Package ‘irtQ’

July 6, 2023

Type Package

Title Unidimensional Item Response Theory Modeling

Version 0.2.0

Description Fit unidimensional item response theory (IRT) models to a mixture of dichotomous and polytomous data, calibrate online item parameters (i.e., pretest and operational items), estimate examinees’ abilities, and examine the IRT model-data fit on item-level in different ways as well as provide useful functions related to IRT analyses such as IRT model-data fit evaluation and differential item functioning analysis.

The bring.flexmirt() and write.flexmirt() functions were written by modifying the read.flexmirt() function (Pritikin & Falk (2022) <doi:10.1177/0146621620929431>). The bring.bilog() and bring.parscale() functions were written by modifying the read.bilog() and read.parscale() functions, respectively (Weeks (2010) <doi:10.18637/jss.v035.i12>). The bisection() function was written by modifying the bisection() function (Howard (2017, ISBN:9780367657918)). The code of the inverse test characteristic curve scoring in the est_score() function was written by modifying the irt.eq.tse() function (González (2014) <doi:10.18637/jss.v059.i07>). In est_score() function, the code of weighted likelihood estimation method was written by referring to the Pi(), Ji(), and Ii() functions of the catR package (Magis & Barrada (2017) <doi:10.18637/jss.v076.c01>).

Description

Fit unidimensional item response theory (IRT) models to a mixture of dichotomous and polytomous data, calibrate online item parameters (i.e., pretest and operational items), estimate examinees’ abilities, and provide useful functions related to unidimensional IRT such as IRT model-data fit evaluation and differential item functioning analysis.

For the item parameter estimation, the marginal maximum likelihood estimation via the expectation-maximization (MMLE-EM) algorithm (Bock & Aitkin, 1981) is used. Also, the fixed item parameter calibration (FIPC) method (Kim, 2006) and the fixed ability parameter calibration (FAPC) method, (Ban, Hanson, Wang, Yi, & Harris, 2001; stocking, 1988), often called Stocking’s Method A, are provided. For the ability estimation, several popular scoring methods (e.g., ML, EAP, and MAP) are implemented.

In addition, there are many useful functions related to IRT analyses such as evaluating IRT model-data fit, analyzing differential item functioning (DIF), importing item and/or ability parameters from popular IRT software, running flexMIRT (Cai, 2017) through R, generating simulated data, computing the conditional distribution of observed scores using the Lord-Wingersky recursion formula, computing item and test information functions, computing item and test characteristic curve functions, and plotting item and test characteristic curves and item and test information functions.

Details

Following five sections describe a) how to implement the online item calibration using FIPC, a) how to implement the online item calibration using Method A, b) two illustrations of the online calibration, and c) IRT Models used in irtQ package.

Online item calibration with the fixed item parameter calibration method (e.g., Kim, 2006)

The fixed item parameter calibration (FIPC) is one of useful online item calibration methods for computerized adaptive testing (CAT) to put the parameter estimates of pretest items on the same scale of operational item parameter estimates without post hoc linking/scaling (Ban, Hanson, Wang, Yi, & Harris, 2001; Chen & Wang, 2016). In FIPC, the operational item parameters are fixed to estimate the characteristic of the underlying latent variable prior distribution when calibrating the pretest items. More specifically, the underlying latent variable prior distribution of the operational items is estimated during the calibration of the pretest items to put the item parameters of the pretest items on the scale of the operational item parameters (Kim, 2006). In the irtQ package, FIPC is implemented with two main steps:
1. Prepare a response data set and the item metadata of the fixed (or operational) items.
2. Implement FIPC to estimate the item parameters of pretest items using the \texttt{est_irt} function.

**1. Preparing a data set**
To run the \texttt{est_irt} function, it requires two data sets:

1. Item metadata set (i.e., model, score category, and item parameters. see the description of the argument \texttt{x} in the function \texttt{est_irt}).
2. Examinees’ response data set for the items. It should be a matrix format where a row and column indicate the examinees and the items, respectively. The order of the columns in the response data set must be exactly the same as the order of rows of the item metadata.

**2. Estimating the pretest item parameters**
When FIPC is implemented in \texttt{est_irt} function, the pretest item parameters are estimated by fixing the operational item parameters. To estimate the item parameters, you need to provide the item metadata in the argument \texttt{x} and the response data in the argument \texttt{data}.

It is worthwhile to explain about how to prepare the item metadata set in the argument \texttt{x}. A specific form of a data frame should be used for the argument \texttt{x}. The first column should have item IDs, the second column should contain the number of score categories of the items, and the third column should include IRT models. The available IRT models are "1PLM", "2PLM", "3PLM", and "DRM" for dichotomous items, and "GRM" and "GPCM" for polytomous items. Note that "DRM" covers all dichotomous IRT models (i.e., "1PLM", "2PLM", and "3PLM") and "GRM" and "GPCM" represent the graded response model and (generalized) partial credit model, respectively. From the fourth column, item parameters should be included. For dichotomous items, the fourth, fifth, and sixth columns represent the item discrimination (or slope), item difficulty, and item guessing parameters, respectively. When "1PLM" or "2PLM" is specified for any items in the third column, NAs should be inserted for the item guessing parameters. For polytomous items, the item discrimination (or slope) parameters should be contained in the fourth column and the item threshold (or step) parameters should be included from the fifth to the last columns. When the number of categories differs between items, the empty cells of item parameters should be filled with NAs. See ‘est_irt’ for more details about the item metadata.

Also, you should specify in the argument \texttt{fipc = TRUE} and a specific FIPC method in the argument \texttt{fipc.method}. Finally, you should provide a vector of the location of the items to be fixed in the argument \texttt{fix.loc}. For more details about implementing FIPC, see the description of the function \texttt{est_irt}.

When implementing FIPC, you can estimate both the empirical histogram and the scale of latent variable prior distribution by setting \texttt{EmpHist = TRUE}. If \texttt{EmpHist = FALSE}, the normal prior distribution is used during the item parameter estimation and the scale of the normal prior distribution is updated during the EM cycle.

The \texttt{est_item} function requires a vector of the number of score categories for the items in the argument \texttt{cats}. For example, a dichotomous item has two score categories. If a single numeric value is specified, that value will be recycled across all items. If NULL and all items are binary items (i.e., dichotomous items), it assumes that all items have two score categories. If necessary, you need to specify whether prior distributions of item slope and guessing parameters (only for the IRT 3PL model) are used in the arguments of \texttt{use.aprior} and \texttt{use.gprior}, respectively. If you decide to use the prior distributions, you should specify what distributions will be used for the prior distributions in the arguments of \texttt{aprior} and \texttt{gprior}, respectively. Currently three probability distributions of Beta, Log-normal, and Normal distributions are available.
In addition, if the response data include missing values, you must indicate the missing value in argument `missing`.

Once the `est_irt` function has been implemented, you’ll get a list of several internal objects such as the item parameter estimates, standard error of the parameter estimates.

### Online item calibration with the fixed ability parameter calibration method (e.g., Stocking, 1988)

In CAT, the fixed ability parameter calibration (FAPC), often called Stocking’s Method A, is the relatively simplest and most straightforward online calibration method, which is the maximum likelihood estimation of the item parameters given the proficiency estimates. In CAT, FAPC can be used to put the parameter estimates of pretest items on the same scale of operational item parameter estimates and recalibrate the operational items to evaluate the parameter drifts of the operational items (Chen & Wang, 2016; Stocking, 1988). Also, FAPC is known to result in accurate, unbiased item parameters calibration when items are randomly rather than adaptively administered to examinees, which occurs most commonly with pretest items (Ban, Hanson, Wang, Yi, & Harris, 2001; Chen & Wang, 2016). Using `irtQ` package, the FAPC is implemented to calibrate the items with two main steps:

1. **Preparing a data set** To run the `est_item` function, it requires two data sets:
   1. Examinees’ ability (or proficiency) estimates. It should be in the format of a numeric vector.
   2. response data set for the items. It should be in the format of matrix where a row and column indicate the examinees and the items, respectively. The order of the examinees in the response data set must be exactly the same as that of the examinees’ ability estimates.

2. **Estimating the pretest item parameters** The `est_item` function estimates the pretest item parameters given the proficiency estimates. To estimate the item parameters, you need to provide the response data in the argument `data` and the ability estimates in the argument `score`.

   Also, you should provide a string vector of the IRT models in the argument `model` to indicate what IRT model is used to calibrate each item. Available IRT models are "1PLM", "2PLM", "3PLM", and "DRM" for dichotomous items, and "GRM" and "GPCM" for polytomous items. "GRM" and "GPCM" represent the graded response model and (generalized) partial credit model, respectively. Note that "DRM" is considered as "3PLM" in this function. If a single character of the IRT model is specified, that model will be recycled across all items.

   The `est_item` function requires a vector of the number of score categories for the items in the argument `cats`. For example, a dichotomous item has two score categories. If a single numeric value is specified, that value will be recycled across all items. If NULL and all items are binary items (i.e., dichotomous items), it assumes that all items have two score categories. If necessary, you need to specify whether prior distributions of item slope and guessing parameters (only for the IRT 3PL model) are used in the arguments of `use.aprior` and `use.gprior`, respectively. If you decide to use the prior distributions, you should specify what distributions will be used for the prior distributions in the arguments of `aprior` and `gprior`, respectively. Currently three probability distributions of Beta, Log-normal, and Normal distributions are available.
In addition, if the response data include missing values, you must indicate the missing value in argument missing.

Once the est_item function has been implemented, you'll get a list of several internal objects such as the item parameter estimates, standard error of the parameter estimates.

Three examples of R script

The example code below shows how to implement the online calibration and how to evaluate the IRT model-data fit:

```r
# Attach the packages
library(irtQ)

# 1. The example code below shows how to prepare the data sets and how to implement the fixed item parameter calibration (FIPC):

### Step 1: prepare a data set
# In this example, we generated examinees' true proficiency parameters and simulated the item response data using the function "simdat".

# import the "-prm.txt" output file from flexMIRT
flex_sam <- system.file("extdata", "flexmirt_sample-prm.txt", package = "irtQ")

# select the item metadata
x <- bring.flexmirt(file=flex_sam, "par")$Group1$full_df

# generate 1,000 examinees' latent abilities from N(0.4, 1.3)
set.seed(20)
score <- rnorm(1000, mean=0.4, sd=1.3)

# simulate the response data
sim.dat <- simdat(x=x, theta=score, D=1)

### Step 2: Estimate the item parameters
# fit the 3PL model to all dichotomous items, fit the GRM model to all polytomous data,
# fix the five 3PL items (1st - 5th items) and three GRM items (53rd to 55th items)
# also, estimate the empirical histogram of latent variable
fix.loc <- c(1:5, 53:55)
(mod.fix1 <- est_irt(x=x, data=sim.dat, D=1, use.gprior=TRUE,
                     gprior=list(dist="beta", params=c(5, 16)), EmpHist=TRUE, Etol=1e-3,
                     fipc=TRUE, fipc.method="MEM", fix.loc=fix.loc))

summary(mod.fix1)

# plot the estimated empirical histogram of latent variable prior distribution
(emphist <- getirt(mod.fix1, what="weights"))
plot(emphist$weight ~ emphist$theta, xlab="Theta", ylab="Density")
```
2. The example code below shows how to prepare the data sets and how to estimate the item parameters using the fixed ability parameter calibration (FAPC):

Step 1: prepare a data set
In this example, we generated examinees' true proficiency parameters and simulated the item response data using the function "simdat". Because, the true proficiency parameters are not known in reality, however, the true proficiencies would be replaced with the proficiency estimates for the calibration.

import the "-prm.txt" output file from flexMIRT

```
flex_sam <- system.file("extdata", "flexmirt_sample-prm.txt", package = "irtQ")
```

# select the item metadata
```
x <- bring.flexmirt(file=flex_sam, "par")$Group1$full_df
```

# modify the item metadata so that some items follow 1PLM, 2PLM and GPCM
```
x[c(1:3, 5), 3] <- "1PLM"
x[c(1:3, 5), 4] <- 1
x[c(1:3, 5), 6] <- 0
x[c(4, 8:12), 3] <- "2PLM"
x[c(4, 8:12), 6] <- 0
x[54:55, 3] <- "GPCM"
```

# generate examinees' abilities from N(0, 1)
```
set.seed(23)
score <- rnorm(500, mean=0, sd=1)
```

# simulate the response data
```
data <- simdat(x=x, theta=score, D=1)
```

Step 2: Estimate the item parameters
1) item parameter estimation: constrain the slope parameters of the 1PLM to be equal
```
(mod1 <- est_item(x, data, score, D=1, fix.a.1pl=FALSE, use.gprior=TRUE, gprior=list(dist="beta", params=c(5, 17)), use.startval=FALSE))
```

```
summary(mod1)
```

2) item parameter estimation: fix the slope parameters of the 1PLM to 1
```
(mod2 <- est_item(x, data, score, D=1, fix.a.1pl=TRUE, a.val.1pl=1, use.gprior=TRUE, gprior=list(dist="beta", params=c(5, 17)), use.startval=FALSE))
```

```
summary(mod2)
```

3) item parameter estimation: fix the guessing parameters of the 3PLM to 0.2
```
(mod3 <- est_item(x, data, score, D=1, fix.a.1pl=TRUE, fix.g=TRUE, a.val.1pl=1, g.val=.2, use.startval=FALSE))
```

```
IRT Models

In the \texttt{irtQ} package, both dichotomous and polytomous IRT models are available. For dichotomous items, IRT one-, two-, and three-parameter logistic models (1PLM, 2PLM, and 3PLM) are used. For polytomous items, the graded response model (GRM) and the (generalized) partial credit model (GPCM) are used. Note that the item discrimination (or slope) parameters should be fixed to 1 when the partial credit model is fit to data.

In the following, let $Y$ be the response of an examinee with latent ability $\theta$ on an item and suppose that there are $K$ unique score categories for each polytomous item.

**IRT 1-3PL models** For the IRT 1-3PL models, the probability that an examinee with $\theta$ provides a correct answer for an item is given by,

$$P(Y = 1|\theta) = g + \frac{(1 - g)}{1 + \exp(-Da(\theta - b))},$$

where $a$ is the item discrimination (or slope) parameter, $b$ represents the item difficulty parameter, $g$ refers to the item guessing parameter. $D$ is a scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function when $D = 1.702$. When the 1PLM is used, $a$ is either fixed to a constant value (e.g., $a = 1$) or constrained to have the same value across all 1PLM item data. When the IRT 1PLM or 2PLM is fit to data, $g = 0$ is set to 0.

**GRM** For the GRM, the probability that an examinee with latent ability $\theta$ responds to score category $k$ ($k = 0, 1, ..., K - 1$) of an item is a given by,

$$P(Y = k|\theta) = P^*(Y \geq k|\theta) - P^*(Y \geq k + 1|\theta),$$

$$P^*(Y \geq k|\theta) = \frac{1}{1 + \exp(-Da(\theta - b_k))}, \text{ and}$$

$$P^*(Y \geq k + 1|\theta) = \frac{1}{1 + \exp(-Da(\theta - b_{k+1}))},$$

where $P^*(Y \geq k|\theta)$ refers to the category boundary (threshold) function for score category $k$ of an item and its formula is analogous to that of 2PLM. $b_k$ is the difficulty (or threshold) parameter for category boundary $k$ of an item. Note that $P(Y = 0|\theta) = 1 - P^*(Y \geq 1|\theta)$ and $P(Y = K - 1|\theta) = P^*(Y \geq K - 1|\theta)$.

**GPCM** For the GPCM, the probability that an examinee with latent ability $\theta$ responds to score category $k$ ($k = 0, 1, ..., K - 1$) of an item is a given by,

$$P(Y = k|\theta) = \frac{\exp(\sum_{v=0}^{k} Da(\theta - b_v))}{\sum_{h=0}^{K-1} \exp(\sum_{v=0}^{h} Da(\theta - b_v))}$$

where $b_v$ is the difficulty parameter for category boundary $v$ of an item. In other contexts, the difficulty parameter $b_v$ can also be parameterized as $b_v = \beta - \tau_v$, where $\beta$ refers to the location (or overall difficulty) parameter and $\tau_v$ represents a threshold parameter for score category $v$ of an item. In the \texttt{irtQ} package, $K - 1$ difficulty parameters are necessary when an item has $K$ unique score categories because $b_0 = 0$. When a partial credit model is fit to data, $a$ is fixed to 1.

**bind.fill**  
*Bind Fill*

**Description**

This function creates a cbind matrix or rbind matrix using a list containing different length of numeric vectors.

**Usage**

```r
bind.fill(List, type = c("rbind", "cbind"))
```

**Arguments**

- **List** A list containing different length of numeric vectors
- **type** A character string specifying whether rbind is used or cbind is used.
Value

A matrix.

Author(s)

Hwanggyu Lim <hglim83@gmail.com>

Examples

```r
# sample list
score_list <- list(item1=c(0:3), item2=c(0:2), item3=c(0:5), item3=c(0:4))

# examples
# 1) create a rbind with the sample score list
bind.fill(score_list, type="rbind")

# 2) create a cbind with the sample score list
bind.fill(score_list, type="cbind")
```

---

bisection

The bisection method to find a root

Description

This function is a modified version of the bisection function in the cmna R package (Howard, 2017) to find a root of the function .funs with respect to its first argument. Unlike the bisection of the cmna, this bisection function accepts additional arguments of the function .fun.

Usage

```r
bisection(.fun, ..., lb, ub, tol = 1e-04, max.it = 100)
```

Arguments

- `.fun` A function for which the root is searched.
- `...` Additional arguments to be passed to `.fun`.
- `lb` A lower bound of the interval to be searched.
- `ub` An upper bound of the interval to be searched.
- `tol` The tolerance of error. Default is 1e-4.
- `max.it` The maximum number of iterations. Default is 100.

Details

The bisection method is a well-known root finding numerical algorithm that works for any continuous function when the lower (lb) and upper (ub) bounds with opposite signs are provided. This method repeatedly bisects the defined interval by two values with opposite signs until the absolute difference of two values becomes less than the error tolerance (tol) or the maximum number of iterations (max.it) is reached.
Value

A list with three internal objects. The first object is the root found, the second object is the number of iterations used, and the third object is the approximate accuracy of the root (i.e., absolute difference between the final two values with opposite signs).

Examples

```r
## example: find a theta corresponding to the probability of 
## correct answer using the item response function of 2PLM 
## (a = 1, b = 0.2)

# set a function of theta
find.th <- function(theta, p) {p - drm(theta=theta, a=1, b=0.2, D=1)}

# find the theta corresponding to p = 0.2
bisection(.fun=find.th, p=0.2, lb=-10, ub=10)$root

# find the theta corresponding to p = 0.8
bisection(.fun=find.th, p=0.8, lb=-10, ub=10)$root
```

bring.flexmirt

Import Item and Ability Parameters from IRT Software

Description

These functions import item and/or ability parameters from BILOG-MG 3, PARSCALE 4, flexMIRT, and mirt (R package).

Usage

```r
bring.flexmirt(
  file,
  type = c("par", "sco"),
  rePar = TRUE,
  rePar.gpc = TRUE,
  n.factor = 1
)
```
bring.bilog(file, type = c("par", "sco"))

bring.parscale(file, type = c("par", "sco"))

bring.mirt(x)

**Arguments**

- **file** A file name (including a directory) containing the item or ability parameters.
- **type** A character string indicating a type of output file. Available types are "par" for a file containing item parameter estimates and "sco" for a file containing ability parameter estimates.
- **rePar** A logical value. If TRUE and when the IRT dichotomous model (e.g., 3PLM) or GRM is fit to data, the item intercept and logit of item guessing parameters are reparameterized into the item difficulty and item guessing parameters, respectively. Default is TRUE.
- **rePar.gpc** A logical value. If TRUE and when (G)PCM is fit to data, the nominal model parameters in the flexMIRT parameter output file are reparameterized into the (G)PCM slope/difficulty parameters. Default is TRUE.
- **n.factor** A numeric value indicating the number of estimated factors. This argument should be specified when type = "sco". Default is 1.
- **x** An output object obtained from the function mirt.

**Details**

The `bring.flexmirt` was written by modifying the function `read.flexmirt` (Pritikin & Falk, 2020). The functions `bring.bilog` and `bring.parscale` were written by modifying the functions `read.bilog` and `read.parscale` (Weeks, 2010), respectively.

The file extensions for item parameter and ability files, respectively, are: ".par" and ".sco" for BILOG-MG and PARSCALE, and ".prm.txt" and ".sco.txt" for flexMIRT. For mirt, the name of the output object is specified by the user.

Although `bring.flexmirt` is able to extract multidimensional item and ability parameter estimates, this package only deals with unidimensional IRT methods.

For polytomous item parameters, `bring.flexmirt` and `bring.mirt` are able to import the item parameters of the graded response model and the (generalized) partial credit model.

**Value**

These functions return a list including several objects. Only for the output of flexMIRT, the results of multiple group analysis can be returned. In that case, each element of the list contains the estimation results for each group.

**Sample Output Files of IRT software**

To illustrate how to import the item parameter estimate files of PARSCALE 4 and flexMIRT using `bring.parscale` and `bring.flexmirt`, two item parameter estimate output files are included in this package.
Among the two output files, one of them is from PARSACLE 4 with a file extension of ".PAR" (i.e., "parscale_sample.PAR") and another one is from flexMIRT with a file extension of "-prm.txt" (i.e., "flexmirt_sample-prm.txt").

For the two item parameter estimate output files, both are mixed-format tests with 55 items consisting of fifty dichotomous items following the IRT 3PL model and five polytomous items with five categories following the graded response model. The examples below show how to import those output files.

Note

Regarding the item parameter files for any IRT software, only the internal object "full_df" in the returned list is necessary for the IRT linking. The object "full_df" is a data frame containing the item metadata in a test form (e.g., item parameters, number of categories, models). See info or simdat for more details about the item metadata.

Also, when item parameters are estimated using the partial credit or the generalized partial credit model, item step parameters are returned in the object "full_df". Item step parameters are the overall item difficulty (or location) parameter subtracted by the difficulty (or threshold) parameter for each category. See irtfit for more details about the parameterization of the (generalized) partial credit model.

cac_lee

Classification accuracy and consistency using Lee's (2010) approach.

Description

This function computes the classification accuracy and consistency indices for complex assessments using the method proposed by Lee (2010). The function can handle both dichotomous and polytomous item response theory (IRT) models.

Usage

cac_lee(x, cutscore, theta = NULL, weights = NULL, D = 1, cut.obs = TRUE)

Arguments

x A data frame containing the item metadata (e.g., item parameters, number of score categories, models ...). See est_irt, irtfit, info or simdat for more detail about the item metadata.
cutscore A numeric vector specifying the cut scores for classification. Cut scores are the points that separate different performance categories (e.g., pass vs. fail, or different grades).
theta A numeric vector of ability estimates. Ability estimates (theta values) are the individual proficiency estimates obtained from the IRT model. The theta parameter is optional and can be NULL.
weights An optional two-column data frame or matrix where the first column is the quadrature points (nodes) and the second column is the corresponding weights. This is typically used in quadrature-based IRT analysis.
D A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.
cut.obs A logical value. If TRUE, it indicates the cut scores on the observed-summed score metric. If FALSE, it indicates they are on the IRT theta score metric. Default is TRUE.
Details

The function works by first checking the provided inputs. If both theta and weights are NULL, the function will stop and return an error message. Depending on the provided inputs, the function will then compute the classification accuracy and consistency indices using either the quadrature points and corresponding weights (D method) or individual ability estimates (P method). The function returns a list containing the confusion matrix, marginal and conditional classification accuracy and consistency indices, probabilities of being assigned to each level category, and cut scores.

Value

A list containing the following elements:

- confusion: A confusion matrix showing the cross table between true and expected levels.
- marginal: A data frame showing the marginal classification accuracy and consistency indices.
- conditional: A data frame showing the conditional classification accuracy and consistency indices.
- prob.level: A data frame showing the probability of being assigned to each level category.
- cutscore: A numeric vector showing the cut scores used in the analysis.

---

cac_rud  

Description

This function computes the classification accuracy and consistency based on the methods proposed by Rudner (2001, 2005). It can handle both situations where the empirical ability distribution of the population is available and when individual ability estimates are available.
Usage

cac_rud(cutscore, theta = NULL, se, weights = NULL)

Arguments

cutscore  A numeric vector specifying the cut scores for classification. Cut scores are the points that separate different performance categories (e.g., pass vs. fail, or different grades).
theta     A numeric vector of ability estimates. Ability estimates (theta values) are the individual proficiency estimates obtained from the IRT model. The theta parameter is optional and can be NULL.
se         A numeric vector of the same length as theta indicating the standard errors of the ability estimates.
weights    An optional two-column data frame or matrix where the first column is the quadrature points (nodes) and the second column is the corresponding weights. This is typically used in quadrature-based IRT analysis.

Details

The function first checks the provided inputs for correctness. It then computes the probabilities that an examinee with a specific ability is assigned to each level category, and calculates the conditional classification accuracy and consistency for each theta value. Finally, it computes the marginal accuracy and consistency.

Value

A list containing the following elements:

- confusion: A confusion matrix showing the cross table between true and expected levels.
- marginal: A data frame showing the marginal classification accuracy and consistency indices.
- conditional: A data frame showing the conditional classification accuracy and consistency indices.
- prob.level: A data frame showing the probability of being assigned to each level category.
- cutscore: A numeric vector showing the cut scores used in the analysis.

