- **na_range**: A numeric vector of length two giving the (inclusive) extents of the range. Use `-Inf` and `Inf` if you want the range to be open ended.
- **label**: A short, human-readable description of the vector.

Examples

```r
x1 <- labelled_spss(1:10, c(Good = 1, Bad = 8), na_values = c(9, 10))
is.na(x1)

x2 <- labelled_spss(1:10, c(Good = 1, Bad = 8), na_range = c(9, Inf),
                     label = "Quality rating")
is.na(x2)

# Print data and metadata
x2
```

---

**print_labels**

*Print the labels of a labelled vector*

Description

This is a convenience function, useful to explore the variables of a newly imported dataset.

Usage

```r
print_labels(x, name = NULL)
```

Arguments

- **x**: A labelled vector
- **name**: The name of the vector (optional)
Examples

```r
s1 <- labelled(c("M", "M", "F"), c(Male = "M", Female = "F"))
s2 <- labelled(c(1, 1, 2), c(Male = 1, Female = 2))
labelled_df <- tibble::tibble(s1, s2)

for (var in names(labelled_df)) {
  print_labels(labelled_df[[var]], var)
}
```

read_dta

**Read and write Stata DTA files**

Description

Currently haven can read and write logical, integer, numeric, character and factors. See `labelled()` for how labelled variables in Stata are handled in R.

Usage

```r
read_dta(
  file,
  encoding = NULL,
  col_select = NULL,
  skip = 0,
  n_max = Inf,
  .name_repair = "unique"
)
```

```r
read_stata(
  file,
  encoding = NULL,
  col_select = NULL,
  skip = 0,
  n_max = Inf,
  .name_repair = "unique"
)
```

```r
write_dta(data, path, version = 14, label = attr(data, "label"))
```

Arguments

- **file**: Either a path to a file, a connection, or literal data (either a single string or a raw vector).

  Files ending in `.gz`, `.bz2`, `.xz`, or `.zip` will be automatically uncompressed. Files starting with `http://`, `https://`, `ftp://`, or `ftps://` will be automatically downloaded. Remote gz files can also be automatically downloaded and decompressed.
**read_dta**

Literal data is most useful for examples and tests. It must contain at least one new line to be recognised as data (instead of a path) or be a vector of greater than length 1.

Using a value of `clipboard()` will read from the system clipboard.

- **encoding**
  The character encoding used for the file. Generally, only needed for Stata 13 files and earlier. See Encoding section for details.

- **col_select**
  One or more selection expressions, like in `dplyr::select()`. Use `c()` or `list()` to use more than one expression. See ?dplyr::select for details on available selection options. Only the specified columns will be read from `data_file`.

- **skip**
  Number of lines to skip before reading data.

- **n_max**
  Maximum number of lines to read.

- **.name_repair**
  Treatment of problematic column names:

  - "minimal": No name repair or checks, beyond basic existence,
  - "unique": Make sure names are unique and not empty,
  - "check_unique": (default value), no name repair, but check they are unique,
  - "universal": Make the names unique and syntactic
    - a function: apply custom name repair (e.g., `.name_repair = make.names` for names in the style of base R).
    - A purrr-style anonymous function, see `rlang::as_function()`

  This argument is passed on as `repair` to `vctrs::vec_as_names()`. See there for more details on these terms and the strategies used to enforce them.

- **data**
  Data frame to write.

- **path**
  Path to a file where the data will be written.

- **version**

- **label**
  Dataset label to use, or NULL. Defaults to the value stored in the "label" attribute of data. Must be <= 80 characters.

**Value**

A tibble, data frame variant with nice defaults.

Variable labels are stored in the "label" attribute of each variable. It is not printed on the console, but the RStudio viewer will show it.

If a dataset label is defined in Stata, it will stored in the "label" attribute of the tibble.

`write_dta()` returns the input data invisibly.

**Character encoding**

Prior to Stata 14, files did not declare a text encoding, and the default encoding differed across platforms. If `encoding = NULL`, haven assumes the encoding is windows-1252, the text encoding used by Stata on Windows. Unfortunately Stata on Mac and Linux use a different default encoding, "latin1". If you encounter an error such as "Unable to convert string to the requested encoding", try `encoding = "latin1"`

For Stata 14 and later, you should not need to manually specify encoding value unless the value was incorrectly recorded in the source file.
read_sas

**Read and write SAS files**

**Examples**

```r
path <- system.file("examples", "iris.dta", package = "haven")
read_dta(path)

tmp <- tempfile(fileext = ".dta")
write_dta(mtcars, tmp)
read_dta(tmp)
read_stata(tmp)
```

**Description**

`read_sas()` supports both sas7bdat files and the accompanying sas7bcat files that SAS uses to record value labels. `write_sas()` is currently experimental and only works for limited datasets.

