Package ‘ipaddress’
October 13, 2022

Title  Tidy IP Addresses
Version 0.5.5
Description Classes and functions for working with IP (Internet Protocol) addresses and networks, inspired by the Python 'ipaddress' module. Offers full support for both IPv4 and IPv6 (Internet Protocol versions 4 and 6) address spaces. It is specifically designed to work well with the 'tidyverse'.

Index

address_in_network  Network membership of addresses

Description

These functions check whether an address falls within a network.

- `is_within()` performs a one-to-one matching between addresses and networks.
- `is_within_any()` checks if each address falls within any of the networks.

Usage

```r
is_within(address, network)

is_within_any(address, network)
```
collapse_networks

Arguments

    address       An ip_address vector
    network       An ip_network vector

Value

A logical vector

See Also

Use is_subnet() to check if an ip_network is within another ip_network.

Examples

    is_within(ip_address("192.168.2.6"), ip_network("192.168.2.0/28"))
    is_within(ip_address("192.168.3.6"), ip_network("192.168.2.0/28"))
    is_within_any(ip_address("192.168.3.6"), ip_network(c("192.168.2.0/28", "192.168.3.0/28")))

Description

Given a vector of networks, this returns the minimal set of networks required to represent the same
range of addresses.

Usage

    collapse_networks(network)

Arguments

    network       An ip_network vector

Value

An ip_network vector (potentially shorter than the input)

See Also

    exclude_networks()

Examples

    collapse_networks(ip_network(c("192.168.0.0/24", "192.168.1.0/24")))
**common_network**  
*Find the common network of two addresses*

**Description**

Returns the smallest network that contains both addresses. This can construct a network from its first and last addresses. However, if the address range does not match the network boundaries, then the result extends beyond the original address range. Use `summarize_address_range()` to receive a list of networks that exactly match the address range.

**Usage**

```
common_network(address1, address2)
```

**Arguments**

- `address1`: An `ip_address` vector
- `address2`: An `ip_address` vector

**Value**

An `ip_network` vector

**See Also**

- `summarize_address_range()`

**Examples**

```r
# address range matches network boundaries
common_network(ip_address("192.168.0.0"), ip_address("192.168.0.15"))

# address range does not match network boundaries
common_network(ip_address("192.167.255.255"), ip_address("192.168.0.16"))
```

---

**exclude_networks**  
*Remove networks from others*

**Description**

`exclude_networks()` takes lists of networks to include and exclude. It then calculates the address ranges that are included but not excluded (similar to `setdiff()`), and finally returns the minimal set of networks needed to describe the remaining address ranges.
exclude_networks(include, exclude)

Arguments

include An ip_network vector
exclude An ip_network vector

Value

An ip_network vector

See Also

collapse_networks(), setdiff()

Examples

exclude_networks(ip_network("192.0.2.0/28"), ip_network("192.0.2.1/32"))
exclude_networks(ip_network("192.0.2.0/28"), ip_network("192.0.2.15/32"))

iana_ipv4

Description

A dataset containing the registry of allocated blocks in IPv4 address space.

Usage

iana_ipv4

Format

A data frame with 122 rows and 3 variables:

network Address block (an ip_network vector)
allocation There are three types of allocation:
  • reserved
  • managed by regional Internet registry (RIR)
  • assigned to organization
label The RIR, organization or purpose for reservation

Note

Last updated 2020-08-18
Source

https://www.iana.org/assignments/ipv4-address-space

See Also

is_reserved()

Examples

iana_ipv6

<table>
<thead>
<tr>
<th>iana_ipv6</th>
<th>IPv6 address space allocation</th>
</tr>
</thead>
</table>

Description

A dataset containing the registry of allocated blocks in IPv6 address space.

Usage

iana_ipv6

Format

A data frame with 47 rows and 3 variables:

- **network**  Address block (an `ip_network` vector)
- **allocation** There are two types of allocation:
  - reserved
  - managed by regional Internet registry (RIR)
- **label**  The RIR or purpose for reservation

Note

is_reserved()

Examples

iana_ipv6
Description

There are multiple mechanisms designed to help with the transition from IPv4 to IPv6. These functions make it possible to extract the embedded IPv4 address from an IPv6 address.