```
**Description**

This function analyzes DIF on an item using CATSIB procedure (Nandakumar & Roussos, 2004), which is a modified version of SIBTEST (Shealy & Stout, 1993). The CATSIB procedure can be applied to a computerized adaptive testing (CAT) environment for differential item functioning (DIF) detection. In CATSIB, examinees are matched on IRT-based ability estimates adjusted by employing a regression correction method (Shealy & Stout, 1993) to reduce a statistical bias of the CATSIB statistic due to impact.

**Usage**

```r
catsib(
  x = NULL,
  data, 
  score = NULL,
  se = NULL,
  group, 
  focal.name, 
  D = 1,
  n.bin = c(80, 10),
  min.binsize = 3,
  max.del = 0.075,
  weight.group = c("comb", "foc", "ref"),
  alpha = 0.05,
  missing = NA,
  purify = FALSE,
  max.iter = 10,
  min.resp = NULL,
  method = "ML",
  range = c(-5, 5),
  norm.prior = c(0, 1),
  nquad = 41,
  weights = NULL,
  ncore = 1,
  verbose = TRUE,
  ...
)
```

**Arguments**

- **x**
  
  A data frame containing the item metadata (e.g., item parameters, number of categories, models ...). x should to be provided to estimate latent ability parameters when score = NULL or purify = TRUE. Default is NULL. See `est_irt`, `irtfit`, `info` or `simdat` for more detail about the item metadata.
data A matrix containing examinees’ response data of the items in the argument \( x \). A row and column indicate the examinees and items, respectively.

text

score A vector of examinees’ ability estimates. If the abilities are not provided (i.e., \( \text{score} = \text{NULL} \)), \text{catsib} computes the ability estimates before computing the CATSIB statistics. See \text{est_score} for more detail about scoring methods. Default is NULL.

text

se A vector of the standard errors of the ability estimates. The standard errors should be ordered in accordance with the order of the ability estimates specified in the \text{score} argument. Default is NULL.

text

group A numeric or character vector indicating group membership of examinees. The length of vector should be the same with the number of rows in the response data matrix.

text

focal.name A single numeric or character scalar representing the level associated with the focal group. For instance, given \( \text{group} = c(0, 1, 0, 1, 1) \) and ‘1’ indicating the focal group, set \text{focal.name} = 1.

D A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.

n.bin A vector of two positive integers to set the maximum and minimum numbers of bins (or intervals) on the ability scale. The first and second values indicate the maximum and minimum numbers of the bins, respectively. See below for more detail.

min.binsize A positive integer value to set the minimum size of each bin. To ensure stable statistical estimation, each bin is required to have a certain number of examinees (e.g, 3), at least, from both reference and focal groups if it was to be included in calculation of \( \hat{\beta} \). All bins with fewer than the minimum number are not used for the computation. Default is 3. See below for more detail.

max.del A numerical value to set the maximum permissible proportion of examinees to be deleted from either reference group or focal group when automatically determining the number of bins on the ability scale. Default is 0.075. See below for more detail.

weight.group A single character string to specify a target ability distribution over which the expectation of DIF measure, called \( \hat{\beta} \), and the corresponding standard error are computed. Available options are "comb" for the combined ability distribution from both the reference and focal groups, "foc" for the ability distribution of the focal group, and "ref" for the ability distribution of the reference group. Default is "comb". See below for more detail.

alpha A numeric value to specify significance \( \alpha \)-level of the hypothesis test using the CATSIB statistics. Default is 0.05.

missing A value indicating missing values in the response data set. Default is NA.

purify A logical value indicating whether a purification process will be implemented or not. Default is FALSE. See below for more detail.

max.iter A positive integer value specifying the maximum number of iterations for the purification process. Default is 10.
min.resp  A positive integer value specifying the minimum number of item responses for an examinee required to compute the ability estimate. Default is NULL. See details below for more information.

method  A character string indicating a scoring method. Available methods are "ML" for the maximum likelihood estimation, "WL" for the weighted likelihood estimation, "MAP" for the maximum a posteriori estimation, and "EAP" for the expected a posteriori estimation. Default method is "ML".

range  A numeric vector of two components to restrict the range of ability scale for the ML, WL, MLF, and MAP scoring methods. Default is c(-5, 5).

norm.prior  A numeric vector of two components specifying a mean and standard deviation of the normal prior distribution. These two parameters are used to obtain the gaussian quadrature points and the corresponding weights from the normal distribution. Default is c(0,1). Ignored if method is "ML" or "WL".

nquad  An integer value specifying the number of gaussian quadrature points from the normal prior distribution. Default is 41. Ignored if method is "ML", "WL", or "MAP".

weights  A two-column matrix or data frame containing the quadrature points (in the first column) and the corresponding weights (in the second column) of the latent variable prior distribution. The weights and quadrature points can be easily obtained using the function gen.weight. If NULL and method is "EAP", default values are used (see the arguments of norm.prior and nquad). Ignored if method is "ML", "WL", or "MAP".

ncore  The number of logical CPU cores to use. Default is 1. See est_score for details.

verbose  A logical value. If TRUE, the progress messages of purification procedure are suppressed. Default is TRUE.

...  Additional arguments that will be forwarded to the est_score function.

Details

In CATSIB procedure (Nandakumar & Roussos, 2004), because $\hat{\beta}^*$, which is the expected $\theta$ regressed on $\hat{\beta}$, is a continuous variable, the range of $\hat{\beta}^*$ is divided into $K$ equal intervals and examinees are classified into one of $K$ intervals on the basis of their $\hat{\beta}^*$. Then, any intervals that contain less than three examinees in either reference or focal groups were excluded from the computation of $\hat{\beta}$, which is a measure of the amount of DIF, to ensure stable statistical estimation. According to Nandakumar and Roussos (2004), a default minimum size of each bin is set to 3 in min.binsize.

To carefully choose the number of intervals (K), the catsib automatically determines it by gradually decreasing K from a larger to smaller numbers based the rule used in Nandakumar and Roussos (2004). Specifically, beginning with an arbitrary large number (e.g., 80), if more than a certain permissible percentage, let's say 7.5%, of examinees in either the reference or focal groups were removed, the catsib automatically decreases the number of bins by one unit until a total number of examinees in each group reaches to more than or equal to 92.5%. However, Nandakumar and Roussos (2004) recommended setting the minimum K to 10 to avoid a situation that extremely a few intervals are left, even if the number of remaining examinees in each group is less than 92.5%. Thus, the maximum and minimum number of bins are set to 80 and 10, respectively, as default in
n.bin. Also, a default maximum permissible proportion of examinees to be deleted from either reference group or focal group is set to 0.075 in max.del.

When it comes to the target ability distribution used to compute \( \hat{\beta} \), Li and Stout (1996) and Nandakumar and Roussos (2004) used the combined-group target ability distribution, which is a default option in weight.group. See Nandakumar and Roussos (2004) for more detail about the CATSIB method.

Although Nandakumar and Roussos (2004) did not propose a purification procedure for DIF analysis using CATSIB, the catsib can implement an iterative purification process in a similar way as in Lim, Choe, and Han (2022). Simply, at each iterative purification, examinees’ latent abilities are computed using purified items and scoring method specified in the method argument. The iterative purification process stops when no further DIF items are found or the process reaches a predetermined limit of iteration, which can be specified in the max.iter argument. See Lim et al. (2022) for more details about the purification procedure.

Scoring with a limited number of items can result in large standard errors, which may impact the effectiveness of DIF detection within the CATSIB procedure. The min.resp argument can be employed to avoid using scores with significant standard errors when calculating the CATSIB statistic, particularly during the purification process. For instance, if min.resp is not NULL (e.g., min.resp=5), item responses from examinees whose total item responses fall below the specified minimum number are treated as missing values (i.e., NA). Consequently, their ability estimates become missing values and are not utilized in computing the CATSIB statistic. If min.resp=NULL, an examinee’s score will be computed as long as there is at least one item response for the examinee.

Value

This function returns a list of four internal objects. The four objects are:

- **no_purify**
  A list of several sub-objects containing the results of DIF analysis without a purification procedure. The sub-objects are:
  - **dif_stat** A data frame containing the results of CATSIB statistics across all evaluated items. From the first column, each column indicates item’s ID, CATSIB (beta) statistic, standard error of the beta, standardized beta, p-value of the beta, sample size of the reference group, sample size of the focal group, and total sample size, respectively.
  - **dif_item** A numeric vector showing potential DIF items flagged by CATSIB statistic.
  - **contingency** A contingency table of each item used to compute CATSIB statistic.

- **purify**
  A logical value indicating whether the purification process was used.

- **with_purify**
  A list of several sub-objects containing the results of DIF analysis with a purification procedure. The sub-objects are:
  - **dif_stat** A data frame containing the results of CATSIB statistics across all evaluated items. From the first column, each column indicates item’s ID, CATSIB (beta) statistic, standard error of the beta, standardized beta, p-value of the beta, sample size of the reference group, sample size of the focal group, and total sample size, and nth iteration where the CATSIB statistic was computed, respectively.
**dif_item** A numeric vector showing potential DIF items flagged by CATSIB statistic.

**n.iter** A total number of iterations implemented for the purification.

**complete** A logical value indicating whether the purification process was completed. If FALSE, it means that the purification process reached the maximum iteration number but it was not complete.

**contingency** A contingency table of each item used to compute CATSIB statistic.

**alpha** A significance $\alpha$-level used to compute the p-values of RDIF statistics.

**covirt**

Asymptotic variance-covariance matrices of item parameter estimates

**Description**

This function calculates the analytical asymptotic variance-covariance matrices (e.g., Li & Lissitz, 2004; Thissen & Wainer, 1982) of item parameter estimates for dichotomous and polytomous IRT Models without examinee’s responses to test items, given a set of item parameter estimates and sample size. The square roots of variance terms in the matrices can be used as the asymptotic standard errors of maximum likelihood item parameter estimates.

**Usage**

```r
covirt(
  x,
  D = 1,
  nstd = 1000,
  pcm.loc = NULL,
  norm.prior = c(0, 1),
  nquad = 41,
  weights = NULL
)
```

**Arguments**

- `x` A data frame containing the item metadata (e.g., item parameters, number of categories, models ...). See `irtfit`, `info`, or `simdat` for more details about the item metadata. This data frame can be easily obtained using the function `shape_df`.
- `D` A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.
- `nstd` An integer value or a vector of integer values indicating a sample size. When a vector is specified, length of the vector must be the same as the number of test items in the argument `x`. Default is 1,000. See below for details.
- `pcm.loc` A vector of integer values indicating the locations of partial credit model (PCM) items. For the PCM items, the variance-covariance matrices are computed only for the item category difficulty parameters. Default is NULL. See below for details.
norm.prior  A numeric vector of two components specifying a mean and standard deviation of the normal prior distribution. These two parameters are used to obtain the gaussian quadrature points and the corresponding weights from the normal distribution. Default is c(0,1).

nquad  An integer value specifying the number of gaussian quadrature points from the normal prior distribution. Default is 41.

weights  A two-column matrix or data frame containing the theta values (in the first column) and the weights (in the second column) for the prior distribution. The weights and theta values can be easily obtained using the function gen.weight. If NULL, default values can be used for the prior distribution (see the arguments of norm.prior and nquad). Default is NULL.

Details
The standard errors obtained from the analytical approach are likely to represent lower bounds for the actual standard errors (Thissen & Wainer, 1982). Therefore, they may be useful for assessing the degree of precision of a set of item parameter estimates when the corresponding standard errors of the estimates are not presented in literature or research reports.

Sometimes item parameters need to be estimated using different sample size. If the item parameters in the argument x were calibrated with different number of examinees, a vector of different sample sizes should be specified in the argument nstd. Suppose that you want to compute the variance-covariance matrices of five IRT 3PLM items and the five items were calibrated with 500, 600, 1,000, 2,000, and 700 examinees, respectively. Then, nstd = c(500, 600, 1000, 2000, 700) must be specified.

Because you can specify only "GPCM" for both the partial credit model (PCM) or the generalized partial credit model (GPCM) in the item metadata, you must indicate which items are the PCM items through the argument pcm.loc. This is because the item category difficulty parameters are estimated from the PCM, meaning that the variance-covariance of item parameter estimates must be computed for the item category difficulty parameters. Suppose that you want to compute the variance-covariance matrices of five polytomous items and the last two items were calibrated with the PCM. Then, pcm.loc = c(4, 5) must be specified.

Value
A list of two internal objects. The first internal object contains a list of the variance-covariance matrices of item parameter estimates. The second internal object contains a list of the standard errors of item parameter estimates.

### drm

#### Dichotomous Response Model (DRM) Probabilities

**Description**

This function computes the probability of correct answers for multiple items for a given set of theta values using the IRT 1PL, 2PL, and 3PL models.

**Usage**

```r
drm(theta, a, b, g = NULL, D = 1)
```

**Arguments**

- `theta`: A vector of ability values.
- `a`: A vector of item discrimination (or slope) parameters.
- `b`: A vector of item difficulty (or threshold) parameters.
- `g`: A vector of item guessing parameters.
- `D`: A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.

**Details**

`g` does not need to be specified when the response probabilities of the 1PL and 2PL models are computed.

**Value**

This function returns a matrix where a row indicates the ability and a column represents the item.

dr

Description

This function fits unidimensional item response (IRT) models to a mixture of dichotomous and poly-
tomous data using the marginal maximum likelihood estimation via the expectation-maximization (MMLE-EM) algorithm (Bock & Aitkin, 1981). This function also implements the fixed item pa-
rameter calibration (FIPC; Kim, 2006). As Method A (Stocking, 1988), FIPC is one of useful online item calibration methods for computerized adaptive testing (CAT) to put the parameter estimates of pretest items on the same scale of operational item parameter estimates (Ban, Hanson, Wang, Yi, & Harris, 2001). For dichotomous items, IRT one-, two-, and three-parameter logistic models are available. For polytomous items, the graded response model (GRM) and the (generalized) partial credit model (GPCM) are available.

Usage

est_irt(
  x = NULL,
  data,

fix.id = NULL,
se = TRUE,
verbose = TRUE
)

Arguments

x A data frame containing the item metadata. This metadata is necessary to obtain the information of each item (i.e., number of score categories and IRT model) to be calibrated. You can easily create an empty item metadata using the function shape_df. When use.startval = TRUE, the item parameters specified in the item metadata are used as the starting values for the item parameter estimation. If x = NULL, the arguments of model and cats must be specified. Note that when fipc = TRUE to implement the FIPC method, the item metadata of a test form must be provided in the argument x. See below for details. Default is NULL.

data A matrix containing examinees’ response data for the items in the argument x. A row and column indicate the examinees and items, respectively.

D A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.

model A vector of character strings indicating what IRT model is used to calibrate each item. Available IRT models are "1PLM", "2PLM", "3PLM", and "DRM" for dichotomous items, and "GRM" and "GPCM" for polytomous items. "GRM" and "GPCM" represent the graded response model and (generalized) partial credit model, respectively. Note that "DRM" is considered as "3PLM" in this function. If a single character of the IRT model is specified, that model will be recycled across all items. The provided information in the model argument is used only when x = NULL and fipc = FALSE. Default is NULL.

cats A numeric vector specifying the number of score categories for each item. For example, a dichotomous item has two score categories. If a single numeric value is specified, that value will be recycled across all items. If cats = NULL and all specified models in the model argument are the dichotomous models
(i.e., 1PLM, 2PLM, 3PLM, or DRM), it assumes that all items have two score categories. The provided information in the cats argument is used only when x = NULL and fipc = FALSE. Default is NULL.

item.id A character vector of item IDs. If NULL, the item IDs are generated automatically. When fipc = TRUE and the Item IDs are given by the item.id argument, the Item IDs in the x argument are overridden. Default is NULL.

fix.a.1pl A logical value. If TRUE, the slope parameters of the 1PLM items are fixed to a specific value specified in the argument a.val.1pl. Otherwise, the slope parameters of all 1PLM items are constrained to be equal and estimated. Default is FALSE.

fix.a.gpcm A logical value. If TRUE, the GPCM items are calibrated with the partial credit model and the slope parameters of the GPCM items are fixed to a specific value specified in the argument a.val.gpcm. Otherwise, the slope parameter of each GPCM item is estimated. Default is FALSE.

fix.g A logical value. If TRUE, the guessing parameters of the 3PLM items are fixed to a specific value specified in the argument g.val. Otherwise, the guessing parameter of each 3PLM item is estimated. Default is FALSE.

a.val.1pl A numeric value. This value is used to fixed the slope parameters of the 1PLM items.

a.val.gpcm A numeric value. This value is used to fixed the slope parameters of the GPCM items.

g.val A numeric value. This value is used to fixed the guessing parameters of the 3PLM items.

use.aprior A logical value. If TRUE, a prior distribution for the slope parameters is used for the parameter calibration across all items. Default is FALSE.

use.bprior A logical value. If TRUE, a prior distribution for the difficulty (or threshold) parameters is used for the parameter calibration across all items. Default is FALSE.

use.gprior A logical value. If TRUE, a prior distribution for the guessing parameters is used for the parameter calibration across all 3PLM items. Default is TRUE.

aprior A list containing the information of the prior distribution for item slope parameters. Three probability distributions of Beta, Log-normal, and Normal distributions are available. In the list, a character string of the distribution name must be specified in the first internal argument and a vector of two numeric values for the two parameters of the distribution must be specified in the second internal argument. Specifically, when Beta distribution is used, "beta" should be specified in the first argument. When Log-normal distribution is used, "lnorm" should be specified in the first argument. When Normal distribution is used, "norm" should be specified in the first argument. In terms of the two parameters of the three distributions, see dbeta(), dlnorm(), and dnorm() in the stats package for more details.

bprior A list containing the information of the prior distribution for item difficulty (or threshold) parameters. Three probability distributions of Beta, Log-normal, and Normal distributions are available. In the list, a character string of the distribution name must be specified in the first internal argument and a vector of
two numeric values for the two parameters of the distribution must be specified in the second internal argument. Specifically, when Beta distribution is used, "beta" should be specified in the first argument. When Log-normal distribution is used, "lnorm" should be specified in the first argument. When Normal distribution is used, "norm" should be specified in the first argument. In terms of the two parameters of the three distributions, see dbeta(), dlnorm(), and dnorm() in the stats package for more details.

gprior A list containing the information of the prior distribution for item guessing parameters. Three probability distributions of Beta, Log-normal, and Normal distributions are available. In the list, a character string of the distribution name must be specified in the first internal argument and a vector of two numeric values for the two parameters of the distribution must be specified in the second internal argument. Specifically, when Beta distribution is used, "beta" should be specified in the first argument. When Log-normal distribution is used, "lnorm" should be specified in the first argument. When Normal distribution is used, "norm" should be specified in the first argument. In terms of the two parameters of the three distributions, see dbeta(), dlnorm(), and dnorm() in the stats package for more details.

missing A value indicating missing values in the response data set. Default is NA.

Quadrature A numeric vector of two components specifying the number of quadrature points (in the first component) and the symmetric minimum and maximum values of these points (in the second component). For example, a vector of c(49, 6) indicates 49 rectangular quadrature points over -6 and 6. The quadrature points are used in the E step of the EM algorithm. Default is c(49, 6).

weights A two-column matrix or data frame containing the quadrature points (in the first column) and the corresponding weights (in the second column) of the latent variable prior distribution. If not NULL, the scale of the latent ability distribution will be fixed to the scale of the provided quadrature points and weights. The weights and quadrature points can be easily obtained using the function gen.weight. If NULL, a normal prior density is used based on the information provided in the arguments of Quadrature, group.mean, and group.var). Default is NULL.

group.mean A numeric value to set the mean of latent variable prior distribution when weights = NULL. Default is 0. This value is fixed to remove the indeterminacy of item parameter scale when calibrating items. However, the scale of prior distribution is updated when FIPC is implemented.

group.var A positive numeric value to set the variance of latent variable prior distribution when weights = NULL. Default is 1. This value is fixed to remove the indeterminacy of item parameter scale when calibrating items. However, the scale of prior distribution is updated when FIPC is implemented.

EmpHist A logical value. If TRUE, the empirical histogram of the latent variable prior distribution is simultaneously estimated with the item parameters using Woods’s (2007) approach. The items are calibrated against the estimated empirical prior distributions. See below for details.

use.startval A logical value. If TRUE, the item parameters provided in the item metadata (i.e., the argument x) are used as the starting values for the item parameter esti-
Etol

A positive numeric value. This value sets the convergence criterion for E steps of the EM algorithm. Default is 1e-4.

MaxE

A positive integer value. This value determines the maximum number of the E steps in the EM algorithm. Default is 500.

control

A list of control parameters to be passed to the optimization function of \( \text{nlminb}() \) in the \textit{stats} package. The control parameters set the conditions of M steps of the EM algorithm. For example, the maximum number of iterations in each of the iterative M steps can be set by \( \text{control} = \text{list(iter.max=200)} \). Default maximum number of iterations in each M step is 200. See \( \text{nlminb}() \) in the \textit{stats} package for other control parameters.

fipc

A logical value. If TRUE, FIPC is implemented for item parameter estimation. When \( \text{fipc} = \text{TRUE} \), the information of which items are fixed needs to be provided via either \text{fix.loc} or \text{fix.id}. See below for details.

fipc.method

A character string specifying the FIPC method. Available methods include "OEM" for "No Prior Weights Updating and One EM Cycle (NWU-OEM; Wainer & Mislevy, 1990)" and "MEM" for "Multiple Prior Weights Updating and Multiple EM Cycles (MWU-MEM; Kim, 2006)." When \( \text{fipc.method = "OEM"} \), the maximum number of the E steps of the EM algorithm is set to 1 no matter what number is specified in the argument \text{MaxE}.

fix.loc

A vector of positive integer values specifying the locations of the items to be fixed in the item metadata (i.e., \( x \)) when the FIPC is implemented (i.e., \( \text{fipc = TRUE} \)). For example, suppose that five items located in the 1st, 2nd, 4th, 7th, and 9th rows of the item metadata \( x \) should be fixed. Then \( \text{fix.loc = c(1, 2, 4, 7, 9)} \). Note that when the \( \text{fix.id} \) argument is not NULL, the information provided into the \text{fix.loc} argument is ignored. See below for details.

fix.id

A vector of character strings specifying IDs of the items to be fixed when the FIPC is implemented (i.e., \( \text{fipc = TRUE} \)). For example, suppose that five items in which IDs are CMC1, CMC2, CMC3, CMC4, and CMC5 should be fixed and all item IDs are provided in the \( x \) argument or \text{item.id} argument. Then \( \text{fix.id} = \text{c("CMC1", "CMC2", "CMC3", "CMC4", "CMC5")} \). Note that when the \( \text{fix.id} \) argument is not NULL, the information provided into the \text{fix.loc} argument is ignored. See below for details.

se

A logical value. If FALSE, the standard errors of the item parameter estimates are not computed. Default is TRUE.

verbose

A logical value. If FALSE, all progress messages including the process information on the EM algorithm are suppressed. Default is TRUE.

