Package ‘httr2’

May 11, 2022

Title  Perform HTTP Requests and Process the Responses

Version  0.2.1

Description  Tools for creating and modifying HTTP requests, then performing them and processing the results. ‘httr2’ is a modern re-imagining of ‘httr’ that uses a pipe-based interface and solves more of the problems that API wrapping packages face.

License  MIT + file LICENSE

BugReports  https://github.com/r-lib/httr2/issues

Depends  R (>= 3.4)

Imports  cli (>= 3.0.0), curl, glue, magrittr, openssl, R6, rappdirs, rlang (>= 1.0.0), withr

Suggests  askpass, bench, clipr, covr, docopt, httpuv, jose, jsonlite, knitr, purrr, rmarkdown, testthat (>= 3.0.0), tibble, webfakes, xml2

VignetteBuilder  knitr

Config/Needs/website  tidyverse/tidytemplate

Config/testthat/edition  3

Encoding  UTF-8

RoxygenNote  7.1.2

NeedsCompilation  no

Index 49
curl_translate  

**Translate curl syntax to httr2**

**Description**

The curl command line tool is commonly used to demonstrate HTTP APIs and can easily be generated from browser developer tools. curl_translate() saves you the pain of manually translating these calls by implementing a partial, but frequently used, subset of curl options. Use curl_help() to see the supported options, and curl_translate() to translate a curl invocation copy and pasted from elsewhere.

Inspired by curlconverter written by Bob Rudis.

**Usage**

```r
curl_translate(cmd)
curl_help()
```

**Arguments**

- `cmd`  
  Call to curl. If omitted and the clipr package is installed, will be retrieved from the clipboard.

**Value**

A string containing the translated httr2 code. If the input was copied from the clipboard, the translation will be copied back to the clipboard.

**Examples**

```r
curl_translate("curl http://example.com")
curl_translate("curl http://example.com -X DELETE")
curl_translate("curl http://example.com --header A:1 --header B:2")
curl_translate("curl http://example.com --verbose")
```

jwt_claim  

**Create and encode a JWT**

**Description**

jwt_claim() is a wrapper around jose::jwt_claim() that creates a JWT claim set with a few extra default values. jwt_encode_sig() and jwt_encode_hmac() are thin wrappers around jose::jwt_encode_sig() and jose::jwt_encode_hmac() that exist primarily to make specification in other functions a little simpler.
使用权

```r
jwt_claim(
  iss = NULL,
  sub = NULL,
  aud = NULL,
  exp = unix_time() + 5L * 60L,
  nbf = unix_time(),
  iat = unix_time(),
  jti = NULL,
  ...
)
```

```r
jwt_encode_sig(claim, key, size = 256, header = list())
```

```r
jwt_encode_hmac(claim, secret, size = size, header = list())
```

**Arguments**

- **iss**: Issuer claim. Identifies the principal that issued the JWT.
- **sub**: Subject claim. Identifies the principal that is the subject of the JWT (i.e. the entity that the claims apply to).
- **aud**: Audience claim. Identifies the recipients that the JWT is intended. Each principle intended to process the JWT must be identified with a unique value.
- **exp**: Expiration claim. Identifies the expiration time on or after which the JWT MUST NOT be accepted for processing. Defaults to 5 minutes.
- **nbf**: Not before claim. Identifies the time before which the JWT MUST NOT be accepted for processing. Defaults to current time.
- **iat**: Issued at claim. Identifies the time at which the JWT was issued. Defaults to current time.
- **jti**: JWT ID claim. Provides a unique identifier for the JWT. If omitted, uses a random 32-byte sequence encoded with base64url.
- **...**: Any additional claims to include in the claim set.
- **claim**: Claim set produced by `jwt_claim()`.
- **key**: RSA or EC private key either specified as a path to a file, a connection, or a string (PEM/SSH format), or a raw vector (DER format).
- **size**: Size, in bits, of sha2 signature, i.e. 256, 384 or 512. Only for HMAC/RSA, not applicable for ECDSA keys.
- **header**: A named list giving additional fields to include in the JWT header.
- **secret**: String or raw vector with a secret passphrase.

**Value**

An S3 list with class `jwt_claim`. 
last_response

Examples

```r
claim <- jwt_claim()
str(claim)
```

---

**Description**

These functions retrieve the most recent request made by httr and the response it received, to facilitate debugging problems after they occur. If the request did not succeed (or no requests have been made) `last_response()` will be `NULL`.

**Usage**

```r
last_response()
last_request()
```

**Value**

An HTTP response/request.

**Examples**

```r
invisible(request("http://httr2.r-lib.org") %>% req_perform())
lst_request()
lst_response()
```

---

**multi_req_perform**

**Perform multiple requests in parallel**

**Description**

This variation on `req_perform()` performs multiple requests in parallel. Unlike `req_perform()` it always succeeds; it will never throw an error. Instead it will return error objects, which are your responsibility to handle.

Exercise caution when using this function; it’s easy to pummel a server with many simultaneous requests. Only use it with hosts designed to serve many files at once.

**Usage**

```r
multi_req_perform(reqs, paths = NULL, pool = NULL, cancel_on_error = FALSE)
```
Arguments

- **reqs**: A list of requests.
- **paths**: An optional list of paths, if you want to download the request bodies to disks. If supplied, must be the same length as `reqs`.
- **pool**: Optionally, a curl pool made by `curl::new_pool()`. Supply this if you want to override the defaults for total concurrent connections (100) or concurrent connections per host (6).
- **cancel_on_error**: Should all pending requests be cancelled when you hit an error. Set this to `TRUE` to stop all requests as soon as you hit an error. Responses that were never performed will have class `http2_cancelled` in the result.

Value

A list the same length as `reqs` where each element is either a response or an error.

Limitations

- Will not retrieve a new OAuth token if it expires part way through the requests.
- Does not perform throttling with `req_throttle()`.
- Does not attempt retries as described by `req_retry()`.
- Consults the cache set by `req_cache()` before/after all requests.

In general, where `req_perform()` might make multiple requests due to retries or OAuth failures, `multi_req_perform()` will make only make 1.

Examples

```
# Requesting these 4 pages one at a time would take four seconds:
reqs <- list(
  request("https://httpbin.org/delay/1"),
  request("https://httpbin.org/delay/1"),
  request("https://httpbin.org/delay/1"),
  request("https://httpbin.org/delay/1")
)
# But it's much faster if you request in parallel
system.time(resps <- multi_req_perform(reqs))

reqs <- list(
  request("https://httpbin.org/status/200"),
  request("https://httpbin.org/status/400"),
  request("FAILURE")
)
# multi_req_perform() will always succeed
resps <- multi_req_perform(reqs)
# you'll need to inspect the results to figure out which requests fails
fail <- vapply(resps, inherits, "error", FUN.VALUE = logical(1))
resps[fail]
```
oauth_client

Create an OAuth client

Description

An OAuth app is the combination of a client, a set of endpoints (i.e. urls where various requests should be sent), and an authentication mechanism. A client consists of at least a client_id, and also often a client_secret. You'll get these values when you create the client on the API's website.

