Package ‘jsonlite’

October 21, 2022

Version 1.8.3
Title A Simple and Robust JSON Parser and Generator for R
License MIT + file LICENSE
Depends methods
BugReports https://github.com/jeroen/jsonlite/issues
Maintainer Jeroen Ooms <jeroen@berkeley.edu>
VignetteBuilder knitr, R.rsp
Description A reasonably fast JSON parser and generator, optimized for statistical
data and the web. Offers simple, flexible tools for working with JSON in R, and
is particularly powerful for building pipelines and interacting with a web API.
The implementation is based on the mapping described in the vignette (Ooms, 2014).
In addition to converting JSON data from/to R objects, 'jsonlite' contains
functions to stream, validate, and prettify JSON data. The unit tests included
with the package verify that all edge cases are encoded and decoded consistently
for use with dynamic data in systems and applications.
Suggests httr, vctrs, testthat, knitr, rmarkdown, R.rsp, sf
RoxygenNote 7.2.1
Encoding UTF-8
NeedsCompilation yes

R topics documented:

base64 .................................................. 2
flatten .................................................. 3
base64

Description

Simple in-memory base64 encoder and decoder. Used internally for converting raw vectors to text. Interchangeable with encoder from base64enc or openssl package.

Usage

base64_dec(input)
base64_enc(input)
base64url_enc(input)
base64url_dec(input)

Arguments

input string or raw vector to be encoded/decoded

Details

The base64url_enc and base64url_dec functions use a variation of base64 that substitute characters +/- for -_ respectively, such that the output does not require URL-encoding. See also section 5 of rfc4648.

Examples

str <- base64_enc(serialize(iris, NULL))
out <- unserialize(base64_dec(str))
stopifnot(identical(out, iris))
flatten Flatten nested data frames

Description

In a nested data frame, one or more of the columns consist of another data frame. These structures frequently appear when parsing JSON data from the web. We can flatten such data frames into a regular 2 dimensional tabular structure.

Usage

\[
\text{flatten}(x, \text{recursive} = \text{TRUE})
\]

Arguments

\[
x \quad \text{a data frame}
\]
\[
\text{recursive} \quad \text{flatten recursively}
\]

Examples

```r
options(stringsAsFactors = FALSE)
x <- data.frame(driver = c("Bowser", "Peach"), occupation = c("Koopa", "Princess"))
x$vehicle <- data.frame(model = c("Piranha Prowler", "Royal Racer"))
x$vehicle$stats <- data.frame(speed = c(55, 34), weight = c(67, 24), drift = c(35, 32))
str(x)
str(flatten(x))
str(flatten(x, recursive = FALSE))
```

```
## Not run:
data1 <- fromJSON("https://api.github.com/users/hadley/repos")
colnames(data1)
colnames(data1$owner)
colnames(flatten(data1))
```

```
# or for short:
data2 <- fromJSON("https://api.github.com/users/hadley/repos", flatten = TRUE)
colnames(data2)
```

## End(Not run)
**gzjson**

_Gzipped JSON_

**Description**

Wrapper to generate and parse gzipped JSON, in order to save some disk or network space. This is mainly effective for larger json objects with many repeated keys, as is common in serialized data frames.

**Usage**

- `as_gzjson_raw(x, ...)`
- `as_gzjson_b64(x, ...)`
- `parse_gzjson_raw(buf, ...)`
- `parse_gzjson_b64(b64, ...)`

**Arguments**

- `x` R data object to be converted to JSON
- `...` passed down to `toJSON` or `fromJSON`
- `buf` raw vector with gzip compressed data
- `b64` base64 encoded string containing gzipped json data

**Details**

The `as_gzjson_raw` and `parse_gzjson_raw` functions work with raw (binary) vectors of compressed data. To use this in a place where only text is allowed you can wrap the output again in `base64` as done by `as_gzjson_b64` and `parse_gzjson_b64`. This increases the size again with about 33%.

**Examples**

```r
cat <- as_gzjson_b64(iris[1:5,])
cat(str)
parse_gzjson_b64(str)
```
**prettify, minify**

Prettify or minify a JSON string

**Description**

Prettify adds indentation to a JSON string; minify removes all indentation/whitespace.

