Package ‘jsonlite’

December 6, 2022

**Version** 1.8.4

**Title** A Simple and Robust JSON Parser and Generator for R

**License** MIT + file LICENSE

**Depends** methods

**BugReports** [https://github.com/jeroen/jsonlite/issues](https://github.com/jeroen/jsonlite/issues)

**Maintainer** Jeroen Ooms <jeroen@berkeley.edu>

**VignetteBuilder** knitr, R.rsp

**Description** A reasonably fast JSON parser and generator, optimized for statistical data and the web. Offers simple, flexible tools for working with JSON in R, and is particularly powerful for building pipelines and interacting with a web API. The implementation is based on the mapping described in the vignette (Ooms, 2014). In addition to converting JSON data from/to R objects, `jsonlite` contains functions to stream, validate, and prettify JSON data. The unit tests included with the package verify that all edge cases are encoded and decoded consistently for use with dynamic data in systems and applications.

**Suggests** httr, vctrs, testthat, knitr, rmarkdown, R.rsp, sf

**RoxygenNote** 7.2.1

**Encoding** UTF-8

**NeedsCompilation** yes

**Author** Jeroen Ooms [aut, cre] (<https://orcid.org/0000-0002-4035-0289>), Duncan Temple Lang [ctb], Lloyd Hilaiel [cph] (author of bundled libyajl)

**Repository** CRAN

**Date/Publication** 2022-12-06 08:10:02 UTC

**R topics documented:**

- `base64` ............................................................................. 2
- `flatten` ........................................................................... 3
Description

Simple in-memory base64 encoder and decoder. Used internally for converting raw vectors to text. Interchangeable with encoder from base64enc or openssl package.

Usage

base64_dec(input)

base64_enc(input)

base64url_enc(input)

base64url_dec(input)

Arguments

input string or raw vector to be encoded/decoded

Details

The base64url_enc and base64url_dec functions use a variation of base64 that substitute characters +/ for -_ respectively, such that the output does not require URL-encoding. See also section 5 of rfc4648.

Examples

str <- base64_enc(serialize(iris, NULL))
out <- unserialize(base64_dec(str))
stopifnot(identical(out, iris))
**flatten**

Flatten nested data frames

**Description**

In a nested data frame, one or more of the columns consist of another data frame. These structures frequently appear when parsing JSON data from the web. We can flatten such data frames into a regular 2 dimensional tabular structure.

**Usage**

```r
flatten(x, recursive = TRUE)
```

**Arguments**

- `x`: a data frame
- `recursive`: flatten recursively

**Examples**

```r
options(stringsAsFactors=FALSE)
x <- data.frame(driver = c("Bowser", "Peach"), occupation = c("Koopa", "Princess"))
x$vehicle <- data.frame(model = c("Piranha Prowler", "Royal Racer"))
x$vehicle$stats <- data.frame(speed = c(55, 34), weight = c(67, 24), drift = c(35, 32))
str(x)
str(flatten(x))
str(flatten(x, recursive = FALSE))
## Not run:
data1 <- fromJSON("https://api.github.com/users/hadley/repos")
colnames(data1)
colnames(data1$owner)
colnames(flatten(data1))
## End(Not run)

# or for short:
data2 <- fromJSON("https://api.github.com/users/hadley/repos", flatten = TRUE)
colnames(data2)
## End(Not run)
**gzjson**  

_Gzipped JSON_

**Description**

Wrapper to generate and parse gzipped JSON, in order to save some disk or network space. This is mainly effective for larger json objects with many repeated keys, as is common in serialized data frames.

**Usage**

- `as_gzjson_raw(x, ...)`
- `as_gzjson_b64(x, ...)`
- `parse_gzjson_raw(buf, ...)`
- `parse_gzjson_b64(b64, ...)`

**Arguments**

- **x**: R data object to be converted to JSON
- **...**: passed down to `toJSON` or `fromJSON`
- **buf**: raw vector with gzip compressed data
- **b64**: base64 encoded string containing gzipped json data

**Details**

The `as_gzjson_raw` and `parse_gzjson_raw` functions work with raw (binary) vectors of compressed data. To use this in a place where only text is allowed you can wrap the output again in base64 as done by `as_gzjson_b64` and `parse_gzjson_b64`. This increases the size again with about 33%.

**Examples**