Details

A specific form of a data frame should be used for the argument \( x \). The first column should have item IDs, the second column should contain unique score category numbers of the items, and the third column should include IRT models being fit to the items. The available IRT models are "1PLM", "2PLM", "3PLM", and "DRM" for dichotomous item data, and "GRM" and "GPCM" for polytomous item data. Note that "DRM" covers all dichotomous IRT models (i.e., "1PLM", "2PLM", "3PLM", and "4PLM"), and "GRM" covers all polytomous IRT models (i.e., "GPCM", "GRM", and "GPCM")
"2PLM", and "3PLM") and "GRM" and "GPCM" represent the graded response model and (generalized) partial credit model, respectively. The next columns should include the item parameters of the fitted IRT models. For dichotomous items, the fourth, fifth, and sixth columns represent the item discrimination (or slope), item difficulty, and item guessing parameters, respectively. When "1PLM" and "2PLM" are specified in the third column, NAs should be inserted in the sixth column for the item guessing parameters. For polytomous items, the item discrimination (or slope) parameters should be included in the fourth column and the item difficulty (or threshold) parameters of category boundaries should be contained from the fifth to the last columns. When the number of unique score categories differs between items, the empty cells of item parameters should be filled with NAs. In the *irtQ* package, the item difficulty (or threshold) parameters of category boundaries for GPCM are expressed as the item location (or overall difficulty) parameter subtracted by the threshold parameter for unique score categories of the item. Note that when an GPCM item has $K$ unique score categories, $K-1$ item difficulty parameters are necessary because the item difficulty parameter for the first category boundary is always 0. For example, if an GPCM item has five score categories, four item difficulty parameters should be specified. An example of a data frame with a single-format test is as follows:

<table>
<thead>
<tr>
<th>ITEM</th>
<th>N</th>
<th>Model</th>
<th>a</th>
<th>b</th>
<th>NaN</th>
</tr>
</thead>
<tbody>
<tr>
<td>ITEM1</td>
<td>2</td>
<td>1PLM</td>
<td>1.000</td>
<td>1.461</td>
<td>NA</td>
</tr>
<tr>
<td>ITEM2</td>
<td>2</td>
<td>2PLM</td>
<td>1.921</td>
<td>-1.049</td>
<td>NA</td>
</tr>
<tr>
<td>ITEM3</td>
<td>2</td>
<td>3PLM</td>
<td>1.736</td>
<td>1.501</td>
<td>0.203</td>
</tr>
<tr>
<td>ITEM4</td>
<td>2</td>
<td>3PLM</td>
<td>0.835</td>
<td>-1.049</td>
<td>0.182</td>
</tr>
<tr>
<td>ITEM5</td>
<td>2</td>
<td>DRM</td>
<td>0.926</td>
<td>0.394</td>
<td>0.099</td>
</tr>
</tbody>
</table>

And an example of a data frame for a mixed-format test is as follows:

<table>
<thead>
<tr>
<th>ITEM</th>
<th>N</th>
<th>Model</th>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
<th>NaN</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

See IRT Models section in the page of *irtQ-package* for more details about the IRT models used in the *irtQ* package. An easier way to create a data frame for the argument *x* is by using the function `shape_df`.

To fit the IRT models to data, the IRT model and the number of score category information for the estimated items must be provided as well as the item response data. There are two way to provide the IRT model and score category information. The first way is to provide the item metadata to the argument *x*. As explained above, the item metadata can be easily created by the function `shape_df`. The second way is specify the IRT models and the score category information into the arguments of `model` and `cats`. Thus, if *x=NULL*, the specified information in `model` and `cats` are used.

To implement FIPC, however, the item metadata must be provided in the argument *x*. This is because the item parameters of the fixed items in the item metadata are used to estimate the characteristic of the underlying latent variable prior distribution when calibrating the rest of freely estimated items. More specifically, the underlying latent variable prior distribution of the fixed items is esti-
estimated during the calibration of the freely estimated items to put the item parameters of the freely estimated items on the scale of the fixed item parameters (Kim, 2006).

In terms of approaches for FIPC, Kim (2006) described five different methods. Among them, two methods are available in the function `est_irt`. The first method is "NWU-OEM" where uses just one E step in the EM algorithm, involving data from only the fixed items, and just one M step, involving data from only non-fixed items. This method is suggested by Wainer and Mislevy (1990) in the context of online calibration. This method can be implemented by setting `fipc.method = "OEM"`. The second method is "MWU-MEM" which iteratively updates the latent variable prior distribution and finds the parameter estimates of the non-fixed items. In this method, the same procedure of NWU-OEM method is applied to the first EM cycle. From the second EM cycle, both the parameters of non-fixed items and the weights of the prior distribution are concurrently updated. This method can be implemented by setting `fipc.method = "MEM"`. See Kim (2006) for more details.

When `fipc = TRUE`, the information of which items are fixed needs to be provided via either `fix.loc` or `fix.id`. For example, suppose that five items in which IDs are CMC1, CMC2, CMC3, CMC4, and CMC5 should be fixed and all item IDs are provided in `X` or `item.id`. Also, the five items are located in the 1st through 5th rows of the item metadata (i.e., `x`). Then the item metadata of the five items can be fixed by setting `fix.loc = c(1, 2, 3, 4, 5)` or `fix.id = c("CMC1", "CMC2", "CMC3", "CMC4", "CMC5")`. Note that if both arguments are not NULL, the information provided into the `fix.loc` argument is ignored.

When `EmpHist = TRUE`, the empirical histogram (i.e., densities at the quadrature points) of latent variable prior distribution is simultaneously estimated with the item parameters. If `fipc = TRUE` given `EmpHist = TRUE`, the scale parameters of the empirical prior distribution are estimated as well. If `fipc = FALSE` given `EmpHist = TRUE`, the scale parameters of the empirical prior distribution are fixed to the values specified in the arguments of `group.mean` and `group.var`. When `EmpHist = FALSE`, the normal prior distribution is used during the item parameter estimation. If `fipc = TRUE` given `EmpHist = FALSE`, the scale parameters of the normal prior distribution are estimated as well as the item parameters. If `fipc = FALSE` given `EmpHist = FALSE`, the scale parameters of the normal prior distribution are fixed to the values specified in the arguments of `group.mean` and `group.var`.

**Value**

This function returns an object of class `est_irt`. Within this object, several internal objects are contained such as:

- `estimates`: A data frame containing both the item parameter estimates and the corresponding standard errors of estimates.
- `par.est`: A data frame containing the item parameter estimates.
- `se.est`: A data frame containing the standard errors of the item parameter estimates. Note that the standard errors are estimated using the cross-production approximation method (Meilijson, 1989).
- `pos.par`: A data frame containing the position number of each item parameter being estimated. The position information is useful when interpreting the variance-covariance matrix of item parameter estimates.
- `covariance`: A matrix of variance-covariance matrix of item parameter estimates.
loglikelihood A sum of the log-likelihood values of the observed data set (marginal log-likelihood) across all items in the data set.
aic A model fit statistic of Akaike information criterion based on the loglikelihood.
bic A model fit statistic of Bayesian information criterion based on the loglikelihood.
group.par A data frame containing the mean, variance, and standard deviation of latent variable prior distribution.
weights A two-column data frame containing the quadrature points (in the first column) and the corresponding weights (in the second column) of the (updated) latent variable prior distribution.
posterior.dist A matrix of normalized posterior densities for all the response patterns at each of the quadrature points. The row and column indicate each individual’s response pattern and the quadrature point, respectively.
data A data.frame of the examinees’ response data set.
scale.D A scaling factor in IRT models.
ncase A total number of response patterns.
nitem A total number of items included in the response data.
Etol A convergence criteria for E steps of the EM algorithm.
MaxE The maximum number of E steps in the EM algorithm.
aprior A list containing the information of the prior distribution for item slope parameters.
gprior A list containing the information of the prior distribution for item guessing parameters.
npar.est A total number of the estimated parameters.
niter The number of EM cycles completed.
maxpar.diff A maximum item parameter change when the EM cycles were completed.
EMtime Time (in seconds) spent for the EM cycles.
SEtime Time (in seconds) spent for computing the standard errors of the item parameter estimates.
TotalTime Time (in seconds) spent for total computation.
test.1 Status of the first-order test to report if the gradients has vanished sufficiently for the solution to be stable.
test.2 Status of the second-order test to report if the information matrix is positive definite, which is a prerequisite for the solution to be a possible maximum.
var.note A note to report if the variance-covariance matrix of item parameter estimates is obtainable from the information matrix.
fipc A logical value to indicate if FIPC was used.
fipc.method A method used for the FIPC.
fix.loc A vector of integer values specifying the locations of the fixed items when the FIPC was implemented.

The internal objects can be easily extracted using the function `getirt`.

**Description**

This function performs the fixed ability parameter calibration (FAPC), often called Method A, which is the maximum likelihood estimation of item parameters given the ability estimates (Baker & Kim, 2004; Ban, Hanson, Wang, Yi, & Harris, 2001; Stocking, 1988). Also, this could be considered as a special type of the joint maximum likelihood estimation where only one cycle of parameter estimation is implemented given the ability estimates (Birnbaum, 1968). FAPC is one of potentially useful online item calibration methods for computerized adaptive testing (CAT) to put the parameter estimates of pretest items on the same scale of operational item parameter estimates and recalibrate the operational items to evaluate the parameter drifts of the operational items (Chen & Wang, 2016; Stocking, 1988).

**Usage**

```r
est_item(
  x = NULL,  # Input data
  data,     # Dataframe containing the data
  score,    # Vectorcontaining the scores
  D = 1,    # Data format
  model = NULL,  # Model specification
  cats = NULL,  # Category information
)```

)

**Arguments**

- **x**: A data frame containing the item metadata. This metadata is necessary to obtain the information of each item (i.e., number of score categories and IRT model) to be calibrated. You can easily create an empty item metadata using the function `shape_df`. When `use.startval = TRUE`, the item parameters specified in the item metadata are used as the starting values for the item parameter estimation. If `x = NULL`, the arguments of `model` and `cats` must be specified. See `irtfit`, `info` or `simdat` for more details about the item metadata. Default is `NULL`.

- **data**: A matrix containing examinees’ response data for the items in the argument `x`. A row and column indicate the examinees and items, respectively.

- **score**: A vector of examinees’ ability estimates. Length of the vector must be the same as the number of rows in the response data set.

- **D**: A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.

- **model**: A vector of character strings indicating what IRT model is used to calibrate each item. Available IRT models are "1PLM", "2PLM", "3PLM", and "DRM" for dichotomous items, and "GRM" and "GPCM" for polytomous items. "GRM" and "GPCM" represent the graded response model and (generalized) partial credit model, respectively. Note that "DRM" is considered as "3PLM" in this function. If a single character of the IRT model is specified, that model will be recycled across all items. The provided information in the `model` argument is used only when `x = NULL`. Default is `NULL`.

- **cats**: A numeric vector specifying the number of score categories for each item. For example, a dichotomous item has two score categories. If a single numeric value is specified, that value will be recycled across all items. If `cats = NULL` and all specified models in the `model` argument are the dichotomous models (i.e., 1PLM, 2PLM, 3PLM, or DRM), it assumes that all items have two score
categories. The provided information in the `cats` argument is used only when `x = NULL`. Default is `NULL`.

**item.id**
A character vector of item IDs. If `NULL`, the item IDs are generated automatically. Default is `NULL`.

**fix.a.1pl**
A logical value. If `TRUE`, the slope parameters of the 1PLM items are fixed to a specific value specified in the argument `a.val.1pl`. Otherwise, the slope parameters of all 1PLM items are constrained to be equal and estimated. Default is `FALSE`.

**fix.a.gpcm**
A logical value. If `TRUE`, the GPCM items are calibrated with the partial credit model and the slope parameters of the GPCM items are fixed to a specific value specified in the argument `a.val.gpcm`. Otherwise, the slope parameter of each GPCM item is estimated. Default is `FALSE`.

**fix.g**
A logical value. If `TRUE`, the guessing parameters of the 3PLM items are fixed to a specific value specified in the argument `g.val`. Otherwise, the guessing parameter of each 3PLM item is estimated. Default is `FALSE`.

**a.val.1pl**
A numeric value. This value is used to fix the slope parameters of the 1PLM items.

**a.val.gpcm**
A numeric value. This value is used to fix the slope parameters of the GPCM items.

**g.val**
A numeric value. This value is used to fix the guessing parameters of the 3PLM items.

**use.aprior**
A logical value. If `TRUE`, a prior distribution for the slope parameters is used for the parameter calibration across all items. Default is `FALSE`.

**use.bprior**
A logical value. If `TRUE`, a prior distribution for the difficulty (or threshold) parameters is used for the parameter calibration across all items. Default is `FALSE`.

**use.gprior**
A logical value. If `TRUE`, a prior distribution for the guessing parameters is used for the parameter calibration across all 3PLM items. Default is `TRUE`.

**aprior**
A list containing the information of the prior distribution for item slope parameters. Three probability distributions of Beta, Log-normal, and Normal distributions are available. In the list, a character string of the distribution name must be specified in the first internal argument and a vector of two numeric values for the two parameters of the distribution must be specified in the second internal argument. Specifically, when Beta distribution is used, "beta" should be specified in the first argument. When Log-normal distribution is used, "lnorm" should be specified in the first argument. When Normal distribution is used, "norm" should be specified in the first argument. In terms of the two parameters of the three distributions, see `dbeta()`, `dlnorm()`, and `dnorm()` in the `stats` package for more details.

**bprior**
A list containing the information of the prior distribution for item difficulty (or threshold) parameters. Three probability distributions of Beta, Log-normal, and Normal distributions are available. In the list, a character string of the distribution name must be specified in the first internal argument and a vector of two numeric values for the two parameters of the distribution must be specified in the second internal argument. Specifically, when Beta distribution is used,
"beta" should be specified in the first argument. When Log-normal distribution is used, "lnorm" should be specified in the first argument. When Normal distribution is used, "norm" should be specified in the first argument. In terms of the two parameters of the three distributions, see dbeta(), dlnorm(), and dnorm() in the stats package for more details.

gprior
A list containing the information of the prior distribution for item guessing parameters. Three probability distributions of Beta, Log-normal, and Normal distributions are available. In the list, a character string of the distribution name must be specified in the first internal argument and a vector of two numeric values for the two parameters of the distribution must be specified in the second internal argument. Specifically, when Beta distribution is used, "beta" should be specified in the first argument. When Log-normal distribution is used, "lnorm" should be specified in the first argument. When Normal distribution is used, "norm" should be specified in the first argument. In terms of the two parameters of the three distributions, see dbeta(), dlnorm(), and dnorm() in the stats package for more details.

missing
A value indicating missing values in the response data set. Default is NA.

use.startval
A logical value. If TRUE, the item parameters provided in the item metadata (i.e., the argument x) are used as the starting values for the item parameter estimation. Otherwise, internal starting values of this function are used. Default is FALSE.

control
A list of control parameters to be passed to the optimization function of nlmminb() in the stats package. The control parameters set the conditions of the item parameter estimation process such as the maximum number of iterations. See nlmminb() in the stats package for details.

verbose
A logical value. If FALSE, all progress messages are suppressed. Default is TRUE.

Details
In most cases, the function est_item will return successfully converged item parameter estimates using the default internal starting values. However, if there is a convergence problem in the calibration, one possible solution is using different starting values. When the item parameter values are specified in the item metadata (i.e., the argument x), those values can be used as the starting values for the item parameter calibration by setting use.startval = TRUE.

Value
This function returns an object of class est_item. Within this object, several internal objects are contained such as:

estimates
A data frame containing both the item parameter estimates and the corresponding standard errors of estimates.

par.est
A data frame containing the item parameter estimates.

se.est
A data frame containing the standard errors of the item parameter estimates. Note that the standard errors are estimated using observed information functions.
A data frame containing the position number of item parameters being estimated. The position information is useful when interpreting the variance-covariance matrix of item parameter estimates.

covariance

A matrix of variance-covariance matrix of item parameter estimates.

loglikelihood

A sum of the log-likelihood values of the complete data set across all estimated items.

data

A data frame of the examinees’ response data set.

score

A vector of the examinees’ ability values used as the fixed effects.

scale.D

A scaling factor in IRT models.

convergence

A string indicating the convergence status of the item parameter estimation.

nitem

A total number of items included in the response data.

deleted.item

The items which have no item response data. Those items are excluded from the item parameter estimation.

npar.est

A total number of the estimated parameters.

n.response

An integer vector indicating the number of item responses for each item used to estimate the item parameters.

TotalTime

Time (in seconds) spent for total computation.

The internal objects can be easily extracted using the function `getirt`.

Multiple-group item calibration using MMLE-EM algorithm

Description

This function conducts a multiple-group item calibration (Bock & Zimowski, 1997) using the marginal maximum likelihood estimation via the expectation-maximization (MMLE-EM) algorithm (Bock & Aitkin, 1981). This function also implements the multiple-group fixed item parameter calibration (MG-FIPC; e.g., Kim & Kolen, 2016). The MG-FIPC is an extension of the single-group FIPC method (Kim, 2006) to multiple-group data. For dichotomous items, IRT one-, two-, and three-parameter logistic models are available. For polytomous items, the graded response model (GRM) and the (generalized) partial credit model (GPCM) are available.

Usage

```r
est_mg(
  x = NULL,
  data,
  group.name = NULL,
  D = 1,
  model = NULL,
  cats = NULL,
  item.id = NULL,
  free.group = NULL,

  fipc = FALSE,
)```
est_mg

fipc.method = "MEM",
fix.loc = NULL,
fix.id = NULL,
se = TRUE,
verbose = TRUE
)

Arguments

x A list containing item metadata across all groups to be analyzed. For example, if five group data are analyzed, the list should include five internal objects of the item metadata for the five groups. The internal objects of the list should be ordered in accordance with the order of the group names specified in the group.name argument. An item metadata of each group test contains the meta information about items (i.e., number of score categories and IRT model) to be calibrated. See est_irt, irtfit, info or simdat for more details about the item metadata. When use.startval = TRUE, the item parameters specified in the item metadata are used as the starting values for the item parameter estimation. If x = NULL, the model and cats arguments must be specified. Note that when fipc = TRUE to implement the MG-FIPC method, a list of item metadata must be provided into x. In other words, x cannot be NULL in that case. Default is NULL.

data A list containing item response matrices across all groups to be analyzed. For example, if five group data are analyzed, the list should include five internal objects of the response data matrices for the five groups. The internal objects of the list should be ordered in accordance with the order of the group names specified in the group.name argument. An item response matrix for each group includes examinees' response data corresponding to the items in the item metadata of that group. In a response data matrix, a row and column indicate the examinees and items, respectively.

group.name A vector of character strings indicating group names. For example, if five group data are analyzed, group.names = c("G1", "G2", "G3", "G4", "G5"). Any group names can be used.

D A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.

model A list containing character vectors of the IRT models used to calibrate items across all groups' data. For example, if five group data are analyzed, the list should include five internal objects of the character vectors for the five groups. The internal objects of the list should be ordered in accordance with the order of the group names specified in the group.name argument. Available IRT models are "1PLM", "2PLM", "3PLM", and "DRM" for dichotomous items, and "GRM" and "GPCM" for polytomous items. "GRM" and "GPCM" represent the graded response model and (generalized) partial credit model, respectively. Note that "DRM" is considered as "3PLM" in this function. If a single character of the IRT model is provided in the internal objects of the list, that model will be recycled across all items in the corresponding groups. The provided information in the model argument is used only when x = NULL and fipc = FALSE. Default is NULL.
cats
A list containing numeric vectors specifying the number of score categories of items across all groups’ data to be analyzed. For example, if five group data are analyzed, the list should include five internal objects of the numeric vectors for the five groups. The internal objects of the list should be ordered in accordance with the order of the group names specified in the group.name argument. If a single numeric value is specified in the internal objects of the list, that value will be recycled across all items in the corresponding groups. If cats = NULL and all specified models in the model argument are the dichotomous models (i.e., 1PLM, 2PLM, 3PLM, or DRM), the function assumes that all items have two score categories across all groups. The provided information in the cats argument is used only when x = NULL and fipc = FALSE. Default is NULL.

item.id
A list containing character vectors of item IDs across all groups’ data to be analyzed. For example, if five group data are analyzed, the list should include five internal objects of the character vectors of item IDs for the five groups. The internal objects of the list should be ordered in accordance with the order of the group names specified in the group.name argument. When fipc = TRUE and the Item IDs are given by the item.id argument, the Item IDs in the x argument are overridden. Default is NULL.

free.group
A numeric or character vector indicating groups in which scales (i.e., a mean and standard deviation) of the latent ability distributions are freely estimated. The scales of other groups not specified in this argument are fixed based on the information provided in the group.mean and group.var arguments, or the weights argument. For example, suppose that five group data are analyzed and the corresponding group names are "G1", "G2", "G3", "G4", and "G5", respectively. If the scales of the 2nd through 5th groups are freely estimated, then free.group = c(2, 3, 4, 5) or free.group = c("G3", "G4", "G4", "G5"). Also, the first group (i.e., "G1") will have the fixed scale (e.g., a mean of 0 and variance of 1 when group.mean = 0, group.var = 1, and weights = NULL).

fix.a.1pl
A logical value. If TRUE, the slope parameters of the 1PLM items are fixed to a specific value specified in the argument a.val.1pl. Otherwise, the slope parameters of all 1PLM items are constrained to be equal and estimated. Default is FALSE.

fix.a.gpcm
A logical value. If TRUE, the GPCM items are calibrated with the partial credit model and the slope parameters of the GPCM items are fixed to a specific value specified in the argument a.val.gpcm. Otherwise, the slope parameter of each GPCM item is estimated. Default is FALSE.

fix.g
A logical value. If TRUE, the guessing parameters of the 3PLM items are fixed to a specific value specified in the argument g.val. Otherwise, the guessing parameter of each 3PLM item is estimated. Default is FALSE.

a.val.1pl
A numeric value. This value is used to fixed the slope parameters of the 1PLM items.

a.val.gpcm
A numeric value. This value is used to fixed the slope parameters of the GPCM items.

g.val
A numeric value. This value is used to fixed the guessing parameters of the 3PLM items.

use.aprior
A logical value. If TRUE, a prior distribution for the slope parameters is used for the parameter calibration across all items. Default is FALSE.
use.bprior  A logical value. If TRUE, a prior distribution for the difficulty (or threshold) parameters is used for the parameter calibration across all items. Default is FALSE.

use.gprior A logical value. If TRUE, a prior distribution for the guessing parameters is used for the parameter calibration across all 3PLM items. Default is TRUE.

aprior A list containing the information of the prior distribution for item slope parameters. Three probability distributions of Beta, Log-normal, and Normal distributions are available. In the list, a character string of the distribution name must be specified in the first internal argument and a vector of two numeric values for the two parameters of the distribution must be specified in the second internal argument. Specifically, when Beta distribution is used, "beta" should be specified in the first argument. When Log-normal distribution is used, "lnorm" should be specified in the first argument. When Normal distribution is used, "norm" should be specified in the first argument. In terms of the two parameters of the three distributions, see dbeta(), dlnorm(), and dnorm() in the stats package for more details.

bprior A list containing the information of the prior distribution for item difficulty (or threshold) parameters. Three probability distributions of Beta, Log-normal, and Normal distributions are available. In the list, a character string of the distribution name must be specified in the first internal argument and a vector of two numeric values for the two parameters of the distribution must be specified in the second internal argument. Specifically, when Beta distribution is used, "beta" should be specified in the first argument. When Log-normal distribution is used, "lnorm" should be specified in the first argument. When Normal distribution is used, "norm" should be specified in the first argument. In terms of the two parameters of the three distributions, see dbeta(), dlnorm(), and dnorm() in the stats package for more details.

gprior A list containing the information of the prior distribution for item guessing parameters. Three probability distributions of Beta, Log-normal, and Normal distributions are available. In the list, a character string of the distribution name must be specified in the first internal argument and a vector of two numeric values for the two parameters of the distribution must be specified in the second internal argument. Specifically, when Beta distribution is used, "beta" should be specified in the first argument. When Log-normal distribution is used, "lnorm" should be specified in the first argument. When Normal distribution is used, "norm" should be specified in the first argument. In terms of the two parameters of the three distributions, see dbeta(), dlnorm(), and dnorm() in the stats package for more details.

missing A value indicating missing values in the response data set. Default is NA.