Usage

is_ipv4_mapped(x)

is_6to4(x)

is_teredo(x)

extract_ipv4_mapped(x)

extract_6to4(x)

extract_teredo_server(x)

extract_teredo_client(x)

Arguments

x  An ip_address vector

Details

The IPv6 transition mechanisms are described in the IETF memos:

• IPv4-mapped: RFC 4291
• 6to4: RFC 3056
• Teredo: RFC 4380

Value

• is_xxx() functions return a logical vector
• extract_xxx() functions return an ip_address vector.

Examples

# these examples show the reserved networks
is_ipv4_mapped(ip_network("::ffff:0.0.0.0/96"))

is_6to4(ip_network("2002::/16"))
is_teredo(ip_network("2001::/32"))

# these examples show embedded IPv4 addresses
extract_ipv4_mapped(ip_address("::ffff:192.168.0.1"))
extract_6to4(ip_address("2002:c000:0204::"))

---

**ip_address**  
*Vector of IP addresses*

**Description**  
ip_address() constructs a vector of IP addresses.  
is_ip_address() checks if an object is of class ip_address.  
as_ip_address() casts an object to ip_address.

**Usage**  
ip_address(x = character())

is_ip_address(x)
as_ip_address(x)

## S3 method for class 'character'
as_ip_address(x)

## S3 method for class 'ip_interface'
as_ip_address(x)

## S3 method for class 'ip_address'
as.character(x, ...)

## S3 method for class 'ip_address'
format(x, exploded = FALSE, ...)

**Arguments**  
  
  x  
  - For ip_address(): A character vector of IP addresses, in dot-decimal notation (IPv4) or hexadecimal notation (IPv6)  
  - For is_ip_address(): An object to test  
  - For as_ip_address(): An object to cast
ip_interface

- For as.character(): An ip_address vector

... Included for S3 generic consistency

exploded Logical scalar. Should IPv6 addresses display leading zeros? (default: FALSE)

Details

An address in IPv4 space uses 32-bits. It is usually represented as 4 groups of 8 bits, each shown as decimal digits (e.g. 192.168.0.1). This is known as dot-decimal notation.

An address in IPv6 space uses 128-bits. It is usually represented as 8 groups of 16 bits, each shown as hexadecimal digits (e.g. 2001:db8:85a3:0000:0000:8a2e:0370:7334). This representation can also be compressed by removing leading zeros and replacing consecutive groups of zeros with double-colon (e.g. 2001:db8:85a3::8a2e:370:7334). Finally, there is also the dual representation. This expresses the final two groups as an IPv4 address (e.g. 2001:db8:85a3::8a2e:3.112.115.52).

The ip_address() constructor accepts a character vector of IP addresses in these two formats. It checks whether each string is a valid IPv4 or IPv6 address, and converts it to an ip_address object. If the input is invalid, a warning is emitted and NA is stored instead.

When casting an ip_address object back to a character vector using as.character(), IPv6 addresses are reduced to their compressed representation. A special case is IPv4-mapped IPv6 addresses (see is_ipv4_mapped()), which are returned in the dual representation (e.g. ::ffff:192.168.0.1).

ip_address vectors support a number of operators.