**Usage**

```r
prettify(txt, indent = 4)
minify(txt)
```

**Arguments**

- `txt` JSON string
- `indent` number of spaces to indent

**Examples**

```r
myjson <- toJSON(cars)
cat(myjson)
prettify(myjson)
minify(myjson)
```

---

**rbind_pages**

Combine pages into a single data frame

**Description**

The `rbind_pages` function is used to combine a list of data frames into a single data frame. This is often needed when working with a JSON API that limits the amount of data per request. If we need more data than what fits in a single request, we need to perform multiple requests that each retrieve a fragment of data, not unlike pages in a book. In practice this is often implemented using a page parameter in the API. The `rbind_pages` function can be used to combine these pages back into a single dataset.

**Usage**

```r
rbind_pages(pages)
```

**Arguments**

- `pages` a list of data frames, each representing a page of data
Details

The `rbind_pages` function uses `vctrs::vec_rbind()` to bind the pages together. This generalizes `base::rbind()` in two ways:

- Not each column has to be present in each of the individual data frames; missing columns will be filled up in NA values.
- Data frames can be nested (can contain other data frames).

Examples

```r
# Basic example
x <- data.frame(foo = rnorm(3), bar = c(TRUE, FALSE, TRUE))
y <- data.frame(foo = rnorm(2), col = c("blue", "red"))
rbind_pages(list(x, y))
```

```r
baseUrl <- "https://projects.propublica.org/nonprofits/api/v2/search.json"
pages <- list()
for(i in 0:20){
  mydata <- fromJSON(paste0(baseUrl, "?order=revenue&sort_order=desc&page=", i))
  message("Retrieving page ", i)
  pages[[i+1]] <- mydata$organizations
}
organizations <- rbind_pages(pages)
nrow(organizations)
colnames(organizations)
```

---

**read_json**  
Read/write JSON

### Description

These functions are similar to `toJSON()` and `fromJSON()` except they explicitly distinguish between path and literal input, and do not simplify by default.

### Usage

```r
read_json(path, simplifyVector = FALSE, ...)
```

```r
parse_json(json, simplifyVector = FALSE, ...)
```

```r
write_json(x, path, ...)
```

**Arguments**

- **path**
  - file on disk
- **simplifyVector**
  - simplifies nested lists into vectors and data frames. See `fromJSON()`.
- **...**
  - additional conversion arguments, see also `toJSON()` or `fromJSON()`
- **json**
  - string with literal json or connection object to read from
- **x**
  - an object to be serialized to JSON

**See Also**

- `fromJSON()`, `stream_in()`

**Examples**

```r

# Example

tmp <- tempfile()
write_json(iris, tmp)
# Nested lists
read_json(tmp)
# A data frame
read_json(tmp, simplifyVector = TRUE)
```

**serializeJSON**

serialize R objects to JSON

**Description**

The `serializeJSON()` and `unserializeJSON()` functions convert between R objects to JSON data. Instead of using a class based mapping like `toJSON()` and `fromJSON()`, the serialize functions base the encoding schema on the storage type, and capture all data and attributes from any object. Thereby the object can be restored almost perfectly from its JSON representation, but the resulting JSON output is very verbose. Apart from environments, all standard storage types are supported.

**Usage**

```r

serializeJSON(x, digits = 8, pretty = FALSE)

unserializeJSON(txt)
```

**Arguments**

- **x**
  - an R object to be serialized
- **digits**
  - max number of digits (after the dot) to print for numeric values
- **pretty**
  - add indentation/whitespace to JSON output. See `prettify()`
- **txt**
  - a JSON string which was created using `serializeJSON`
Note

JSON is a text based format which leads to loss of precision when printing numbers.