Quadrature A numeric vector of two components specifying the number of quadrature points (in the first component) and the symmetric minimum and maximum values of these points (in the second component). For example, a vector of c(49, 6) indicates 49 rectangular quadrature points over -6 and 6. The quadrature points are used in the E step of the EM algorithm. Default is c(49, 6).

weights A two-column matrix or data frame containing the quadrature points (in the first column) and the corresponding weights (in the second column) of the latent
variable prior distribution. If not NULL, the scale of the latent ability distributions of the groups that are not freely estimated (i.e., the groups not specified in the free.group argument) are fixed to the scale of the provided quadrature points and weights. The weights and quadrature points can be easily obtained using the function gen.weight. If NULL, a normal prior density is used based on the information provided in the arguments of Quadrature, group.mean, and group.var). Default is NULL.

**group.mean**
A numeric value to set the mean of latent variable prior distribution when weights = NULL. Default is 0. The means of the distributions of the groups that are not specified in the free.group are fixed to the value provided in this argument to remove the indeterminacy of item parameter scales.

**group.var**
A positive numeric value to set the variance of latent variable prior distribution when weights = NULL. Default is 1. The variances of the distributions of the groups that are not specified in the free.group are fixed to the value provided in this argument to remove the indeterminacy of item parameter scales.

**EmpHist**
A logical value. If TRUE, the empirical histograms of the latent variable prior distributions across all groups are simultaneously estimated with the item parameters using Woods’s (2007) approach. The items are calibrated against the estimated empirical prior distributions.

**use.startval**
A logical value. If TRUE, the item parameters provided in the item metadata (i.e., the argument x) are used as the starting values for the item parameter estimation. Otherwise, internal starting values of this function are used. Default is FALSE.

**Etol**
A positive numeric value. This value sets the convergence criterion for E steps of the EM algorithm. Default is 1e-3.

**MaxE**
A positive integer value. This value determines the maximum number of the E steps in the EM algorithm. Default is 500.

**control**
A list of control parameters to be passed to the optimization function of nlminb() in the stats package. The control parameters set the conditions of M steps of the EM algorithm. For example, the maximum number of iterations in each of the iterative M steps can be set by control = list(iter.max=200). Default maximum number of iterations in each M step is 200. See nlminb() in the stats package for other control parameters.

**fipc**
A logical value. If TRUE, the MG-FIPC is implemented for item parameter estimation. When fipc = TRUE, the information of which items are fixed needs to be provided via either of fix.loc or fix.id. See below for details.

**fipc.method**
A character string specifying the FIPC method. Available methods include "OEM" for "No Prior Weights Updating and One EM Cycle (NWU-OEM; Wainer & Mislevy, 1990)" and "MEM" for "Multiple Prior Weights Updating and Multiple EM Cycles (MWU-MEM; Kim, 2006)." When fipc.method = "OEM", the maximum number of the E steps of the EM algorithm is set to 1 no matter what number is specified in the argument MaxE.

**fix.loc**
A list of positive integer vectors. Each internal integer vector indicates the locations of the items to be fixed in the item metadata (i.e., x) for each group when the MG-FIPC is implemented (i.e., fipc = TRUE). The internal objects of the list should be ordered in accordance with the order of group names specified
in the group.name argument. For example, suppose that three group data are analyzed. For the first group data, the 1st, 3rd, and 5th items are fixed, for the second group data, the 2nd, 3rd, 4th, and 7th items are fixed, and for the third group data, the 1st, 2nd, and 6th items are fixed. Then fix.loc = list(c(1, 3, 5), c(2, 3, 4, 7), c(1, 2, 6)). Note that when the fix.id argument is not NULL, the information provided into the fix.loc argument is ignored. See below for details.

fix.id
A vector of character strings specifying IDs of the items to be fixed when the MG-FIPC is implemented (i.e., fipc = TRUE). For example, suppose that three group data are analyzed. For the first group data, three items in which IDs are G1I1, C1I1, are C1I2 are fixed. For the second group data, four items in which IDs are C1I1, C1I2, C2I1, and C2I2 are fixed. For the third group data, three items in which IDs are C2I1, C2I2, and G3I1 are fixed. Then there are six unique items to be fixed across the three groups (i.e., G1I1, C1I1, C1I2, C2I1, C2I2, and G3I1) because C1I1 and C1I2 are common items between the first and the second groups, and C2I1 and C2I2 are common items between the second and the third groups. Thus, fix.id = c("G1I1", "C1I1", "C1I2", "C2I1", "C2I2", "G3I1") should be specified. Note that when the fix.id argument is not NULL, the information provided into the fix.loc argument is ignored. See below for details.

se
A logical value. If FALSE, the standard errors of the item parameter estimates are not computed. Default is TRUE.

verbose
A logical value. If FALSE, all progress messages including the process information on the EM algorithm are suppressed. Default is TRUE.

Details
The multiple-group (MG) item calibration (Bock & Zimowski, 1996) provides a unified approach to the testing situations or problems involving multiple groups such as nonequivalent groups equating, vertical scaling, and identification of differential item functioning (DIF). In such contexts, typically there exist test takers from different groups responding to the same test form or to the common items shared between different test forms.

The goal of the MG item calibration is to estimate the item parameters and the latent ability distributions of the multiple groups simultaneously (Bock & Zimowski, 1996). In the {irtQ} package, the est_mg function supports the MG item calibration using the marginal maximum likelihood estimation via the expectation-maximization (MMLE-EM) algorithm (Bock & Aitkin, 1981). In addition, The function also supports the MG fixed item parameter calibration (MG-FIPC; e.g., Kim & Kolen, 2016) if the parameters of certain items need to be fixed across multiple test forms,

In MG IRT analyses, it is commonly seen that the test forms of multiple groups share some common (or anchor) items between the groups. By default the common items that have the same item IDs between different groups are automatically constrained so that they can have the same item parameter estimates across the groups in the code est_mg function.

Most of the features of the est_mg function are similar with those of the est_irt function. The main difference is that several arguments in the est_mg functions take an object of a list format which contains several internal objects corresponding to the groups to be analyzed. Those arguments include x, data, model, cats, item.id, and fix.loc.
Also, the `est_mg` has two new arguments, the `group.name` and `free.group`. The `group.name` is required to assign a unique group name to each group. The order of internal objects in the lists provided in the `x`, `data`, `model`, `cats`, `item.id`, and `fix.loc` arguments must match that of the group names supplied to the `group.name` argument.

The `free.group` argument is necessary to indicate the freed groups in which scales (i.e., a mean and standard deviation) of the latent ability distributions are estimated. When no item parameters are fixed (i.e., `fipc = FALSE`), at least one group should have a fixed scale (e.g., a mean of 0 and variance of 1) of the latent ability distribution among the multiple groups that shares common items in order to solve the scale indeterminancy in IRT estimation. By providing which are the freed groups into the `free.group` argument, the scales of the groups specified in the `free.group` argument are freely estimated while the scales of all other groups not specified in the argument are fixed based on the information provided in the `group.mean` and `group.var` arguments or the `weights` argument.

The situations where the implementation of MG-FIPC is necessary arise when the new latent ability scales from MG test data are linked to the established scale (e.g., the scale of an item bank). In a single run of MG-FIPC method, all the parameters of freed items across multiple test forms and the density of the latent ability distributions for multiple groups can be estimated on the scale of the fixed items (Kim & Kolen, 2016). Suppose that three different test forms, Form 1, Form 2, and Form 3, are administered to three nonequivalent groups, Group1, Group2, and Group3. Form 1 and Form 2 share 12 common items, C1I1 to C1I12, and Form 2 and Form 3 share 10 common items, C2I1 to C2I10, while there is no common item between Form 1 and Form 3. Also, suppose that all unique items of Form 1 came from an item bank, which were already calibrated on the scale of the item bank. In this case, the goal of the MG-FIPC is to estimate the parameters of all the items across the three test forms, except the unique items in Form 1, and the latent ability distributions of the three groups on the same scale of the item bank. To accomplish this task, the unique items in Form 1 need to be fixed during the MG-FIPC to link the current MG test data and the item bank.

The `est_mg` function can implement the MG-FIPC by setting `fipc = TRUE`. Then, the information of which items are fixed needs to be supplied via either of `fix.loc` or `fix.id`. When utilizing the `fix.loc` argument, a list of the locations of the items that are fixed in each group test form should be prepared. For example, suppose that three group data are analyzed. For the first group test form, the 1st, 3rd, and 5th items are fixed, for the second group test form, the 2nd, 3rd, 4th, and 7th items are fixed, and for the third group test form, the 1st, 2nd, and 6th items are fixed. Then `fix.loc = list(c(1, 3, 5), c(2, 3, 4, 7), c(1, 2, 6))`. Instead of using the `fix.loc`, the `fix.id` argument can be used by providing a vector of the IDs of the items to be fixed. Again suppose that the three group data are analyzed. For the first group test form, the three items in which IDs are G1I1, C1I1, are C1I2 are fixed. For the second group test form, the four items in which IDs are C1I1, C1I2, C2I1, and C2I2 are fixed. For the third group test form, the three items in which IDs are C2I1, C2I2, and G3I1 are fixed. Then there are six unique items to be fixed across the three groups (i.e., G1I1, C1I1, C1I2, C2I1, C2I2, and G3I1) because C1I1 and C1I2 are common items between the first and the second groups, and C2I1 and C2I2 are common items between the second and the third groups. Thus, `fix.id = c("G1I1", "C1I1", "C1I2", "C2I1", "C2I2", "G3I1")` should be set. Note that when the information of item IDs supplied in the `fix.id` argument overrides the information provided into the `fix.loc` argument.

**Value**

This function returns an object of class `est_mg`. Within this object, several internal objects are contained such as:
<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>estimates</td>
<td>A list containing two internal objects (i.e., overall and group) of the item parameter estimates and the corresponding standard errors of estimates. The first internal object (overall) is a data frame of the item parameter and standard error estimates for the combined data set across all groups. Accordingly, the data frame includes unique items across all groups. The second internal object (group) is a list of group specific data frames containing item parameter and standard error estimates.</td>
</tr>
<tr>
<td>par.est</td>
<td>A list containing two internal objects (i.e., overall and group) of the item parameter estimates. The format of the list is the same with the internal object of 'estimates'.</td>
</tr>
<tr>
<td>se.est</td>
<td>A list containing two internal objects (i.e., overall and group) of the standard errors of item parameter estimates. The format of the list is the same with the internal object of 'estimates'. Note that the standard errors are estimated using the cross-production approximation method (Meilijson, 1989).</td>
</tr>
<tr>
<td>pos.par</td>
<td>A data frame containing the position number of each item parameter being estimated. This item position data frame was created based on the combined data sets across all groups (see the first internal object of 'estimates'). The position information is useful when interpreting the variance-covariance matrix of item parameter estimates.</td>
</tr>
<tr>
<td>covariance</td>
<td>A matrix of variance-covariance matrix of item parameter estimates. This matrix was created based on the combined data sets across all groups (see the first internal object of 'estimates').</td>
</tr>
<tr>
<td>loglikelihood</td>
<td>A list containing two internal objects (i.e., overall and group) of the log-likelihood values of observed data set (marginal log-likelihood). The format of the list is the same with the internal object of 'estimates'. Specifically, the first internal object (overall) contains a sum of the log-likelihood values of the observed data set across all unique items of all groups. The second internal object (group) shows the group specific log-likelihood values.</td>
</tr>
<tr>
<td>aic</td>
<td>A model fit statistic of Akaike information criterion based on the loglikelihood of all unique items.</td>
</tr>
<tr>
<td>bic</td>
<td>A model fit statistic of Bayesian information criterion based on the loglikelihood of all unique items.</td>
</tr>
<tr>
<td>group.par</td>
<td>A list containing the summary statistics (i.e., a mean, variance, and standard deviation) of latent variable prior distributions across all groups.</td>
</tr>
<tr>
<td>weights</td>
<td>A list of the two-column data frames containing the quadrature points (in the first column) and the corresponding weights (in the second column) of the (updated) latent variable prior distributions for all groups.</td>
</tr>
<tr>
<td>posterior.dist</td>
<td>A matrix of normalized posterior densities for all the response patterns at each of the quadrature points. The row and column indicate each individual’s response pattern and the quadrature point, respectively.</td>
</tr>
<tr>
<td>data</td>
<td>A list containing two internal objects (i.e., overall and group) of the examinees’ response data sets. The format of the list is the same with the internal object of 'estimates'.</td>
</tr>
<tr>
<td>scale.D</td>
<td>A scaling factor in IRT models.</td>
</tr>
</tbody>
</table>
ncase A list containing two internal objects (i.e., overall and group) with the total number of response patterns. The format of the list is the same with the internal object of 'estimates'.

nitem A list containing two internal objects (i.e., overall and group) with the total number of items included in the response data set. The format of the list is the same with the internal object of 'estimates'.

Etol A convergence criteria for E steps of the EM algorithm.

MaxE The maximum number of E steps in the EM algorithm.

aprior A list containing the information of the prior distribution for item slope parameters.

gprior A list containing the information of the prior distribution for item guessing parameters.

npar.est A total number of the estimated parameters across all unique items.

niter The number of EM cycles completed.

maxpar.diff A maximum item parameter change when the EM cycles were completed.

EMtime Time (in seconds) spent for the EM cycles.

SEtime Time (in seconds) spent for computing the standard errors of the item parameter estimates.

TotalTime Time (in seconds) spent for total computation.

test.1 Status of the first-order test to report if the gradients has vanished sufficiently for the solution to be stable.

test.2 Status of the second-order test to report if the information matrix is positive definite, which is a prerequisite for the solution to be a possible maximum.

var.note A note to report if the variance-covariance matrix of item parameter estimates is obtainable from the information matrix.

fipc A logical value to indicate if FIPC was used.

fipc.method A method used for the FIPC.

fix.loc A list containing two internal objects (i.e., overall and group) with the locations of the fixed items when the FIPC was implemented. The format of the list is the same with the internal object of 'estimates'.

The internal objects can be easily extracted using the function `getirt`.

## Description

This function estimates examinees’ latent ability parameters. Available scoring methods are maximum likelihood estimation (ML), maximum likelihood estimation with fences (MLF; Han, 2016), weighted likelihood estimation (Warm, 1989), maximum a posteriori estimation (MAP; Hambleton et al., 1991), expected a posteriori estimation (EAP; Bock & Mislevy, 1982), EAP summed scoring (Thissen et al., 1995; Thissen & Orlando, 2001), and inverse test characteristic curve (TCC) scoring (e.g., Kolen & Brennan, 2004; Kolen & Tong, 2010; Stocking, 1996).

## Usage

est_score(x, ...)

## Default S3 method:
est_score(
x,
data,
D = 1,
method = "ML",
range = c(-5, 5),
norm.prior = c(0, 1),
nquad = 41,
weights = NULL,
fence.a = 3,
fence.b = NULL,
tol = 1e-04,
max.iter = 100,
se = TRUE,
stval.opt = 1,
intpol = TRUE,
range.tcc = c(-7, 7),
missing = NA,
ncore = 1,
...
}

## S3 method for class 'est_irt'
est_score(
  x,
  method = "ML",
  range = c(-5, 5),
norm.prior = c(0, 1),
nquad = 41,
weights = NULL,
fence.a = 3,
fence.b = NULL,
tol = 1e-04,
max.iter = 100,
se = TRUE,
stval.opt = 1,
intpol = TRUE,
range.tcc = c(-7, 7),
missing = NA,
ncore = 1,
...
)

Arguments

x A data frame containing the item metadata (e.g., item parameters, number of categories, models ...) or an object of class est_irt obtained from the function est_irt. See irtfit, info, or simdat for more details about the item metadata. This data frame can be easily obtained using the function shape_df.

... additional arguments to pass to parallel::makeCluster.

data A matrix or vector containing examinees’ response data for the items in the argument x. When a matrix is used, a row and column indicate the examinees and items, respectively. When a vector is used, it should contains the item response data for an examinee.

D A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.
method  A character string indicating a scoring method. Available methods are "ML" for the maximum likelihood estimation, "MLF" for the maximum likelihood estimation with fences, "WL" for the weighted likelihood estimation, "MAP" for the maximum a posteriori estimation, "EAP" for the expected a posteriori estimation, "EAP.SUM" for the expected a posteriori summed scoring, and "INV.TCC" for the inverse TCC scoring. Default method is "ML".

range  A numeric vector of two components to restrict the range of ability scale for the ML, MLF, WL, and MAP scoring methods. Default is c(-5, 5).

norm.prior  A numeric vector of two components specifying a mean and standard deviation of the normal prior distribution. These two parameters are used to obtain the gaussian quadrature points and the corresponding weights from the normal distribution. Default is c(0,1). Ignored if method is "ML", "MLF", "WL", or "INV.TCC".

nquad  An integer value specifying the number of gaussian quadrature points from the normal prior distribution. Default is 41. Ignored if method is "ML", "MLF", "WL", "MAP", or "INV.TCC".

weights  A two-column matrix or data frame containing the quadrature points (in the first column) and the corresponding weights (in the second column) of the latent variable prior distribution. The weights and quadrature points can be easily obtained using the function gen.weight. If NULL and method is "EAP" or "EAP.SUM", default values are used (see the arguments of norm.prior and nquad). Ignored if method is "ML", "MLF", "WL", "MAP", or "INV.TCC".

fence.a  A numeric value specifying the item slope parameter (i.e., a-parameter) for the two imaginary items in MLF. See below for details. Default is 3.0.

fence.b  A numeric vector of two components specifying the lower and upper fences of item difficulty parameters (i.e., b-parameters) for the two imaginary items, respectively, in MLF. When fence.b = NULL, the range values were used to set the lower and upper fences of item difficulty parameters. Default is NULL.

tol  A numeric value of the convergent tolerance for the ML, MLF, WL, MAP, and inverse TCC scoring methods. For the ML, MLF, WL, and MAP, Newton Raphson method is implemented for optimization. For the inverse TCC scoring, the bisection method is used. Default is 1e-4.

max.iter  An positive integer value specifying the maximum number of iterations of Newton Raphson method. Default is 100.

se  A logical value. If TRUE, the standard errors of ability estimates are computed. However, if method is "EAP.SUM" or "INV.TCC", the standard errors are always returned. Default is TRUE.

stval.opt  An positive integer value specifying the starting value option for the ML, MLF, WL, and MAP scoring methods. Available options are 1 for the brute-force method, 2 for the observed sum score-based method, and 3 for setting to 0. Default is 1. See below for details.

intpol  A logical value. If TRUE and method = "INV.TCC", linear interpolation method is used to approximate the ability estimates corresponding to the observed sum scores in which ability estimates cannot be obtained using the TCC (e.g., observed sum scores less than the sum of item guessing parameters). Default is TRUE. See below for details.
range.tcc  A numeric vector of two components to be used as the lower and upper bounds of ability estimates when method = "INV.TCC". Default is c(-7, 7).
missing  A value indicating missing values in the response data set. Default is NA. See below for details.
ncore  The number of logical CPU cores to use. Default is 1. See below for details.

Details

For MAP scoring method, only the normal prior distribution is available for the population distribution.

When there are missing data in the response data set, the missing value must be specified in missing. The missing data are taken into account when either of ML, MLF, WL, MAP, and EAP is used. When "EAPSUM" or "INV.TCC" is used, however, any missing responses are replaced with incorrect responses (i.e., 0s).

In the maximum likelihood estimation with fences (MLF; Han, 2016), two 2PLM imaginary items are necessary. The first imaginary item serves as the lower fence and its difficulty parameter (i.e., b-parameters) should be lower than any difficulty parameter values in the test form. Likewise, the second imaginary item serves as the upper fence and its difficulty parameter should be greater than any difficulty parameter values in the test form. Also, the two imaginary items should have a very high item slope parameter (i.e., a-parameter) value. See Han (2016) for more details. When fence.b = NULL in MLF, the function automatically sets the lower and upper fences of item difficulty parameters using the values in the range argument.

When "INV.TCC" method is used employing the IRT 3-parameter logistic model (3PLM) in a test, ability estimates for the observed sum scores less than the sum of item guessing parameters are not attainable. In this case, linear interpolation can be applied by setting intpol = TRUE. Let $\theta_{\text{min}}$, $\theta_{\text{max}}$, and $\theta_X$ be the minimum and maximum ability estimates and $\theta_X$ be the ability estimate for the smallest observed sum score, X, but greater than or equal to the sum of item guessing parameters. When linear interpolation method is used, the first value of the range.tcc is set to $\theta_{\text{min}}$. Then, a linear line is constructed between two points of (x=$\theta_{\text{min}}$, y=0) and (x=$\theta_X$, y=X). Also, the first value of the range.tcc is set to $\theta_{\text{max}}$, which is the ability estimates corresponding to the maximum observed sum score. When it comes to the scoring method of "INV.TCC", the standard errors of ability estimates are computed using an approach suggested by Lim, Davey, and Wells (2020). The code for the inverse TCC scoring was written by modifying the function irt.eq.tse of the SNSequate R package (González, 2014).

In terms of the starting value to be used for ML, MLF, WL, and MAP scoring methods, the brute-force method is used when stval.opt = 1. With this option, the log-likelihood values were evaluated at the discrete theta values with increments of 0.1 given range. The theta node that has the largest log-likelihood is used as the starting value. when stval.opt = 2, the starting value is obtained based on the observed sum score. For example, if the maximum observed sum score (max.score) is 30 for a test and an examinee has an observed sum score of 20 (obs.score), then the starting value is "log(obs.score / (max.score - obs.score))". For all incorrect response, the starting value is "log(1 / max.score)" and for all correct responses, it is "log(max.score / 1)".

To speed up the ability estimation for ML, MLF, WL, MAP, and EAP methods, this function applies a parallel process using multiple logical CPU cores. You can set the number of logical CPU cores by specifying a positive integer value in the argument ncore. Default value is 1.

Note that the standard errors of ability estimates are computed using the Fisher expected information for ML, MLF, WL, and MAP methods.
To implement WL method, the \( \Pi \), \( \Ji \), and \( \Ii \) functions of \texttt{catR} (Magis & Barrada, 2017) were referred.