Value

An S3 vector of class ip_address

See Also

ip_operators, vignette("ipaddress-classes")

Examples

# supports IPv4 and IPv6 simultaneously
ip_address(c("192.168.0.1", "2001:db8::8a2e:370:7334"))

# validates inputs and replaces with NA
ip_address(c("255.255.255.256", "192.168.0.1/32"))

ip_interface Vector of IP interfaces

Description

This hybrid class stores both the host address and the network it is on.

ip_interface() constructs a vector of IP interfaces.

is_ip_interface() checks if an object is of class ip_interface.

as_ip_interface() casts an object to ip_interface.
### Usage

```r
ip_interface(...)  
## Default S3 method:  
ip_interface(x = character(), ...)
```

```r
## S3 method for class 'ip_address'
ip_interface(address, prefix_length, ...)
```

```r
is_ip_interface(x)
```

```r
as_ip_interface(x)
```

```r
## S3 method for class 'character'
as_ip_interface(x)
```

```r
## S3 method for class 'ip_interface'
as.character(x, ...)
```

```r
## S3 method for class 'ip_interface'
format(x, exploded = FALSE, ...)
```

### Arguments

- `...`: Included for S3 generic consistency
- `x`:
  - For `ip_interface()`: A character vector of IP interfaces, in CIDR notation (IPv4 or IPv6)
  - For `is_ip_interface()`: An object to test
  - For `as_ip_interface()`: An object to cast
  - For `as.character()`: An `ip_interface` vector

- `address`: An `ip_address` vector
- `prefix_length`: An integer vector
- `exploded`: Logical scalar. Should IPv6 addresses display leading zeros? (default: FALSE)

### Details

Constructing an `ip_interface` vector is conceptually like constructing an `ip_network` vector, except the host bits are retained.

The `ip_interface` class inherits from the `ip_address` class. This means it can generally be used in places where an `ip_address` vector is expected. A few exceptions to this rule are:

- It does not support addition and subtraction of integers
- It does not support bitwise operations
- It cannot be compared to `ip_address` vectors
The \texttt{ip_interface} class additionally supports a few functions typically reserved for \texttt{ip_network} vectors: \texttt{prefix_length()}, \texttt{netmask()} and \texttt{hostmask()}.

For other purposes, you can extract the address and network components using \texttt{as_ip_address()} and \texttt{as_ip_network()}.

When comparing and sorting \texttt{ip_interface} vectors, the network is compared before the host address.

**Value**

An S3 vector of class \texttt{ip_interface}

**See Also**

\texttt{vignette("ipaddress-classes")}

**Examples**

```r
# construct from character vector
ip_interface(c("192.168.0.1/10", "2001:db8:c3::abcd/45"))

# construct from address + prefix length objects
ip_interface(ip_address(c("192.168.0.1", "2001:db8:c3::abcd")), c(10L, 45L))

# extract IP address
x <- ip_interface(c("192.168.0.1/10", "2001:db8:c3::abcd/45"))
as_ip_address(x)

# extract IP network (with host bits masked)
as_ip_network(x)
```

---

**ip_network**

| Vector of IP networks |

**Description**

\texttt{ip_network()} constructs a vector of IP networks.

\texttt{is_ip_network()} checks if an object is of class \texttt{ip_network}.

\texttt{as_ip_network()} casts an object to \texttt{ip_network}.

**Usage**

\texttt{ip_network(...)}

```r
## Default S3 method:
ip_network(x = character(), strict = TRUE, ...)

## S3 method for class 'ip_address'
```
ip_network(address, prefix_length, strict = TRUE, ...)

is_ip_network(x)

as_ip_network(x)

## S3 method for class 'character'
as_ip_network(x)

## S3 method for class 'ip_interface'
as_ip_network(x)

## S3 method for class 'ip_network'
as.character(x, ...)

## S3 method for class 'ip_network'
format(x, exploded = FALSE, ...)

Arguments

... Included for S3 generic consistency
x • For ip_network(): A character vector of IP networks, in CIDR notation (IPv4 or IPv6)
   • For is_ip_network(): An object to test
   • For as_ip_network(): An object to cast
   • For as.character(): An ip_network vector
strict If TRUE (the default) and the input has host bits set, then a warning is emitted and NA is returned. If FALSE, the host bits are set to zero and a valid IP network is returned. If you need to retain the host bits, consider using ip_interface() instead.
address An ip_address vector
prefix_length An integer vector
exploded Logical scalar. Should IPv6 addresses display leading zeros? (default: FALSE)

Details

An IP network corresponds to a contiguous range of IP addresses (also known as an IP block). CIDR notation represents an IP network as the routing prefix address (which denotes the start of the range) and the prefix length (which indicates the size of the range) separated by a forward slash. For example, 192.168.0.0/24 represents addresses from 192.168.0.0 to 192.168.0.255.