Examples

```r
jsoncars <- serializeJSON(mtcars)
mtcars2 <- unserializeJSON(jsoncars)
identical(mtcars, mtcars2)

set.seed('123')
myobject <- list(
  mynull = NULL,
  mycomplex = lapply(eigen(matrix(-rnorm(9),3)), round, 3),
  mymatrix = round(matrix(rnorm(9), 3),3),
  myint = as.integer(c(1,2,3)),
  mydf = cars,
  mylist = list(foo='bar', 123, NA, NULL, list('test')),
  mylogical = c(TRUE,FALSE,NA),
  mychar = c('foo', NA, 'bar'),
  somemissings = c(1,2,NA,NaN,5, Inf, 7 -Inf, 9, NA),
  myrawvec = charToRaw('This is a test')
);
identical(unserializeJSON(serializeJSON(myobject)), myobject);
```

stream_in, stream_out  Streaming JSON input/output

Description

The `stream_in` and `stream_out` functions implement line-by-line processing of JSON data over a connection, such as a socket, url, file or pipe. JSON streaming requires the `ndjson` format, which slightly differs from `fromJSON()` and `toJSON()`, see details.

Usage

```r
stream_in(con, handler = NULL, pagesize = 500, verbose = TRUE, ...)
stream_out(x, con = stdout(), pagesize = 500, verbose = TRUE, prefix = "", ...)
```

Arguments

- **con**: a connection object. If the connection is not open, `stream_in` and `stream_out` will automatically open and later close (and destroy) the connection. See details.
- **handler**: a custom function that is called on each page of JSON data. If not specified, the default handler stores all pages and binds them into a single data frame that will be returned by `stream_in`. See details.
- **pagesize**: number of lines to read/write from/to the connection per iteration.
stream_in, stream_out

verbose       print some information on what is going on.
...
arguments for fromJSON() and toJSON() that control JSON formatting/parsing
where applicable. Use with caution.
x          object to be streamed out. Currently only data frames are supported.
prefix      string to write before each line (use \\u001e to write rfc7464 text sequences)

Details

Because parsing huge JSON strings is difficult and inefficient, JSON streaming is done using lines
of minified JSON records, a.k.a. ndjson. This is pretty standard: JSON databases such as Mon-
goDB use the same format to import/export datasets. Note that this means that the total stream
combined is not valid JSON itself; only the individual lines are. Also note that because line-breaks
are used as separators, prettified JSON is not permitted: the JSON lines must
be minified. In this
respect, the format is a bit different from fromJSON() and toJSON() where all lines are part of a
single JSON structure with optional line breaks.

The handler is a callback function which is called for each page (batch) of JSON data with exactly
one argument (usually a data frame with pagesize rows). If handler is missing or NULL, a default
handler is used which stores all intermediate pages of data, and at the very end binds all pages
together into one single data frame that is returned by stream_in. When a custom handler function
is specified, stream_in does not store any intermediate results and always returns NULL. It is then up
to the handler to process or store data pages. A handler function that does not store intermediate
results in memory (for example by writing output to another connection) results in a pipeline that
can process an unlimited amount of data. See example.

Note that a vector of JSON strings already in R can parsed with stream_in by creating a connection
to it with textConnection().

If a connection is not opened yet, stream_in and stream_out will automatically open and later
close the connection. Because R destroys connections when they are closed, they cannot be reused.
To use a single connection for multiple calls to stream_in or stream_out, it needs to be opened
beforehand. See example.

Value

The stream_out function always returns NULL. When no custom handler is specified, stream_in
returns a data frame of all pages binded together. When a custom handler function is specified,
stream_in always returns NULL.

Examples

# compare formats
x <- iris[1:3,]
toJSON(x)
stream_out(x)

# Trivial example
mydata <- stream_in(url("http://httpbin.org/stream/100"))

## Not run:
#Stream large dataset to file and back
library(nycflights13)
stream_out(flights, file(tmp <- tempfile()))
flights2 <- stream_in(file(tmp))
unlink(tmp)
all.equal(flights2, as.data.frame(flights))

# stream over HTTP
diamonds2 <- stream_in(url("http://jeroen.github.io/data/diamonds.json"))

# stream over HTTP with gzip compression
flights3 <- stream_in(gzcon(url("http://jeroen.github.io/data/nycflights13.json.gz")))
all.equal(flights3, as.data.frame(flights))

# stream over HTTPS (HTTP+SSL) via curl
library(curl)
flights4 <- stream_in(gzcon(curl("https://jeroen.github.io/data/nycflights13.json.gz")))
all.equal(flights4, as.data.frame(flights))

