Package ‘ipred’

August 14, 2018

Title Improved Predictors
Version 0.9-7
Date 2018-08-14
Description Improved predictive models by indirect classification and
    bagging for classification, regression and survival problems
    as well as resampling based estimators of prediction error.
Depends R (>= 2.10)
Imports rpart (>= 3.1-8), MASS, survival, nnet, class, prodlim
Suggests mvtnorm, mlbench, TH.data
License GPL (>= 2)
NeedsCompilation yes

Bagging Classification, Regression and Survival Trees

Description

Bagging for classification, regression and survival trees.

Usage

```r
## S3 method for class 'factor'
ipredbagg(y, X=NULL, nbagg=25, control=
     rpart.control(minsplit=2, cp=0, xval=0),
     comb=NULL, coob=FALSE, ns=length(y), keepX = TRUE, ...)
## S3 method for class 'numeric'
ipredbagg(y, X=NULL, nbagg=25, control=rpart.control(xval=0),
     comb=NULL, coob=FALSE, ns=length(y), keepX = TRUE, ...)
## S3 method for class 'Surv'
ipredbagg(y, X=NULL, nbagg=25, control=rpart.control(xval=0),
     comb=NULL, coob=FALSE, ns=dim(y)[1], keepX = TRUE, ...)
## S3 method for class 'data.frame'
bagging(formula, data, subset, na.action=na.rpart, ...)
```
Arguments

- **y**
  - the response variable: either a factor vector of class labels (bagging classification trees), a vector of numerical values (bagging regression trees) or an object of class *Surv* (bagging survival trees).

- **X**
  - a data frame of predictor variables.

- **nbagg**
  - an integer giving the number of bootstrap replications.

- **coob**
  - a logical indicating whether an out-of-bag estimate of the error rate (misclassification error, root mean squared error or Brier score) should be computed. See `predict.classbagg` for details.

- **control**
  - options that control details of the `rpart` algorithm, see `rpart.control`. It is wise to set `xval = 0` in order to save computing time. Note that the default values depend on the class of `y`.

- **comb**
  - a list of additional models for model combination, see below for some examples. Note that argument `method` for double-bagging is no longer there, `comb` is much more flexible.

- **ns**
  - number of sample to draw from the learning sample. By default, the usual bootstrap `n` out of `n` with replacement is performed. If `ns` is smaller than `length(y)`, subagging (Buehlmann and Yu, 2002), i.e. sampling `ns` out of `length(y)` without replacement, is performed.

- **keepX**
  - a logical indicating whether the data frame of predictors should be returned. Note that the computation of the out-of-bag estimator requires `keepX=TRUE`.

- **formula**
  - a formula of the form `lhs ~ rhs` where `lhs` is the response variable and `rhs` a set of predictors.

- **data**
  - optional data frame containing the variables in the model formula.

- **subset**
  - optional vector specifying a subset of observations to be used.

- **na.action**
  - function which indicates what should happen when the data contain `NA`s. Defaults to `na.rpart`.

- **...**
  - additional parameters passed to `ipredbagg` or `rpart`, respectively.

Details

The random forest implementations `randomForest` and `cforest` are more flexible and reliable for computing bootstrap-aggregated trees than this function and should be used instead.

Bagging for classification and regression trees were suggested by Breiman (1996a, 1998) in order to stabilise trees.

The trees in this function are computed using the implementation in the `rpart` package. The generic function `ipredbagg` implements methods for different responses. If `y` is a factor, classification trees are constructed. For numerical vectors `y`, regression trees are aggregated and if `y` is a survival object, bagging survival trees (Hothorn et al, 2003) is performed. The function `bagging` offers a formula based interface to `ipredbagg`.

`nbagg` bootstrap samples are drawn and a tree is constructed for each of them. There is no general rule when to stop the tree growing. The size of the trees can be controlled by `control` argument or `prune.classbagg`. By default, classification trees are as large as possible whereas regression trees
and survival trees are build with the standard options of rpart.control. If nbagg=1, one single tree is computed for the whole learning sample without bootstrapping.

If coob is TRUE, the out-of-bag sample (Breiman, 1996b) is used to estimate the prediction error corresponding to classHyI. Alternatively, the out-of-bag sample can be used for model combination, an out-of-bag error rate estimator is not available in this case. Double-bagging (Hothorn and Lausen, 2003) computes a LDA on the out-of-bag sample and uses the discriminant variables as additional predictors for the classification trees. comb is an optional list of lists with two elements model and predict. model is a function with arguments formula and data. predict is a function with arguments object, newdata only. If the estimation of the covariance matrix in lda fails due to a limited out-of-bag sample size, one can use slda instead. See the example section for an example of double-bagging. The methodology is not limited to a combination with LDA: bundling (Hothorn and Lausen, 2002b) can be used with arbitrary classifiers.

NOTE: Up to ipred version 0.9-0, bagging was performed using a modified version of the original rpart function. Due to interface changes in rpart 3.1-55, the bagging function had to be rewritten. Results of previous version are not exactly reproducible.

Value

The class of the object returned depends on classHyI: classbagg, regbagg and survbagg. Each is a list with elements

- \( y \) the vector of responses.
- \( X \) the data frame of predictors.
- \( \text{mtrees} \) multiple trees: a list of length nbagg containing the trees (and possibly additional objects) for each bootstrap sample.
- \( \text{OOB} \) logical whether the out-of-bag estimate should be computed.
- \( \text{err} \) if OOB=TRUE, the out-of-bag estimate of misclassification or root mean squared error or the Brier score for censored data.
- \( \text{comb} \) logical whether a combination of models was requested.

For each class methods for the generics pruneNrpart, print, summary and predict are available for inspection of the results and prediction, for example: print.classbagg, summary.classbagg, predict.classbagg and prune.classbagg for classification problems.