The prefix length indicates the number of bits reserved by the routing prefix. This means that larger prefix lengths indicate smaller networks. The maximum prefix length is 32 for IPv4 and 128 for IPv6. These would correspond to an IP network of a single IP address.

The ip_network() constructor accepts a character vector of IP networks in CIDR notation. It checks whether each string is a valid IPv4 or IPv6 network, and converts it to an ip_network object. If the input is invalid, a warning is emitted and NA is stored instead.
An alternative constructor accepts an `ip_address` vector and an integer vector containing the network address and prefix length, respectively. When casting an `ip_network` object back to a character vector using `as.character()`, IPv6 addresses are reduced to their compressed representation. When comparing and sorting `ip_network` vectors, the network address is compared before the prefix length.

Value
An S3 vector of class `ip_network`

See Also

`prefix_length()`, `network_address()`, `netmask()`, `hostmask()`
`vignette("ipaddress-classes")`

Examples

```r
# construct from character vector
ip_network(c("192.168.0.0/24", "2001:db8::/48"))

# validates inputs and replaces with NA
ip_network(c("192.168.0.0/33", "192.168.0.0"))

# IP networks should not have any host bits set
ip_network("192.168.0.1/22")

# but we can mask the host bits if desired
ip_network("192.168.0.1/22", strict = FALSE)

# construct from address + prefix length
ip_network(ip_address("192.168.0.0"), 24L)

# construct from address + netmask
ip_network(ip_address("192.168.0.0"), prefix_length(ip_address("255.255.255.0")))

# construct from address + hostmask
ip_network(ip_address("192.168.0.0"), prefix_length(ip_address("0.0.0.255")))
```

Description

`ip_address` vectors support the following operators:

- bitwise logic operators: ! (NOT), & (AND), | (OR), ^ (XOR)
- bitwise shift operators: %<% (left shift), %>>% (right shift)
- arithmetic operators: + (addition), - (subtraction)
**Examples**

```r
# use ip_to_binary() to understand these examples better

# bitwise NOT
ip_address("192.168.0.1")

# bitwise AND
ip_address("192.168.0.1") & ip_address("255.0.0.255")

# bitwise OR
ip_address("192.168.0.0") | ip_address("255.0.0.255")

# bitwise XOR
ip_address("192.168.0.0") ^ ip_address("255.0.0.255")

# bitwise shift left
ip_address("192.168.0.1") %<<% 1

# bitwise shift right
ip_address("192.168.0.1") %>>% 1

# addition of integers
ip_address("192.168.0.1") + 10

# subtraction of integers
ip_address("192.168.0.1") - 10
```

---

**ip_to_binary**  
*Represent address as binary*

**Description**

Encode or decode an `ip_address` as a binary bit string.

**Usage**

```r
ip_to_binary(x)
binary_to_ip(x)
```

**Arguments**

- `x`  
  - For `ip_to_binary()`: An `ip_address` vector  
  - For `binary_to_ip()`: A character vector containing only 0 and 1 characters
ip_to_bytes

Details
The bits are stored in network order (also known as big-endian order), which is part of the IP standard.
IPv4 addresses use 32 bits, IPv6 addresses use 128 bits, and missing values are encoded as NA.

Value
• For ip_to_binary(): A character vector
• For binary_to_ip(): An ip_address vector

See Also
Other address representations: ip_to_bytes(), ip_to_hex(), ip_to_integer()

Examples
x <- ip_address(c("192.168.0.1", "2001:db8::8a2e:370:7334", NA))
ip_to_binary(x)
binary_to_ip(ip_to_binary(x))

Represent address as raw bytes

Description
Encode or decode an ip_address as a list of raw bytes.