Usage

oauth_client(
  id,
  token_url,  
  secret = NULL,  
  key = NULL,  
  auth = c("body", "header", "jwt_sig"),  
  auth_params = list(),  
  name = hash(id)
)

Arguments

id Client identifier.
token_url Url to retrieve an access token.
secret Client secret. For most apps, this is technically confidential so in principle you should avoid storing it in source code. However, many APIs require it in order to provide a user friendly authentication experience, and the risks of including it are usually low. To make things a little safer, I recommend using obfuscate() when recorded the client secret in public code.
key Client key. As an alternative to using a secret, you can instead supply a confidential private key. This should never be included in a package.
auth Authentication mechanism used by the client to prove itself to the API. Can be one of three built-in methods ("body", "header", or "jwt"), or a function that will be called with arguments req, client, and the contents of auth_params. The most common mechanism in the wild is "body" where the client_id and (optionally) client_secret are added to the body. "header" sends in client_id and client_secret in HTTP Authorization header. "jwt_sig" will generate a JWT, and include it in a client_assertion field in the body. See oauth_client_req_auth() for more details.
auth_params Additional parameters passed to the function specified by auth.
name Optional name for the client. Used when generating cache directory. If NULL, generated from hash of client_id. If you’re defining a package for use in a package, I recommend that you use the package name.
oauth_client_req_auth

Value

An OAuth client: An S3 list with class `httr2_oauth_client`.

Examples

```r
oauth_client("myclient", "http://example.com/token_url", secret = "DONTLOOK")
```

---

**oauth_client_req_auth**  
OAuth client authentication

Description

`oauth_client_req_auth()` authenticates a request using the authentication strategy defined by the `auth` and `auth_param` arguments to `oauth_client()`. This used to authenticate the client as part of the OAuth flow, not to authenticate a request on behalf of a user.

There are three built-in strategies:

- `oauth_client_req_body()` adds the client id and (optionally) the secret to the request body, as described in rfc6749, Section 2.3.1.
- `oauth_client_req_header()` adds the client id and secret using HTTP basic authentication with the Authorization header, as described in rfc6749, Section 2.3.1.
- `oauth_client_jwt_rs256()` adds a client assertion to the body using a JWT signed with `jwt_sign_rs256()` using a private key, as described in rfc7523, Section 2.2.

You will generally not call these functions directly but will instead specify them through the `auth` argument to `oauth_client()`. The `req` and `client` parameters are automatically filled in; other parameters come from the `auth_params` argument.

Usage

```r
oauth_client_req_auth(req, client)
oauth_client_req_auth_header(req, client)
oauth_client_req_auth_body(req, client)
oauth_client_req_auth_jwt_sig(req, client, claim, size = 256, header = list())
```

Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>req</td>
<td>A request.</td>
</tr>
<tr>
<td>client</td>
<td>An <code>oauth_client</code>.</td>
</tr>
<tr>
<td>claim</td>
<td>Claim set produced by <code>jwt_claim()</code>.</td>
</tr>
<tr>
<td>size</td>
<td>Size, in bits, of sha2 signature, i.e. 256, 384 or 512. Only for HMAC/RSA, not applicable for ECDSA keys.</td>
</tr>
<tr>
<td>header</td>
<td>A named list giving additional fields to include in the JWT header.</td>
</tr>
</tbody>
</table>
oauth_token

Value

A modified HTTP request.

Examples

# Show what the various forms of client authentication look like
req <- request("https://example.com/whoami")

client1 <- oauth_client(
  id = "12345",
  secret = "56789",
  token_url = "https://example.com/oauth/access_token",
  name = "oauth-example",
  auth = "body" # the default
)
# calls oauth_client_req_auth_body()
req_dry_run(oauth_client_req_auth(req, client1))

client2 <- oauth_client(
  id = "12345",
  secret = "56789",
  token_url = "https://example.com/oauth/access_token",
  name = "oauth-example",
  auth = "header"
)
# calls oauth_client_req_auth_header()
req_dry_run(oauth_client_req_auth(req, client2))

client3 <- oauth_client(
  id = "12345",
  key = openssl::rsa_keygen(),
  token_url = "https://example.com/oauth/access_token",
  name = "oauth-example",
  auth = "jwt_sig",
  auth_params = list(claim = jwt_claim())
)
# calls oauth_client_req_auth_header_jwt_sig()
req_dry_run(oauth_client_req_auth(req, client3))

---

oauth_token

Create an OAuth token

Description

Creates a S3 object of class <httr2_token> representing an OAuth token returned from the access token endpoint.
Usage

```r
oauth_token(
  access_token,
  token_type = "bearer",
  expires_in = NULL,
  refresh_token = NULL,
  ...
)
```

Arguments

- `access_token`: The access token used to authenticate request
- `token_type`: Type of token; only "bearer" is currently supported.
- `expires_in`: Number of seconds until token expires.
- `refresh_token`: Optional refresh token; if supplied, this can be used to cheaply get a new access token when this one expires.
- `...`: Additional components returned by the endpoint
- `.date`: Date the request was made; used to convert the relative `expires_in` to an absolute `expires_at`.

Value

An OAuth token: an S3 list with class `httr2_token`.

Examples

```r
oauth_token("abcdef")
oauth_token("abcdef", expires_in = Sys.time() + 3600)
oauth_token("abcdef", refresh_token = "ghijkl")
```

---

**obfuscate**

*Obfuscate mildly secret information*

Description

This pair of functions provides a way to obfuscate mildly confidential information, like OAuth client secrets. The secret can not be revealed from your source code, but a good R programmer could still figure it out with a little effort. The main goal is to protect against scraping; there's no way for an automated tool to grab your obfuscated secrets.

Because un-obfuscation happens at the last possible instant, `obfuscated()` only works in limited locations:

- The secret argument to `oauth_client()`
- Elements of the data argument to `req_body_form()`, `req_body_json()`, and `req_body_multipart()`.
Usage

obfuscate(x)
obfuscated(x)

Arguments

x A string to obfuscate, or mark as obfuscated.

Value

obfuscate() prints the obfuscated() call to include in your code. obfuscated() returns an S3 class marking the string as obfuscated so it can be unobfuscated when needed.

Examples

obfuscate("good morning")

# Every time you obfuscate you'll get a different value because it
# includes 16 bytes of random data which protects against certain types of
# brute force attack
obfuscate("good morning")

request

Create a new HTTP request

Description

To perform a HTTP request, first create a request object with request(), then define its behaviour with req_ functions, then perform the request and fetch the response with req_perform().

Usage

request(base_url)

Arguments

base_url Base URL for request.

Value

An HTTP response: an S3 list with class httr2_request.

Examples

request("http://r-project.org")
req_auth_basic Authenticate request with HTTP basic authentication

Description

Usage

```r
req_auth_basic(req, username, password = NULL)
```

Arguments

- `req`: A request.
- `username`: User name.
- `password`: Password. You avoid entering the password directly when calling this function as it will be captured by `.Rhistory`. Instead, leave it unset and the default behaviour will prompt you for it interactively.

Value

A modified HTTP request.