**Usage**

```r
read_sas(
  data_file,
  catalog_file = NULL,
  encoding = NULL,
  catalog_encoding = encoding,
  col_select = NULL,
  skip = 0L,
  n_max = Inf,
  cols_only = "DEPRECATED",
  .name_repair = "unique"
)

write_sas(data, path)
```

**Arguments**

- **data_file**, **catalog_file**
  
  Path to data and catalog files. The files are processed with `readr::datasource()`.

- **encoding**, **catalog_encoding**
  
  The character encoding used for the data_file and catalog_encoding respectively. A value of NULL uses the encoding specified in the file; use this argument to override it if it is incorrect.

- **col_select**
  
  One or more selection expressions, like in `dplyr::select()`. Use `c()` or `list()` to use more than one expression. See `?dplyr::select` for details on available selection options. Only the specified columns will be read from `data_file`.

- **skip**
  
  Number of lines to skip before reading data.
**read_sav()**

Reads both .sav and .zsav files; write_sav() creates .zsav files when compress = TRUE. read_por() reads .por files. read_spss() uses either read_por() or read_sav() based on the file extension.

```r
read_sav(
  file,
  encoding = NULL,
  user_na = FALSE,
  col_select = NULL,
  skip = 0,
)
```

**read_sav()**

Maximum number of lines to read.

**n_max**

**cols_only**

Deprecated: Use col_select instead.

**.name_repair**

Treatment of problematic column names:

- "minimal": No name repair or checks, beyond basic existence,
- "unique": Make sure names are unique and not empty,
- "check_unique": (default value), no name repair, but check they are unique,
- "universal": Make the names unique and syntactic
  - a function: apply custom name repair (e.g., .name_repair = make.names for names in the style of base R).
  - A purrr-style anonymous function, see rlang::as_function()

This argument is passed on as repair to vctrs::vec_as_names(). See there for more details on these terms and the strategies used to enforce them.

**data**

Data frame to write.

**path**

Path to file where the data will be written.

**Value**

A tibble, data frame variant with nice defaults.

Variable labels are stored in the "label" attribute of each variable. It is not printed on the console, but the RStudio viewer will show it.

write_sas() returns the input data invisibly.

**Examples**

```r
path <- system.file("examples", "iris.sas7bdat", package = "haven")
read_sas(path)
```

**Description**

**read_sav()**

Read and write SPSS files

**Usage**

```r
read_sav(
  file,
  encoding = NULL,
  user_na = FALSE,
  col_select = NULL,
  skip = 0,
)```
read_spss

n_max = Inf,
.name_repair = "unique"
)

read_por(
    file,
    user_na = FALSE,
    col_select = NULL,
    skip = 0,
    n_max = Inf,
    .name_repair = "unique"
)

write_sav(data, path, compress = FALSE)

read_spss(
    file,
    user_na = FALSE,
    col_select = NULL,
    skip = 0,
    n_max = Inf,
    .name_repair = "unique"
)

Arguments

file Either a path to a file, a connection, or literal data (either a single string or a raw vector).

Files ending in .gz, .bz2, .xz, or .zip will be automatically uncompressed. Files starting with http://, https://, ftp://, or ftps:// will be automatically downloaded. Remote gz files can also be automatically downloaded and decompressed.

Literal data is most useful for examples and tests. It must contain at least one new line to be recognised as data (instead of a path) or be a vector of greater than length 1. Using a value of clipboard() will read from the system clipboard.

encoding The character encoding used for the file. The default, NULL, use the encoding specified in the file, but sometimes this value is incorrect and it is useful to be able to override it.

user_na If TRUE variables with user defined missing will be read into labelled_spss() objects. If FALSE, the default, user-defined missings will be converted to NA.

col_select One or more selection expressions, like in dplyr::select(). Use c() or list() to use more than one expression. See ?dplyr::select for details on available selection options. Only the specified columns will be read from data_file.

skip Number of lines to skip before reading data.

n_max Maximum number of lines to read.
.name_repair Treatment of problematic column names:

- "minimal": No name repair or checks, beyond basic existence,
- "unique": Make sure names are unique and not empty,
- "check_unique": (default value), no name repair, but check they are unique,
- "universal": Make the names unique and syntactic

A function: apply custom name repair (e.g., .name_repair = make.names for names in the style of base R).

A purrr-style anonymous function, see `rlang::as_function()`

This argument is passed on as repair to `vctrs::vec_as_names()`. See there for more details on these terms and the strategies used to enforce them.

data Data frame to write.

path Path to a file where the data will be written.

compress If TRUE, will compress the file, resulting in a .zsav file. Otherwise the .sav file will be bytecode compressed.

Details

Currently haven can read and write logical, integer, numeric, character and factors. See `labelled_spss()` for how labelled variables in SPSS are handled in R.

Value

A tibble, data frame variant with nice defaults.

Variable labels are stored in the "label" attribute of each variable. It is not printed on the console, but the RStudio viewer will show it.

write_sav() returns the input data invisibly.

Examples