Usage
ip_to_bytes(x)
bytes_to_ip(x)

Arguments
x
• For ip_to_bytes(): An ip_address vector
• For bytes_to_ip(): A list of raw vectors or a blob::blob object

Details
The bytes are stored in network order (also known as big-endian order), which is part of the IP standard.
IPv4 addresses use 4 bytes, IPv6 addresses use 16 bytes, and missing values are encoded as NULL.
Value

- For `ip_to_bytes()`: A list of raw vectors
- For `bytes_to_ip()`: An `ip_address` vector

See Also

Use `blob::as_blob()` to cast result to a blob object

Other address representations: `ip_to_binary()`, `ip_to_hex()`, `ip_to_integer()`

Examples

```r
x <- ip_address(c("192.168.0.1", "2001:db8::8a2e:370:7334", NA))
ip_to_bytes(x)

bytes <- list(
  as.raw(c(0xc0, 0xa8, 0x00, 0x01)),
  as.raw(c(
    0x20, 0x01, 0x0d, 0xb8, 0x00, 0x00, 0x00, 0x00,
    0x00, 0x00, 0x8a, 0x2e, 0x03, 0x70, 0x73, 0x34
  )),
  NULL
)
bytes_to_ip(bytes)
```

---

**ip_to_hex**

*Represent address as hexadecimal*

Description

Encode or decode an `ip_address` as a hexadecimal string.

Usage

```r
ip_to_hex(x)
```

```r
hex_to_ip(x, is_ipv6 = NULL)
```

Arguments

- `x`  
  - For `ip_to_hex()`: An `ip_address` vector
  - For `hex_to_ip()`: A character vector containing hexadecimal strings
- `is_ipv6`  
  - A logical vector indicating whether to construct an IPv4 or IPv6 address. If `NULL` (the default), then IPv4 is preferred but an IPv6 address is constructed when `x` is too large for the IPv4 address space.
### Description

Perform reverse and forward DNS resolution.

**Note:** These functions are significantly slower than others in the `ipaddress` package.

### Usage

```r
ip_to_hostname(x, multiple = FALSE)
hostname_to_ip(x, multiple = FALSE)
```

### Arguments

- `x`  
  - For `ip_to_hostname()`: An `ip_address` vector
  - For `hostname_to_ip()`: A character vector of hostnames

- `multiple`  
  A logical scalar indicating if *all* resolved endpoints are returned, or just the first endpoint (the default). This determines whether a vector or list of vectors is returned.

### Details

These functions require an internet connection. Before processing the input vector, we first check that a known hostname can be resolved. If this fails, an error is raised.

If DNS lookup cannot resolve an input, then `NA` is returned for that input. If an error occurs during DNS lookup, then a warning is emitted and `NA` is returned for that input.

DNS resolution performs a many-to-many mapping between IP addresses and hostnames. For this reason, these two functions can potentially return multiple values for each element of the input vector. The `multiple` argument control whether *all* values are returned (a vector for each input), or just the first value (a scalar for each input).
Value

- For `ip_to_hostname()`: A character vector (multiple = FALSE) or a list of character vectors (multiple = TRUE)
- For `hostname_to_ip()`: An `ip_address` vector (multiple = FALSE) or a list of `ip_address` vectors (multiple = TRUE)

See Also

The base function `ns1()` provides forward DNS resolution to IPv4 addresses, but only on Unix-like systems.

Examples

```r
## Not run:
hostname_to_ip("r-project.org")

ip_to_hostname(hostname_to_ip("r-project.org"))
## End(Not run)
```

---

**ip_to_integer**

Represent address as integer

Description

Encode or decode an `ip_address` as an integer.