Examples

```r
req <- request("http://example.com") %>% req_auth_basic("hadley", "SECRET")
req %>% req_dry_run()

# httr2 does its best to redact the Authorization header so that you don't accidentally reveal confidential data. Use `redact_headers` to reveal it:
print(req, redact_headers = FALSE)
req %>% req_dry_run(redact_headers = FALSE)

# We do this because the authorization header is not encrypted and the so password can easily be discovered:
rawToChar(jsonlite::base64_dec("aGFkbGV5OlNFQ1JFVA=="))
```
**req_auth_bearer_token**  
Authenticate request with bearer token

**Description**

A bearer token gives the bearer access to confidential resources (so you should keep them secure like you would with a user name and password). They are usually produced by some large authentication scheme (like the various OAuth 2.0 flows), but you are sometimes given then directly.

**Usage**

```r
req_auth_bearer_token(req, token)
```

**Arguments**

- `req` A request.
- `token` A bearer token

**Value**

A modified HTTP request.

**See Also**

**Examples**

```r
req <- request("http://example.com") %>% req_auth_bearer_token("sdaljsdf093lkfs")
req
```

# httr2 does its best to redact the Authorization header so that you don't
# accidentally reveal confidential data. Use `redact_headers` to reveal it:
print(req, redact_headers = FALSE)

---

**req_body**  
Send data in request body

**Description**

- `req_body_file()` sends a local file.
- `req_body_raw()` sends a string or raw vector.
- `req_body_json()` sends JSON encoded data.
- `req_body_form()` sends form encoded data.
- `req_body_multipart()` creates a multi-part body.

Adding a body to a request will automatically switch the method to POST.
Usage

req_body_raw(req, body, type = NULL)

req_body_file(req, path, type = NULL)

req_body_json(req, data, auto_unbox = TRUE, digits = 22, null = "null", ...)

req_body_form(.req, ...)

req_body_multipart(.req, ...)

Arguments

req
A request.

body
A literal string or raw vector to send as body.

type
Content type. For req_body_file(), the default will attempt to guess from the extension of path.

path
Path to file to upload.

data
Data to include in body.

auto_unbox
Should length-1 vectors be automatically "unboxed" to JSON scalars?

digits
How many digits of precision should numbers use in JSON?

null
Should NULL be translated to JSON’s null ("null") or an empty list ("list").

...
Name-data pairs used to send data in the body. For req_body_form(), the values must be strings (or things easily coerced to strings); for req_body_multipart() the values must be strings or objects produced by curl::form_file()/curl::form_data(). For req_body_json(), additional arguments passed on to jsonlite::toJSON().

.req
A request.

Value

A modified HTTP request.

Examples

req <- request("http://httpbin.org/post")

# Most APIs expect small amounts of data in either form or json encoded:

req %>%
  req_body_form(x = "A simple text string") %>%
  req_dry_run()

req %>%
  req_body_json(list(x = "A simple text string")) %>%
  req_dry_run()

# For total control over the body, send a string or raw vector

req %>%
```
req_body_raw("A simple text string") %>%
  req_dry_run()

# There are two main ways that APIs expect entire files
path <- tempfile()
writeLines(letters[1:6], path)

# You can send a single file as the body:
req %>%
  req_body_file(path) %>%
  req_dry_run()

# You can send multiple files, or a mix of files and data
# with multipart encoding
req %>%
  req_body_multipart(a = curl::form_file(path), b = "some data") %>%
  req_dry_run()
```

---

### `req_cache`

Automatically cache requests

**Description**

Use `req_perform()` to automatically cache HTTP requests. Most API requests are not cacheable, but static files often are. `req_cache()` caches responses to GET requests that have status code 200 and at least one of the standard caching headers (e.g. Expires, Etag, Last-Modified, Cache-Control), unless caching has been expressly prohibited with Cache-Control: no-store. Typically, a request will still be sent to the server to check that the cached value is still up-to-date, but it will not need to re-download the body value.

To learn more about HTTP caching, I recommend the MDN article [HTTP caching](https://developer.mozilla.org/en-US/docs/Web/HTTP/Headers/Cache-Control).

**Usage**

```
req_cache(req, path, use_on_error = FALSE, debug = FALSE)
```

**Arguments**

- **`req`**
  - A request.
- **`path`**
  - Path to cache directory
- **`use_on_error`**
  - If the request errors, and there's a cache response, should `req_perform()` return that instead of generating an error?
- **`debug`**
  - When TRUE will emit useful messages telling you about cache hits and misses. This can be helpful to understand whether or not caching is actually doing anything for your use case.
Value

A modified HTTP request.

Examples

# GitHub uses HTTP caching for all raw files.
url <- paste0(
  "https://raw.githubusercontent.com/allisonhorst/palmerpenguins/",
  "master/inst/extdata/penguins.csv"
)
# Here I set debug = TRUE so you can see what's happening
req <- request(url) %>% req_cache(tempdir(), debug = TRUE)

# First request downloads the data
resp <- req %>% req_perform()

# Second request retrieves it from the cache
resp <- req %>% req_perform()

---

**req_dry_run**  
*Perform a dry run*

Description

This shows you exactly what httr2 will send to the server, without actually sending anything. It requires the httpuv package because it works by sending the real HTTP request to a local webserver, thanks to the magic of `curl::curl_echo()`.

Usage

```r
req_dry_run(req, quiet = FALSE, redact_headers = TRUE)
```

Arguments

- `req`  
  A request.
- `quiet`  
  If TRUE doesn’t print anything.
- `redact_headers`  
  Redact confidential data in the headers? Currently redacts the contents of the Authorization header to prevent you from accidentally leaking credentials when debugging/reprexing.

Value

Invisibly, a list containing information about the request, including method, path, and headers.
### Examples

```r
# htr2 adds default User-Agent, Accept, and Accept-Encoding headers
request("http://example.com") %>% req_dry_run()

# the Authorization header is automatically redacted to avoid leaking
# credentials on the console
req <- request("http://example.com") %>% req_auth_basic("user", "password")
req %>% req_dry_run()

# if you need to see it, use redact_headers = FALSE
req %>% req_dry_run(redact_headers = FALSE)
```

---

### req_error

**Control handling of HTTP errors**

### Description

`req_perform()` will automatically convert HTTP errors (i.e. any 4xx or 5xx status code) into R errors. Use `req_error()` to either override the defaults, or extract additional information from the response that would be useful to expose to the user.

### Usage

```r
req_error(req, is_error = NULL, body = NULL)
```

### Arguments

- **req** — A request.
- **is_error** — A predicate function that takes a single argument (the response) and returns `TRUE` or `FALSE` indicating whether or not an R error should be signalled.
- **body** — A callback function that takes a single argument (the response) and returns a character vector of additional information to include in the body of the error. This vector is passed along to the `message` argument of `rlang::abort()` so you can use any formatting that it supports.

### Value

A modified HTTP request.

### See Also

- `req_retry()` to control when errors are automatically retried.
Examples

# Performing this request usually generates an error because httr2
# converts HTTP errors into R errors:
req <- request("http://httpbin.org/404")
try(req %>% req_perform())
# You can still retrieve it with last_response()
last_response()

# But you might want to suppress this behaviour:
resp <- req %>%
  req_error(is_error = function(resp) FALSE) %>%
  req_perform()
resp

# Or perhaps you’re working with a server that routinely uses the
# wrong HTTP error codes only 500s are really errors
request("http://example.com") %>%
  req_error(is_error = function(resp) resp_status(resp) == 500)

# Most typically you’ll use req_error() to add additional information
# extracted from the response body (or sometimes header):
error_body <- function(resp) {
  resp_body_json(resp)$error
}
request("http://example.com") %>%
  req_error(body = error_body)
# Learn more in https://httr2.r-lib.org/articles/wrapping-apis.html

req_headers

Modify request headers

Description

req_headers() allows you to set the value of any header.