**Value**

When \texttt{method} is either of "ML", "MLF", "WL", "MAP", or "EAP", a two column data frame including the ability estimates (1st column) and the standard errors of ability estimates (2nd column) is returned. When \texttt{method} is "EAP.SUM" or "INV.TCC", a list of two internal objects are returned. The first object is a three column data frame including the observed sum scores (1st column), the ability estimates (2nd column), and the standard errors of ability estimates (3rd column). The second object is a score table including the possible raw sum scores and corresponding ability and standard error estimates.

**Methods (by class)**

- \texttt{default}: Default method to estimate examinees’ latent ability parameters using a data frame \( x \) containing the item metadata.
- \texttt{est_irt}: An object created by the function \texttt{est_irt}.

```
**gen.weight**  
*Generate Weights*

**Description**

This function generates a set of weights based on a set of theta values to be used in the functions `est_score` and `sx2_fit`.

**Usage**

```r
gen.weight(n = 41, dist = "norm", mu = 0, sigma = 1, l = -4, u = 4, theta)
```

**Arguments**

- `n`: An integer identifying the number of theta (or node) values for which weights are generated. Default is 41.
- `dist`: A character string specifying a probability distribution from which the weights are generated. Available distributions are "norm" for a normal distribution, "unif" for a uniform distribution, and "emp" for an empirical distribution. When `dist = "norm"`, either `n` or `theta` can be specified, when `dist = "unif"`, only `n` can be used, and when `dist = "emp"`, only `theta` can be used.
- `mu, sigma`: A mean and standard deviation of a normal distribution.
- `l, u`: Lower and upper limits of a uniform distribution.
- `theta`: A vector of empirical theta (or node) values for which weights are generated.

**Details**

When the argument `theta` is missing, `n` weights can be generated from either the normal distribution or the uniform distribution. Note that if `dist = "norm"`, gaussian quadrature points and weights from the normal distribution are generated. See `gauss.quad.prob()` in the `statmod` package for more details.

When the argument `theta` is not missing, the weights corresponding to the provided theta values are generated. Specifically, if `dist = "norm"`, normalized weights from the normal distribution are returned. If `dist = "emp"`, every specified theta value has the equal values of normalized weights.

**Value**

This function returns a data frame with two columns, where the first column has theta values (nodes) and the second column provides weights.

Examples

## example 1
## generate 41 gaussian quadrature points and weights of normal distribution
gen.weight(n=41, dist = "norm", mu = 0, sigma = 1)

## example 2
## generate 41 theta values and weights from the uniform normal distribution,
## given the minimum value of -4 and the maximum value of 4
gen.weight(n=41, dist = "unif", l = -4, u = 4)

## example 3
## generate the normalized weights from the standardized normal distribution,
## given a set of theta values
theta <- seq(-4, 4, by=0.1)
gen.weight(dist = "norm", mu = 0, sigma = 1, theta = theta)

## example 4
## generate the same values of normalized weights for the theta values that are
## randomly sampled from the standardized normal distribution
theta <- rnorm(100)
gen.weight(dist = "emp", theta = theta)

getirt

Extract various elements from 'est_irt', 'est_mg', and 'est_item' objects

Description

This method extracts various internal objects from an object of class est_irt, est_mg, or est_item.

Usage

getirt(x, ...)

## S3 method for class 'est_irt'
getirt(x, what, ...)

## S3 method for class 'est_mg'
getirt(x, what, ...)

## S3 method for class 'est_item'
getirt(x, what, ...)
Arguments

- \textit{x} \quad \text{An object of class} \texttt{est_irt}, \texttt{est_mg}, \text{or} \texttt{est_item}.
- \ldots \quad \text{Further arguments passed to or from other methods.}
- \textit{what} \quad \text{A character string indicating what to extract.}

Details

Objects which can be extracted from the object of class \texttt{est_irt} include:

- \textbf{estimates} \quad \text{A data frame containing both the item parameter estimates and the corresponding standard errors of estimates.}
- \textbf{par.est} \quad \text{A data frame containing the item parameter estimates.}
- \textbf{se.est} \quad \text{A data frame containing the standard errors of the item parameter estimates. Note that the standard errors are estimated using the cross-production approximation method (Meilijson, 1989).}
- \textbf{pos.par} \quad \text{A data frame containing the position number of each item parameter being estimated. The position information is useful when interpreting the variance-covariance matrix of item parameter estimates.}
- \textbf{covariance} \quad \text{A matrix of variance-covariance matrix of item parameter estimates.}
- \textbf{loglikelihood} \quad \text{A sum of the log-likelihood values of the observed data set (marginal log-likelihood) across all items in the data set.}
- \textbf{aic} \quad \text{A model fit statistic of Akaike information criterion based on the loglikelihood.}
- \textbf{bic} \quad \text{A model fit statistic of Bayesian information criterion based on the loglikelihood.}
- \textbf{group.par} \quad \text{A data frame containing the mean, variance, and standard deviation of latent variable prior distribution.}
- \textbf{weights} \quad \text{A two-column data frame containing the quadrature points (in the first column) and the corresponding weights (in the second column) of the (updated) latent variable prior distribution.}
- \textbf{posterior.dist} \quad \text{A matrix of normalized posterior densities for all the response patterns at each of the quadrature points. The row and column indicate each individual’s response pattern and the quadrature point, respectively.}
- \textbf{data} \quad \text{A data frame of the examinees’ response data set.}
- \textbf{scale.D} \quad \text{A scaling factor in IRT models.}
- \textbf{ncase} \quad \text{A total number of response patterns.}
- \textbf{nitem} \quad \text{A total number of items included in the response data.}
- \textbf{Etol} \quad \text{A convergence criteria for E steps of the EM algorithm.}
- \textbf{MaxE} \quad \text{The maximum number of E steps in the EM algorithm.}
- \textbf{aprior} \quad \text{A list containing the information of the prior distribution for item slope parameters.}
- \textbf{bprior} \quad \text{A list containing the information of the prior distribution for item difficulty (or threshold) parameters.}
- \textbf{gprior} \quad \text{A list containing the information of the prior distribution for item guessing parameters.}
- \textbf{npar.est} \quad \text{A total number of the estimated parameters.}
niter The number of EM cycles completed.

maxpar.diff A maximum item parameter change when the EM cycles were completed.

EMtime Time (in seconds) spent for the EM cycles.

SEtime Time (in seconds) spent for computing the standard errors of the item parameter estimates.

TotalTime Time (in seconds) spent for total computation.

test.1 Status of the first-order test to report if the gradients has vanished sufficiently for the solution to be stable.

test.2 Status of the second-order test to report if the information matrix is positive definite, which is a prerequisite for the solution to be a possible maximum.

var.note A note to report if the variance-covariance matrix of item parameter estimates is obtainable from the information matrix.

fipc A logical value to indicate if FIPC was used.

fipc.method A method used for the FIPC.

fix.loc A vector of integer values specifying the locations of the fixed items when the FIPC was implemented.

Objects which can be extracted from the object of class est_mg include:

estimates A list containing two internal objects (i.e., overall and group) of the item parameter estimates and the corresponding standard errors of estimates. The first internal object (overall) is a data frame of the item parameter and standard error estimates for the combined data set across all groups. Accordingly, the data frame includes unique items across all groups. The second internal object (group) is a list of group specific data frames containing item parameter estimates and standard error estimates.

par.est A list containing two internal objects (i.e., overall and group) of the item parameter estimates. The format of the list is the same with the internal object of 'estimates'.

se.est A list containing two internal objects (i.e., overall and group) of the standard errors of item parameter estimates. The format of the list is the same with the internal object of 'estimates'. Note that the standard errors are estimated using the cross-production approximation method (Meilijson, 1989).

pos.par A data frame containing the position number of each item parameter being estimated. This item position data frame was created based on the combined data sets across all groups (see the first internal object of 'estimates'). The position information is useful when interpreting the variance-covariance matrix of item parameter estimates.

covariance A matrix of variance-covariance matrix of item parameter estimates. This matrix was created based on the combined data sets across all groups (see the first internal object of 'estimates').

loglikelihood A list containing two internal objects (i.e., overall and group) of the log-likelihood values of observed data set (marginal log-likelihood). The format of the list is the same with the internal object of 'estimates'. Specifically, the first internal object (overall) contains a sum of the log-likelihood values of the observed data set across all unique items of all groups. The second internal object (group) shows the group specific log-likelihood values.

aic A model fit statistic of Akaike information criterion based on the loglikelihood of all unique items.
bic  A model fit statistic of Bayesian information criterion based on the loglikelihood of all unique items.

`group.par` A list containing the summary statistics (i.e., a mean, variance, and standard deviation) of latent variable prior distributions across all groups.

weights  a list of the two-column data frames containing the quadrature points (in the first column) and the corresponding weights (in the second column) of the (updated) latent variable prior distributions for all groups.

`posterior.dist` A matrix of normalized posterior densities for all the response patterns at each of the quadrature points. The row and column indicate each individual’s response pattern and the quadrature point, respectively.

`data` A list containing two internal objects (i.e., overall and group) of the examinees’ response data sets. The format of the list is the same with the internal object of ‘estimates’.

`scale.D` A scaling factor in IRT models.

`ncase` A list containing two internal objects (i.e., overall and group) with the total number of response patterns. The format of the list is the same with the internal object of ‘estimates’.

`nitem` A list containing two internal objects (i.e., overall and group) with the total number of items included in the response data set. The format of the list is the same with the internal object of ‘estimates’.

`Etol` A convergence criteria for E steps of the EM algorithm.

`MaxE` The maximum number of E steps in the EM algorithm.

`aprior` A list containing the information of the prior distribution for item slope parameters.

`gprior` A list containing the information of the prior distribution for item guessing parameters.

`npar.est` A total number of the estimated parameters across all unique items.

`niter` The number of EM cycles completed.

`maxpar.diff` A maximum item parameter change when the EM cycles were completed.

`EMtime` Time (in seconds) spent for the EM cycles.

`SEtime` Time (in seconds) spent for computing the standard errors of the item parameter estimates.

`TotalTime` Time (in seconds) spent for total computation.

`test.1` Status of the first-order test to report if the gradients has vanished sufficiently for the solution to be stable.

`test.2` Status of the second-order test to report if the information matrix is positive definite, which is a prerequisite for the solution to be a possible maximum.

`var.note` A note to report if the variance-covariance matrix of item parameter estimates is obtainable from the information matrix.

`fipc` A logical value to indicate if FIPC was used.

`fipc.method` A method used for the FIPC.

`fix.loc` A list containing two internal objects (i.e., overall and group) with the locations of the fixed items when the FIPC was implemented. The format of the list is the same with the internal object of ‘estimates’.

Objects which can be extracted from the object of class `est_item` include:
estimates  A data frame containing both the item parameter estimates and the corresponding standard errors of estimates.

par.est  A data frame containing the item parameter estimates.

se.est  A data frame containing the standard errors of the item parameter estimates. Note that the standard errors are estimated using observed information functions.

pos.par  A data frame containing the position number of each item parameter being estimated. The position information is useful when interpreting the variance-covariance matrix of item parameter estimates.

covariance  A matrix of variance-covariance matrix of item parameter estimates.

loglikelihood  A sum of the log-likelihood values of the complete data set across all estimated items.

data  A data frame of the examinees’ response data set.

score  A vector of the examinees’ ability values used as the fixed effects.

scale.D  A scaling factor in IRT models.

convergence  A string indicating the convergence status of the item parameter estimation.

nitem  A total number of items included in the response data.

deleted.item  The items which have no item response data. Those items are excluded from the item parameter estimation.

npar.est  A total number of the estimated parameters.

n.response  An integer vector indicating the number of item responses for each item used to estimate the item parameters.

TotalTime  Time (in seconds) spent for total computation.

See est_irt, est_mg, and est_item for more details.

Value

The internal objects extracted from an object of class est_irt, est_mg, or est_item.

Methods (by class)

- est_irt: An object created by the function est_irt.
- est_mg: An object created by the function est_mg.
- est_item: An object created by the function est_item.

**grdif**  
*Generalized IRT residual-based DIF detection framework for multiple groups (GRDIF)*

**Description**

This function computes three GRDIF statistics, $GRDIF_R$, $GRDIF_S$, and $GRDIF_{RS}$, for analyzing differential item functioning (DIF) among multiple groups (Lim, Zhu, Choe, & Han, 2023). They are specialized to capture uniform DIF, nonuniform DIF, and mixed DIF, respectively.

**Usage**

```r
grdif(x, ...)
```

```r
## Default S3 method:
grdif(
x,  
data,  
score = NULL,  
group,  
focal.name,  
D = 1,  
alpha = 0.05,  
missing = NA,  
purify = FALSE,  
purify.by = c("grdifrs", "grdifr", "grdifs"),  
max.iter = 10,  
min.resp = NULL,  
post.hoc = TRUE,  
method = "ML",  
range = c(-4, 4),  
norm.prior = c(0, 1),
```
```r
grdif

nquad = 41,
weights = NULL,
ncore = 1,
verbose = TRUE,
...
)

## S3 method for class 'est_irt'
grdif(
x,
score = NULL,
group,
focal.name,
alpha = 0.05,
missing = NA,
purify = FALSE,
purify.by = c("grdifrs", "grdifr", "grdfs"),
max.iter = 10,
min.resp = NULL,
post.hoc = TRUE,
method = "ML",
range = c(-4, 4),
norm.prior = c(0, 1),
nquad = 41,
weights = NULL,
ncore = 1,
verbose = TRUE,
...
)

## S3 method for class 'est_item'
grdif(
x,
group,
focal.name,
alpha = 0.05,
missing = NA,
purify = FALSE,
purify.by = c("grdifrs", "grdifr", "grdfs"),
max.iter = 10,
min.resp = NULL,
post.hoc = TRUE,
method = "ML",
range = c(-4, 4),
norm.prior = c(0, 1),
nquad = 41,
weights = NULL,
ncore = 1,
```
verbose = TRUE,
...
)

**Arguments**

- **x**: A data frame containing item metadata (e.g., item parameters, number of categories, models, etc.), an object of class `est_item` obtained from the function `est_item`, or an object of class `est_irt` obtained from the function `est_irt`. The item metadata can be easily created using the function `shape_df`. See `est_irt`, `irtfit`, `info` or `simdat` for more details about the item metadata.

- **data**: Additional arguments that will be forwarded to the `est_score` function.

- **score**: A vector of examinees’ ability estimates. If abilities are not provided, `grdif` estimates abilities before computing GRDIF statistics. See `est_score` for more details about scoring methods. Default is NULL.

- **group**: A numeric or character vector indicating group membership of examinees. The length of the vector should be the same as the number of rows in the response data matrix.

- **focal.name**: A character or numeric vector representing levels associated with focal groups. For instance, consider `group = c(0, 0, 1, 2, 3, 3)` where '1', '2', and '3' indicate three distinct focal groups, and '0' represents the reference group. In this case, set `focal.name = c(1, 2, 3)`.

- **D**: A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.

- **alpha**: A numeric value to specify the significance \( \alpha \)-level of the hypothesis test using GRDIF statistics. Default is .05.

- **missing**: A value indicating missing values in the response data set. Default is NA.

- **purify**: A logical value indicating whether a purification process will be implemented or not. Default is FALSE.

- **purify.by**: A character string specifying a GRDIF statistic with which the purification is implemented. Available statistics are "grdifrs" for \( GRDIF_{RS} \), "grdifr" for \( GRDIF_{R} \), and "grdifs" for \( GRDIF_{S} \).

- **max.iter**: A positive integer value specifying the maximum number of iterations for the purification process. Default is 10.

- **min.resp**: A positive integer value specifying the minimum number of item responses for an examinee required to compute the ability estimate. Default is NULL. See details below for more information.

- **post.hoc**: A logical value indicating whether to conduct a post-hoc RDIF analysis for all possible combinations of paired groups for statistically flagged items. The default is TRUE. See below for more details.

- **method**: A character string indicating a scoring method. Available methods are "ML" for maximum likelihood estimation, "WL" for the weighted likelihood estimation, "MAP" for maximum a posteriori estimation, and "EAP" for expected a posteriori estimation. The default method is "ML".
range
A numeric vector with two components to restrict the ability scale range for ML, WL, EAP, and MAP scoring methods. The default is c(-5, 5).

norm.prior
A numeric vector with two components specifying the mean and standard deviation of the normal prior distribution. These parameters are used to obtain Gaussian quadrature points and their corresponding weights from the normal distribution. The default is c(0,1). Ignored if method is "ML" or "WL".

nquad
An integer value specifying the number of Gaussian quadrature points from the normal prior distribution. The default is 41. Ignored if method is "ML", "WL", or "MAP".

weights
A two-column matrix or data frame containing the quadrature points (in the first column) and their corresponding weights (in the second column) for the latent variable prior distribution. The weights and quadrature points can be obtained using the \texttt{gen.weight} function. If NULL and method is "EAP", default values are used (see the norm.prior and nquad arguments). Ignored if method is "ML", "WL", or "MAP".

ncore
The number of logical CPU cores to use. The default is 1. See \texttt{est_score} for details.

verbose
A logical value. If TRUE, progress messages for the purification procedure are suppressed. The default is TRUE.

Details
The GRDIF framework (Lim et al., 2023) is a generalized version of the RDIF detection framework, designed to assess DIF for multiple groups. The GRDIF framework comprises three statistics: GRDIF\(_R\), GRDIF\(_S\), and GRDIF\(_RS\), which focus on detecting uniform, nonuniform, and mixed DIF, respectively. Under the null hypothesis that a test contains no DIF items, GRDIF\(_R\), GRDIF\(_S\), and GRDIF\(_RS\) asymptotically follow the \(\chi^2\) distributions with \(G-1\), \(G-1\), and \(2(G-1)\) degrees of freedom, respectively, where \(G\) represents the total number of groups being compared. For more information on the GRDIF framework, see Lim et al. (2023).

The \texttt{grdif} function calculates all three GRDIF statistics: GRDIF\(_R\), GRDIF\(_S\), and GRDIF\(_RS\). The current version of the \texttt{grdif} function supports both dichotomous and polytomous item response data. To compute these statistics, the \texttt{grdif} function requires (1) item parameter estimates obtained from aggregate data, regardless of group membership, (2) examinees’ ability estimates (e.g., MLE), and (3) examinees’ item response data. Note that the ability estimates must be computed using the aggregate data-based item parameter estimates. The item parameter estimates should be provided in the \texttt{x} argument, the ability estimates in the \texttt{score} argument, and the response data in the \texttt{data} argument. When abilities are not given in the \texttt{score} argument (i.e., \texttt{score = NULL}), the \texttt{grdif} function estimates examinees’ abilities automatically using the scoring method specified in the \texttt{method} argument (e.g., \texttt{method = "ML"}).

The \texttt{group} argument accepts a vector with numeric or character values, indicating the group membership of examinees. The vector may include multiple distinct values, where one value represents the reference group and the others represent the focal groups. The length of the vector should be the same as the number of rows in the \texttt{response} data, with each value indicating the group membership of each examinee. After specifying the \texttt{group}, a numeric or character vector should be provided in the \texttt{focal.name} argument to define which group values in the \texttt{group} argument represent the focal groups. The reference group will be the group not included in the \texttt{focal.name} vector.
Similar to the original RDIF framework for two-groups comparison, the GRDIF framework can implement an iterative purification process. When `purify = TRUE`, the purification process is executed based on one of the GRDIF statistics specified in the `purify.by` argument (e.g., `purify.by="grdifrs"`). During each iterative purification, examinees’ latent abilities are calculated using purified items and the scoring method specified in the `method` argument. The iterative purification process stops when no additional DIF items are identified or when the process reaches a predetermined limit of iterations, which can be set in the `max.iter` argument. For more information about the purification procedure, refer to Lim et al. (2022).

Scoring with a limited number of items can result in large standard errors, which may impact the effectiveness of DIF detection within the GRDIF framework. The `min.resp` argument can be employed to avoid using scores with significant standard errors when calculating the GRDIF statistics, particularly during the purification process. For instance, if `min.resp` is not NULL (e.g., `min.resp=5`), item responses from examinees whose total item responses fall below the specified minimum number are treated as missing values (i.e., NA). Consequently, their ability estimates become missing values and are not utilized in computing the GRDIF statistics. If `min.resp=NULL`, an examinee’s score will be computed as long as there is at least one item response for the examinee.

The `post.hoc` argument allows you to perform a post-hoc RDIF analysis for all possible combinations of paired groups for items flagged as statistically significant. For example, consider four groups of examinees: A, B, C, and D. If `post.hoc = TRUE`, the `grdif` function will perform a post-hoc RDIF analysis for all possible pairs of groups (A-B, A-C, A-D, B-C, B-D, and C-D) for each flagged item. This helps to identify which specific pairs of groups have DIF for each item, providing a more detailed understanding of the DIF patterns in the data. Note that when purification is implemented (i.e., `purify = TRUE`), the post-hoc RDIF analysis is conducted for each flagged item during each single iteration of the purification process.

**Value**

This function returns a list of four internal objects. The four objects are:

- `no_purify` A list of several sub-objects containing the results of DIF analysis without a purification procedure. The sub-objects are:
  - `dif_stat` A data frame containing the results of three RDIF statistics for all evaluated items. Starting from the first column, each column represents the item’s ID, \( GRDIF_R \) statistic, \( GRDIF_S \) statistic, \( GRDIF_{RS} \) statistic, p-value of \( GRDIF_R \), p-value of \( GRDIF_S \), p-value of \( GRDIF_{RS} \), sample size of the reference group, sample sizes of the focal groups, and the total sample size, respectively.
  - `moments` A list of three data frames detailing the means of raw residuals (MRRs) and mean squared residuals (MSRs) across all compared groups. The first data frame contains the means of MRR and MSR, the second data frame includes the variances of MRR and MSR, and the last one displays the covariances of MRR and MSR for all groups.
  - `dif_item` A list of three numeric vectors indicating potential DIF items flagged by each of the GRDIF statistics. Each numeric vector corresponds to the items identified by \( GRDIF_R \), \( GRDIF_S \), and \( GRDIF_{RS} \), respectively.
  - `score` A vector of ability estimates used to compute the GRDIF statistics.
  - `post.hoc` A list of three data frames containing the post-hoc RDIF analysis results of all possible combinations of paired groups. The first, second, and
third data frames present the post-hoc analysis outcomes for the items identified by the $RDIF_R$, $RDIF_S$, and $RDIF_{RS}$ statistics, respectively.

purify A logical value indicating whether the purification process was used.

with_purify A list of several sub-objects containing the results of DIF analysis with a purification procedure. The sub-objects are:

- **purify.by** A character string indicating which GRDIF statistic is used for the purification. "grdifr", "grdifs", and "grdifrs" refers to $GRDIF_R$, $GRDIF_S$, and $GRDIF_{RS}$, respectively.

- **dif_stat** A data frame containing the results of three GRDIF statistics for all evaluated items. Starting from the first column, each column represents the item's ID, $GRDIF_R$ statistic, $GRDIF_S$ statistic, $GRDIF_{RS}$ statistic, p-value of $GRDIF_R$, p-value of $GRDIF_S$, p-value of $GRDIF_{RS}$, sample size of the reference group, sample sizes of the focal groups, total sample size, and $n$th iteration where the GRDIF statistics were computed, respectively.

- **moments** A list of three data frames detailing the moments of mean raw residuals (MRRs) and mean squared residuals (MSRs) across all compared groups. The first data frame contains the means of MRR and MSR, the second data frame includes the variances of MRR and MSR, and the last one displays the covariances of MRR and MSR for all groups. In each data frame, the last column indicates the $n$th iteration where the GRDIF statistics were computed.

- **n.iter** The total number of iterations implemented for the purification.

- **score** A vector of final purified ability estimates used to compute the GRDIF statistics.

- **post.hoc** A data frame containing the post-hoc RDIF analysis results for the flagged items across all possible combinations of paired groups. The post-hoc RDIF analysis is conducted for each flagged item at every iteration.

- **complete** A logical value indicating whether the purification process was completed. If FALSE, it means that the purification process reached the maximum iteration number but was not completed.

- **alpha** A significance $\alpha$-level used to compute the p-values of RDIF statistics.

**Methods (by class)**

- **default**: Default method to computes three GRDIF statistics with multiple group data using a data frame $x$ containing the item metadata.

- **est_irt**: An object created by the function `est_irt`.

- **est_item**: An object created by the function `est_item`.

info Item and Test Information Function

**Description**

This function computes both item and test information functions (Hambleton et al., 1991) given a set of theta values.

**Usage**

info(x, ...)

