Package ‘ktweedie’

November 2, 2022

Title 'Tweedie' Compound Poisson Model in the Reproducing Kernel Hilbert Space

Version 1.0.1

Date 2022-11-01

Description Kernel-based 'Tweedie' compound Poisson gamma model using high-dimensional predictors for the analyses of zero-inflated response variables. The package features built-in estimation, prediction and cross-validation tools and supports choice of different kernel functions.

as.kernelMatrix

Description

as.kernelMatrix in package KERE can be used to coerce the kernelMatrix class to matrix objects representing a kernel matrix. These matrices can then be used with the kernelMatrix interfaces which most of the functions in KERE support.

Usage

## S4 method for signature 'matrix'
as.kernelMatrix(x, center = FALSE)

Arguments

  x        matrix to be assigned the kernelMatrix class
  center   center the kernel matrix in feature space (default: FALSE)

Author(s)

Alexandros Karatzoglou
<alexandros.karatzoglou@ci.tuwien.ac.at>

See Also

  kernelMatrix, dots

Examples

## Create toy data
x <- rbind(matrix(rnorm(10),,2),matrix(rnorm(10,mean=3),,2))
y <- matrix(c(rep(1,5),rep(-1,5)))

### Use as.kernelMatrix to label the cov. matrix as a kernel matrix
### which is eq. to using a linear kernel
K <- as.kernelMatrix(crossprod(t(x)))
K
**dat**  

*A demo dataset*

**Description**

A simulated dataset with covariate matrix \(x\) of size 30 x 5 and an outcome vector \(y\) of length 30.

**Usage**

\[
\text{data(dat)}
\]

**Format**

A list with 2 items:

- \(x\) Covariate matrix
- \(y\) Outcome vector

**Details**

\(x\) is generated from standard normal distribution. \(y\) is generated from Tweedie distribution with mean equal to \(\exp(\sin(x) \odot \odot (6, -4, 0, 0, 0))\). Only the first two variables are associated with the outcome.

**dots**  

**Kernel Functions**

**Description**

The kernel generating functions provided in KERE.

The Gaussian RBF kernel \(k(x, x') = \exp(-\sigma \|x - x'\|^2)\)

The Polynomial kernel \(k(x, x') = (\text{scale} < x, x' > + \text{offset})^{\text{degree}}\)

The Linear kernel \(k(x, x') = < x, x' >\)

The Hyperbolic tangent kernel \(k(x, x') = \tanh(\text{scale} < x, x' > + \text{offset})\)

The Laplacian kernel \(k(x, x') = \exp(-\sigma \|x - x'\|)\)

The Bessel kernel \(k(x, x') = (-Bessel_{(v+1)}^{v})^{ \sigma \|x - x'\|^2}\)

The ANOVA RBF kernel \(k(x, x') = \sum_{1 \leq i_1 \ldots < i_D \leq N} \prod_{d=1}^{D} k(x_{id}, x'_{id})\) where \(k(x, x)\) is a Gaussian RBF kernel.

The Spline kernel \(\prod_{d=1}^{D} 1 + x_i x_j + x_i x_j \min(x_i, x_j) - \frac{x_i + x_j}{2} \min(x_i, x_j)^2 + \frac{\min(x_i, x_j)^3}{3} \)

Usage

rbfdot(sigma = 1)

polydot(degree = 1, scale = 1, offset = 1)

tanhdot(scale = 1, offset = 1)

vanilladot()

laplacedot(sigma = 1)

besseldot(sigma = 1, order = 1, degree = 1)

anovadot(sigma = 1, degree = 1)

splinedot()

Arguments

sigma
The inverse kernel width used by the Gaussian the Laplacian, the Bessel and the ANOVA kernel

degree
The degree of the polynomial, bessel or ANOVA kernel function. This has to be an positive integer.

scale
The scaling parameter of the polynomial and tangent kernel is a convenient way of normalizing patterns without the need to modify the data itself

offset
The offset used in a polynomial or hyperbolic tangent kernel

order
The order of the Bessel function to be used as a kernel

Details

The kernel generating functions are used to initialize a kernel function which calculates the dot (inner) product between two feature vectors in a Hilbert Space. These functions can be passed as a kernel argument on almost all functions in KERE (e.g., ksvm, kPCA etc).