```r
str <- as_gzjson_b64(iris[1:5,])
cat(str)
parse_gzjson_b64(str)
```
**prettify, minify**  

**Prettify or minify a JSON string**

**Description**

Prettify adds indentation to a JSON string; minify removes all indentation/whitespace.

**Usage**

prettify(txt, indent = 4)

minify(txt)

**Arguments**

- **txt**  
  JSON string

- **indent**  
  number of spaces to indent

**Examples**

```r
myjson <- toJSON(cars)
cat(myjson)
prettify(myjson)
minify(myjson)
```

---

**rbind_pages**  

**Combine pages into a single data frame**

**Description**

The `rbind_pages` function is used to combine a list of data frames into a single data frame. This is often needed when working with a JSON API that limits the amount of data per request. If we need more data than what fits in a single request, we need to perform multiple requests that each retrieve a fragment of data, not unlike pages in a book. In practice this is often implemented using a page parameter in the API. The `rbind_pages` function can be used to combine these pages back into a single dataset.

**Usage**

`rbind_pages(pages)`

**Arguments**

- **pages**  
  a list of data frames, each representing a *page* of data
Details

The `rbind_pages` function uses `vctrs::vec_rbind()` to bind the pages together. This generalizes `base::rbind()` in two ways:

- Not each column has to be present in each of the individual data frames; missing columns will be filled up in NA values.
- Data frames can be nested (can contain other data frames).

Examples

```r
# Basic example
x <- data.frame(foo = rnorm(3), bar = c(TRUE, FALSE, TRUE))
y <- data.frame(foo = rnorm(2), col = c("blue", "red"))
rbind_pages(list(x, y))

baseurl <- "https://projects.propublica.org/nonprofits/api/v2/search.json"
pages <- list()
for(i in 0:20){
  mydata <- fromJSON(paste0(baseurl, "?order=revenue&sort_order=desc&page=", i))
  message("Retrieving page ", i)
  pages[[i+1]] <- mydata$organizations
}
organizations <- rbind_pages(pages)
nrow(organizations)
colnames(organizations)
```

---

**read_json**

*Read/write JSON*

Description

These functions are similar to `toJSON()` and `fromJSON()` except they explicitly distinguish between path and literal input, and do not simplify by default.

Usage

```r
read_json(path, simplifyVector = FALSE, ...)
parse_json(json, simplifyVector = FALSE, ...)
write_json(x, path, ...)
```
serializeJSON

Arguments

path file on disk
simplifyVector simplifies nested lists into vectors and data frames. See fromJSON().
... additional conversion arguments, see also toJSON() or fromJSON()
json string with literal json or connection object to read from
x an object to be serialized to JSON

See Also

c fromJSON(), stream_in()

Examples

tmp <- tempfile()
write_json(iris, tmp)

# Nested lists
read_json(tmp)

# A data frame
read_json(tmp, simplifyVector = TRUE)

Description

The serializeJSON() and unserializeJSON() functions convert between R objects to JSON data. Instead of using a class based mapping like toJSON() and fromJSON(), the serialize functions base the encoding schema on the storage type, and capture all data and attributes from any object. Thereby the object can be restored almost perfectly from its JSON representation, but the resulting JSON output is very verbose. Apart from environments, all standard storage types are supported.

Usage

serializeJSON(x, digits = 8, pretty = FALSE)

unserializeJSON(txt)

Arguments

x an R object to be serialized
digits max number of digits (after the dot) to print for numeric values
pretty add indentation/whitespace to JSON output. See prettify()
txt a JSON string which was created using serializeJSON
Note

JSON is a text based format which leads to loss of precision when printing numbers.

Examples