Usage

```r
ip_to_integer(x)

integer_to_ip(x, is_ipv6 = NULL)
```

Arguments

- **x**
  - For `ip_to_integer()`: An `ip_address` vector
  - For `integer_to_ip()`: A `bignum::biginteger` vector
- **is_ipv6**
  - A logical vector indicating whether to construct an IPv4 or IPv6 address. If `NULL` (the default), then IPv4 is preferred but an IPv6 address is constructed when `x` is too large for the IPv4 address space.
Details

It is common to represent an IP address as an integer, by reinterpreting the bit sequence as a big-endian unsigned integer. This means IPv4 and IPv6 addresses can be represented by 32-bit and 128-bit unsigned integers. In this way, the IPv4 addresses 0.0.0.0 and 255.255.255.255 would be represented as 0 and 4,294,967,295.

The numeric data types within base R (integer and double) have insufficient precision to cover the IPv6 address space. Instead we return a bignum::biginteger vector, which supports arbitrary precision integers.

Value

- For ip_to_integer(): A bignum::biginteger vector
- For integer_to_ip(): An ip_address vector

See Also

Other address representations: ip_to_binary(), ip_to_bytes(), ip_to_hex()

Examples

```r
x <- ip_address(c("192.168.0.1", "2001:db8::8a2e:370:7334", NA))
ip_to_integer(x)

integer_to_ip(ip_to_integer(x))

# with IPv4 only, we can use numeric data type
as.numeric(ip_to_integer(ip_address("192.168.0.1")))

integer_to_ip(3232235521)
```

is_ipv6

Version of the address space

Description

Version of the address space

Usage

```r
is_ipv4(x)

is_ipv6(x)
```

Arguments

x An ip_address or ip_network vector
Value
A logical vector

See Also
max_prefix_length()

Examples
ip <- ip_address(c("192.168.0.1", "2001:db8::7334"))
is_ipv4(ip)
is_ipv6(ip)

<table>
<thead>
<tr>
<th>is_reserved</th>
<th>Reserved addresses</th>
</tr>
</thead>
</table>

Description
Most of these functions check if an address or network is reserved for special use. The exception is is_global(), which checks if it is not reserved.
A network is considered reserved if both the network_address() and broadcast_address() are reserved.

Usage
is_private(x)
is_global(x)
is_multicast(x)
is_unspecified(x)
is_reserved(x)
is_loopback(x)
is_link_local(x)
is_site_local(x)

Arguments
x An ip_address or ip_network vector
Details

Here are hyperlinks to the IANA registries of allocated address space:

- **IPv4**: allocations, special purpose
- **IPv6**: allocations, special purpose

Value

A logical vector

See Also

Addresses reserved by IPv6 transition mechanisms can be identified by functions described in `ipv6-transition`.

Examples

```r
is_private(ip_network(c("192.168.0.0/16", "2001:db8::/32")))
is_global(ip_network(c("1.0.0.0/8", "2002::/32")))
is_multicast(ip_network(c("224.0.0.0/4", "ff00::/8")))
is_unspecified(ip_network(c("0.0.0.0/32", "::/128")))
is_reserved(ip_network(c("240.0.0.0/4", "f000::/5")))

is_site_local(ip_network("fec0::/10"))
```

---

### max_prefix_length

**Size of the address space**

Description

The total number of bits available in the address space. IPv4 uses 32-bit addresses and IPv6 uses 128-bit addresses.

Usage

```
max_prefix_length(x)
```

Arguments

- `x` An `ip_address` or `ip_network` vector
Value

An integer vector

See Also

is_ipv4(), is_ipv6(), prefix_length()

Examples

```r
x <- ip_address(c("192.168.0.1", "2001:db8::7334"));
max_prefix_length(x)
```

<table>
<thead>
<tr>
<th>netmask</th>
<th>Network mask</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

prefix_length(), netmask() and hostmask() extract different (but equivalent) representations of the network mask. They accept an `ip_network` or `ip_interface` vector.

The functions can also convert between these alternative representations. For example, prefix_length() can infer the prefix length from an `ip_address` vector of netmasks and/or hostmasks, while netmask() and hostmask() can accept a vector of prefix lengths.