```R
## Default S3 method:
info(x, theta, D = 1, tif = TRUE, ...)
```

```R
## S3 method for class 'est_item'
info(x, theta, tif = TRUE, ...)
```

```R
## S3 method for class 'est_irt'
info(x, theta, tif = TRUE, ...)
```

**Arguments**

- `x`: A data frame containing the item metadata (e.g., item parameters, number of categories, models ...), an object of class `est_item` obtained from the function `est_item`, or an object of class `est_irt` obtained from the function `est_irt`. The data frame of item metadata can be easily obtained using the function `shape_df`. See below for details.

- `...`: Further arguments passed to or from other methods.

- `theta`: A vector of theta values where item and test information values are computed.

- `D`: A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.

- `tif`: A logical value. If TRUE, the test information function is computed. Default is TRUE.
Details

A specific form of a data frame should be used for the argument \( x \). The first column should have item IDs, the second column should contain unique score category numbers of the items, and the third column should include IRT models being fit to the items. The available IRT models are "1PLM", "2PLM", "3PLM", and "DRM" for dichotomous item data, and "GRM" and "GPCM" for polytomous item data. Note that "DRM" covers all dichotomous IRT models (i.e., "1PLM", "2PLM", and "3PLM") and "GRM" and "GPCM" represent the graded response model and (generalized) partial credit model, respectively. The next columns should include the item parameters of the fitted IRT models. For dichotomous items, the fourth, fifth, and sixth columns represent the item discrimination (or slope), item difficulty, and item guessing parameters, respectively. When "1PLM" and "2PLM" are specified in the third column, NAs should be inserted in the sixth column for the item guessing parameters. For polytomous items, the item discrimination (or slope) parameters should be included in the fourth column and the item difficulty (or threshold) parameters of category boundaries should be contained from the fifth to the last columns. When the number of unique score categories differs between items, the empty cells of item parameters should be filled with NAs. In the \texttt{irtQ} package, the item difficulty (or threshold) parameters of category boundaries for GPCM are expressed as the item location (or overall difficulty) parameter subtracted by the threshold parameter for unique score categories of the item. Note that when an GPCM item has \( K \) unique score categories, \( K-1 \) item difficulty parameters are necessary because the item difficulty parameter for the first category boundary is always 0. For example, if an GPCM item has five score categories, four item difficulty parameters should be specified. An example of a data frame with a single-format test is as follows:

\[
\begin{array}{cccc}
\text{ITEM1} & 2 & \text{1PLM} & 1.000 \\
\text{ITEM2} & 2 & \text{2PLM} & 1.921 \\
\text{ITEM3} & 2 & \text{3PLM} & 1.736 \\
\text{ITEM4} & 2 & \text{3PLM} & 0.835 \\
\text{ITEM5} & 2 & \text{DRM} & 0.926 \\
\end{array}
\]

And an example of a data frame for a mixed-format test is as follows:

\[
\begin{array}{cccc}
\text{ITEM1} & 2 & \text{1PLM} & 1.000 \\
\text{ITEM2} & 2 & \text{2PLM} & 1.921 \\
\text{ITEM3} & 2 & \text{3PLM} & 0.926 \\
\text{ITEM4} & 2 & \text{DRM} & 1.052 \\
\text{ITEM5} & 4 & \text{GRM} & 1.913 \\
\text{ITEM6} & 5 & \text{GRM} & 1.278 \\
\text{ITEM7} & 4 & \text{GPCM} & 1.137 \\
\text{ITEM8} & 5 & \text{GPCM} & 1.233 \\
\end{array}
\]

See \texttt{IRT Models} section in the page of \texttt{irtQ-package} for more details about the IRT models used in the \texttt{irtQ} package. An easier way to create a data frame for the argument \( x \) is by using the function \texttt{shape_df}.

Value

This function returns an object of class \texttt{info}. This object contains item and test information values given the specified theta values.
Methods (by class)

- default: Default method to compute item and test information functions for a data frame containing the item metadata.
- est_item: An object created by the function est_item.
- est_irt: An object created by the function est_irt.

Examples

```r
## example 1.
## using the function "shape_df" to create a data frame of test metadata
# create a list containing the dichotomous item parameters
par.drm <- list(a=c(1.1, 1.2, 0.9, 1.8, 1.4),
                 b=c(0.1, -1.6, -0.2, 1.0, 1.2),
                 g=rep(0.2, 5))

# create a list containing the polytomous item parameters
par.prm <- list(a=c(1.4, 0.6),
                d=list(c(-1.9, 0.0, 1.2), c(0.4, -1.1, 1.5, 0.2)))

# create a numeric vector of score categories for the items
cats <- c(2, 4, 2, 2, 2, 5, 2, 2)

# create a character vector of IRT models for the items
model <- c("DRM", "GRM", "DRM", "DRM", "GPCM", "DRM", "DRM")

# create an item metadata set
test <- shape_df(par.drm=par.drm, par.prm=par.prm,
                  cats=cats, model=model) # create a data frame

# set theta values
theta <- seq(-2, 2, 0.1)

# compute item and test information values given the theta values
info(x=test, theta=theta, D=1, tif=TRUE)
```
## Example 2.

Using a "-prm.txt" file obtained from a flexMIRT

```r
# import the "-prm.txt" output file from flexMIRT
fex_prm <- system.file("extdata", "flexmirt_sample-prm.txt", 
  package = "irtQ")

# read item parameters and transform them to item metadata
test_flex <- bring.flexmirt(file=fex_prm, "par")$Group1$full_df

# set theta values
theta <- seq(-2, 2, 0.1)

# compute item and test information values given the theta values
info(x=test_flex, theta=theta, D=1, tif=TRUE)
```

---

**irtfit**

*Traditional IRT item fit statistics*

### Description

This function computes traditional IRT item fit statistics (i.e., $\chi^2$ fit statistic (e.g., Bock, 1960; Yen, 1981), loglikelihood ratio $\chi^2$ fit statistic ($G^2$; McKinley & Mills, 1985), and infit and outfit statistics (Ames et al., 2015)) and returns contingency tables to compute the $\chi^2$ and $G^2$ fit statistics. Note that caution is needed in interpreting the infit and outfit statistics for non-Rasch models. The saved object of this function, especially the object of contingency tables, is used in the function of `plot.irtfit` to draw a raw and standardized residual plots (Hambleton et al., 1991).

### Usage

```r
irtfit(x, ...)
```

```r

## Default S3 method:

irtfit(
  x,
  score,
  data,
  group.method = c("equal.width", "equal.freq"),
  n.width = 10,
  loc.theta = "average",
  range.score = NULL,
  D = 1,
  alpha = 0.05,
  missing = NA,
  overSR = 2,
  min.collapse = 1,
```
Arguments

x  
A data frame containing the item metadata (e.g., item parameters, number of categories, models ...), an object of class est_item obtained from the function est_item, or an object of class est_irt obtained from the function est_irt. The data frame of item metadata can be easily obtained using the function shape_df. See below for more detail.

... 
Further arguments passed to or from other methods.

score  
A vector of examinees’ ability estimates.

data  
A matrix containing examinees’ response data for the items in the argument x. A row and column indicate the examinees and items, respectively.

group.method  
A character string indicating how to group examinees along the ability scale for computing the $\chi^2$ and $G^2$ fit statistics. Available methods are "equal.width" for
grouping examinees by dividing the ability scale into intervals of equal width and "equal.freq" for grouping examinees by dividing the ability scale into intervals with equal frequencies of examinees. However, "equal.freq" does not always guarantee exactly the same frequency of examinees for all groups. Default is "equal.width". To divide the ability scale, the range of ability scale and the number of divided groups must be specified in the arguments of range.score and n.width, respectively. See below for details.

n.width
An integer value to specify the number of divided groups along the ability scale. Default is 10. See below for more detail.

loc.theta
A character string to indicate the location of ability point at each group (or interval) where the expected probabilities of score categories are calculated using the IRT models. Available locations are "average" for computing the expected probability at the average point of examinees’ ability estimates in each group and "middle" for computing the expected probability at the midpoint of each group. Default is "average".

range.score
A vector of two numeric values to restrict the range of ability scale. All ability estimates less than the first value are transformed to the first value. All ability estimates greater than the second value are transformed to the second value. If NULL, the minimum and maximum values of ability estimates in the argument score is used as the range of ability scale. Note that selection of grouping method in the argument group.method has nothing to do with the range of ability scale. Default is NULL.

D
A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.

alpha
A numeric value to specify significance α-level of the hypothesis test for the χ² and G² fit statistics. Default is .05.

missing
A value indicating missing values in the response data set. Default is NA.

overSR
A numeric value to specify a criterion to find ability groups (or intervals) which have standardized residuals greater than the specified value. Default is 2.

min.collapse
An integer value to indicate the minimum frequency of cells to be collapsed when computing the χ² and G² fit statistics. Neighboring interval groups will be collapsed to avoid expected interval frequencies less than the specified minimum cell frequency. Default is 1.

pcm.loc
A vector of integer values indicating the locations of partial credit model (PCM) items whose slope parameters are fixed.

Details
A specific form of a data frame should be used for the argument x. The first column should have item IDs, the second column should contain unique score category numbers of the items, and the third column should include IRT models being fit to the items. The available IRT models are "1PLM", "2PLM", "3PLM", and "DRM" for dichotomous item data, and "GRM" and "GPCM" for polytomous item data. Note that "DRM" covers all dichotomous IRT models (i.e., "1PLM", "2PLM", and "3PLM") and "GRM" and "GPCM" represent the graded response model and (generalized) partial credit model, respectively. The next columns should include the item parameters of the fitted IRT models. For dichotomous items, the fourth, fifth, and sixth columns represent the
item discrimination (or slope), item difficulty, and item guessing parameters, respectively. When "1PLM" and "2PLM" are specified in the third column, NAs should be inserted in the sixth column for the item guessing parameters. For polytomous items, the item discrimination (or slope) parameters should be included in the fourth column and the item difficulty (or threshold) parameters of category boundaries should be contained from the fifth to the last columns. When the number of unique score categories differs between items, the empty cells of item parameters should be filled with NAs. In the \texttt{irtQ} package, the item difficulty (or threshold) parameters of category boundaries for GPCM are expressed as the item location (or overall difficulty) parameter subtracted by the threshold parameter for unique score categories of the item. Note that when an GPCM item has \( K \) unique score categories, \( K-1 \) item difficulty parameters are necessary because the item difficulty parameter for the first category boundary is always 0. For example, if an GPCM item has five score categories, four item difficulty parameters should be specified. An example of a data frame with a single-format test is as follows:

\[
\begin{array}{cccc}
\text{ITEM1} & 2 & 1PLM & 1.000 \\
\text{ITEM2} & 2 & 2PLM & 1.921 \\
\text{ITEM3} & 2 & 3PLM & 1.736 \\
\text{ITEM4} & 2 & 3PLM & 0.835 \\
\text{ITEM5} & 2 & DRM & 0.926 \\
\end{array}
\]

And an example of a data frame for a mixed-format test is as follows:

\[
\begin{array}{cccccc}
\text{ITEM1} & 2 & 1PLM & 1.000 & 1.461 & NA \\
\text{ITEM2} & 2 & 2PLM & 1.921 & -1.049 & NA \\
\text{ITEM3} & 2 & 3PLM & 0.926 & 0.394 & 0.203 \\
\text{ITEM4} & 2 & DRM & 1.052 & -0.407 & 0.201 \\
\text{ITEM5} & 4 & GRM & 1.913 & -1.869 & -1.238 & -0.714 \\
\text{ITEM6} & 5 & GRM & 1.278 & -0.724 & -0.068 & 0.568 & 1.072 \\
\text{ITEM7} & 4 & GPCM & 1.137 & -0.374 & 0.215 & 0.848 & NA \\
\text{ITEM8} & 5 & GPCM & 1.233 & -2.078 & -1.347 & -0.705 & -0.116 \\
\end{array}
\]

See \textit{IRT Models} section in the page of \texttt{irtQ-package} for more detail about the IRT models used in the \texttt{irtQ} package. An easier way to create a data frame for the argument \( x \) is by using the function \texttt{shape_df}.

To calculate the \( \chi^2 \) and \( G^2 \) fit statistics, two methods are used in the argument \texttt{group.method} to divide the ability scale into several groups. If \texttt{group.method = "equal.width"}, the examinees are grouped based on equal length of intervals. If \texttt{group.method = "equal.freq"}, the examinees are grouped so that all groups have equal frequencies. However, the grouping method of "equal.freq" does guarantee that every group has the exactly same frequency of examinees. This is because the examinees are divided by the same size of quantile.

When dividing the ability scale into intervals to compute the \( \chi^2 \) and \( G^2 \) fit statistics, the intervals should be wide enough not to include too small number of examinees. On the other hand, the interval should be narrow enough to include homogeneous examinees in terms of ability (Hambleton et al, 1991). Thus, if you want to divide the ability scale into other than ten groups, you need to specify the number of groups in the argument \texttt{n.width}. Yen (1981) fixed the number of groups to 10, whereas Bock (1960) allowed for any number of groups.

Regarding degrees of freedom (\textit{df}), the \( \chi^2 \) is assumed to be distributed approximately as a chi-
square with \( df \) equal to the number of groups less the number of the IRT model parameters (Ames et al., 2015) whereas the \( G^2 \) is assumed to be distributed approximately as a chi-square with \( df \) equal to the number of groups (Ames et al., 2015; Muraki & Bock, 2003).

Note that if "DRM" is specified for an item in the item metadata set, the item is considered as "3PLM" to compute degrees of freedom of the \( \chi^2 \) fit statistic.

**Value**

This function returns an object of class `irtfit`. Within this object, several internal objects are contained such as:

- `fit_stat`: A data frame containing the results of three IRT fit statistics (i.e., \( \chi^2 \) and \( G^2 \), infit, outfit statistics) across all evaluated items. In the data frame, the columns indicate item’s ID, \( \chi^2 \) fit statistic, \( G^2 \) fit statistic, degrees of freedom for the \( \chi^2 \), degrees of freedom for the \( G^2 \), critical value for the \( \chi^2 \), critical value for the \( G^2 \), p-value for the \( \chi^2 \), p-value for the \( G^2 \), outfit statistic, infit statistic, the number of examinees used to compute the five fit statistics, and the proportion of ability groups (or intervals), before collapsing the cells, that have standardized residuals greater than the specified criterion in the argument `overSR`, respectively.

- `contingency.fitstat`: A list of contingency tables used to compute the \( \chi^2 \) and \( G^2 \) fit statistics for all items. Note that the collapsing cell strategy is implemented to these contingency tables.

- `contingency.plot`: A list of contingency tables used to draw a raw and standardized residual plots (Hambleton et al., 1991) in the function of `plot.irtfit`. Note that the collapsing cell strategy is not implemented to these contingency tables.

- `individual.info`: A list of data frames including individual residual and variance values. Those information are used to compute infit and outfit statistics.

- `item_df`: The item metadata specified in the argument `x`.

- `ancillary`: A list of ancillary information used in the item fit analysis.

**Methods (by class)**

- `default`: Default method to compute the traditional IRT item fit statistics for a data frame `x` containing the item metadata.

- `est_item`: An object created by the function `est_item`.

- `est_irt`: An object created by the function `est_irt`.

Examples

```r
## example 1
## use the simulated CAT data
# find the location of items that have more than 10,000 responses
over10000 <- which(colSums(simCAT_MX$res.dat, na.rm=TRUE) > 10000)

# select the items that have more than 10,000 responses
x <- simCAT_MX$item.prm[over10000,]

# select the response data for the items
data <- simCAT_MX$res.dat[, over10000]

# select the examinees' abilities
score <- simCAT_MX$score

# compute fit statistics
fit1 <- irtfit(x=x, score=score, data=data, group.method="equal.width",
               n.width=10, loc.theta="average", range.score=NULL, D=1, alpha=0.05,
               missing=NA, overSR=2)

# fit statistics
fit1$fit_stat

# contingency tables
fit1$contingency.fitstat
```
### Example 2

```r
# Import the "-prm.txt" output file from flexMIRT
flex_sam <- system.file("extdata", "flexmirt_sample-prm.txt", package = "irtQ")

# Select the first two dichotomous items and last polytomous item
x <- bring.flexmirt(file=flex_sam, "par")$Group1$full_df[c(1:2, 55), ]

# Generate examinees' abilities from N(0, 1)
set.seed(10)
theta <- rnorm(1000, mean=0, sd=1)

# Simulate the response data
data <- simdat(x=x, theta=theta, D=1)

# Compute fit statistics
fit2 <- irtfit(x=x, score=theta, data=data, group.method="equal.freq",
               n.width=11, loc.theta="average", range.score=c(-4, 4), D=1, alpha=0.05)

# Fit statistics
fit2$fit_stat

# Contingency tables
fit2$contingency.fitstat

# Residual plots for the first item (dichotomous item)
plot(x=fit2, item.loc=1, type = "both", ci.method = "wald", show.table=TRUE, ylim.sr.adjust=TRUE)

# Residual plots for the third item (polytomous item)
plot(x=fit2, item.loc=3, type = "both", ci.method = "wald", show.table=FALSE, ylim.sr.adjust=TRUE)
```

---

**llike_score**

### Loglikelihood of Ability Parameters

#### Description

This function computes the loglikelihood of ability parameters given the item parameters and response data.

#### Usage

```r
llike_score(
x,  
data,  
theta,  
D = 1,  
method = "ML",  
norm.prior = c(0, 1),
```

```
llike_score

fence.a = 3,
fence.b = NULL,
missing = NA
)

Arguments

x
A data frame containing the item metadata (e.g., item parameters, number of score categories, models). This can be created easily using the `shape_df` function. See `est_irt`, `irtfit`, `codeinfo`, or `simdat` for more details about the item metadata.

data
A matrix representing examinees’ response data for the items in x. Each row and column corresponds to an examinee and an item, respectively.

theta
A numeric vector of ability parameters for which the loglikelihood values will be computed.

D
A scaling factor in IRT models that adjusts the logistic function to approximate the normal ogive function (set to 1.7). The default is 1.

method
A character string specifying the scoring method. Options include "ML" for maximum likelihood estimation, "MLF" for maximum likelihood estimation with fences, and "MAP" for maximum a posteriori estimation. The default method is "MLE".

norm.prior
A numeric vector of two elements indicating the mean and standard deviation of the normal prior distribution. These parameters are used to obtain the Gaussian quadrature points and corresponding weights from the normal distribution. Default is c(0,1). This parameter is ignored if method is "ML" or "MLF".

fence.a
A numeric value defining the item slope parameter (a-parameter) for the two imaginary items in the MLF method. Default is 3.0.

fence.b
A numeric vector of two elements specifying the lower and upper fences of item difficulty parameters (b-parameters) for the two imaginary items in the MLF method. If fence.b = NULL, the range values are used to set the fences. The default is NULL.

missing
A value used to denote missing values in the response data set. Default is NA.

Details

The function computes the loglikelihood value of the ability parameter given the item parameters and response data for each item. As an example, to assess the loglikelihoods of abilities for two examinees who have taken the same test items specified in x, supply their item response data matrix with two rows in data and a vector of ability values for which loglikelihood needs to be computed in theta.

Value

A data frame of loglikelihood values. Each row indicates the ability parameter for which the loglikelihood was computed, and each column represents a response pattern.
Examples

```r
# Import the "-prm.txt" output file from flexMIRT
flex_sam <- system.file("extdata", "flexmirt_sample-prm.txt", package = "irtQ")

# Read item parameters and transform them into item metadata
x <- bring.flexmirt(file=flex_sam, "par")$Group1$full_df

# Generate examinees' abilities from N(0, 1)
set.seed(10)
score <- rnorm(5, mean=0, sd=1)

# Simulate the response data
data <- simdat(x=x, theta=score, D=1)

# Specify the ability values for which the loglikelihood values will be computed
theta <- seq(-3, 3, 0.5)

# Compute the loglikelihood values (using the MLE method)
llike_score(x=x, data=data, theta=theta, D=1, method="ML")
```

LSAT6 data

**Description**

Well-known LSAT6 dichotomous response data set from Thissen (1982).

**Usage**

LSAT6

**Format**

This data contains 1,000 dichotomous response patterns of five items obtained from the Law School Admissions Test, section 6.

**Author(s)**

Hwanggyu Lim <hglim83@gmail.com>

**References**

Description

This function computes the conditional distributions of number-correct (or observed) scores given probabilities of category responses to items or given a set of theta values using Lord and Wingersky recursion formula (1984).

Usage

lwrc(x = NULL, theta, prob = NULL, cats, D = 1)

Arguments

x A data frame containing the item metadata (e.g., item parameters, number of categories, models ...). See irtfit, info or simdat for more details about the item metadata. This data frame can be easily obtained using the function shape_df. If prob = NULL, this data frame is used in the recursion formula. See below for details.

theta A vector of theta values where the conditional distribution of observed scores are computed. The theta values are only required when a data frame is specified in the argument x.

prob A matrix containing the probability of answering each category of an item. Each row indicates an item and each column represents each category of the item. When the number of categories differs between items, the empty cells should be filled with zeros or NA values. If x = NULL, this probability matrix is used in the recursion Formula.

cats A numeric vector specifying the number of categories for each item. For example, a dichotomous item has two categories. This information is only required when a probability matrix is specified in the argument prob.

D A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.

Details

The Lord and Wingersky recursive algorithm is an efficient way of calculating the compound probabilities of any number-correct scores on a test based on IRT models. This algorithm is particularly useful when computing the IRT model-based observed score distribution for a test.

To compute the conditional distributions of observed scores, either the item metadata set specified in x or the probability matrix specified in prob can be used.

Value

When the prob argument is provided, this function returns a vector of the probabilities of obtaining every observed score on a test. When the x argument is specified, the function returns a matrix of conditional probabilities across all possible observed scores and theta values.
Examples

## example 1: when a matrix of probabilities is used as a data set
## this is an example from Kolen and Brennan (2004, p. 183)
# create a matrix of probabilities of getting correct and incorrect answers for three items
probs <- matrix(c(.74, .73, .82, .26, .27, .18), nrow=3, ncol=2, byrow = FALSE)

# create a vector of score categories for the three items
cats <- c(2,2,2)

# compute the conditional distributions of observed scores
lwrc(prob=probs, cats=cats)

## example 2: when a matrix of probabilities is used as a data set
## with a mixed-format test
# category probabilities for a dichotomous item
p1 <- c(0.2, 0.8, 0, 0, 0)
# category probabilities for a dichotomous item
p2 <- c(0.4, 0.6, NA, NA, NA)
# category probabilities for a polytomous item with five categories
p3 <- c(0.1, 0.2, 0.2, 0.4, 0.1)
# category probabilities for a polytomous item with three categories
p4 <- c(0.5, 0.3, 0.2, NA, NA)

# rbind the probability vectors
p <- rbind(p1, p2, p3, p4)

# create a vector of score categories for the four items
cats <- c(2, 2, 5, 3)

# compute the conditional distributions of observed scores
lwrc(prob=p, cats=cats)

## example 3: when a data frame for the item metadata of
## a mixed-format test is used.
# import the "-prm.txt" output file from flexMIRT
flex_prm <- system.file("extdata", "flexmirt_sample-prm.txt", package = "irtQ")

# read item parameters and transform them to item metadata
x <- bring.flexmirt(file=flex_prm, "par")$Group1$full_df
# compute the conditional distributions of observed scores
lwrc(x=x, theta=seq(-4, 4, 0.2), D=1)

---

**plot.info**  
*Plot Item and Test Information Functions*

**Description**

This method function plots item or test information function given a specified theta values. In addition, it displays the conditional standard errors at a test level.