```r
jsoncars <- serializeJSON(mtcars)
mtcars2 <- unserializeJSON(jsoncars)
identical(mtcars, mtcars2)

set.seed('123')
myobject <- list(
  mynull = NULL,
  mycomplex = lapply(eigen(matrix(-rnorm(9),3)), round, 3),
  mymatrix = round(matrix(rnorm(9), 3),3),
  myint = as.integer(c(1,2,3)),
  mydf = cars,
  mylist = list(foo='bar', 123, NA, NULL, list('test')),
  mylogical = c(TRUE,FALSE,NA),
  mychar = c('foo', NA, 'bar'),
  somemissings = c(1,2,NA,NaN,Inf, 7 -Inf, 9, NA),
  myrawvec = charToRaw('This is a test')
);
identical(unserializeJSON(serializeJSON(myobject)), myobject);
```

**stream_in, stream_out**  
*Streaming JSON input/output*

**Description**

The `stream_in` and `stream_out` functions implement line-by-line processing of JSON data over a connection, such as a socket, url, file or pipe. JSON streaming requires the ndjson format, which slightly differs from `fromJSON()` and `toJSON()`, see details.

**Usage**

```r
stream_in(con, handler = NULL, pagesize = 500, verbose = TRUE, ...)
stream_out(x, con = stdout(), pagesize = 500, verbose = TRUE, prefix = "", ...)
```

**Arguments**

- `con`  
a connection object. If the connection is not open, `stream_in` and `stream_out` will automatically open and later close (and destroy) the connection. See details.

- `handler`  
a custom function that is called on each page of JSON data. If not specified, the default handler stores all pages and binds them into a single data frame that will be returned by `stream_in`. See details.

- `pagesize`  
number of lines to read/write from/to the connection per iteration.
stream_in, stream_out

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>verbose</td>
<td>print some information on what is going on.</td>
</tr>
<tr>
<td>...</td>
<td>arguments for <code>fromJSON()</code> and <code>toJSON()</code> that control JSON formatting/parsing where applicable. Use with caution.</td>
</tr>
<tr>
<td>x</td>
<td>object to be streamed out. Currently only data frames are supported.</td>
</tr>
<tr>
<td>prefix</td>
<td>string to write before each line (use <code>\u001e</code> to write rfc7464 text sequences)</td>
</tr>
</tbody>
</table>

Details

Because parsing huge JSON strings is difficult and inefficient, JSON streaming is done using **lines of minified JSON records**, a.k.a. ndjson. This is pretty standard: JSON databases such as MongoDB use the same format to import/export datasets. Note that this means that the total stream combined is not valid JSON itself; only the individual lines are. Also note that because line-breaks are used as separators, prettified JSON is not permitted: the JSON lines must be minified. In this respect, the format is a bit different from `fromJSON()` and `toJSON()` where all lines are part of a single JSON structure with optional line breaks.

The **handler** is a callback function which is called for each page (batch) of JSON data with exactly one argument (usually a data frame with `pagesize` rows). If `handler` is missing or `NULL`, a default handler is used which stores all intermediate pages of data, and at the very end binds all pages together into one single data frame that is returned by `stream_in`. When a custom handler function is specified, `stream_in` does not store any intermediate results and always returns `NULL`. It is then up to the handler to process or store data pages. A `handler` function that does not store intermediate results in memory (for example by writing output to another connection) results in a pipeline that can process an unlimited amount of data. See example.

Note that a vector of JSON strings already in R can parsed with `stream_in` by creating a connection to it with `textConnection()`.

If a connection is not opened yet, `stream_in` and `stream_out` will automatically open and later close the connection. Because R destroys connections when they are closed, they cannot be reused. To use a single connection for multiple calls to `stream_in` or `stream_out`, it needs to be opened beforehand. See example.

Value

The `stream_out` function always returns `NULL`. When no custom handler is specified, `stream_in` returns a data frame of all pages binded together. When a custom handler function is specified, `stream_in` always returns `NULL`.

Examples

```r
# compare formats
x <- iris[1:3,]
toJSON(x)
stream_out(x)

# Trivial example
mydata <- stream_in(url("http://httpbin.org/stream/100"))

## Not run:
#stream large dataset to file and back
library(nycflights13)
stream_out(flights, file(tmp <- tempfile()))
flights2 <- stream_in(file(tmp))
unlink(tmp)
all.equal(flights2, as.data.frame(flights))