Examples

library("MASS")
library("survival")

# Classification: Breast Cancer data
data("BreastCancer", package = "mlbench")

# Test set error bagging (nbagg = 50): 3.7% (Breiman, 1998, Table 5)
mod <- bagging(Class ~ Cl.thickness + Cell.size
+ Cell.shape + Marg.adhesion
+ Epith.c.size + Bare.nuclei
+ Bl.cromatin + Normal.nucleoli
+ Mitoses, data=BreastCancer, coob=TRUE)
print(mod)

# Test set error bagging (nbagg=50): 7.9% (Breiman, 1996a, Table 2)
data("Ionosphere", package = "mlbench")
Ionosphere$V2 <- NULL # constant within groups
bagging(Class ~ ., data=Ionosphere, coob=TRUE)

# Double-Bagging: combine LDA and classification trees
# predict returns the linear discriminant values, i.e. linear combinations
# of the original predictors
comb.lda <- list(list(model=lda, predict=function(obj, newdata)
    predict(obj, newdata$x))

# Note: out-of-bag estimator is not available in this situation, use
# errorest
mod <- bagging(Class ~ ., data=Ionosphere, comb=comb.lda)
predict(mod, Ionosphere[1:10,])

# Regression:
data("BostonHousing", package = "mlbench")

# Test set error (nbagg=25, trees pruned): 3.41 (Breiman, 1996a, Table 8)
mod <- bagging(medv ~ ., data=BostonHousing, coob=TRUE)
print(mod)

library("mlbench")
learn <- as.data.frame(mlbench.friedman1(200))

# Test set error (nbagg=25, trees pruned): 2.47 (Breiman, 1996a, Table 8)
mod <- bagging(y ~ ., data=learn, coob=TRUE)
print(mod)

# Survival data
# Brier score for censored data estimated by
# 10 times 10-fold cross-validation: 0.2 (Hothorn et al, # 2002)
data("DLBCL", package = "ipred")
mod <- bagging(Surv(time,cens) ~ MGEc.1 + MGEc.2 + MGEc.3 + MGEc.4 + MGEc.5 +
               MGEc.6 + MGEc.7 + MGEc.8 + MGEc.9 +
               MGEc.10 + IP1, data=DLBCL, coob=TRUE)

print(mod)

---

**bootest**

**Bootstrap Error Rate Estimators**

**Description**

Those functions are low-level functions used by errorest and are normally not called by users.

**Usage**

```r
# S3 method for class 'factor'
bootest(y, formula, data, model, predict, nboot=25,
          bc632plus=FALSE, list.tindx = NULL, predictions = FALSE,
          both.boot = FALSE, ...)
```

**Arguments**

- `y` the response variable, either of class factor (classification), numeric (regression) or Surv (survival).
- `formula` a formula object.
- `data` data frame of predictors and response described in formula.
- `model` a function implementing the predictive model to be evaluated. The function model can either return an object representing a fitted model or a function with argument newdata which returns predicted values. In this case, the predict argument to errorest is ignored.
- `predict` a function with arguments object and newdata only which predicts the status of the observations in newdata based on the fitted model in object.
- `nboot` number of bootstrap replications to be used.
control.errorest

bc632plus logical. Should the bias corrected version of misclassification error be computed?
predictions logical, return a matrix of predictions. The ith column contains predictions of the ith out-of-bootstrap sample and 'NA's corresponding to the ith bootstrap sample.
list.tindx list of numeric vectors, indicating which observations are included in each bootstrap sample.
both.boot logical, return both (bootstrap and 632plus) estimations or only one of them.
...

Details
See errorest.

control.errorest

Description
Some parameters that control the behaviour of errorest.

Usage
control.errorest(k = 10, nboot = 25, strat = FALSE, random = TRUE, predictions = FALSE, getmodels = FALSE, list.tindx = NULL)

Arguments
k integer, specify $k$ for $k$-fold cross-validation.
nboot integer, number of bootstrap replications.
strat logical, if TRUE, cross-validation is performed using stratified sampling (for classification problems).
random logical, if TRUE, cross-validation is performed using a random ordering of the data.
predictions logical, indicates whether the prediction for each observation should be returned or not (classification and regression only). For a bootstrap based estimator a matrix of size 'number of observations' times nboot is returned with predicted values of the ith out-of-bootstrap sample in column i and 'NA's for those observations not included in the ith out-of-bootstrap sample.
getmodels logical, indicates a list of all models should be returned. For cross-validation only.
list.tindx list of numeric vectors, indicating which observations are included in each bootstrap or cross-validation sample, respectively.

Value
A list with the same components as arguments.
Cross-validated Error Rate Estimators.

Description

Those functions are low-level functions used by errorest and are normally not called by users.

Usage

```r
## S3 method for class 'factor'
cv(y, formula, data, model, predict, k=10, random=TRUE,
    strat=FALSE,
    predictions=NULL, getmodels=NULL, list.tindx = NULL, ...)
```

Arguments

- `y`: response variable, either of class factor (classification), numeric (regression) or Surv (survival).
- `formula`: a formula object.
- `data`: data frame of predictors and response described in formula.
- `model`: a function implementing the predictive model to be evaluated. The function model can either return an object representing a fitted model or a function with argument newdata which returns predicted values. In this case, the predict argument to errorest is ignored.
- `predict`: a function with arguments object and newdata only which predicts the status of the observations in newdata based on the fitted model in object.
- `k`: k-fold cross-validation.
- `random`: logical, indicates whether a random order or the given order of the data should be used for sample splitting or not, defaults to TRUE.
- `strat`: logical, stratified sampling or not, defaults to FALSE.
- `predictions`: logical, return the prediction of each observation.
- `getmodels`: logical, return a list of models for each fold.
- `list.tindx`: list of numeric vectors, indicating which observations are included in each cross-validation sample.
- `...`: additional arguments to model.