Usage

```r
prefix_length(...)
netmask(...)
hostmask(...)
```

S3 methods:

```
## S3 method for class 'ip_network'
prefix_length(x, ...)

## S3 method for class 'ip_network'
netmask(x, ...)

## S3 method for class 'ip_network'
hostmask(x, ...)

## S3 method for class 'ip_interface'
prefix_length(x, ...)

## S3 method for class 'ip_interface'
netmask(x, ...)
```
Arguments

  ...  Arguments to be passed to other methods
  x    An \texttt{ip\_network} or \texttt{ip\_interface} vector
  mask An \texttt{ip\_address} vector of netmasks and/or hostmasks. Ambiguous cases (all zeros, all ones) are treated as netmasks.
  prefix\_length An integer vector
  is\_ipv6 A logical vector

Value

  \begin{itemize}
    \item \texttt{prefix\_length()} returns an integer vector
    \item \texttt{netmask()} and \texttt{hostmask()} return an \texttt{ip\_address} vector
  \end{itemize}

See Also

  \texttt{max\_prefix\_length()}

Examples

  \begin{verbatim}
x <- ip\_network(c("192.168.0.0/22", "2001:db00::0/26"))

  prefix\_length(x)
  netmask(x)
  hostmask(x)

  # construct netmask/hostmask from prefix length
  netmask(c(22L, 26L), c(FALSE, TRUE))
  hostmask(c(22L, 26L), c(FALSE, TRUE))

  # extract prefix length from netmask/hostmask
  prefix\_length(ip\_address(c("255.255.255.0", "0.255.255.255"))))

  # invalid netmask/hostmask raise a warning and return NA
  prefix\_length(ip\_address("255.255.255.1"))
  \end{verbatim}
network_in_network

Network membership of other networks

Description

is_supernet() and is_subnet() check if one network is a true supernet or subnet of another network; overlaps() checks for any overlap between two networks.

Usage

is_supernet(network, other)

is_subnet(network, other)

overlaps(network, other)

Arguments

<table>
<thead>
<tr>
<th>network</th>
<th>An ip_network vector</th>
</tr>
</thead>
<tbody>
<tr>
<td>other</td>
<td>An ip_network vector</td>
</tr>
</tbody>
</table>

Value

A logical vector

See Also

Use is_within() to check if an ip_address is within an ip_network. Use supernet() and subnets() to traverse the network hierarchy.

Examples

```r
net1 <- ip_network("192.168.1.128/30")
net2 <- ip_network("192.168.1.0/24")

is_supernet(net1, net2)

is_subnet(net1, net2)

overlaps(net1, net2)
```
Description

network_address() and broadcast_address() yield the first and last addresses of the network; num_addresses() gives the total number of addresses in the network.

Usage

network_address(x)
broadcast_address(x)
um_addresses(x)

Arguments

x An ip_network vector

Details

The broadcast address is a special address at which any host connected to the network can receive messages. That is, packets sent to this address are received by all hosts on the network. In IPv4, the last address of a network is the broadcast address. Although IPv6 does not follow this approach to broadcast addresses, the broadcast_address() function still returns the last address of the network.

Value

- network_address() and broadcast_address() return an ip_address vector
- num_addresses() returns a numeric vector

See Also

Use seq.ip_network() to generate all addresses in a network.

Examples

x <- ip_network(c("192.168.0.0/22", "2001:db8::/33"))
network_address(x)
broadcast_address(x)
num_addresses(x)
**reverse_pointer** \hspace{1cm} *Reverse DNS pointer*

**Description**

Returns the PTR record used by reverse DNS.

**Usage**

```r
reverse_pointer(x)
```

**Arguments**

- `x` An `ip_address` vector

**Details**

These documents describe reverse DNS lookup in more detail:

- IPv4: RFC-1035 Section 3.5
- IPv6: RFC-3596 Section 2.5

**Value**

A character vector

**Examples**

```r
reverse_pointer(ip_address("127.0.0.1"))

reverse_pointer(ip_address("2001:db8::1"))
```

---

**sample** \hspace{1cm} *Sample random addresses*

**Description**

`sample_ipv4()` and `sample_ipv6()` sample from the entire address space; `sample_network()` samples from a specific network.