# stream over HTTP
diamonds2 <- stream_in(url("http://jeroen.github.io/data/diamonds.json"))

# stream over HTTP with gzip compression
flights3 <- stream_in(gzcon(url("http://jeroen.github.io/data/nycflights13.json.gz")))
all.equal(flights3, as.data.frame(flights))

# stream over HTTPS (HTTP+SSL) via curl
library(curl)
flights4 <- stream_in(gzcon(curl("https://jeroen.github.io/data/nycflights13.json.gz")))
all.equal(flights4, as.data.frame(flights))

# or alternatively:
flights5 <- stream_in(gzcon(pipe("curl https://jeroen.github.io/data/nycflights13.json.gz")))
all.equal(flights5, as.data.frame(flights))

# Full JSON IO stream from URL to file connection.
# Calculate delays for flights over 1000 miles in batches of 5k
library(dplyr)
con_in <- gzcon(url("http://jeroen.github.io/data/nycflights13.json.gz"))
con_out <- file(tmp <- tempfile(), open = "wb")
stream_in(con_in, handler = function(df){
  df <- dplyr::filter(df, distance > 1000)
  df <- dplyr::mutate(df, delta = dep_delay - arr_delay)
  stream_out(df, con_out, pagesize = 1000)
}, pagesize = 5000)
close(con_out)

# stream it back in
mydata <- stream_in(file(tmp))
nrow(mydata)
unlink(tmp)

# Data from http://openweathermap.org/current#bulk
# Each row contains a nested data frame.
```
daily14 <- stream_in(gzcon(url("http://78.46.48.103/sample/daily_14.json.gz")), pagesize=50)
subset(daily14, city$name == "Berlin")$data[[1]]

# Or with dplyr:
library(dplyr)
daily14f <- flatten(daily14)
filter(daily14f, city.name == "Berlin")$data[[1]]

# Stream import large data from zip file
tmp <- tempfile()
companies <- stream_in(unz(tmp, "companies.json"))

## End(Not run)

toJSON, fromJSON

Convert R objects to/from JSON

Description

These functions are used to convert between JSON data and R objects. The toJSON() and fromJSON() functions use a class based mapping, which follows conventions outlined in this paper: https://arxiv.org/abs/1403.2805 (also available as vignette).

Usage

fromJSON(
  txt,
  simplifyVector = TRUE,
  simplifyDataFrame = simplifyVector,
  simplifyMatrix = simplifyVector,
  flatten = FALSE,
  ...
)

toJSON(
  x,
  dataframe = c("rows", "columns", "values"),
  matrix = c("rowmajor", "columnmajor"),
  Date = c("ISO8601", "epoch"),
  POSIXt = c("string", "ISO8601", "epoch", "mongo"),
  factor = c("string", "integer"),
  complex = c("string", "list"),
  raw = c("base64", "hex", "mongo", "int", "js"),
  null = c("list", "null"),
  na = c("null", "string"),
  auto_unbox = FALSE,
  digits = 4,
pretty = FALSE,
force = FALSE,
... 
)

Arguments

txt a JSON string, URL or file
simplifyVector coerce JSON arrays containing only primitives into an atomic vector
simplifyDataFrame coerce JSON arrays containing only records (JSON objects) into a data frame
simplifyMatrix coerce JSON arrays containing vectors of equal mode and dimension into matrix or array
flatten automatically flatten() nested data frames into a single non-nested data frame
... arguments passed on to class specific print methods
x the object to be encoded
dataframe how to encode data.frame objects: must be one of 'rows', 'columns' or 'values'
matrix how to encode matrices and higher dimensional arrays: must be one of 'rowmajor' or 'columnmajor'.
Date how to encode Date objects: must be one of 'ISO8601' or 'epoch'
POSIXt how to encode POSIXt (datetime) objects: must be one of 'string', 'ISO8601', 'epoch' or 'mongo'
factor how to encode factor objects: must be one of 'string' or 'integer'
complex how to encode complex numbers: must be one of 'string' or 'list'
raw how to encode raw objects: must be one of 'base64', 'hex' or 'mongo'
null how to encode NULL values within a list: must be one of 'null' or 'list'
na how to print NA values: must be one of 'null' or 'string'. Defaults are class specific
auto_unbox automatically unbox() all atomic vectors of length 1. It is usually safer to avoid this and instead use the unbox() function to unbox individual elements. An exception is that objects of class AsIs (i.e. wrapped in I()) are not automatically unboxed. This is a way to mark single values as length-1 arrays.
digits max number of decimal digits to print for numeric values. Use I() to specify significant digits. Use NA for max precision.
pretty adds indentation whitespace to JSON output. Can be TRUE/FALSE or a number specifying the number of spaces to indent. See prettify()
force unclass/skip objects of classes with no defined JSON mapping

Details

The toJSON() and fromJSON() functions are drop-in replacements for the identically named functions in packages rjson and RJSONIO. Our implementation uses an alternative, somewhat more consistent mapping between R objects and JSON strings.
The `serializeJSON()` and `unserializeJSON()` functions in this package use an alternative system to convert between R objects and JSON, which supports more classes but is much more verbose. A JSON string is always unicode, using UTF-8 by default, hence there is usually no need to escape any characters. However, the JSON format does support escaping of unicode characters, which are encoded using a backslash followed by a lower case “u” and 4 hex characters, for example: “Z\u00FCrich”. The `fromJSON` function will parse such escape sequences but it is usually preferable to encode unicode characters in JSON using native UTF-8 rather than escape sequences.

See Also

`read_json()`, `stream_in()`

Examples