Usage

req_headers(.req, ...)

Arguments

.req
  A request.

... Name-value pairs of headers and their values.
  • Use NULL to reset a value to httr’s default
  • Use "" to remove a header
  • Use a character vector to repeat a header.
Value

A modified HTTP request.

Examples

```r
req <- request("http://example.com")

# Use req_headers() to add arbitrary additional headers to the request
req %>%
  req_headers(MyHeader = "MyValue") %>%
  req_dry_run()

# Repeated use overrides the previous value:
req %>%
  req_headers(MyHeader = "Old value") %>%
  req_headers(MyHeader = "New value") %>%
  req_dry_run()

# Setting Accept to NULL uses curl's default:
req %>%
  req_headers(Accept = NULL) %>%
  req_dry_run()

# Setting it to "" removes it:
req %>%
  req_headers(Accept = "") %>%
  req_dry_run()

# If you need to repeat a header, provide a vector of values
# (this is rarely needed, but is important in a handful of cases)
req %>%
  req_headers(HeaderName = c("Value 1", "Value 2", "Value 3")) %>%
  req_dry_run()
```

---

**req_method**  
*Set HTTP method in request*

**Description**

Use this function to use a custom HTTP method like HEAD, DELETE, PATCH, UPDATE, or OPTIONS. The default method is GET for requests without a body, and POST for requests with a body.

**Usage**

```r
req_method(req, method)
```

**Arguments**

- `req`  
  A request.

- `method`  
  Custom HTTP method
Value

A modified HTTP request.

Examples

```r
request("http://httpbin.org") %>% req_method("PATCH")
request("http://httpbin.org") %>% req_method("PUT")
request("http://httpbin.org") %>% req_method("HEAD")
```

---

**req_oauth_auth_code**  
OAuth authentication with authorization code

Description

This uses `oauth_flow_auth_code()` to generate an access token, which is then used to authenticate the request with `req_auth_bearer_token()`. The token is automatically cached (either in memory or on disk) to minimise the number of times the flow is performed.

Usage

```r
req_oauth_auth_code(
  req,
  client,
  auth_url,
  cache_disk = FALSE,
  cache_key = NULL,
  scope = NULL,
  pkce = TRUE,
  auth_params = list(),
  token_params = list(),
  host_name = "localhost",
  host_ip = "127.0.0.1",
  port = httpuv::randomPort()
)
```

Arguments

- `req`  
  A request.
- `client`  
  An `oauth_client()`.
- `auth_url`  
  Authorization url; you’ll need to discover this by reading the documentation.
- `cache_disk`  
  Should the access token be cached on disk? This reduces the number of times that you need to re-authenticate at the cost of storing access credentials on disk. Cached tokens are encrypted and automatically deleted 30 days after creation.
- `cache_key`  
  If you want to cache multiple tokens per app, use this key to disambiguate them.
- `scope`  
  Scopes to be requested from the resource owner.
Use "Proof Key for Code Exchange"? This adds an extra layer of security and should always be used if supported by the server.

List containing additional parameters passed to oauth_flow_auth_code_url().

List containing additional parameters passed to the token_url.

Host name used to generate redirect_uri.

IP address web server will be bound to.

Port to bind web server to. By default, this uses a random port. You may need to set it to a fixed port if the API requires that the redirect_uri specified in the client exactly matches the redirect_uri generated by this function.

A modified HTTP request.

The authorization code flow is used for both web applications and native applications (which are equivalent to R packages). rfc8252 spells out important considerations for native apps. Most importantly there’s no way for native apps to keep secrets from their users. This means that the server should either not require a client_secret (i.e. a public client not an confidential client) or ensure that possession of the client_secret doesn’t bestow any meaningful rights.

Only modern APIs from the bigger players (Azure, Google, etc) explicitly native apps. However, in most cases, even for older APIs, possessing the client_secret gives you no ability to do anything harmful, so our general principle is that it’s fine to include it in an R package, as long as it’s mildly obfuscated to protect it from credential scraping. There’s no incentive to steal your client credentials if it takes less time to create a new client than find your client secret.

```r
client <- oauth_client(
  id = "28acfec0674bb3da9f38",
  secret = obfuscated(paste0(
    "J9iiGmyelHltyxqrHXXW41ZFPZamyUNxSX1_uKnv",
    "PeinhhxET_ZFFUs20LLKotXY2bpgOMoHRCo"
  )),
  token_url = "https://github.com/login/oauth/access_token",
  name = "hadley-oauth-test"
)

request("https://api.github.com/user") %>%
  req_oauth_auth_code(client, auth_url = "https://github.com/login/oauth/authorize")
```
req_oauth_bearer_jwt

**Description**

This uses `oauth_flow_bearer_jwt()` to generate an access token which is then used to authenticate the request with `req_auth_bearer_token()`. The token is cached in memory.

**Usage**

```r
req_oauth_bearer_jwt(
  req,
  client,
  claim,
  signature = "jwt_encode_sig",
  signature_params = list(),
  scope = NULL,
  token_params = list()
)
```

**Arguments**

- `req` A request.
- `client` An `oauth_client()`.
- `claim` A list of claims. If all elements of the claim set are static apart from `iat`, `nbf`, `exp`, or `jti`, provide a list and `jwt_claim()` will automatically fill in the dynamic components. If other components need to vary, you can instead provide a zero-argument callback function which should call `jwt_claim()`.
- `signature` Function use to sign `claim`, e.g. `jwt_encode_sig()`.
- `signature_params` Additional arguments passed to `signature`, e.g. `size`, `header`.
- `scope` Scopes to be requested from the resource owner.
- `token_params` List containing additional parameters passed to the `token_url`.

**Value**

A modified HTTP request.

**Examples**

```r
client <- oauth_client("example", "https://example.com/get_token")
claim <- jwt_claim()
req <- request("https://example.com")

req %>% req_oauth_bearer_jwt(client, claim)
```
**req_oauth_client_credentials**

_**OAuth authentication with client credentials**_

**Description**

This uses `oauth_flow_client_credentials()` to generate an access token, which is then used to authenticate the request with `req_auth_bearer_token()`. The token is cached in memory.

**Usage**

```r
req_oauth_client_credentials(req, client, scope = NULL, token_params = list())
```

**Arguments**

- **req**: A request.
- **client**: An `oauth_client()`.
- **scope**: Scopes to be requested from the resource owner.
- **token_params**: List containing additional parameters passed to the `token_url`.

**Value**

A modified HTTP request.