**Usage**

```r
sample_ipv4(size, replace = FALSE)

sample_ipv6(size, replace = FALSE)

sample_network(x, size, replace = FALSE)
```
sequence

Arguments

size Integer specifying the number of addresses to return
replace Should sampling be with replacement?
x An ip_network scalar

Value

An ip_address vector

See Also

Use seq.ip_network() to generate all addresses in a network.

Examples

sample_ipv4(5)
sample_ipv6(5)
sample_network(ip_network("192.168.0.0/16"), 5)
sample_network(ip_network("2001:db8::/48"), 5)

sequence List addresses within a network

Description

seq() returns all hosts
hosts() returns only usable hosts

Usage

## S3 method for class 'ip_network'
seq(x, ...)

hosts(x)

Arguments

x An ip_network scalar
...

Included for generic consistency
summarize_address_range

Details
In IPv4, the unusable hosts are the network address and the broadcast address (i.e. the first and last addresses in the network). In IPv6, the only unusable host is the subnet router anycast address (i.e. the first address in the network).

For networks with a prefix length of 31 (for IPv4) or 127 (for IPv6), the unusable hosts are included in the results of hosts().

The ipaddress package does not support long vectors (i.e. vectors with more than 2^31 - 1 elements). As a result, these two functions do not support networks larger than this size. This corresponds to prefix lengths less than 2 (for IPv4) or 98 (for IPv6). However, you might find that machine memory imposes stricter limitations.

Value
An ip_address vector

See Also
Use network_address() and broadcast_address() to get the first and last address of a network. Use sample_network() to randomly sample addresses from a network. Use subnets() to list the subnetworks within a network.

Examples
seq(ip_network("192.168.0.0/30"))
seq(ip_network("2001:db8::/126"))
hosts(ip_network("192.168.0.0/30"))
hosts(ip_network("2001:db8::/126"))

summarize_address_range(address1, address2)

Description
Given an address range, this returns the list of constituent networks.

If you know the address range matches the boundaries of a single network, it might be preferable to use common_network(). This returns an ip_network vector instead of a list of ip_network vectors.

Usage
summarize_address_range(address1, address2)
### Arguments

- `address1`: An `ip_address` vector
- `address2`: An `ip_address` vector

### Value

A list of `ip_network` vectors

### See Also

- `common_network()`

### Examples

```r
# address range matches network boundaries
summarize_address_range(ip_address("192.168.0.0"), ip_address("192.168.0.15"))

# address range does not match network boundaries
summarize_address_range(ip_address("192.167.255.255"), ip_address("192.168.0.16"))
```

---

### traverse_hierarchy

**Traverse the network hierarchy**

### Description

These functions step up and down the network hierarchy. `supernet()` returns the supernetwork containing the given network. `subnets()` returns the list of subnetworks which join to make the given network.

### Usage

```r
supernet(x, new_prefix = prefix_length(x) - 1L)
subnets(x, new_prefix = prefix_length(x) + 1L)
```

### Arguments

- `x`: For `supernet()`: An `ip_network` vector
  - For `subnets()`: An `ip_network` scalar
- `new_prefix`: An integer vector indicating the desired prefix length. By default, this steps a single level through the hierarchy.

### Details

The ipaddress package does not support long vectors (i.e. vectors with more than $2^{31} - 1$ elements). The limita the number of subnetworks that `subnets()` can return. However, you might find that machine memory imposes stricter limitations.
Value
An ip_network vector

See Also
Use seq.ip_network() to list the addresses within a network.
Use is_supernet() and is_subnet() to check if one network is contained within another.

Examples
supernet(ip_network("192.168.0.0/24"))
supernet(ip_network("192.168.0.0/24"), new_prefix = 10L)
subnets(ip_network("192.168.0.0/24"))
subnets(ip_network("192.168.0.0/24"), new_prefix = 27L)