**Usage**

```r
## S3 method for class 'info'
plot(
  x,
  item.loc = NULL,
  overlap = FALSE,
  csee = FALSE,
  xlab.text, ylab.text,
  main.text,
  lab.size = 15,
  main.size = 15,
  axis.size = 15,
  line.color,
  line.size = 1,
  layout.col = 4,
  strip.size = 12,
  ...
)
```

**Arguments**

- `x` An object of class `info`.
- `item.loc` A vector of numeric values indicating that the item information functions of the `n`th items (or the location of items in a test form) are plotted. If NULL, the test information function for the total test form is drawn. Default is NULL.
- `overlap` Logical value indicating whether multiple item information functions are plotted in one panel. If FALSE, multiple item information functions are displayed in multiple panels, one for each.
- `csee` Logical value indicating whether the function displays the conditional standard error of estimation (CSEE) at a test level. If FALSE, item/test information function is plotted. Note that the CSEE plot is displayed only at a test level.
- `xlab.text, ylab.text` A title for the x and y axes.
An overall title for the plot.

The size of xlab and ylab. Default is 15.

The size of main.text. Default is 15.

The size of labels along the x and y axes. Default is 15.

The size of lines. Default is 1.

An integer value indicating the number of columns in the panel when displaying the item information functions of the multiple items. Default is 4.

The size of facet labels when the item information functions of the multiple items are drawn.

Further arguments passed from the function `geom_line()` in the `ggplot2` package.

All of the plots are drawn using the ggplot2 package. The object of class `info` can be obtained from the function `info`.

This method function displays the item or test information function plot. When `csee = TRUE`, the conditional standard error is returned at the test level.

## the use of a "-prm.txt" file obtained from a flexMIRT
# import the "-prm.txt" output file from flexMIRT
flex_prm <- system.file("extdata", "flexmirt_sample-prm.txt", package = "irtQ")

# read item parameters and transform them to item metadata
test_flex <- bring.flexmirt(file=flex_prm, "par")$Group1$full_df

# set theta values
theta <- seq(-4, 4, 0.1)

# compute item and test information values given the theta values
x <- info(x=test_flex, theta=theta, D=1, tif=TRUE)
```
plot.irtfit

# draw a plot of the test information function
plot(x)

# draw a plot of the item information function for the second item
plot(x, item.loc=2)

# draw a plot of multiple item information functions across the multiple panels
plot(x, item.loc=1:8, overlap=FALSE)

# draw a plot of multiple item information functions in one panel
plot(x, item.loc=1:8, overlap=TRUE)

# draw a plot of conditional standard error at a test level
plot(x, csee=TRUE)

plot.irtfit

Draw raw and standardized residual plots

Description

This method function provides graphical displays to look at residuals between the observed data and model-based predictions (Hambleton, Swaminathan, & Rogers, 1991). This function gives two residual plots for each score category of an item: (a) the raw residual plot and (b) the standardized residual plot. Note that for dichotomous items the residual plots are drawn only for the score category of 1.

Usage

## S3 method for class 'irtfit'
plot(x, 
    item.loc = NULL, 
    type = "both", 
    ci.method = c("wald", "wilson", "wilson.cr"), 
    show.table = TRUE, 
    layout.col = 2, 
    xlab.text, 
    ylab.text, 
    main.text, 
    lab.size = 15, 
    main.size = 15, 
    axis.size = 15, 
    line.size = 1, 
    point.size = 2.5, 
    strip.size = 12, 
    ylim.icc = c(0, 1), 
    ylim.sr.adjust = FALSE,
ylim.sr = c(-4, 4),
...
)

Arguments

x

An object of class irtfit.

type

A character string indicating what type of residual plot is returned. Available options are "icc" for the raw residual plot, "sr" for the standardized residual plot, and "both" for both of them. Default is "both".

ci.method

A character string indicating what method is used to estimate the confidence interval for the raw residual plot. Available options are "wald" for Wald method, "wilson" for Wilson score interval, and "wilson.cr" for Wilson score interval with continuity correction. Default is "wald". See below for details.

show.table

A logical value. If TRUE, a contingency table containing the information used to draw the residual plots for the studied item is returned. This contingency table is the same as one contained in the internal object of contingency.plot in the object of class irtfit. Default is TRUE.

layout.col

An integer value indicating the number of columns in the panel when a polytomous item is used. Default is 2.

xlab.text

A title for the x axis. If missing, the default string is used.

ylab.text

A title for the y axis. If type = "both", two character strings can be specified for the raw residual and standardized residual plots, respectively. If missing, the default strings are used.

main.text

An overall title for the plot. If type = "both", two character strings can be specified for the raw residual and standardized residual plots, respectively. If missing, the default strings are used.

lab.size

The size of xlab and ylab. Default is 15.

main.size

The size of main.text. Default is 15.

axis.size

The size of labels along the x and y axes. Default is 15.

line.size

The size of lines. Default is 1.

point.size

The size of points. Default is 2.5.

strip.size

The size of facet labels. Default is 12.

ylim.icc

A vector of two numeric values specifying the range of y axis for the raw residual plot. Default is c(0, 1).

ylim.sr.adjust

A logical value. If TRUE, the range of y axis for the standardized residual plot is adjusted for each item. If FALSE, the range of y axis for the standardized residual plot is fixed to the values specified in the argument ylim.sr.

ylim.sr

A vector of two numeric values specifying the range of y axis for the standardized residual plot. Default is c(-4, 4).

...

Further arguments passed from the function ggplot() in the ggplot2 package.
Details

All of the plots are drawn using the ggplot2 package.

Once the results of the IRT model fit analysis are obtained from the function \texttt{irtfit}, an object of class \texttt{irtfit} can be used to draw the IRT raw residual and standardized residual plots. Especially, the information contained in an internal object of \texttt{contingency.plot} are mainly used to draw the residual plots.

Because the residual plots are drawn for an item at a time, you have to indicate which item will be evaluated. For this, you should specify an integer value, which is the location of the studied item, in the argument \texttt{item.loc}. For example, if you want to draw the residual plots for the third item, then \texttt{item.loc = 3}.

In terms of the raw residual plot, the argument \texttt{ci.method} is used to select a method to estimate the confidence intervals among four methods. Those methods are "wald" for the Wald interval, which is based on the normal approximation (Laplace, 1812), "wilson" for Wilson score interval (Wilson, 1927), and "wilson.cr" for Wilson score interval with continuity correction (Newcombe, 1998). See \url{https://en.wikipedia.org/wiki/Binomial_proportion_confidence_interval} for more details about the binomial proportion confidence intervals. Note that the width of confidence interval is determined by the \texttt{alpha-level} specified in the argument \texttt{alpha} of the function \texttt{irtfit}.

Regarding the standardized residual plot, any standardized residuals greater than the specified criterion value in the argument \texttt{overSR} of the function \texttt{irtfit} are displayed with circles. Otherwise, they are displayed with crosses.

Value

This method function displays the IRT raw residual plot, the standard residual plot, or both of the studied item. when \texttt{show.table = TRUE}, a contingency table used to draw the residual plots is also returned. See \texttt{irtfit} for more detail about the contingency table.

Examples

```r
## import the "-prm.txt" output file from flexMIRT
flex_sam <- system.file("extdata", "flexmirt_sample-prm.txt", package = "irtQ")

# select the first two dichotomous items and last polytomous item
x <- bring.flexmirt(file=flex_sam, "par")$Group1$full_df[c(1:2, 55), ]

# generate examinees' abilities from N(0, 1)
set.seed(23)
score <- rnorm(1000, mean=0, sd=1)

# simulate the response data
data <- simdat(x=x, theta=score, D=1)

# compute fit statistics
fit <- irtfit(x=x, score=score, data=data, group.method="equal.freq”,
              n.width=11, loc.theta="average", range.score=c(-4, 4), D=1, alpha=0.05, overSR=1.5)

# residual plots for the first item (dichotomous item)
plot(x=fit, item.loc=1, type = "both", ci.method = "wald", show.table=TRUE, ylim.sr.adjust=TRUE)

# residual plots for the third item (polytomous item)
plot(x=fit, item.loc=3, type = "both", ci.method = "wald", show.table=FALSE, ylim.sr.adjust=TRUE)

# raw residual plot for the third item (polytomous item)
plot(x=fit, item.loc=3, type = "icc", ci.method = "wald", show.table=TRUE, ylim.sr.adjust=TRUE)

# standardized residual plot for the third item (polytomous item)
plot(x=fit, item.loc=3, type = "sr", ci.method = "wald", show.table=TRUE, ylim.sr.adjust=TRUE)
```

Description

This method function plots item or test characteristic curve using the ggplot2 package. The item characteristic (or category) curve (ICC) or item score curve is drawn for an individual item. The test characteristic curve (TCC) is drawn based on a total test form.

Usage

```r
## S3 method for class 'traceline'
plot(
  x,
  item.loc = NULL,
  score.curve = FALSE,
```

plot.traceline  
Plot ICC and TCC
overlap = FALSE,
layout.col = 2,
xlab.text,
ylab.text,
main.text,
lab.size = 15,
main.size = 15,
axis.size = 15,
line.color,
line.size = 1,
strip.size = 12,

Arguments

x An object of class traceline.
item.loc A numeric value indicating that the nth item (or the location of item) is plotted. If NULL, the TCC based on a total test form is drawn. Default is NULL.
score.curve Logical value. If TRUE, item score curve (i.e., a weighted sum of item category probabilities over the item scores) is plotted in a panel. Otherwise, ICCs for all score categories are plotted in separate panels. For a dichotomous item, the item score curve is the same as the ICC of score category 1. Ignored when item.loc = NULL. Default is FALSE.
overlap Logical value indicating whether multiple item score curves are plotted in one panel. If FALSE, the multiple item score curves are displayed with multiple panels, one for each.
layout.col An integer value indicating the number of columns in the panel when displaying ICCs for an item or when displaying multiple item scores with multiple panels.
xlab.text, ylab.text A title for the x and y axes.
main.text An overall title for the plot.
lab.size The size of xlab and ylab. Default is 15.
main.size The size of main.text. Default is 15.
axis.size The size of labels along the x and y axes. Default is 15.
line.color A character string specifying the color for a line. See http://www.cookbook-r.com/Graphs/Colors_(ggplot2)/ for more details about colors used in ggplot2.
line.size The size of lines. Default is 1.
strip.size The size of facet labels when ICCs for an item are plotted.
... Further arguments passed from the function geom_line() in the ggplot2 package.
Details

All of the plots are drawn using the ggplot2 package. If `item.loc = NULL`, the TCC based on the total test form is plotted. In the argument `item.loc`, a vector of positive integer values should be specified to indicate the nth items among the total test form. For example, if there are ten items in the test form and the score curves of the 1st, 2nd, and 3rd items should be plotted, then `item.loc = 1:3`.

Value

This method function displays ICC or TCC plots of the studied item(s).

# with multiple panels
plot(x, item.loc=53:55, score.curve=TRUE, overlap=FALSE)

# plot item score curves for the last three polytomous items
# in one panel
plot(x, item.loc=53:55, score.curve=TRUE, overlap=TRUE)

---

prm

Polytomous Response Model (PRM) Probabilities (GRM and GPCM)

Description

This function computes the probability of selecting a specific category for an item for a given set of theta values using the graded response model and (generalized) partial credit model.

Usage

prm(theta, a, d, D = 1, pr.model = c("GRM", "GPCM"))

Arguments

- **theta**: A vector of ability values.
- **a**: A numeric value of item discrimination (or slope) parameter.
- **d**: A vector of item difficulty (or threshold) parameters.
- **D**: A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.
- **pr.model**: A character string indicating the polytomous model being used. Available models are "GRM" for the the graded response model and "GPCM" for the (generalized) partial credit model.

Details

When the category probabilities are computed for an item with the partial credit model, provide a = 1 for that item. When model = "GPCM", d should include the item difficulty (or threshold) parameters. In the irtQ package, the item difficulty (or threshold) parameters of category boundaries for GPCM are expressed as the item location (or overall difficulty) parameter subtracted by the threshold parameter for unique score categories of the item. Note that when an GPCM item has K unique
score categories, $K-1$ item difficulty parameters are necessary because the item difficulty parameter for the first category boundary is always 0. For example, if an GPCM item has five score categories, four item difficulty parameters should be specified. For more details about the parameterization of the (generalized) partial credit model, See IRT Models section in the page of irtQ-package.

Value

This function returns a matrix where a row indicates the ability and a column represents score categories of the item.

Arguments

x A data frame containing the item metadata (e.g., item parameters, number of categories, models ...), an object of class est_item obtained from the function est_item, or an object of class est_irt obtained from the function est_irt. The item metadata can be easily created using the function shape_df. See est_irt, irtfit, info or simdat for more details about the item metadata.

... Additional arguments that will be forwarded to the est_score function.

data A matrix containing examinees’ response data for the items in the argument x. A row and column indicate the examinees and items, respectively.

score A vector of examinees’ ability estimates. If the abilities are not provided, rdif estimates the abilities before computing the RDIF statistics. See est_score for more details about scoring methods. Default is NULL.

group A numeric or character vector indicating group membership of examinees. The length of the vector should be the same with the number of rows in the response data matrix.

focal.name A single numeric or character scalar representing the level associated with the focal group. For instance, given group = c(0, 1, 0, 1, 1) and ‘1’ indicating the focal group, set focal.name = 1.

D A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.

alpha A numeric value to specify significance $\alpha$-level of the hypothesis test using the RDIF statistics. Default is .05.

missing A value indicating missing values in the response data set. Default is NA.

purify A logical value indicating whether a purification process will be implemented or not. Default is FALSE.

purify.by A character string specifying a RDIF statistic with which the purification is implemented. Available statistics are "rdifrs" for $RDIF_{RS}$, "rdifr" for $RDIF_I$, and "rdifs" for $RDIF_S$. 

max.iter  A positive integer value specifying the maximum number of iterations for the purification process. Default is 10.

min.resp  A positive integer value specifying the minimum number of item responses for an examinee required to compute the ability estimate. Default is NULL. See details below for more information.

method  A character string indicating a scoring method. Available methods are "ML" for the maximum likelihood estimation, "WL" for the weighted likelihood estimation, "MAP" for the maximum a posteriori estimation, and "EAP" for the expected a posteriori estimation. Default method is "ML".

range  A numeric vector of two components to restrict the range of ability scale for the ML, WL, EAP, and MAP scoring methods. Default is c(-5, 5).

norm.prior  A numeric vector of two components specifying a mean and standard deviation of the normal prior distribution. These two parameters are used to obtain the gaussian quadrature points and the corresponding weights from the normal distribution. Default is c(0,1). Ignored if method is "ML" or "WL".

nquad  An integer value specifying the number of gaussian quadrature points from the normal prior distribution. Default is 41. Ignored if method is "ML", "WL", or "MAP".

weights  A two-column matrix or data frame containing the quadrature points (in the first column) and the corresponding weights (in the second column) of the latent variable prior distribution. The weights and quadrature points can be easily obtained using the function gen.weight. If NULL and method is "EAP", default values are used (see the arguments of norm.prior and nquad). Ignored if method is "ML", "WL" or "MAP".

ncore  The number of logical CPU cores to use. Default is 1. See est_score for details.

verbose  A logical value. If TRUE, the progress messages of purification procedure are suppressed. Default is TRUE.

Details

The RDIF framework (Lim et al., 2022) consists of three IRT residual-based statistics: \( RDIF_R \), \( RDIF_S \), and \( RDIF_{RS} \). Under the null hypothesis that a test contains no DIF items, \( RDIF_R \) and \( RDIF_S \) follow normal distributions asymptotically. \( RDIF_{RS} \) is a based on a bivariate normal distribution of \( RDIF_R \) and \( RDIF_S \) statistics. Under the null hypothesis of no DIF items, it follows a \( \chi^2 \) distribution asymptotically with 2 degrees of freedom. See Lim et al. (2022) for more details about RDIF framework.

The \texttt{rdif} function computes all three RDIF statistics of \( RDIF_R \), \( RDIF_S \), and \( RDIF_{RS} \). The current version of \texttt{rdif} function supports both dichotomous and polytomous item response data. To compute the three statistics, the \texttt{rdif} function requires (1) item parameter estimates obtained from aggregate data regardless of group membership, (2) examinees’ ability estimates (e.g., ML), and (3) examinees’ item response data. Note that the ability estimates need to be computed using the aggregate data-based item parameter estimates. The item parameter estimates should be provided in the \texttt{x} argument, the ability estimates should be provided in the \texttt{score} argument, and the response data should be provided in the \texttt{data} argument. When the abilities are not given in the \texttt{score}
argument (i.e., score = NULL), the \texttt{rdif} function estimates examinees’ abilities automatically using the scoring method specified in the \texttt{method} argument (e.g., \texttt{method = "ML"}).

The group argument accepts a vector of either two distinct numeric or character variables. Between two distinct variable, one is to represent the reference group and another one is to represent the focal group. The length of the vector should be the same with the number of rows in the response data and each value in the vector should indicate each examinee of the response data. Once the \texttt{group} is specified, a single numeric or character value needs to be provided in the \texttt{focal.name} argument to define which group variable in the \texttt{group} argument represents the focal group.

As other DIF detection approaches, an iterative purification process can be implemented for the RDIF framework. When \texttt{purify = TRUE}, the purification process is implemented based on one of RDIF statistics specified in the \texttt{purify.by} argument (e.g., \texttt{purify.by = "rdifrs"}). At each iterative purification, examinees’ latent abilities are computed using purified items and scoring method specified in the \texttt{method} argument. The iterative purification process stops when no further DIF items are found or the process reaches a predetermined limit of iteration, which can be specified in the \texttt{max.iter} argument. See Lim et al. (2022) for more details about the purification procedure.

Scoring with a limited number of items can result in large standard errors, which may impact the effectiveness of DIF detection within the RDIF framework. The \texttt{min.resp} argument can be employed to avoid using scores with significant standard errors when calculating the RDIF statistics, particularly during the purification process. For instance, if \texttt{min.resp} is not NULL (e.g., \texttt{min.resp=5}), item responses from examinees whose total item responses fall below the specified minimum number are treated as missing values (i.e., NA). Consequently, their ability estimates become missing values and are not utilized in computing the RDIF statistics. If \texttt{min.resp=NULL}, an examinee’s score will be computed as long as there is at least one item response for the examinee.

\section*{Value}

This function returns a list of four internal objects. The four objects are:

- \texttt{no_purify} A list of several sub-objects containing the results of DIF analysis without a purification procedure. The sub-objects are:
  - \texttt{dif_stat} A data frame containing the results of three RDIF statistics across all evaluated items. From the first column, each column indicates item’s ID, $RDIF_R$ statistic, standardized $RDIF_R$, $RDIF_S$ statistic, standardized $RDIF_S$, $RDIF_{RS}$ statistic, p-value of the $RDIF_R$, p-value of the $RDIF_S$, p-value of the $RDIF_{RS}$, sample size of the reference group, sample size of the focal group, and total sample size, respectively. Note that $RDIF_{RS}$ does not have its standardized value because it is a $\chi^2$ statistic.
  - \texttt{moments} A data frame containing the moments of three RDIF statistics. From the first column, each column indicates item’s ID, mean of $RDIF_R$, standard deviation of $RDIF_R$, mean of $RDIF_S$, standard deviation of $RDIF_S$, and covariance of $RDIF_R$ and $RDIF_S$, respectively.
  - \texttt{dif_item} A list of three numeric vectors showing potential DIF items flagged by each of the RDIF statistics. Each of the numeric vector means the items flagged by $RDIF_R$, $RDIF_S$, and $RDIF_{RS}$, respectively.
  - \texttt{score} A vector of ability estimates used to compute the RDIF statistics.

- \texttt{purify} A logical value indicating whether the purification process was used.
A list of several sub-objects containing the results of DIF analysis with a purification procedure. The sub-objects are:

- `purify.by` A character string indicating which RDIF statistic is used for the purification. "rdifr", "rdifs", and "rdifrs" refers to $RDIF_R$, $RDIF_S$, and $RDIF_{RS}$, respectively.

- `dif_stat` A data frame containing the results of three RDIF statistics across all evaluated items. From the first column, each column indicates item's ID, $RDIF_R$ statistic, standardized $RDIF_R$, $RDIF_S$ statistic, standardized $RDIF_S$, $RDIF_{RS}$ statistic, p-value of the $RDIF_R$, p-value of the $RDIF_S$, p-value of the $RDIF_{RS}$, sample size of the reference group, sample size of the focal group, total sample size, and $n$th iteration where the RDIF statistics were computed, respectively.

- `moments` A data frame containing the moments of three RDIF statistics. From the first column, each column indicates item's ID, mean of $RDIF_R$, standard deviation of $RDIF_R$, mean of $RDIF_S$, standard deviation of $RDIF_S$, covariance of $RDIF_R$ and $RDIF_S$, and $n$th iteration where the RDIF statistics were computed, respectively.

- `dif_item` A list of three numeric vectors showing potential DIF items flagged by each of the RDIF statistics. Each of the numeric vector means the items flagged by $RDIF_R$, $RDIF_S$, and $RDIF_{RS}$, respectively.

- `n.iter` A total number of iterations implemented for the purification.

- `score` A vector of final purified ability estimates used to compute the RDIF statistics.

- `complete` A logical value indicating whether the purification process was completed. If FALSE, it means that the purification process reached the maximum iteration number but it was not complete.

- `alpha` A significance $\alpha$-level used to compute the p-values of RDIF statistics.

### Methods (by class)

- **default**: Default method to computes three RDIF statistics using a data frame `x` containing the item metadata.
- **est_irt**: An object created by the function `est_irt`.
- **est_item**: An object created by the function `est_item`.

run_flexmirt

**Run flexMIRT through R**

**Description**
This function implements flexMIRT (Cai, 2017) to run a model specified in the syntax file of flexMIRT (i.e., *.flexmirt) through R. To run this function, flexMIRT software must be installed in advance. This function will be useful especially when conducting a simulation study using flexMIRT.

**Usage**