# or alternatively:
flights5 <- stream_in(gzcon(pipe(curl https://jeroen.github.io/data/nycflights13.json.gz")))
all.equal(flights5, as.data.frame(flights))

# Full JSON IO stream from URL to file connection.
# Calculate delays for flights over 1000 miles in batches of 5k
library(dplyr)
con_in <- gzcon(url("http://jeroen.github.io/data/nycflights13.json.gz"))
con_out <- file(tmp <- tempfile(), open = "wb")
stream_in(con_in, handler = function(df){
  df <- dplyr::filter(df, distance > 1000)
  df <- dplyr::mutate(df, delta = dep_delay - arr_delay)
  stream_out(df, con_out, pagesize = 1000)
}, pagesize = 5000)
close(con_out)

# stream it back in
mydata <- stream_in(file(tmp))
nrow(mydata)
unlink(tmp)

# Data from http://openweathermap.org/current#bulk
# Each row contains a nested data frame.
daily14 <- stream_in(gzcon(url("http://78.46.48.103/sample/daily_14.json.gz")), pagesize=50)
subset(daily14, city$name == "Berlin")$data[[1]]

# Or with dplyr:
library(dplyr)
daily14f <- flatten(daily14)
filter(daily14f, city.name == "Berlin")$data[[1]]

# Stream import large data from zip file
tmp <- tempfile()
companies <- stream_in(unz(tmp, "companies.json"))

## End(Not run)

### toJSON, fromJSON

Convert R objects to/from JSON

#### Description

These functions are used to convert between JSON data and R objects. The `toJSON()` and `fromJSON()` functions use a class based mapping, which follows conventions outlined in this paper: https://arxiv.org/abs/1403.2805 (also available as vignette).

#### Usage

```r
fromJSON(
  txt,
  simplifyVector = TRUE,
  simplifyDataFrame = simplifyVector,
  simplifyMatrix = simplifyVector,
  flatten = FALSE,
  ...
)
```

```r
toJSON(
  x,
  dataframe = c("rows", "columns", "values"),
  matrix = c("rowmajor", "columnmajor"),
  Date = c("ISO8601", "epoch"),
  POSIXt = c("string", "ISO8601", "epoch", "mongo"),
  factor = c("string", "integer"),
  complex = c("string", "list"),
  raw = c("base64", "hex", "mongo", "int", "js"),
  null = c("list", "null"),
  na = c("null", "string"),
  auto_unbox = FALSE,
  digits = 4,
)```

#### Example

```r
daily14 <- stream_in(gzcon(url("http://78.46.48.103/sample/daily_14.json.gz")), pagesize=50)
subset(daily14, city$name == "Berlin")$data[[1]]

# Or with dplyr:
library(dplyr)
daily14f <- flatten(daily14)
filter(daily14f, city.name == "Berlin")$data[[1]]

# Stream import large data from zip file
tmp <- tempfile()
companies <- stream_in(unz(tmp, "companies.json"))

## End(Not run)
pretty = FALSE,
force = FALSE,
...
)

Arguments

txt    a JSON string, URL or file
simplifyVector  coerce JSON arrays containing only primitives into an atomic vector
simplifyDataFrame  coerce JSON arrays containing only records (JSON objects) into a data frame
simplifyMatrix  coerce JSON arrays containing vectors of equal mode and dimension into matrix or array
flatten  automatically flatten() nested data frames into a single non-nested data frame
...  arguments passed on to class specific print methods
x  the object to be encoded
dataframe  how to encode data.frame objects: must be one of 'rows', 'columns' or 'values'
matrix  how to encode matrices and higher dimensional arrays: must be one of 'rowmajor' or 'columnmajor'.
Date  how to encode Date objects: must be one of 'ISO8601' or 'epoch'
POSIXt  how to encode POSIXt (datetime) objects: must be one of 'string', 'ISO8601', 'epoch' or 'mongo'
factor  how to encode factor objects: must be one of 'string' or 'integer'
complex  how to encode complex numbers: must be one of 'string' or 'list'
raw  how to encode raw objects: must be one of 'base64', 'hex' or 'mongo'
null  how to encode NULL values within a list: must be one of 'null' or 'list'
na  how to print NA values: must be one of 'null' or 'string'. Defaults are class specific
auto_unbox  automatically unbox() all atomic vectors of length 1. It is usually safer to avoid this and instead use the unbox() function to unbox individual elements. An exception is that objects of class AsIs (i.e. wrapped in I()) are not automatically unboxed. This is a way to mark single values as length-1 arrays.
digits  max number of decimal digits to print for numeric values. Use I() to specify significant digits. Use NA for max precision.
pretty  adds indentation whitespace to JSON output. Can be TRUE/FALSE or a number specifying the number of spaces to indent. See prettify()
force  unclass/skip objects of classes with no defined JSON mapping