Details

See errorest.
**Diffuse Large B-Cell Lymphoma**

**Description**

A data frame with gene expression data from diffuse large B-cell lymphoma (DLBCL) patients.

**Usage**

```r
data("DLBCL")
```

**Format**

This data frame contains the following columns:

- **DLCL.Sample**  DLBCL identifier.
- **Gene.Expression**  Gene expression group.
- **time**  survival time in month.
- **cens**  censoring: 0 censored, 1 dead.
- **IPI**  International prognostic index.
- **MGEc.1**  mean gene expression in cluster 1.
- **MGEc.2**  mean gene expression in cluster 2.
- **MGEc.3**  mean gene expression in cluster 3.
- **MGEc.4**  mean gene expression in cluster 4.
- **MGEc.5**  mean gene expression in cluster 5.
- **MGEc.6**  mean gene expression in cluster 6.
- **MGEc.7**  mean gene expression in cluster 7.
- **MGEc.8**  mean gene expression in cluster 8.
- **MGEc.9**  mean gene expression in cluster 9.
- **MGEc.10**  mean gene expression in cluster 10.

**Source**

Except of MGE, the data is published at [http://llmpp.nih.gov/lymphoma/data.shtml](http://llmpp.nih.gov/lymphoma/data.shtml). MGEc.* is the mean of the gene expression in each of ten clusters derived by agglomerative average linkage hierarchical cluster analysis (Hothorn et al., 2002).

dystrophy

Examples

```r
set.seed(290875)
data("DLBCL", package="ipred")
library("survival")
survfit(Surv(time, cens) ~ 1, data=DLBCL)
```

**dystrophy**

*Detection of muscular dystrophy carriers.*

**Description**

The `dystrophy` data frame has 209 rows and 10 columns.

**Usage**

```r
data(dystrophy)
```

**Format**

This data frame contains the following columns:

- **OBS** numeric. Observation number.
- **HospID** numeric. Hospital ID number.
- **AGE** numeric. Age in years.
- **M** numeric. Month of examination.
- **Y** numeric. Year of examination.
- **CK** numeric. Serum marker creatine kinase.
- **H** numeric. Serum marker hemopexin.
- **PK** numeric. Serum marker pyruvate kinase.
- **LD** numeric. Serum marker lactate dehydroginase.
- **Class** factor with levels, carrier and normal.

**Details**

Duchenne Muscular Dystrophy (DMD) is a genetically transmitted disease, passed from a mother to her children. Affected female offspring usually suffer no apparent symptoms, male offspring with the disease die at young age. Although female carriers have no physical symptoms they tend to exhibit elevated levels of certain serum enzymes or proteins.

The `dystrophy` dataset contains 209 observations of 75 female DMD carriers and 134 female DMD non-carrier. It includes 6 variables describing age of the female and the serum parameters serum marker creatine kinase (CK), serum marker hemopexin (H), serum marker pyruvate kinase (PK) and serum marker lactate dehydroginase (LD). The serum markers CK and H may be measured rather inexpensive from frozen serum, PK and LD requires fresh serum.
errorest

Examples

```r
## Not run:

data("dystrophy")
library("rpart")
errorest(Class~CK+H+AGE+PK+LD, data = dystrophy, model = inbag, pFUN = list(list(model = lm, predict = mypredict.lm)), ns = 0.75, estimator = "cv")

## End(Not run)
```

**errorest**  
Estimators of Prediction Error

Description
Resampling based estimates of prediction error: misclassification error, root mean squared error or Brier score for survival data.

Usage

```r
## S3 method for class 'data.frame'
errorest(formula, data, subset, na.action=na.omit, model=NULL, predict=NULL, estimator=c("cv", "boot", "632plus"), est пара=control.errorest(), ...)```

Arguments

- **formula**: a formula of the form lhs ~ rhs. Either describing the model of explanatory and response variables in the usual way (see `lm`) or the model between explanatory and intermediate variables in the framework of indirect classification, see `inclass`.
- **data**: a data frame containing the variables in the model formula and additionally the class membership variable if `model = inclass`. `data` is required for indirect classification, otherwise `formula` is evaluated in the calling environment.
- **subset**: optional vector, specifying a subset of observations to be used.
na.action function which indicates what should happen when the data contains NA's, defaults to na.omit.

model function. Modelling technique whose error rate is to be estimated. The function model can either return an object representing a fitted model or a function with argument newdata which returns predicted values. In this case, the predict argument to errorest is ignored.

predict function. Prediction method to be used. The vector of predicted values must have the same length as the the number of to-be-predicted observations. Predictions corresponding to missing data must be replaced by NA. Additionally, predict has to return predicted values comparable to the responses (that is: factors for classification problems). See the example on how to make this sure for any predictor.

estimator estimator of the misclassification error: cv cross-validation, boot bootstrap or 632plus bias corrected bootstrap (classification only).

est.par a list of additional parameters that control the calculation of the estimator, see control.errorest for details.

... additional parameters to model.

**Details**

The prediction error for classification and regression models as well as predictive models for censored data using cross-validation or the bootstrap can be computed by errorest. For classification problems, the estimated misclassification error is returned. The root mean squared error is computed for regression problems and the Brier score for censored data (Graf et al., 1999) is reported if the response is censored.

Any model can be specified as long as it is a function with arguments model(formula, data, subset, na.action, ...). If a method predict.model(object, newdata, ...) is available, predict does not need to be specified. However, predict has to return predicted values in the same order and of the same length corresponding to the response. See the examples below.

k$-fold cross-validation and the usual bootstrap estimator with est.par$boot bootstrap replications can be computed for all kind of problems. The bias corrected .632+ bootstrap by Efron and Tibshirani (1997) is available for classification problems only. Use control.errorest to specify additional arguments.

errorest is a formula based interface to the generic functions cv or bootest which implement methods for classification, regression and survival problems.

**Value**

The class of the object returned depends on the class of the response variable and the estimator used. In each case, it is a list with an element error and additional information. print methods are available for the inspection of the results.