```r
run_flexmirt(file.syntax, dir.flex = NULL, show.output.on.console = FALSE, ...)
```

**Arguments**

- `file.syntax`: A single string or vector containing the file path(s) of a flexmirt syntax file(s) to be run. An example is "C:/Users/Data/irtmodel.flexmirt".
- `dir.flex`: A path of directory where flexMIRT is installed. The path may include a folder name with "flexMIRT" (e.g., flexMIRT3, flexMIRT 3.6). If NULL, a path where flexMIRT is installed will be searched in "C:/Program Files" and it will be used as a default path (e.g., "C:/Program Files/flexMIRT3", "C:/Program Files/flexMIRT 3.6").
- `show.output.on.console`: A logical value to indicate whether to capture the output of the command and show it on the R console. Default is FALSE. See `system`.
- `...`: Further arguments passed from the function `system`.

**Details**
When a path of directory where flexMIRT (with a version < 3.6) is installed is provided in the argument `dir.flex`, the directory must include following six file of

- WinFlexMIRT.exe
- FlexMIRT_x64.exe
- FlexMIRT_x86.exe
- vpg.dll
- vpg.licensing.client.dll
- vpg.licensing.dll

When a path of directory where flexMIRT (with a version >= 3.6) is installed is provided in the argument `dir.flex`, the directory must include following six files of

- WinFlexMIRT.exe
- vpg.dll
run_flexmirt

- vpg.licensing.client.dll
- vpg.licensing.dll
- VPGLicenseClientNet.dll

and an additional directory of "Resources" that contains two files which are
- flexMIRT_x64_AVX.exe
- flexMIRT_x86_AVX.exe

Value
output files of flexMIRT

# Examples below will run when flexMIRT software is installed
# in a default path of "C:/Program Files/flexMIRT3".
# Otherwise provide a path where flexMIRT software is installed
# in the argument 'dir.flex'.

## Not run:
# (1) run a single syntax file
# import an example of flexMIRT syntax file to run the item parameter estimation of IRT 3PL model
file.syntax <- system.file("extdata", "2PLM_example.flexmirt", package = "irtQ")

# run flexMIRT to estimate the item parameters of IRT 3PL model
run_flexmirt(file.syntax=file.syntax, dir.flex=NULL, show.output=TRUE)

# check the output file
out.file <- system.file("extdata", "2PLM_example-prm.txt", package = "irtQ")
bring.flexmirt(out.file, type="par")

# (2) run multiple syntax files
# import two examples of flexMIRT syntax files
file.syntax1 <- system.file("extdata", "2PLM_example.flexmirt", package = "irtQ")
file.syntax2 <- system.file("extdata", "3PLM_example.flexmirt", package = "irtQ")

# run flexMIRT to estimate the item parameters
run_flexmirt(file.syntax=c(file.syntax1, file.syntax2), dir.flex=NULL, show.output=FALSE)

# check the output file
out.file1 <- system.file("extdata", "2PLM_example-prm.txt", package = "irtQ")
out.file2 <- system.file("extdata", "3PLM_example-prm.txt", package = "irtQ")
bring.flexmirt(out.file1, type="par")
bring.flexmirt(out.file2, type="par")

## End(Not run)

shape_df

Create a data frame of item metadata

Description

This function creates a data frame which includes item meta (e.g., item parameter, categories, models ...) to be used for the IRT model-data fit analysis as well as other analyses.

Usage

shape_df(
  par.drm = list(a = NULL, b = NULL, g = NULL),
  par.prm = list(a = NULL, d = NULL),
  item.id = NULL,
  cats,
  model,
  default.par = FALSE
)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>par.drm</td>
<td>A list containing three vectors of dichotomous item parameters. Namely, the item discrimination (a), item difficulty (b), and item guessing parameters.</td>
</tr>
<tr>
<td>par.prm</td>
<td>A list containing a vector of polytomous item discrimination (or slope) parameters and a list of polytomous item threshold (or step) parameters. In this list, the argument a should have a vector of slope parameters and the argument d should include a list of threshold (or step) parameters. See below for more details.</td>
</tr>
<tr>
<td>item.id</td>
<td>A character vector of item IDs. If NULL, an ID is automatically given to each item.</td>
</tr>
<tr>
<td>cats</td>
<td>A vector containing the number of score categories for items.</td>
</tr>
<tr>
<td>model</td>
<td>A character vector of IRT models corresponding to items. The available IRT models are &quot;1PLM&quot;, &quot;2PLM&quot;, &quot;3PLM&quot;, and &quot;DRM&quot; for dichotomous items, and &quot;GRM&quot; and &quot;GPCM&quot; for polytomous items. Note that &quot;DRM&quot; covers all dichotomous IRT models (i.e, &quot;1PLM&quot;, &quot;2PLM&quot;, and &quot;3PLM&quot;) and &quot;GRM&quot; and &quot;GPCM&quot; represent the graded response model and (generalized) partial credit model, respectively.</td>
</tr>
</tbody>
</table>
default.par  A logical value to create an item meta with default item parameters. If TRUE, the number of score categories and corresponding IRT models should be specified in the arguments of cats and model, respectively. In the default item meta, the item slope parameter has a fixed value of 1, the item difficulty (or threshold) parameter(s) has(have) a fixed value of 0, and the item guessing parameter has a fixed value of .2. Default is FALSE.

Details

For any item where "1PLM" or "2PLM" is specified in model, the item guessing parameter will be NA. If model is a vector of length = 1, the specified model is replicated across all items. As in the function simdat, it is important to clearly specify cats according to the order of items in the test form when a data frame for a mixed-format test needs to be created. See simdat for more details about how to specify cats.

When specifying item parameters in par.drm and/or par.prm, keep the order of item parameter types. For example, in the par.drm argument, the first argument a should contain the slope parameter vector, the second argument b should contain the difficulty vector, and the third argument g should contain the guessing parameter vector. In the par.drm argument, the first argument a should contain the slope parameter vector and the second argument d should contain a list including vectors of item threshold (or step) parameters for polytomous response IRT models. Note that when an item follows the (generalized) partial credit model, the item step parameters are the overall item difficulty (or location) parameter subtracted by the difficulty (or threshold) parameter for each category. Thus, the number of step parameters for item with m categories is m-1 because a step parameter for the first category does not affect the category probabilities.

Value

This function returns a data frame.

**simCAT_DC**

*Simulated single-item format CAT Data*

**Description**

This data set contains an item pool information, response data, and examinee’s ability estimates.

**Usage**

simCAT_DC

**Format**

This data includes a list of length three. The first internal object is a data.frame of the item pool consisting of 100 dichotomous items. The item parameters of the first 90 items were generated with the IRT 2PL model and calibrated with the same model. However, the item parameters of the last 10 items were generated with the IRT 3PL model but calibrated with the IRT 2PL model. The second internal object is the response data set including a sparse response data set of 10,000 examinees for the items in the item pool. The third internal object is the examinee’s ability estimates for 10,000 examinees.

**Author(s)**

Hwanggyu Lim <hglm83@gmail.com>
Description

This data set contains an item pool information, response data, and examinee’s ability estimates.

Usage

simCAT_MX

Format

This data includes a list of length three. The first internal object is a data.frame of the item pool consisting of 200 dichotomous items and 30 polytomous items. The dichotomous items were calibrated with the IRT 3PL model and the polytomous items were calibrated with the generalized partial credit model. All polytomous items have three score categories (i.e., 0, 1, 2). The second internal object is the response data set including a sparse response data set of 30,000 examinees for the items in the item pool. The third internal object is the examinee’s ability estimates for 30,000 examinees.

Author(s)

Hwanggyu Lim <hglim83@gmail.com>

Description

This function generates a simulated response data for a single- or a mixed-format test forms. For dichotomous item response data, the IRT 1PL, 2PL, and 3PL models are available. For polytomous item response data, the graded response model, the partial credit model, and the generalized partial credit model are available.

Usage

simdat(
    x = NULL,
    theta,
    a.drm,
    b.drm,
    g.drm = NULL,
    a.prm,
    d.prm,
    cats,
Arguments

x  A data frame containing the item metadata (e.g., item parameters, number of categories, models ...). This data frame can be easily obtained using the function `shape_df`. See below for details.

theta  A vector of theta values.

a.drm  A vector of item discrimination (or slope) parameters for dichotomous response IRT models.

b.drm  A vector of item difficulty (or threshold) parameters for dichotomous response IRT models.

g.drm  A vector of item guessing parameters for dichotomous IRT models.

a.prm  A vector of item discrimination (or slope) parameters for polytomous response IRT models.

d.prm  A list containing vectors of item threshold (or step) parameters for polytomous response IRT models.

cats  A vector containing the number of score categories for items.

pr.model  A vector of character strings specifying the polytomous model with which response data are simulated. For each polytomous model, "GRM" for the graded response model or "GPCM" for the (generalized) partial credit model can be specified.

D  A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.

Details

There are two ways of generating the simulated response data. The first way is by using the argument x to read in a data frame of item metadata. In the data frame, the first column should have item IDs, the second column should contain unique score category numbers of the items, and the third column should include IRT models being fit to the items. The available IRT models are "1PLM", "2PLM", "3PLM", and "DRM" for dichotomous item data, and "GRM" and "GPCM" for polytomous item data. Note that "DRM" covers all dichotomous IRT models (i.e, "1PLM", "2PLM", and "3PLM") and "GRM" and "GPCM" represent the graded response model and (generalized) partial credit model, respectively. The next columns should include the item parameters of the fitted IRT models. For dichotomous items, the fourth, fifth, and sixth columns represent the item discrimination (or slope), item difficulty, and item guessing parameters, respectively. When "1PLM" and "2PLM" are specified in the third column, NAs should be inserted in the sixth column for the item guessing parameters. For polytomous items, the item discrimination (or slope) parameters should be included in the fourth column and the item difficulty (or threshold) parameters of category boundaries should be contained from the fifth to the last columns. When the number of unique score categories differs between items, the empty cells of item parameters should be filled with NAs. In the `irtQ` package, the item difficulty (or threshold) parameters of category boundaries for GPCM are expressed as the item location (or overall difficulty) parameter subtracted by the
threshold parameter for unique score categories of the item. Note that when an GPCM item has $K$ unique score categories, $K-1$ item difficulty parameters are necessary because the item difficulty parameter for the first category boundary is always 0. For example, if an GPCM item has five score categories, four item difficulty parameters should be specified. An example of a data frame with a single-format test is as follows:

<table>
<thead>
<tr>
<th>ITEM</th>
<th>item number</th>
<th>model</th>
<th>$d_1$</th>
<th>$d_2$</th>
<th>$d_3$</th>
<th>$d_4$</th>
</tr>
</thead>
<tbody>
<tr>
<td>ITEM1</td>
<td>2</td>
<td>1PLM</td>
<td>1.000</td>
<td>1.461</td>
<td>NA</td>
<td></td>
</tr>
<tr>
<td>ITEM2</td>
<td>2</td>
<td>2PLM</td>
<td>1.921</td>
<td>-1.049</td>
<td>NA</td>
<td></td>
</tr>
<tr>
<td>ITEM3</td>
<td>2</td>
<td>3PLM</td>
<td>1.736</td>
<td>1.501</td>
<td>0.203</td>
<td></td>

</tr>
</tbody>
</table>

See IRT Models section in the page of irtQ-package for more details about the IRT models used in the irtQ package. An easier way to create a data frame for the argument $x$ is by using the function `shape_df`.

The second way is by directly specifying item parameters for each item for which response data should be simulated (i.e., without using a data frame, as shown in the examples that follow). In addition to item parameters, theta, cats, pr.model, and $D$ should be specified as well. g.drm does not need to be specified when only the 1PL and 2PL models are used for dichotomous item response data. For dichotomous items, 2s should be specified in cats. For polytomous items, the number of unique score categories should be specified in cats. When a response data set is generated with a mixed-format test, it is important to clearly specify cats according to the order of items in the test form. Suppose that the response data of ten examinees are simulated with five items, including three dichotomous items and two polytomous items with three categories. Also, suppose that the second and the forth items are the polytomous items. Then, cats = c(2, 3, 2, 3, 2) should be used. Additionally, among those two polytomous items, if the first and second item response data are simulated from the graded response model and generalized partial credit model, respectively, then pr.model = c('GRM', 'GPCM').

Value

This function returns a vector or a matrix. When a matrix is returned, rows indicate theta values and columns represent items.

Examples

## example 1.
## simulates response data with a mixed-format test.
## for the first two polytomous items, the generalized partial credit model is used
## for the last polytomous item, the graded response model is used
# 100 examinees are sampled
theta <- rnorm(100)

# set item parameters for three dichotomous items with the 3PL model
a.drm <- c(1, 1.2, 1.3); b.drm <- c(-1, 0, 1); g.drm <- rep(0.2, 3)

# set item parameters for three polytomous item parameters
# note that 4, 4, and 5 categories are used for polytomous items
a.prm <- c(1.3, 1.2, 1.7)
d.prm <- list(c(-1.2, -0.3, 0.4), c(-0.2, 0.5, 1.6), c(-1.7, 0.2, 1.1, 2.0))

cats <- c(2, 2, 4, 4, 5, 2)

# create a character vector of the IRT model for the polytomous items
pr.model <- c("GPCM", "GPCM", "GRM")

# simulate the response data
simdat(theta=theta, a.drm=a.drm, b.drm=b.drm, g.drm=NULL, a.prm=a.prm, d.prm=d.prm, cats=cats, pr.model=pr.model, D=1)

## example 2.
## simulates response data with a single-format test with the 2PL model.
# create a numeric vector of score categories for the three 2PL model items
cats <- rep(2, 3)

# simulate the response data
simdat(theta=theta, a.drm=a.drm, b.drm=b.drm, cats=cats, D=1)

## example 3.
## the use of a "-prm.txt" file obtained from a flexMIRT
# import the "-prm.txt" output file from flexMIRT
flex_prm <- system.file("extdata", "flexmirt_sample-prm.txt", package = "irtQ")

# read item parameters and transform them to item metadata
test_flex <- bring.flexmirt(file=flex_prm, "par")$Group1$full_df

# simulate the response data
simdat(x=test_flex, theta=theta, D=1) # use a data.frame of item meta information
**Description**

This data set has a list consisting of item metadata, item response data, and group names of three simulated groups.

**Usage**

simMG

**Format**

This data set includes a list of three internal objects: (1) a list of item metadata (item.prm) for three groups, (2) a list of item response data (res.dat) for the three groups, and (3) a vector of group names (group.name) for the three groups.

The first internal object (item.prm) contains a list of item metadata of three test forms for the three groups. In terms of test forms, the test forms for the first and second groups have fifty items consisting of forty seven 3PLM items and three GRM items. The test form for the third group has thirty eight items consisting of thirty seven 3PLM items and one GRM item. Among the three forms, the first and second test forms share twelve common items (C1I1 through C1I12) and the second and third test forms share ten common items (C2I1 through c2I10). There is no common item between the first and third forms. The item parameters in the item metadata were used to simulate the item response data sets for the three groups (see the second object of the list).

Regrading the second internal object, all three response data sets were simulated with 2,000 latent abilities randomly sampled from $N(0, 1)$ (Group 1), $N(0.5, 0.8^2)$ (Group 2), and $N(-0.3, 1.3^2)$ (Group 3), respectively, using the true item parameters provided in the item metadata.

The third internal object is a vector of three group names which are "Group1", "Group2", and "Group3".

Hwanggyu Lim <hglim83@gmail.com>

**Description**

This method function summarizes the IRT calibration results of `est_irt` or `est_item` object.
Usage

summary(object, ...)

## S3 method for class 'est_irt'
summary(object, ...)

## S3 method for class 'est_mg'
summary(object, ...)

## S3 method for class 'est_item'
summary(object, ...)

Arguments

object An object of class `est_irt` or `est_item`.

... Further arguments passed to or from other methods.

Value

The method function returns a list of internal objects extracted from `est_irt` or `est_item` object and displays a summary of the IRT calibration results on the console panel.

Methods (by class)

- `est_irt`: An object created by the function `est_irt`.
- `est_mg`: An object created by the function `est_mg`.
- `est_item`: An object created by the function `est_item`.

Examples

# fit the 1PL model to LSAT6 data and constrain the slope parameters to be equal
fit.1pl <- est_irt(data=LSAT6, D=1, model="1PLM", cats=2, fix.a.1pl=FALSE)

# summary of the estimation
summary(fit.1pl)
sx2_fit  

S-X2 fit statistic

Description

This function computes $S - X^2$ (Orlando & Thissen, 2000, 2003) item fit statistic.

Usage

sx2_fit(x, ...)

## Default S3 method:

sx2_fit(
  x,
  data,
  D = 1,
  alpha = 0.05,
  min-collapse = 1,
  norm.prior = c(0, 1),
  nquad = 30,
  weights,
  pcm.loc = NULL,
  ...
)

## S3 method for class 'est_item'

sx2_fit(
  x,
  alpha = 0.05,
  min-collapse = 1,
  norm.prior = c(0, 1),
  nquad = 30,
  weights,
  pcm.loc = NULL,
  ...
)

## S3 method for class 'est_irt'

sx2_fit(
  x,
  alpha = 0.05,
  min-collapse = 1,
  norm.prior = c(0, 1),
  nquad = 30,
  weights,
  pcm.loc = NULL,
  ...
)
Arguments

- **x**: A data frame containing the item metadata (e.g., item parameters, number of categories, models ...), an object of class `est_item` obtained from the function `est_item`, or an object of class `est_irt` obtained from the function `est_irt`. See `irtfit`, `info`, or `simdat` for more details about the item metadata. The data frame of item metadata can be easily obtained using the function `shape_df`.

- **data**: A matrix containing examinees’ response data for the items in the argument `x`. A row and column indicate the examinees and items, respectively.

- **D**: A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.

- **alpha**: A numeric value to specify significance $\alpha$-level of the hypothesis test for $S - X^2$ fit statistic. Default is .05.

- **min.collapse**: An integer value to indicate the minimum frequency of cells to be collapsed. Default is 1. See below for details.

- **norm.prior**: A numeric vector of two components specifying a mean and standard deviation of the normal prior distribution. These two parameters are used to obtain the gaussian quadrature points and the corresponding weights from the normal distribution. Default is c(0,1).

- **nquad**: An integer value specifying the number of gaussian quadrature points from the normal prior distribution. Default is 30.

- **weights**: A two-column matrix or data frame containing the quadrature points (in the first column) and the corresponding weights (in the second column) of the latent variable prior distribution. The weights and quadrature points can be easily obtained using the function `gen.weight`. If missing, default values are used (see the arguments of `norm.prior` and `nquad`).

- **pcm.loc**: A vector of integer values indicating the locations of partial credit model (PCM) items whose slope parameters are fixed to certain values. Default is NULL.

Details

Often, very small expected frequencies in the contingency tables used to compute $\chi^2$ fit statistics could compromise the accuracy of the $\chi^2$ approximation for their distribution (Orlando & Thissen, 2000). To avoid this problem, Orlando and Thissen (2000) used an algorithm of collapsing adjacent test score groups to maintain a minimum expected category frequency of 1. However, if Orlando and Thissen’s cell collapsing approach is applied to polytomous data, too much information would be lost (Kang & Chen, 2008). Thus, Kang and Chen (2008) collapsed adjacent cells of item score categories for a specific score group to ensure a minimum expected category frequency of 1. The same collapsing strategies were applied in the function `sx2_fit`. If a minimum expected category frequency needs to be set to different number, you can specify the minimum value in the argument `min.collapse`.

Note that if "DRM" is specified for an item in the item metadata set, the item is considered as "3PLM" to compute degree of freedom of the $S - X^2$ fit statistic.

Also, any missing responses in data are replaced with incorrect responses (i.e., 0s).
Value

This function returns a list. Within a list, several internal objects are contained such as:

- **fit_stat**: A data frame containing the results of $S - X^2$ fit statistics for all items.
- **item_df**: The item metadata specified in the argument x.
- **exp_freq**: A list containing the collapsed expected frequency tables for all items.
- **obs_freq**: A list containing the collapsed observed frequency tables for all items.
- **exp_prob**: A list containing the collapsed expected probability tables for all items.
- **obs_prop**: A list containing the collapsed observed proportion tables for all items.

Methods (by class)

- **default**: Default method to compute $S - X^2$ fit statistics for a data frame x containing the item metadata.
- **est_item**: An object created by the function `est_item`.
- **est_irt**: An object created by the function `est_irt`.

Examples

```r
## example 1: all five polytomous IRT models are GRM
## import the "-prm.txt" output file from flexMI RT
flex_sam <- system.file("extdata", "flexmirt_sample-prm.txt", package = "irtQ")

# select the item metadata
x <- bring.flexmirt(file=flex_sam, "par")$Group1$full_df

# generate examinees' abilities from N(0, 1)
set.seed(23)
```
```r
score <- rnorm(500, mean=0, sd=1)
# simulate the response data
data <- simdat(x=x, theta=score, D=1)

# compute fit statistics
fit1 <- sx2_fit(x=x, data=data, nquad=30)
# fit statistics
fit1$fit_stat

## example 2: first 39th and 40th items follows GRM and 53rd, 54th, and 55th items
## follow PCM (thus, the slope parameters are fixed to 1)
# replace the model names with GPCM and
# assign 1 to the slope parameters for the 53rd, 54th, and 55th items
x[53:55, 3] <- "GPCM"
x[53:55, 4] <- 1

# generate examinees' abilities from N(0, 1)
set.seed(25)
score <- rnorm(1000, mean=0, sd=1)
# simulate the response data
data <- simdat(x=x, theta=score, D=1)

# compute fit statistics
fit2 <- sx2_fit(x=x, data=data, nquad=30, pcm.loc=53:55)
# fit statistics
fit2$fit_stat
```

---

**traceline**

*Compute Item/Test Characteristic Functions*

**Description**

This function computes the item category probabilities, item characteristic function, and test characteristic function given a set of theta values. The returned object of this function can be used to draw the item or test characteristic curve using the function `plot.traceline`.

**Usage**

```r
traceline(x, ...)
```

## Default S3 method:
traceline(x, theta, D = 1, ...)  
## S3 method for class 'est_item'  
traceline(x, theta, ...)  
## S3 method for class 'est_irt'  
traceline(x, theta, ...)

Arguments

x  A data frame containing the item metadata (e.g., item parameters, number of categories, models ...), an object of class est_item obtained from the function est_item, or an object of class est_irt obtained from the function est_irt.  
See irtfit, info, or simdat for more details about the item metadata. The data frame of item metadata can be easily obtained using the function shape_df.  

...  Further arguments passed to or from other methods.  

theta  A vector of theta values.  

D  A scaling factor in IRT models to make the logistic function as close as possible to the normal ogive function (if set to 1.7). Default is 1.

Value

This function returns an object of class traceline. This object contains a list containing the item category probabilities, item characteristic function, and test characteristic function.

Methods (by class)

• default: Default method to compute the item category probabilities, item characteristic function, and test characteristic function for a data frame x containing the item metadata.  
• est_item: An object created by the function est_item.  
• est_irt: An object created by the function est_irt.

traceline(x=test_flex, theta, D=1)

---

write.flexmirt  
Write a ".prm.txt" file for flexMIRT

Description

This function writes an output file of ".prm.txt" for flexMIRT (Cai, 2017). The current version of this function can be used only for the unidimensional IRT models. This function was written by modifying the function read.flexmirt (Pritikin & Falk, 2020).

Usage

write.flexmirt(
  x,
  file = NULL,
  norm.pop = c(0, 1),
  rePar = TRUE,
  mgroup = FALSE,
  group.name = NULL
)

Arguments

x  
A data frame containing the item metadata (e.g., item parameters, number of categories, models ...) for a single group or a list of the item metadata for multiple groups. See est_irt, irtfit.info, or simdat for more details about the item metadata. The item metadata can be easily created using the function shape_df.

file  
The destination file name.

norm.pop  
A numeric vector of two components specifying a mean and standard deviation of the normal population ability distribution for a single group or a list of the numeric vectors of length two for multiple groups. When a list is provided, each internal numeric vector should contain a mean and standard deviation of the ability distribution of each group (e.g., norm.pop = list(c(0, 1), c(0, 0.8), c(0.5, 1.2)) for three groups). When mgroup = TRUE and a single vector of length two is provided (e.g., norm.pop = c(0, 1)), the same vector will be recycled across all groups. Default is c(0,1).

rePar  
A logical value indicating whether the item parameters in the item metadata are the reparameterized item parameters. If TRUE, the item intercepts and logits of item guessing parameters should be included in the item metadata. If FALSE,
the item difficulty and item guessing parameters should be included in the item metadata.

mgroup A logical value indicating whether a ".-prm.txt" file is created for a single group or multiple groups. Default is FALSE.

group.name A character vector of group names. If NULL, the group names are automatically generated (e.g., Group1).

Value
A ".-prm.txt" file.