**Examples**

```r
client <- oauth_client("example", "https://example.com/get_token")
req <- request("https://example.com")

req %>% req_oauth_client_credentials(client)
```

---

**req_oauth_device**

_**OAuth authentication with device flow**_

**Description**

This uses `oauth_flow_device()` to generate an access token, which is then used to authenticate the request with `req_auth_bearer_token()`. The token is automatically cached (either in memory or on disk) to minimise the number of times the flow is performed.
Usage

```r
req_oauth_device(
  req,
  client,
  cache_disk = FALSE,
  cache_key = NULL,
  scope = NULL,
  auth_params = list(),
  token_params = list()
)
```

Arguments

- **req**: A request.
- **client**: An `oauth_client()`.
- **cache_disk**: Should the access token be cached on disk? This reduces the number of times that you need to re-authenticate at the cost of storing access credentials on disk. Cached tokens are encrypted and automatically deleted 30 days after creation.
- **cache_key**: If you want to cache multiple tokens per app, use this key to disambiguate them.
- **scope**: Scopes to be requested from the resource owner.
- **auth_params**: List containing additional parameters passed to `oauth_flow_auth_code_url()`.
- **token_params**: List containing additional parameters passed to the `token_url`.

Value

A modified HTTP request.

Examples

```r
client <- oauth_client("example", "https://example.com/get_token")
req <- request("https://example.com")

req %>% req_oauth_device(client)
```

---

**req_oauth_password**  
OAuth authentication with username and password

Description

This uses `oauth_flow_password()` to generate an access token, which is then used to authentication the request with `req_auth_bearer_token()`. The token, not the password is automatically cached (either in memory or on disk); the password is used once to get the token and is then discarded.
Usage

```r
req_oauth_password(
  req, 
  client, 
  username, 
  password = NULL, 
  cache_disk = FALSE, 
  scope = NULL, 
  token_params = list()
)
```

Arguments

- **req**: A request.
- **client**: An `oauth_client()`.
- **username**: User name.
- **password**: Password. You avoid entering the password directly when calling this function as it will be captured by `.Rhistory`. Instead, leave it unset and the default behaviour will prompt you for it interactively.
- **cache_disk**: Should the access token be cached on disk? This reduces the number of times that you need to re-authenticate at the cost of storing access credentials on disk. Cached tokens are encrypted and automatically deleted 30 days after creation.
- **scope**: Scopes to be requested from the resource owner.
- **token_params**: List containing additional parameters passed to the `token_url`.

Value

A modified HTTP request.

Examples

```r
client <- oauth_client("example", "https://example.com/get_token")
req <- request("https://example.com")

if (interactive()) {
  req %>% req_oauth_password(client, "username")
}
```
Description

This uses `oauth_flow_refresh()` to generate an access token, which is then used to authenticate the request with `req_auth_bearer_token()`. This is primarily useful for testing: you can manually execute another OAuth flow (e.g. by calling `oauth_flow_auth_code()` or `oauth_flow_device()`), extract the refresh token from the result, and then save in an environment variable for future use in automated tests.

When requesting an access token, the server may also return a new refresh token. If this happens, `oauth_flow_refresh()` will error, and you’ll have to create a new refresh token following the same procedure you did to get the first token (so it’s a good idea to document what you did the first time because you might need to do it again).

Usage

```r
req_oauth_refresh(
  req,  # A request.
  client,  # An `oauth_client()`.
  refresh_token = Sys.getenv("HTTR_REFRESH_TOKEN"),  # A refresh token. This is equivalent to a password so shouldn’t be typed into the console or stored in a script. Instead, we recommend placing in an environment variable; the default behaviour is to look in HTTR_REFRESH_TOKEN.
  scope = NULL,  # Scopes to be requested from the resource owner.
  token_params = list()  # List containing additional parameters passed to the token_url.
)
```

Arguments

- `req`: A request.
- `client`: An `oauth_client()`.
- `refresh_token`: A refresh token. This is equivalent to a password so shouldn’t be typed into the console or stored in a script. Instead, we recommend placing in an environment variable; the default behaviour is to look in HTTR_REFRESH_TOKEN.
- `scope`: Scopes to be requested from the resource owner.
- `token_params`: List containing additional parameters passed to the token_url.

Value

A modified HTTP request.

Examples

```r
client <- oauth_client("example", "https://example.com/get_token")
req <- request("https://example.com")
req %>% req_oauth_refresh(client)
```
Description

After preparing a request, call `req_perform()` to perform it, fetching the results back to R as a response.

The default HTTP method is GET unless a body (set by `req_body_json` and friends) is present, in which case it will be POST. You can override these defaults with `req_method()`.

Usage

```r
req_perform(
  req,
  path = NULL,
  verbosity = NULL,
  mock = getOption("httr2_mock", NULL)
)
```

Arguments

- **req**: A request.
- **path**: Optionally, path to save body of request. This is useful for large responses since it avoids storing the response in memory.
- **verbosity**: How much information to print? This is a wrapper around `req_verbose()` that uses an integer to control verbosity:
  - 0: no output
  - 1: show headers
  - 2: show headers and bodies
  - 3: show headers, bodies, and curl status messages.
  Use `withverbosity()` to control the verbosity of requests that you can’t affect directly.
- **mock**: A mocking function. If supplied, this function is called with the request. It should return either NULL (if it doesn’t want to handle the request) or a response (if it does). See `with_mock()`/`local_mock()` for more details.

Value

If request is successful (i.e. the request was successfully performed and a response with HTTP status code <400 was received), an HTTP response; otherwise throws an error. Override this behaviour with `req_error()`.
Requests

Note that one call to `req_perform()` may perform multiple HTTP requests:

- If the url is redirected with a 301, 302, 303, or 307, curl will automatically follow the Location header to the new location.
- If you have configured retries with `req_retry()` and the request fails with a transient problem, `req_perform()` will try again after waiting a bit. See `req_retry()` for details.
- If you are using OAuth, and the cached token has expired, `req_perform()` will get a new token either using the refresh token (if available) or by running the OAuth flow.

Examples

```r
request("https://google.com") %>%
  req_perform()
```

---

**req_proxy**

*Use a proxy for a request*

### Description

Use a proxy for a request

### Usage

```r
req_proxy(
  req,
  url, port = NULL,
  username = NULL,
  password = NULL,
  auth = "basic"
)
```

### Arguments

- `req` A request.
- `url, port` Location of proxy.
- `username, password` Login details for proxy, if needed.
- `auth` Type of HTTP authentication to use. Should be one of the following: basic, digest, digest_ie, gssnegotiate, ntlm, any.
### Examples

```r
# Proxy from https://www.proxynova.com/proxy-server-list/
## Not run:
request("http://hadley.nz") %>%
  req_proxy("20.116.130.70", 3128) %>%
  req_perform()

## End(Not run)
```

---

#### Description

`req_retry()` alters `req_perform()` so that it will automatically retry in the case of failure. To activate it, you must specify either the total number of requests to make with `max_tries` or the total amount of time to spend with `max_seconds`. Then `req_perform()` will retry if:

- The either the HTTP request or HTTP response doesn’t complete successfully leading to an error from curl, the lower-level library that httr uses to perform HTTP request. This occurs, for example, if your wifi is down.
- The error is “transient”, i.e. it’s an HTTP error that can be resolved by waiting. By default, 429 and 503 statuses are treated as transient, but if the API you are wrapping has other transient status codes (or conveys transient-ness with some other property of the response), you can override the default with `is_transient`.

It’s a bad idea to immediately retry a request, so `req_perform()` will wait a little before trying again:

- If the response contains the `Retry-After` header, httr2 will wait the amount of time it specifies. If the API you are wrapping conveys this information with a different header (or other property of the response) you can override the default behaviour with `retry_after`.
- Otherwise, httr2 will use "truncated exponential backoff with full jitter", i.e. it will wait a random amount of time between one second and $2^\text{tries}$ seconds, capped to at most 60 seconds. In other words, it waits $\text{runif}(1, 1, 2)$ seconds after the first failure, $\text{runif}(1, 1, 4)$ after the second, $\text{runif}(1, 1, 8)$ after the third, and so on. If you’d prefer a different strategy, you can override the default with `backoff`.