```r
path <- system.file("examples", "iris.sav", package = "haven")
read_sav(path)

tmp <- tempfile(fileext = ".sav")
write_sav(mtcars, tmp)
read_sav(tmp)
```

Description

The SAS transport format is a open format, as is required for submission of the data to the FDA.
Usage

```r
read_xpt(
  file,
  col_select = NULL,
  skip = 0,
  n_max = Inf,
  .name_repair = "unique"
)
```

```r
write_xpt(data, path, version = 8, name = NULL)
```

Arguments

- **file**
  - Either a path to a file, a connection, or literal data (either a single string or a raw vector).
  - Files ending in `.gz`, `.bz2`, `.xz`, or `.zip` will be automatically uncompressed.
  - Files starting with `http://`, `https://`, `ftp://`, or `ftps://` will be automatically downloaded. Remote gz files can also be automatically downloaded and decompressed.
  - Literal data is most useful for examples and tests. It must contain at least one new line to be recognised as data (instead of a path) or be a vector of greater than length 1.
  - Using a value of `clipboard()` will read from the system clipboard.

- **col_select**
  - One or more selection expressions, like in `dplyr::select()`. Use `c()` or `list()` to use more than one expression. See `?dplyr::select` for details on available selection options. Only the specified columns will be read from `data_file`.

- **skip**
  - Number of lines to skip before reading data.

- **n_max**
  - Maximum number of lines to read.

- **.name_repair**
  - Treatment of problematic column names:
    - "minimal": No name repair or checks, beyond basic existence,
    - "unique": Make sure names are unique and not empty,
    - "check_unique": (default value), no name repair, but check they are unique,
    - "universal": Make the names unique and syntactic
    - a function: apply custom name repair (e.g., `.name_repair = make.names` for names in the style of base R).
      - A purrr-style anonymous function, see `rlang::as_function()`
  - This argument is passed on as `repair` to `vctrs::vec_as_names()`. See there for more details on these terms and the strategies used to enforce them.

- **data**
  - Data frame to write.

- **path**
  - Path to a file where the data will be written.

- **version**
  - Version of transport file specification to use: either 5 or 8.

- **name**
  - Member name to record in file. Defaults to file name sans extension. Must be <= 8 characters for version 5, and <= 32 characters for version 8.
**Value**

A tibble, data frame variant with nice defaults.

Variable labels are stored in the "label" attribute of each variable. It is not printed on the console, but the RStudio viewer will show it.

write_xpt() returns the input data invisibly.

**Examples**

```r
tmp <- tempfile(fileext = ".xpt")
write_xpt(mtcars, tmp)
read_xpt(tmp)
```

---

**tagged_na**

"Tagged" missing values

**Description**

"Tagged" missing values work exactly like regular R missing values except that they store one additional byte of information a tag, which is usually a letter ("a" to "z"). When by loading a SAS and Stata file, the tagged missing values always use lower case values.

**Usage**

```r
tagged_na(...)
na_tag(x)
is_tagged_na(x, tag = NULL)
format_tagged_na(x, digits = getOption("digits"))
print_tagged_na(x, digits = getOption("digits"))
```

**Arguments**

- `...`: Vectors containing single character. The letter will be used to "tag" the missing value.
- `x`: A numeric vector
- `tag`: If NULL, will only return true if the tag has this value.
- `digits`: Number of digits to use in string representation

**Details**

format_tagged_na() and print_tagged_na() format tagged NA's as NA(a), NA(b), etc.
Examples