```
**Description**

The GlaucomaMVF data has 170 observations in two classes. 66 predictors are derived from a confocal laser scanning image of the optic nerve head, from a visual field test, a fundus photography and a measurement of the intra ocular pressure.

**Usage**

```r
data("GlaucomaMVF")
```

**Format**

This data frame contains the following predictors describing the morphology of the optic nerve head, the visual field, the intra ocular pressure and a membership variable:

- `ag` area global.
- `at` area temporal.
- `as` area superior.
- `an` area nasal.
- `ai` area inferior.
- `eag` effective area global.
- `eat` effective area temporal.
- `eas` effective area superior.
- `ean` effective area nasal.
- `eai` effective area inferior.
- `abrg` area below reference global.
- `abrt` area below reference temporal.
- `abrs` area below reference superior.
- `abrn` area below reference nasal.
- `abri` area below reference inferior.
- `hic` height in contour.
- `mhcg` mean height contour global.
- `mhct` mean height contour temporal.
- `mhcs` mean height contour superior.
- `mhcns` mean height contour nasal.
- `mhci` mean height contour inferior.
- `phcg` peak height contour.
- `phct` peak height contour temporal.
phcs peak height contour superior.
phcn peak height contour nasal.
phci peak height contour inferior.
hvc height variation contour.
vbsg volume below surface global.
vbst volume below surface temporal.
vbsi volume below surface superior.
vbsn volume below surface nasal.
vbsi volume below surface inferior.
vasg volume above surface global.
vast volume above surface temporal.
vass volume above surface superior.
vasn volume above surface nasal.
vasi volume above surface inferior.
vbrg volume below reference global.
vbrt volume below reference temporal.
vbrs volume below reference superior.
vbrn volume below reference nasal.
vбри volume below reference inferior.
varg volume above reference global.
vart volume above reference temporal.
vars volume above reference superior.
varn volume above reference nasal.
vari volume above reference inferior.
mdg mean depth global.
mdt mean depth temporal.
mds mean depth superior.
mdn mean depth nasal.
mdi mean depth inferior.
tmg third moment global.
tmt third moment temporal.
tms third moment superior.
tmn third moment nasal.
tmi third moment inferior.
mr mean radius.
rnf retinal nerve fiber thickness.
mdic mean depth in contour.
emd  effective mean depth.

mv  mean variability.

tension  intra ocular pressure.

clv  corrected loss variance, variability of the visual field.

cs  contrast sensitivity of the visual field.

lora  loss of rim area, measured by fundus photography.

Class  a factor with levels glaucoma and normal.

Details

Confocal laser images of the eye background are taken with the Heidelberg Retina Tomograph and variables 1-62 are derived. Most of these variables describe either the area or volume in certain parts of the papilla and are measured in four sectors (temporal, superior, nasal and inferior) as well as for the whole papilla (global). The global measurement is, roughly, the sum of the measurements taken in the four sector.

The perimeter ‘Octopus’ measures the visual field variables clv and cs, stereo optic disks photographs were taken with a telecentric fundus camera and lora is derived.

Observations of both groups are matched by age and sex, to prevent for possible confounding.

Note

GlaucomaMVF overlaps in some parts with GlaucomaM.

Source

Examples

```r
## Not run:

data("GlaucomaMVF", package = "ipred")
library("rpart")

response <- function (data) {
  attach(data)
  res <- ifelse((!is.na(clv) & !is.na(lora) & clv >= 5.1 & lora >= 49.23372) | (!is.na(clv) & !is.na(lora) & !is.na(cs) & clv < 5.1 & lora >= 58.55409 & cs < 1.405) | (is.na(clv) & !is.na(lora) & !is.na(cs) & lora >= 58.55409 & cs < 1.405) | (!is.na(clv) & is.na(lora) & cs < 1.405), 0, 1)
  detach(data)
  factor (res, labels = c("glaucoma", "normal"))
}

errorest(Class=clv+lora+cs~, data = GlaucomaMVF, model=inclass,
estimator="cv", pFUN = list(list(model = rpart)), cFUN = response)
```
## inbagg

### Indirect Bagging

**Description**

Function to perform the indirect bagging and subagging.

**Usage**

```r
## S3 method for class 'data.frame'
inbagg(formula, data, pFUN=NULL,
       cFUN=list(model = NULL, predict = NULL, training.set = NULL),
       nbagg = 25, ns = 0.5, replace = FALSE, ...)
```

**Arguments**

- `formula`: formula. A formula specified as \( y \sim w_1 + w_2 + w_3 \sim x_1 + x_2 + x_3 \) describes how to model the intermediate variables \( w_1, w_2, w_3 \) and the response variable \( y \), if no other formula is specified by the elements of `pFUN` or in `cFUN`.
- `data`: data frame of explanatory, intermediate and response variables.
- `pFUN`: list of lists, which describe models for the intermediate variables, details are given below.
- `cFUN`: either a fixed function with argument `newdata` and returning the class membership by default, or a list specifying a classifying model, similar to one element of `pFUN`. Details are given below.
- `nbagg`: number of bootstrap samples.
- `ns`: proportion of sample to be drawn from the learning sample. By default, subagging with 50% is performed, i.e. draw 0.5*n out of n without replacement.
- `replace`: logical. Draw with or without replacement.
- `...`: additional arguments (e.g. `subset`).

**Details**

A given data set is subdivided into three types of variables: explanatory, intermediate and response variables.