#### Usage

```r
req_retry(
  req,
  max_tries = NULL,
  max_seconds = NULL,
  is_transient = NULL,
  backoff = NULL,
  after = NULL
)
```
Arguments

req A request.
max_tries, max_seconds
Cap the maximum number of attempts with max_tries or the total elapsed time from the first request with max_seconds. If neither option is supplied (the default), req_perform() will not retry.
is_transient A predicate function that takes a single argument (the response) and returns TRUE or FALSE specifying whether or not the response represents a transient error.
backoff A function that takes a single argument (the number of failed attempts so far) and returns the number of seconds to wait.
after A function that takes a single argument (the response) and returns either a number of seconds to wait or NULL, which indicates that a precise wait time is not available that the backoff strategy should be used instead.

Value
A modified HTTP request.

See Also
req_throttle() if the API has a rate-limit but doesn’t expose the limits in the response.

Examples

# google APIs assume that a 500 is also a transient error
request("http://google.com") %>%
  req_retry(is_transient = ~ resp_status(.x) %in% c(429, 500, 503))

# use a constant 10s delay after every failure
request("http://example.com") %>%
  req_retry(backoff = ~ 10)

# When rate-limited, GitHub’s API returns a 403 with
# ‘X-RateLimit-Remaining: 0’ and an Unix time stored in the
# ‘X-RateLimit-Reset’ header. This takes a bit more work to handle:
github_is_transient <- function(resp) {
  resp_status(resp) == 403 &&
  identical(resp_header(resp, "X-RateLimit-Remaining"), "0")
}
github_after <- function(resp) {
  time <- as.numeric(resp_header(resp, "X-RateLimit-Reset"))
  time - unclass(Sys.time())
}
request("http://api.github.com") %>%
  req_retry(
    is_transient = github_is_transient,
    after = github_after
  )
**req_stream**

*Perform a request, streaming data back to R*

**Description**

After preparing a request, call `req_stream()` to perform the request and handle the result with a streaming callback. This is useful for streaming HTTP APIs where potentially the stream never ends.

**Usage**

```r
req_stream(req, callback, timeout_sec = Inf, buffer_kb = 64)
```

**Arguments**

- **req**  
  A request.
- **callback**  
  A single argument callback function. It will be called repeatedly with a raw vector whenever there is at least `buffer_kb` worth of data to process. It must return `TRUE` to continue streaming.
- **timeout_sec**  
  Number of seconds to process stream for.
- **buffer_kb**  
  Buffer size, in kilobytes.

**Value**

An HTTP response.

**Examples**

```r
show_bytes <- function(x) {
  cat("Got ", length(x), " bytes\n", sep = "")
  TRUE
}
resp <- request("http://httpbin.org/stream-bytes/100000") %>%
  req_stream(show_bytes, buffer_kb = 32)
```

---

**req_template**

*Set request method/path from a template*

**Description**

Many APIs document their methods with a lightweight template mechanism that looks like `GET /user/{user}` or `POST /organisation/:org`. This function makes it easy to copy and paste such snippets and retrieve template variables either from function arguments or the current environment. `req_template()` will append to the existing path so that you can set a base url in the initial `request()`. This means that you’ll generally want to avoid multiple `req_template()` calls on the same request.
Usage

```r
req_template(req, template, ..., .env = parent.frame())
```

Arguments

- `req` A request.
- `template` A template string which consists of an optional HTTP method and a path containing variables labelled like either `:foo` or `{foo}`.
- `...` Template variables.
- `.env` Environment in which to look for template variables not found in `...`. Expert use only.

Value

A modified HTTP request.

Examples

```r
httpbin <- request("http://httpbin.org")

# You can supply template parameters in `...`
httpbin %>% req_template("GET /bytes/{n}", n = 100)

# or you retrieve from the current environment
n <- 200
httpbin %>% req_template("GET /bytes/{n}")

# Existing path is preserved:
httpbin_cookies <- request("http://httpbin.org/cookies")
nname <- "id"
value <- "a3fWa"
httpbin_cookies %>% req_template("GET /set/{n}/"{value}")
```

---

**req_throttle**

*Throttle a request by automatically adding a delay*

Description

Use `req_throttle()` to ensure that repeated calls to `req_perform()` never exceed a specified rate.

Usage

```r
req_throttle(req, rate, realm = NULL)
```
**req_timeout**

Set time limit for a request

**Description**

An error will be thrown if the request does not complete in the time limit.

**Usage**

```r
req_timeout(req, seconds)
```

**Arguments**

- `req` *A request.*
- `seconds` Maximum number of seconds to wait

**Value**

A modified HTTP request.

**Examples**

```r
# Give up after at most 10 seconds
request("http://example.com") %>% req_timeout(10)
```
Description

- `req_url()` replaces the entire url
- `req_url_query()` modifies the components of the query
- `req_url_path()` modifies the path
- `req_url_path_append()` adds to the path

Usage

```r
req_url(req, url)
req_url_query(.req, ...)
req_url_path(req, ...)
req_url_path_append(req, ...)
```

Arguments

- `req` A request.
- `url` New URL; completely replaces existing.
- `.req` A request.
- `...` For `req_url_query()`: Name-value pairs that provide query parameters. Each value must be either length-1 atomic vector or NULL (which is automatically dropped).
  For `req_url_path()` and `req_url_path_append()`: A sequence of path components that will be combined with `/`.

Value

A modified HTTP request.

Examples

```r
req <- request("http://example.com")

# Change url components
req %>%
  req_url_path_append("a") %>%
  req_url_path_append("b") %>%
  req_url_path_append("search.html") %>%
  req_url_query(q = "the cool ice")
```
# Change complete url
req %>%
  req_url("http://google.com")

---

**req_user_agent**  
*Set user-agent for a request*

**Description**

This overrides the default user-agent set by httr2 which includes the version numbers of httr2, the curl package, and libcurl.

**Usage**

```r
req_user_agent(req, string = NULL)
```

**Arguments**

- `req`  
  A request.

- `string`  
  String to be sent in the User-Agent header. If NULL, will use default.

**Value**

A modified HTTP request.

**Examples**

```r
# Default user-agent:
request("http://example.com") %>% req_dry_run()
request("http://example.com") %>% req_user_agent("MyString") %>% req_dry_run()

# If you're wrapping in an API in a package, it's polite to set the
# user agent to identify your package.
request("http://example.com") %>%
  req_user_agent("MyPackage (http://mypackage.com)") %>%
  req_dry_run()
```
Description

`req_verbose()` uses the following prefixes to distinguish between different components of the HTTP requests and responses:

- `*` informative curl messages
- `<-` request headers
- `<<` request body
- `->` response headers
- `>>` response body

Usage

```r
define_usage()
  req_verbose(
    req,  # A request.
    header_req = TRUE,  # Show request/response headers?
    header_resp = TRUE,  # Should request/response bodies? When the response body is compressed, this
    body_req = FALSE,  # will show the number of bytes received in each "chunk".
    body_resp = FALSE,  # Show informational text from curl? This is mainly useful for debugging https
    info = FALSE,  # and auth problems, so is disabled by default.
    redact_headers = TRUE  # Redact confidential data in the headers? Currently redacts the contents of the
  )  # Authorization header to prevent you from accidentally leaking credentials when
```

Arguments

- `req` A request.
- `header_req, header_resp` Show request/response headers?
- `body_req, body_resp` Should request/response bodies? When the response body is compressed, this will show the number of bytes received in each "chunk".
- `info` Show informational text from curl? This is mainly useful for debugging https and auth problems, so is disabled by default.
- `redact_headers` Redact confidential data in the headers? Currently redacts the contents of the Authorization header to prevent you from accidentally leaking credentials when debugging/reprexing.