Details

The toJSON() and fromJSON() functions are drop-in replacements for the identically named functions in packages rjson and RJSONIO. Our implementation uses an alternative, somewhat more consistent mapping between R objects and JSON strings.
The `serializeJSON()` and `unserializeJSON()` functions in this package use an alternative system to convert between R objects and JSON, which supports more classes but is much more verbose. A JSON string is always unicode, using UTF-8 by default, hence there is usually no need to escape any characters. However, the JSON format does support escaping of unicode characters, which are encoded using a backslash followed by a lower case "u" and 4 hex characters, for example: "Z\u00FCrich". The `fromJSON` function will parse such escape sequences but it is usually preferable to encode unicode characters in JSON using native UTF-8 rather than escape sequences.

References

See Also

`read_json()`, `stream_in()`

Examples

```r
# Stringify some data
tojsoncars <- toJSON(mtcars, pretty=TRUE)
cat(tojsoncars)

# Parse it back
fromJSON(tojsoncars)

# Parse escaped unicode
fromJSON('{{"city" : "Z\u00FCrich"}')

# Decimal vs significant digits
tojson(pi, digits=3)
tojson(pi, digits=I(3))

## Not run:
# retrieve data frame
data1 <- fromJSON("https://api.github.com/users/hadley/orgs")
names(data1)
data1$login

# Nested data frames:
data2 <- fromJSON("https://api.github.com/users/hadley/repos")
names(data2)
names(data2$owner)
data2$owner$login

# Flatten the data into a regular non-nested dataframe
names(flatten(data2))

# Flatten directly (more efficient):
data3 <- fromJSON("https://api.github.com/users/hadley/repos", flatten = TRUE)
identical(data3, flatten(data2))
```
## Unbox

**Unbox a vector or data frame**

### Description

This function marks an atomic vector or data frame as a singleton, i.e. a set with exactly 1 element. Thereby, the value will not turn into an array when encoded into JSON. This can only be done for atomic vectors of length 1, or data frames with exactly 1 row. To automatically unbox all vectors of length 1 within an object, use the `auto_unbox` argument in `toJSON()`.

### Usage

```
unbox(x)
```

### Arguments

- **x**  
  atomic vector of length 1, or data frame with 1 row.

### Details

It is usually recommended to avoid this function and stick with the default encoding schema for the various R classes. The only use case for this function is if you are bound to some specific predefined JSON structure (e.g. to submit to an API), which has no natural R representation. Note that the default encoding for data frames naturally results in a collection of key-value pairs, without using `unbox`.

### Value

Returns a singleton version of `x`.

### References

### Examples

```
# Auto unbox vectors of length one:
x = list(x=1:3, y = 4, z = "foo", k = NULL)
toJSON(x)
toJSON(x, auto_unbox = TRUE)

x <- iris[1,]
toJSON(list(rec=x))
toJSON(list(rec=unbox(x)))
```

validate

validate

Validate JSON

Description
Test if a string contains valid JSON. Characters vectors will be collapsed into a single string.

Usage
validate(txt)

Arguments
txt JSON string

Examples
#Output from toJSON and serializeJSON should pass validation
myjson <- toJSON(mtcars)
validate(myjson) #TRUE

#Something bad happened
truncated <- substring(myjson, 1, 100)
validate(truncated) #FALSE