Here, each specified intermediate variable is modelled separately following `pFUN`, a list of lists with elements specifying an arbitrary number of models for the intermediate variables and an optional element `training.set = c("oob", "bag", "all")`. The element `training.set` determines whether, predictive models for the intermediate are calculated based on the out-of-bag sample ("oob"), the default, on the bag sample ("bag") or on all available observations ("all"). The elements of `pFUN`, specifying the models for the intermediate variables are lists as described in
inclass. Note that, if no formula is given in these elements, the functional relationship of formula is used.

The response variable is modelled following cFUN. This can either be a fixed classifying function as described in Peters et al. (2003) or a list, which specifies the modelling technique to be applied. The list contains the arguments model (which model to be fitted), predict (optional, how to predict), formula (optional, of type $y\sim w_1+w_2+w_3+x_1+x_2$ determines the variables the classifying function is based on) and the optional argument training.set = c("fitted.bag", "original", "fitted.subset") specifying whether the classifying function is trained on the predicted observations of the bag sample ("fitted.bag"), on the original observations ("original") or on the predicted observations not included in a defined subset ("fitted.subset"). Per default the formula specified in formula determines the variables, the classifying function is based on.

Note that the default of cFUN = list(model = NULL, training.set = "fitted.bag") uses the function rpart and the predict function predict(object, newdata, type = "class").

Value

An object of class "inbagg", that is a list with elements

- mtrees a list of length nbagg, describing the prediction models corresponding to each bootstrap sample. Each element of mtrees is a list with elements bindx (observations of bag sample), btree (classifying function of bag sample) and bfct (predictive models for intermediates of bag sample).

- y vector of response values.

- w data frame of intermediate variables.

- x data frame of explanatory variables.

Examples

```r
library("MASS")
library("rpart")
y <- as.factor(sample(1:2, 100, replace = TRUE))
w <- mvrnorm(n = 200, mu = rep(0, 3), Sigma = diag(3))
x <- mvrnorm(n = 200, mu = rep(2, 3), Sigma = diag(3))
colnames(w) <- c("w1", "w2", "w3")
```
### Description

A framework for the indirect classification approach.

### Usage

```r
## S3 method for class 'data.frame'
inclass(formula, data, pFUN = NULL, cFUN = NULL, ...)
```

### Arguments

- **formula**: formula. A formula specified as y~w1+w2+w3~x1+x2+x3 models each intermediate variable w1, w2, w3 by w1~x1+x2+x3 and the response by y~w1+w2+w3 if no other formulas are given in pFUN or cFUN.
- **data**: data frame of explanatory, intermediate and response variables.
- **pFUN**: list of lists, which describe models for the intermediate variables, see below for details.
- **cFUN**: either a function or a list which describes the model for the response variable. The function has the argument `newdata` only.
- **...**: additional arguments, passed to model fitting of the response variable.

### Details

A given data set is subdivided into three types of variables: those to be used predicting the class (explanatory variables) those to be used defining the class (intermediate variables) and the class membership variable itself (response variable). Intermediate variables are modelled based on the explanatory variables, the class membership variable is defined on the intermediate variables.

Each specified intermediate variable is modelled separately following `pFUN` and a formula specified by `formula`. `pFUN` is a list of lists, the maximum length of `pFUN` is the number of intermediate variables. Each element of `pFUN` is a list with elements:

- **model**: a function with arguments `formula` and `data`;
- **predict**: an optional function with arguments `object`, `newdata` only, if `predict` is not specified, the predict method of `model` is used;
formula - specifies the formula for the corresponding model (optional), the formula described in y~w1+w2+w3~x1+x2+x3 is used if no other is specified.

The response is classified following cFUN, which is either a fixed function or a list as described below. The determined function cFUN assigns the intermediate (and explanatory) variables to a certain class membership, the list cFUN has the elements formula, model, predict and training.set. The elements formula, model, predict are structured as described by pFUN. The described model is trained on the original (intermediate variables) if training.set="original" or if training.set = NULL, on the fitted values if training.set = "fitted" or on observations not included in a specified subset if training.set = "subset".

A list of prediction models corresponding to each intermediate variable, a predictive function for the response, a list of specifications for the intermediate and for the response are returned. For a detailed description on indirect classification see Hand et al. (2001).

Value

An object of class inclass, consisting of a list of

model.intermediate
  list of fitted models for each intermediate variable.

model.response
  predictive model for the response variable.

para.intermediate
  list, where each element is again a list and specifies the model for each intermediate variable.

para.response
  a list which specifies the model for response variable.

`bagging`, `inclass`

Examples

data("Smoking", package = "ipred")
# Set three groups of variables:
# 1) explanatory variables are: TarY, NicY, COY, Sex, Age
# 2) intermediate variables are: TVPS, BPNL, COHB
# 3) response (resp) is defined by:

classify <- function(data){
  data <- data[,c("TVPS", "BPNL", "COHB")]
  res <- t(t(data) > c(4438, 232.5, 58))
}
**ipredknn**

$k$-Nearest Neighbour Classification

**Description**

$k$-nearest neighbour classification with an interface compatible to `bagging` and `errorest`.

**Usage**

```r
ipredknn(formula, data, subset, na.action, k=5, ...)
```

**Arguments**

- `formula`: a formula of the form `lhs ~ rhs` where `lhs` is the response variable and `rhs` a set of predictors.
- `data`: optional data frame containing the variables in the model formula.
- `subset`: optional vector specifying a subset of observations to be used.
- `na.action`: function which indicates what should happen when the data contain NAs.
- `k`: number of neighbours considered, defaults to 5.
- `...`: additional parameters.

**Details**

This is a wrapper to `knn` in order to be able to use k-NN in `bagging` and `errorest`.

**Value**

An object of class `ipredknn`. See `predict.ipredknn`.
Examples

library("mlbench")
learn <- as.data.frame(mlbench.twonorm(300))

mypredict.knn <- function(object, newdata)
    predict.ipredknn(object, newdata, type="class")

errorest(classes ~., data=learn, model=ipredknn,
    predict=mypredict.knn)

kfoldcv

Subsamples for k-fold Cross-Validation

Description
Computes feasible sample sizes for the k groups in k-fold cv if N/k is not an integer.