```r
x <- c(1:5, tagged_na("a"), tagged_na("z"), NA)

# Tagged NA's work identically to regular NAs
x
is.na(x)

# To see that they're special, you need to use na_tag(),
# is_tagged_na(), or print_tagged_na():
is_tagged_na(x)
na_tag(x)
print_tagged_na(x)

# You can test for specific tagged NAs with the second argument
is_tagged_na(x, "a")

# Because the support for tagged's NAs is somewhat tagged on to R,
# the left-most NA will tend to be preserved in arithmetic operations.
na_tag(tagged_na("a") + tagged_na("z"))
```

---

### zap_empty

Convert empty strings into missing values

#### Description

Convert empty strings into missing values

#### Usage

```r
zap_empty(x)
```

#### Arguments

- `x`: A character vector

#### Value

A character vector with empty strings replaced by missing values.

#### See Also

Other zappers: `zap_formats()`, `zap_labels()`, `zap_label()`, `zap_widths()`

#### Examples

```r
x <- c("a", ",", "c")
zap_empty(x)
```
zap_formats

Remove format attributes

Description
To provide some mild support for round-tripping variables between Stata/SPSS and R, haven stores variable formats in an attribute: `format.stata`, `format.spss`, or `format.sas`. If this causes problems for your code, you can get rid of them with `zap_formats`.

Usage
```r
zap_formats(x)
```

Arguments
- `x`: A vector or data frame.

See Also
Other zappers: `zap_empty()`, `zap_labels()`, `zap_label()`, `zap_widths()`

zap_label

Zap variable labels

Description
Removes variable label, leaving unlabelled vectors as is.

Usage
```r
zap_label(x)
```

Arguments
- `x`: A vector or data frame

See Also
- `zap_labels()` to remove value labels.
- Other zappers: `zap_empty()`, `zap_formats()`, `zap_labels()`, `zap_widths()`
Examples

```r
x1 <- labelled(1:5, c(good = 1, bad = 5), label = "rating")
x1
zap_label(x1)

x2 <- labelled_spss(c(1:4, 9), label = "score", na_values = 9)
x2
zap_label(x2)

# zap_label also works with data frames
df <- tibble::tibble(x1, x2)
str(df)
str(zap_label(df))
```

zap_labels

Zap value labels

Description

Removes value labels, leaving unlabelled vectors as is. Use this if you want to simply drop all labels from a data frame.

Zapping labels from `labelled_spss()` also removes user-defined missing values, replacing with standard NAs.

Usage

`zap_labels(x)`

Arguments

- `x`: A vector or data frame

See Also

- `zap_label()` to remove variable labels.

Other zappers: `zap_empty()`, `zap_formats()`, `zap_label()`, `zap_widths()`

Examples

```r
x1 <- labelled(1:5, c(good = 1, bad = 5))
x1
zap_labels(x1)

x2 <- labelled_spss(c(1:4, 9), c(good = 1, bad = 5), na_values = 9)
x2
zap_labels(x2)

# zap_labels also works with data frames
```
zap_missing

df <- tibble::tibble(x1, x2)
df
zap_labels(df)

---

zap_missing

Zap special missings to regular R missings

Description

This is useful if you want to convert tagged missing values from SAS or Stata, or user-defined missings from SPSS, to regular R `NA`.

Usage

zap_missing(x)

Arguments

x

A vector or data frame

Examples

x1 <- labelled(
  c(1, 5, tagged_na("a", "b")),
  c(Unknown = tagged_na("a"), Refused = tagged_na("b"))
)
x1
zap_missing(x1)

x2 <- labelled_spss(
  c(1, 2, 1, 99),
  c(missing = 99),
  na_value = 99
)
x2
zap_missing(x2)

# You can also apply to data frames
df <- tibble::tibble(x1, x2, y = 4:1)
df
zap_missing(df)
zap_widths

Remove display width attributes

Description
To provide some mild support for round-tripping variables between SPSS and R, haven stores display widths in an attribute: display_width. If this causes problems for your code, you can get rid of them with zap_widths.

Usage
zap_widths(x)

Arguments
x A vector or data frame.