```r
# Stringify some data
jsoncars <- toJSON(mtcars, pretty=TRUE)
cat(jsoncars)

# Parse it back
fromJSON(jsoncars)

# Parse escaped unicode
fromJSON('{"city" : "Z\u00FCrich"}')

# Decimal vs significant digits
toJSON(pi, digits=3)
toJSON(pi, digits=I(3))

## Not run:
#retrieve data frame
data1 <- fromJSON("https://api.github.com/users/hadley/orgs")
names(data1)
data1$login

# Nested data frames:
data2 <- fromJSON("https://api.github.com/users/hadley/repos")
names(data2)
names(data2$owner)
data2$owner$login

# Flatten the data into a regular non-nested dataframe
names(flatten(data2))

# Flatten directly (more efficient):
data3 <- fromJSON("https://api.github.com/users/hadley/repos", flatten = TRUE)
identical(data3, flatten(data2))
```
**unbox**

*Unbox a vector or data frame*

**Description**

This function marks an atomic vector or data frame as a singleton, i.e. a set with exactly 1 element. Thereby, the value will not turn into an array when encoded into JSON. This can only be done for atomic vectors of length 1, or data frames with exactly 1 row. To automatically unbox all vectors of length 1 within an object, use the `auto_unbox` argument in `toJSON()`.

**Usage**

```r
unbox(x)
```

**Arguments**

- `x`: atomic vector of length 1, or data frame with 1 row.

**Details**

It is usually recommended to avoid this function and stick with the default encoding schema for the various R classes. The only use case for this function is if you are bound to some specific predefined JSON structure (e.g. to submit to an API), which has no natural R representation. Note that the default encoding for data frames naturally results in a collection of key-value pairs, without using `unbox`.

**Value**

Returns a singleton version of `x`.

**References**

**Examples**

```r
toJSON(list(foo=123))
toJSON(list(foo=unbox(123)))

# Auto unbox vectors of length one:
x = list(x=1:3, y = 4, z = "foo", k = NULL)
toJSON(x)
toJSON(x, auto_unbox = TRUE)

x <- iris[1,]
toJSON(list(rec=x))
toJSON(list(rec=unbox(x)))
```
**validate**  

---

**Validate JSON**

---

**Description**

Test if a string contains valid JSON. Characters vectors will be collapsed into a single string.

**Usage**

```r
validate(txt)
```

**Arguments**

- **txt**: JSON string

**Examples**

```r
# Output from toJSON and serializeJSON should pass validation
myjson <- toJSON(mtcars)
validate(myjson) # TRUE

# Something bad happened
truncated <- substring(myjson, 1, 100)
validate(truncated) # FALSE
```