Usage

kfoldcv(k, N, nlevel=NULL)

Arguments

k
number of groups.
N
total sample size.
nlevel
a vector of sample sizes for stratified sampling.

Details
If N/k is not an integer, k-fold cv is not unique. Determine meaningful sample sizes.

Value
A vector of length k.

Examples

# 10-fold CV with N = 91
kfoldcv(10, 91)
mypredict.lm  Predictions Based on Linear Models

Description
Function to predict a vector of full length (number of observations), where predictions according to missing explanatory values are replaced by NA.

Usage
mypredict.lm(object, newdata)

Arguments
object an object of class lm.
newdata matrix or data frame to be predicted according to object.

Value
Vector of predicted values.

Note
predict.lm delivers a vector of reduced length, i.e. rows where explanatory variables are missing are omitted. The full length of the predicted observation vector is necessary in the indirect classification approach (predict.inclass).

predict.classbagg  Predictions from Bagging Trees

Description
Predict the outcome of a new observation based on multiple trees.

Usage
## S3 method for class 'classbagg'
predict(object, newdata=NULL, type=c("class", "prob"),
aggregation=c("majority", "average", "weighted"), ...)
## S3 method for class 'regbagg'
predict(object, newdata=NULL, aggregation=c("average",
"weighted"), ...)
## S3 method for class 'survbagg'
predict(object, newdata=NULL,...)
Arguments

- **object**: object of classes `classbagg`, `regbagg` or `survbagg`.
- **newdata**: a data frame of new observations.
- **type**: character string denoting the type of predicted value returned for classification trees. Either `class` (predicted classes are returned) or `prob` (estimated class probabilities are returned).
- **aggregation**: character string specifying how to aggregate, see below.
- ... additional arguments, currently not passed to any function.

Details

There are (at least) three different ways to aggregate the predictions of bagging classification trees. Most famous is class majority voting (aggregation="majority") where the most frequent class is returned. The second way is choosing the class with maximal averaged class probability (aggregation="average"). The third method is based on the "aggregated learning sample", introduced by Hothorn et al. (2003) for survival trees. The prediction of a new observation is the majority class, mean or Kaplan-Meier curve of all observations from the learning sample identified by the nbagg leaves containing the new observation. For regression trees, only averaged or weighted predictions are possible.

By default, the out-of-bag estimate is computed if `newdata` is NOT specified. Therefore, the predictions of `predict(object)` are "honest" in some way (this is not possible for combined models via comb in bagging). If you like to compute the predictions for the learning sample itself, use `newdata` to specify your data.

Value

The predicted class or estimated class probabilities are returned for classification trees. The predicted endpoint is returned in regression problems and the predicted Kaplan-Meier curve is returned for survival trees.

References

Examples

data("Ionosphere", package = "mlbench")
Ionosphere$V2 <- NULL # constant within groups

# nbagg = 10 for performance reasons here
mod <- bagging(Class ~ ., data=Ionosphere)

# out-of-bag estimate
mean(predict(mod) != Ionosphere$Class)
# predictions for the first 10 observations
predict(mod, newdata=Ionosphere[1:10,])
predict(mod, newdata=Ionosphere[1:10,], type="prob")

predict.inbagg Predictions from an Inbagg Object

## Description

Predicts the class membership of new observations through indirect bagging.

## Usage

```r
## S3 method for class 'inbagg'
predict(object, newdata, ...)
```

## Arguments

- `object`: object of class `inbagg`, see `inbagg`.
- `newdata`: data frame to be classified.
- `...`: additional arguments corresponding to the predictive models.

## Details

Predictions of class memberships are calculated. i.e. values of the intermediate variables are predicted following pFUN and classified following cFUN, see `inbagg`.

## Value

The vector of predicted classes is returned.

## References

## See Also

Examples

library("MASS")
library("rpart")
y <- as.factor(sample(1:2, 100, replace = TRUE))
W <- mvrnorm(n = 200, mu = rep(0, 3), Sigma = diag(3))
X <- mvrnorm(n = 200, mu = rep(2, 3), Sigma = diag(3))
colnames(W) <- c("w1", "w2", "w3")
colnames(X) <- c("x1", "x2", "x3")
DATA <- data.frame(y, W, X)

pFUN <- list(list(formula = w1~x1+x2, model = lm),
              list(model = rpart))

RES <- inbag(y~w1+w2+w3~x1+x2+x3, data = DATA, pFUN = pFUN)
predict(RES, newdata = X)

---

**predict.inclass**  
*Predictions from an Inclass Object*

**Description**

Predicts the class membership of new observations through indirect classification.

**Usage**

```r
## S3 method for class 'inclass'
predict(object, newdata, ...)
```

**Arguments**

- `object`  
  object of class inclass, see `inclass`.
- `newdata`  
  data frame to be classified.
- `...`  
  additional arguments corresponding to the predictive models specified in `inclass`.

**Details**

Predictions of class memberships are calculated. i.e. values of the intermediate variables are predicted and classified following cFUN, see `inclass`.

**Value**

The vector of predicted classes is returned.

predict(object = fit, newdata = GlaucomaM)

---

**predict.ipredknn**

**Predictions from k-Nearest Neighbors**

**Description**

Predict the class of a new observation based on k-NN.

**Usage**

```r
## S3 method for class 'ipredknn'
predict(object, newdata, type=c("prob", "class"), ...)
```
predict.slda

Arguments

- **object**: object of class ipredknn.
- **newdata**: a data frame of new observations.
- **type**: return either the predicted class or the proportion of the votes for the winning class.
- **...**: additional arguments.

Details

This function is a method for the generic function `predict` for class ipredknn. For the details see `knn`.