Value

A modified HTTP request.
See Also

`req_perform()` which exposes a limited subset of these options through the `verbosity` argument and `with_verbosity()` which allows you to control the verbosity of requests deeper within the call stack.

Examples

```r
# Use `req_verbose()` to see the headers that are sent back and forth when
# making a request
resp <- request("https://httr2.r-lib.org") %>%
  req_verbose() %>%
  req_perform()

# Or use one of the convenient shortcuts:
resp <- request("https://httr2.r-lib.org") %>%
  req_perform(verbosity = 1)
```

Description

- `resp_body_raw()` returns the raw bytes.
- `resp_body_string()` returns a UTF-8 string.
- `resp_body_json()` returns parsed JSON.
- `resp_body_html()` returns parsed HTML.
- `resp_body_xml()` returns parsed XML.

`resp_body_json()` and `resp_body_xml()` check that the content-type header is correct; if the server returns an incorrect type you can suppress the check with `check_type = FALSE`.

Usage

```r
resp_body_raw(resp)

resp_body_string(resp, encoding = NULL)

resp_body_json(resp, check_type = TRUE, simplifyVector = FALSE, ...)

resp_body_html(resp, check_type = TRUE, ...)

resp_body_xml(resp, check_type = TRUE, ...)
```
Arguments

- resp: A response object.
- encoding: Character encoding of the body text. If not specified, will use the encoding specified by the content-type, falling back to UTF-8 with a warning if it cannot be found. The resulting string is always re-encoded to UTF-8.
- check_type: Check that response has expected content type? Set to FALSE to suppress the automated check.
- simplifyVector: Should JSON arrays containing only primitives (i.e. booleans, numbers, and strings) be caused to atomic vectors?
- ...: Other arguments passed on to `jsonlite::fromJSON()` and `xml2::read_xml()` respectively.

Value

- `resp_body_raw()` returns a raw vector.
- `resp_body_string()` returns a string.
- `resp_body_json()` returns NULL, an atomic vector, or list.
- `resp_body_html()` and `resp_body_xml()` return an `xml2::xml_document`

Examples

```r
resp <- request("https://httr2.r-lib.org") %>% req_perform()
resp

resp %>% resp_body_raw()
resp %>% resp_body_string()

if (requireNamespace("xml2", quietly = TRUE)) {
  resp %>% resp_body_html()
}
```

Description

`resp_content_type()` returns the just the type and subtype of the from the Content-Type header. If Content-Type is not provided; it returns NA. Used by `resp_body_json()`, `resp_body_html()`, and `resp_body_xml()`.

`resp_encoding()` returns the likely character encoding of text types, as parsed from the charset parameter of the Content-Type header. If that header is not found, not valid, or no charset parameter is found, returns UTF-8. Used by `resp_body_string()`.
Usage

resp_content_type(resp)
resp_encoding(resp)

Arguments

resp An HTTP response object, as created by \texttt{req_perform()}.

Value

A string. If no content type is specified \texttt{resp_content_type()} will return a character NA; if no encoding is specified, \texttt{resp_encoding()} will return "UTF-8".

Examples

\begin{verbatim}
resp <- response(header = "Content-type: text/html; charset=utf-8")
resp %>% resp_content_type()
resp %>% resp_encoding()

# No Content-Type header
resp <- response()
resp %>% resp_content_type()
resp %>% resp_encoding()
\end{verbatim}

---

\texttt{resp_date} \textit{Extract request date from response}

Description

All responses contain a request date in the \texttt{Date} header; if not provided by the server will be automatically added by \texttt{httr2}.

Usage

\texttt{resp_date(resp)}

Arguments

resp An HTTP response object, as created by \texttt{req_perform()}.

Value

A \texttt{POSIXct} date-time.
Examples

```r
resp <- response(headers = "Date: Wed, 01 Jan 2020 09:23:15 UTC")
resp %>% resp_date()
```

# If server doesn't add header (unusual), you get the time the request was created:
```r
resp <- response()
resp %>% resp_date()
```

### resp_headers

*Extract headers from a response*

**Description**

- `resp_headers()` retrieves a list of all headers.
- `resp_header()` retrieves a single header.
- `resp_header_exists()` checks if a header is present.

**Usage**

```r
resp_headers(resp, filter = NULL)
```

```r
resp_header(resp, header)
```

```r
resp_header_exists(resp, header)
```

**Arguments**

- **resp** An HTTP response object, as created by `req_perform()`.
- **filter** A regular expression used to filter the header names. NULL, the default, returns all headers.
- **header** Header name (case insensitive)

**Value**

- `resp_headers()` returns a list.
- `resp_header()` returns a string if the header exists and NULL otherwise.
- `resp_header_exists()` returns TRUE or FALSE.
resp_link_url

Parse link URL from a response

Description

Parses URLs out of the Link header as defined by rfc8288.

Usage

resp_link_url(resp, rel)

Arguments

resp An HTTP response object, as created by req_perform().
rel The "link relation type" value for which to retrieve a URL.

Value

Either a string providing a URL, if the specified rel exists, or NULL if not.

Examples

# Simulate response from GitHub code search
resp <- response(headers = paste0("Link: ",
    '<https://api.github.com/search/code?q=addClass+user%3Amozilla&page=2>; rel="next",',
    '<https://api.github.com/search/code?q=addClass+user%3Amozilla&page=34>; rel="last"'))

resp_link_url(resp, "next")
resp_link_url(resp, "last")
resp_link_url(resp, "prev")
**resp_raw**

*Show the raw response*

**Description**

This function reconstructs the HTTP message that httr2 received from the server. It’s unlikely to be exactly byte-for-byte identical (because most servers compress at least the body, and HTTP/2 can also compress the headers), but it conveys the same information.

**Usage**

```r
resp_raw(resp)
```

**Arguments**

- **resp**
  
  An HTTP response

**Value**

```
resp (invisibly).
```

**Examples**

```r
c <- request("https://httpbin.org/json") %>% req_perform()
c %>% resp_raw()
```

**resp_retry_after**

*Extract wait time from a response*

**Description**

Computes how many seconds you should wait before retrying a request by inspecting the Retry-After header. It parses both forms (absolute and relative) and returns the number of seconds to wait. If the heading is not found, it will return `NA`.

**Usage**

```r
resp_retry_after(resp)
```

**Arguments**

- **resp**
  
  An HTTP response object, as created by `req_perform()`.