Value

Either the predicted class or the proportion of the votes for the winning class.

---

**predict.slda**  
*Predictions from Stabilised Linear Discriminant Analysis*

Description

Predict the class of a new observation based on stabilised LDA.

Usage

```r
## S3 method for class 'slda'
predict(object, newdata, ...)  
```

Arguments

- **object**: object of class slda.
- **newdata**: a data frame of new observations.
- **...**: additional arguments passed to `predict.lda`.

Details

This function is a method for the generic function `predict` for class slda. For the details see `predict.lda`.

Value

A list with components

- **class**: the predicted class (a factor).
- **posterior**: posterior probabilities for the classes.
- **x**: the scores of test cases.
Description

Print objects returned by bagging in nice layout.

Usage

## S3 method for class 'classbagg'
print(x, digits, ...)

Arguments

- **x**: object returned by bagging.
- **digits**: how many digits should be printed.
- **...**: further arguments to be passed to or from methods.

Value

none

---

Description

Print objects returned by errorest in nice layout.

Usage

## S3 method for class 'cvclass'
print(x, digits=4, ...)

Arguments

- **x**: an object returned by errorest.
- **digits**: how many digits should be printed.
- **...**: further arguments to be passed to or from methods.

Value

none
**print.inbagg**

*Print Method for Inbagg Object*

**Description**

Print object of class `inbagg` in nice layout.

**Usage**

```r
# S3 method for class 'inbagg'
print(x, ...)
```

**Arguments**

- `x` object of class `inbagg`.
- `...` additional arguments.

**Details**

An object of class `inbagg` is printed. Information about number and names of the intermediate variables, and the number of drawn bootstrap samples is given.

---

**print.inclass**

*Print Method for Inclass Object*

**Description**

Print object of class `inclass` in nice layout.

**Usage**

```r
# S3 method for class 'inclass'
print(x, ...)
```

**Arguments**

- `x` object of class `inclass`.
- `...` additional arguments.

**Details**

An object of class `inclass` is printed. Information about number and names of the intermediate variables, the used modelling technique and the number of drawn bootstrap samples is given.
prune.classbagg  Pruning for Bagging

Description

Prune each of the trees returned by bagging.

Usage

```r
## S3 method for class 'classbagg'
prune(tree, cp=0.01,...)
```

Arguments

- **tree**: an object returned by `bagging` (calling this tree is needed by the generic function `prune` in package `rpart`).
- **cp**: complexity parameter, see `prune.rpart`.
- **...**: additional arguments to `prune.rpart`.

Details

By default, `bagging` grows classification trees of maximal size. One may want to prune each tree, however, it is not clear whether or not this may decrease prediction error.

Value

An object of the same class as `tree` with the trees pruned.

Examples

```r
data("Glass", package = "mlbench")
library("rpart")

mod <- bagging(Type ~ ., data=Glass, nbagg=10, coob=TRUE)
pmod <- prune(mod)
print(pmod)
```
rsurv  

Simulate Survival Data

Description

Simulation Setup for Survival Data.

Usage

```r
rsurv(N, model=c("A", "B", "C", "D", "tree"), gamma=NULL, fact=1, pnon=10, 
gethaz=FALSE)
```

Arguments

- **N**: number of observations.
- **model**: type of model.
- **gamma**: simulate censoring time as runif(N, 0, gamma). Defaults to NULL (no censoring).
- **fact**: scale parameter for model=tree.
- **pnon**: number of additional non-informative variables for the tree model.
- **gethaz**: logical, indicating whether the hazard rate for each observation should be returned.

Details

Simulation setup similar to configurations used in LeBlanc and Crowley (1992) or Keles and Segal (2002) as well as a tree model used in Hothorn et al. (2004). See Hothorn et al. (2004) for the details.

Value

A data frame with elements `time`, `cens`, `X1` ... `X5`. If `pnon > 0`, additional noninformative covariables are added. If `gethaz=TRUE`, the hazard attribute returns the hazard rates.

References

Examples

```r
library("survival")
# 3*X1 + X2
simdat <- rsurv(500, model="c")
coxph(Surv(time, cens) ~ ., data=simdat)
```

---

**sbrier**  
*Model Fit for Survival Data*

**Description**

Model fit for survival data: the integrated Brier score for censored observations.

**Usage**

```r
sbrier(obj, pred, btime = range(obj[,1]))
```

**Arguments**

- `obj`  
an object of class `Surv`.
- `pred`  
predicted values. Either a probability or a list of `survfit` objects.
- `btime`  
numeric vector of times, the integrated Brier score is computed if this is of length > 1. The Brier score at `btime` is returned otherwise.

**Details**

There is no obvious criterion of model fit for censored data. The Brier score for censoring as well as it's integrated version were suggested by Graf et al (1999).

The integrated Brier score is always computed over a subset of the interval given by the range of the time slot of the survival object `obj`.

**Value**

The (integrated) Brier score with attribute `time` is returned.

**References**

**See Also**

More measures for the validation of predicted survival probabilities are implemented in package `pec`.
Examples

```r
library("survival")
data("DLBCL", package = "ipred")
smod <- Surv(DLBCL$time, DLBCL$cens)

KM <- survfit(smod - 1)
# integrated Brier score up to max(DLBCL$time)
sbrier(smod, KM)

# integrated Brier score up to time=50
sbrier(smod, KM, btime=c(0, 50))

# Brier score for time=50
sbrier(smod, KM, btime=50)

# a "real" model: one single survival tree with Intern. Prognostic Index
# and mean gene expression in the first cluster as predictors
mod <- bagging(Surv(time, cens) ~ MGEc.1 + IPI, data=DLBCL, nbagg=1)

# this is a list of survfit objects (==KM-curves), one for each observation
# in DLBCL

### Stabilised Linear Discriminant Analysis

**Description**

Linear discriminant analysis based on left-spherically distributed linear scores.

**Usage**

```r
## S3 method for class 'formula'
slda(formula, data, subset, na.action=na.rpart, ...)
## S3 method for class 'factor'
slda(y, X, q=NULL, ...)
```

**Arguments**

- `y` the response variable: a factor vector of class labels.
- `X` a data frame of predictor variables.
- `q` the number of positive eigenvalues the scores are derived from, see below.
- `formula` a formula of the form `lhs ~ rhs` where `lhs` is the response variable and `rhs` a set of predictors.
- `data` optional data frame containing the variables in the model formula.
- `subset` optional vector specifying a subset of observations to be used.
- `na.action` function which indicates what should happen when the data contain NAs. Defaults to `na.rpart`.
- `...` additional parameters passed to `lda`. 
Details

This function implements the LDA for \( q \)-dimensional linear scores of the original \( p \) predictors derived from the \( PC_q \) rule by Laeuter et al. (1998). Based on the product sum matrix

\[
W = (X - \bar{X})^T(X - \bar{X})
\]

the eigenvalue problem \( WD = \text{diag}(W)DL \) is solved. The first \( q \) columns \( D_q \) of \( D \) are used as a weight matrix for the original \( p \) predictors: \( XD_q \). By default, \( q \) is the number of eigenvalues greater one. The \( q \)-dimensional linear scores are left-spherically distributed and are used as predictors for a classical LDA.

This form of reduction of the dimensionality was developed for discriminant analysis problems by Laeuter (1992) and was used for multivariate tests by Laeuter et al. (1998), Kropf (2000) gives an overview. For details on left-spherically distributions see Fang and Zhang (1990).

Value

An object of class \texttt{slda}, a list with components

- \texttt{scores} the weight matrix.
- \texttt{mylda} an object of class \texttt{lda}.

References

See Also

\texttt{predict.slda}

Examples

```r
library("mlbench")
library("MASS")
learn <- as.data.frame(mlbench.twonorm(100))
test <- as.data.frame(mlbench.twonorm(1000))

mlda <- lda(classes ~ ., data=learn)
mslda <- slda(classes ~ ., data=learn)

print(mean(predict(mlda, newdata=test)$class != test$classes))
print(mean(predict(mslda, newdata=test)$class != test$classes))
```
Description

The Smoking data frame has 55 rows and 9 columns.

Usage

data("Smoking")

Format

This data frame contains the following columns:

NR numeric, patient number.
Sex factor, sex of patient.
Age factor, age group of patient, grouping consisting of those in their twenties, those in their thirties and so on.
TarY numeric, tar yields of the cigarettes.
NicY numeric, nicotine yields of the cigarettes.
COY numeric, carbon monoxide (CO) yield of the cigarettes.
TVPS numeric, total volume puffed smoke.
BPNL numeric, blood plasma nicotine level.
COHB numeric, carboxyhaemoglobin level, i.e. amount of CO absorbed by the blood stream.

Details

The data describes different smoking habits of probands.

Source

Hand and Taylor (1987), Study F Smoking Styles.

References

**summary.classbagg**  Summarising Bagging

**Description**

Summary method for objects returned by `bagging`.

**Usage**

```r
## S3 method for class 'classbagg'
summary(object, ...)
```

**Arguments**

- `object` object returned by `bagging`.
- `...` further arguments to be passed to or from methods.

**Details**

A representation of all trees in the object is printed.

**Value**

none

**summary.inbagg**  Summarising Inbagg

**Description**

Summary of `inbagg` is returned.

**Usage**

```r
## S3 method for class 'inbagg'
summary(object, ...)
```

**Arguments**

- `object` an object of class `inbagg`.
- `...` additional arguments.

**Details**

A representation of an indirect bagging model (the intermediates variables, the number of bootstrap samples, the trees) is printed.
summary.inclass

Value

none

See Also

print.summary.inclass

summary.inclass  Summarising Inclass

Description

Summary of inclass is returned.

Usage

## S3 method for class 'inclass'
summary(object, ...)

Arguments

object  an object of class inclass.
...
additional arguments.

Details

A representation of an indirect classification model (the intermediates variables, which modelling technique is used and the prediction model) is printed.

Value

none

See Also

print.summary.inclass
Description

Three sets of variables are calculated: explanatory, intermediate and response variables.

Usage

varset(N, sigma=0.1, theta=90, threshold=0, u=1:3)

Arguments

N number of simulated observations.
sigma standard deviation of the error term.
theta angle between two u vectors.
threshold cutpoint for classifying to 0 or 1.
u starting values.

Details

For each observation values of two explanatory variables \( x = (x_1, x_2)^\top \) and of two responses \( y = (y_1, y_2)^\top \) are simulated, following the formula:

\[
y = U \ast x + e = (\frac{u_1}{u_2}) \ast x + e
\]

where \( x \) is the evaluation of as standard normal random variable and \( e \) is generated by a normal variable with standard deviation \( \sigma \). \( U \) is a 2*2 Matrix, where

\[
u_1 = (\frac{u_{1,1}}{u_{1,2}}), u_2 = (\frac{u_{2,1}}{u_{2,2}}), ||u_1|| = ||u_2|| = 1,
\]

i.e. a matrix of two normalised vectors.

Value

A list containing the following arguments

- explanatory \( N \times 2 \) matrix of 2 explanatory variables.
- intermediate \( N \times 2 \) matrix of 2 intermediate variables.
- response response vectors with values 0 or 1.

References

Examples

theta0 <- varset(N = 1000, sigma = 0.1, theta = 90, threshold = 0)
theta0 <- varset(N = 1000, sigma = 0.1, theta = 0, threshold = 0)
par(mfrow = c(1, 2))
plot(theta0$intermediate)
plot(theta0$intermediate)