**Value**

Scalar double giving the number of seconds to wait before retrying a request.
**Examples**

```r
resp <- response(headers = "Retry-After: 30")
resp %>% resp_retry_after()

resp <- response(headers = "Retry-After: Mon, 20 Sep 2025 21:44:05 UTC")
resp %>% resp_retry_after()
```

---

**resp_status**

*Extract HTTP status from response*

**Description**

- `resp_status()` retrieves the numeric HTTP status code.
- `resp_status_desc()` retrieves the brief textual description.
- `resp_is_error()` returns `TRUE` if the status code represents an error (i.e. a 4xx or 5xx status).
- `resp_check_status()` turns HTTP errors into R errors.

These functions are mostly for internal use because in most cases you will only ever see a 200 response:

- 1xx are handled internally by curl.
- 3xx redirects are automatically followed. You will only see them if you have deliberately suppressed redirects with `req %>% req_options(followlocation = FALSE)`.
- 4xx client and 5xx server errors are automatically turned into R errors. You can stop them from being turned into R errors with `req_error()`, e.g. `req %>% req_error(is_error = ~ FALSE)`.

**Usage**

```r
resp_status(resp)
resp_status_desc(resp)
resp_is_error(resp)
resp_check_status(resp, info = NULL)
```

**Arguments**

- `resp` An HTTP response object, as created by `req_perform()`.
- `info` A character vector of additional information to include in the error message. Passed to `rlang::abort()`.
Value

• `resp_status()` returns a scalar integer
• `resp_status_desc()` returns a string
• `resp_is_error()` returns TRUE or FALSE
• `resp_check_status()` invisibly returns the response if it’s ok; otherwise it throws an error with class `httr2_http_{status}`.

Examples

```r
# An HTTP status code you're unlikely to see in the wild:
resp <- response(418)
resp %>% resp_is_error()
resp %>% resp_status()
resp %>% resp_status_desc()
```

---

Secret management

httr2 provides a handful of functions designed for working with confidential data. These are useful because testing packages that use httr2 often requires some confidential data that needs to be available for testing, but should not be available to package users.

• `secret_encrypt()` and `secret_decrypt()` work with individual strings
• `secret_write_rds()` and `secret_read_rds()` work with `.rds` files
• `secret_make_key()` generates a random string to use as a key.
• `secret_has_key()` returns TRUE if the key is available; you can use it in examples and vignettes that you want to evaluate on your CI, but not for CRAN/package users.

These all look for the key in an environment variable. When used inside of testthat, they will automatically `testthat::skip()` the test if the env var isn’t found. (Outside of testthat, they’ll error if the env var isn’t found.)

Usage

```r
secret_make_key()

secret_encrypt(x, key)

secret_decrypt(encrypted, key)

secret_write_rds(x, path, key)

secret_read_rds(path, key)

secret_has_key(key)
```
Arguments

- **x**: Object to encrypt. Must be a string for `secret_encrypt()`.
- **key**: Encryption key; this is the password that allows you to "lock" and "unlock" the secret. The easiest way to specify this is as the name of an environment variable. Alternatively, if you already have a base64url encoded string, you can wrap it in `I()`, or you can pass the raw vector in directly.
- **encrypted**: String to decrypt
- **path**: Path to .rds file

Value

- `secret_decrypt()` and `secret_encrypt()` return strings.
- `secret_write_rds()` returns x invisibly; `secret_read_rds()` returns the saved object.
- `secret_make_key()` returns a string with class AsIs.
- `secret_has_key()` returns TRUE or FALSE.

Basic workflow

1. Use `secret_make_key()` to generate a password. Make this available as an env var (e.g. `{MYPACKAGE}_KEY`) by adding a line to your `.Renviron`.
2. Encrypt strings with `secret_encrypt()` and other data with `secret_write_rds()`, setting key = `{MYPACKAGE}_KEY`.
3. In your tests, decrypt the data with `secret_decrypt()` or `secret_read_rds()` to match how you encrypt it.
4. If you push this code to your CI server, it will already "work" because all functions automatically skip tests when your `{MYPACKAGE}_KEY` env var isn’t set. To make the tests actually run, you’ll need to set the env var using whatever tool your CI system provides for setting env vars. Make sure to carefully inspect the test output to check that the skips have actually gone away.

Examples

```r
key <- secret_make_key()

path <- tempfile()
secret_write_rds(mtcars, path, key = key)
secret_read_rds(path, key)

# While you can manage the key explicitly in a variable, it's much
# easier to store in an environment variable. In real life, you should
# NEVER use `Sys.setenv()` to create this env var because you will
# also store the secret in your `.Rhistory`. Instead add it to your
# .Renviron using `usethis::edit_r_environ()` or similar.
Sys.setenv("MY_KEY" = key)

x <- secret_encrypt("This is a secret", "MY_KEY")
x
secret_decrypt(x, "MY_KEY")
```
url_parse  

*Parse and build URLs*

**Description**

`url_parse()` parses a URL into its component pieces; `url_build()` does the reverse, converting a list of pieces into a string URL. See rfc3986 for details of parsing algorithm.

**Usage**

```r
url_parse(url)
url_build(url)
```

**Arguments**

- `url`  
  For `url_parse()` a string to parse into a URL; for `url_build()` a URL to turn back into a string.

**Value**

- `url_build()` returns a string.
- `url_parse()` returns a URL: a S3 list with class `httr2_url` and elements `scheme`, `hostname`, `port`, `path`, `fragment`, `query`, `username`, `password`.

**Examples**

```r
url_parse("http://google.com/")
url_parse("http://google.com:80/")
url_parse("http://google.com:80/?a=1&b=2")
url_parse("http://username@google.com:80/path;test?a=1&b=2#40")
```

```r
url <- url_parse("http://google.com/")
url$port <- 80
url$hostname <- "example.com"
url$query <- list(a = 1, b = 2, c = 3)
url_build(url)
```

with_mock  

*Temporarily mock requests*

**Description**

Mocking allows you to selectively and temporarily replace the response you would typically receive from a request with your own code. It’s primarily used for testing.
Usage

with_mock(mock, code)

local_mock(mock, env = caller_env())

Arguments

mock A single argument function called with a request object. It should return either
      NULL (if it doesn’t want to handle the request) or a response (if it does).

code Code to execute in the temporary environment.

dependent Environment to use for scoping changes.

Value

with_mock() returns the result of evaluating code.

Examples

# This function should perform a response against google.com:
google <- function() {
  request("http://google.com") %>%
  req_perform()
}

# But I can use a mock to instead return my own made up response:
my_mock <- function(req) {
  response(status_code = 403)
}
with_mock(my_mock, google())

with_verbosity

Description

with_verbosity() is useful for debugging htr2 code buried deep inside another package because
it allows you to see exactly what’s been sent and requested.

Usage

with_verbosity(code, verbosity = 1)
Arguments

- **code**: Code to execute
- **verbosity**: How much information to print? This is a wrapper around `req_verbose()` that uses an integer to control verbosity:
  - 0: no output
  - 1: show headers
  - 2: show headers and bodies
  - 3: show headers, bodies, and curl status messages.

Use `with_verbosity()` to control the verbosity of requests that you can’t affect directly.

Value

The result of evaluating `code`.

Examples

```r
fun <- function() {
  request("https://httr2.r-lib.org") %>% req_perform()
}
with_verbosity(fun())
```