Although using one of the existing kernel functions as a kernel argument in various functions in KERE has the advantage that optimized code is used to calculate various kernel expressions, any other function implementing a dot product of class kernel can also be used as a kernel argument. This allows the user to use, test and develop special kernels for a given data set or algorithm.

Value

Return an S4 object of class kernel which extents the function class. The resulting function implements the given kernel calculating the inner (dot) product between two vectors.

kpar
a list containing the kernel parameters (hyperparameters) used.

The kernel parameters can be accessed by the kpar function.
Note
If the offset in the Polynomial kernel is set to 0, we obtain homogeneous polynomial kernels, for positive values, we have inhomogeneous kernels. Note that for negative values the kernel does not satisfy Mercer’s condition and thus the optimizers may fail.

In the Hyperbolic tangent kernel if the offset is negative the likelihood of obtaining a kernel matrix that is not positive definite is much higher (since then even some diagonal elements may be negative), hence if this kernel has to be used, the offset should always be positive. Note, however, that this is no guarantee that the kernel will be positive.

kernelMatrix, kernelMult, kernelPol

Examples
rbfkernel <- rbfdot(sigma = 0.1)
rbfkernel
kpar(rbfkernel)

## create two vectors
x <- rnorm(10)
y <- rnorm(10)

## calculate dot product
rbfkernel(x,y)

kernel-class
Class "kernel" "rbfkernel" "polykernel", "tanhkernel", "vanillakernel"

Description
The built-in kernel classes in KERE

Objects from the Class
Objects can be created by calls of the form new("rbfkernel"), new("polykernel"), new("tanhkernel"), new("vanillakernel"), new("anovakernel"), new("besselkernel"), new("laplacekernel"), new("splinekernel") or by calling the rbfdot, polydot, tanhdot, vanilladot, anovadot, besseldot, laplacedot, splinedot functions etc..
Slots

.Data: Object of class "function" containing the kernel function
   kpar: Object of class "list" containing the kernel parameters

Extends

Class "kernel", directly. Class "function", by class "kernel".

Methods

  kernelMatrix  signature(kernel = "rbfkernel", x = "matrix"): computes the kernel matrix
  kernelMult  signature(kernel = "rbfkernel", x = "matrix"): computes the quadratic kernel expression
  kernelPol  signature(kernel = "rbfkernel", x = "matrix"): computes the kernel expansion
  kernelFast  signature(kernel = "rbfkernel", x = "matrix"): computes parts or the full kernel matrix, mainly used in kernel algorithms where columns of the kernel matrix are computed per invocation

Author(s)

Alexandros Karatzoglou
<alexandros.karatzoglou@ci.tuwien.ac.at>

dots

Examples

  rbfkernel <- rbfdot(sigma = 0.1)
  rbfkernel
  is(rbfkernel)
  kpar(rbfkernel)

   \begin{tabular}{|c|c|}
     \hline
     kernelMatrix & \textit{Kernel Matrix functions} \\
     \hline
   \end{tabular}

Description

  kernelMatrix calculates the kernel matrix \( K_{ij} = k(x_i, x_j) \) or \( K_{ij} = k(x_i, y_j) \).
  kernelPol computes the quadratic kernel expression \( H = z_i z_j k(x_i, x_j) \), \( H = z_i k_j k(x_i, y_j) \).
  kernelMult calculates the kernel expansion \( f(x_i) = \sum_{i=1}^{m} z_i k(x_i, x_j) \).
  kernelFast computes the kernel matrix, identical to \texttt{kernelMatrix}, except that it also requires the squared norm of the first argument as additional input, useful in iterative kernel matrix calculations.
Usage

```r
## S4 method for signature 'kernel'
kernMatrix(kernel, x, y = NULL)
```

```r
## S4 method for signature 'kernel'
kernPol(kernel, x, y = NULL, z, k = NULL)
```

```r
## S4 method for signature 'kernel'
kernMult(kernel, x, y = NULL, z, blocksize = 256)
```

```r
## S4 method for signature 'kernel'
kernFast(kernel, x, y, a)
```

Arguments

- `kernel` the kernel function to be used to calculate the kernel matrix. This has to be a function of class `kernel`, i.e. which can be generated either one of the build in kernel generating functions (e.g., `rbfdot` etc.) or a user defined function of class `kernel` taking two vector arguments and returning a scalar.
- `x` a data matrix to be used to calculate the kernel matrix.
- `y` second data matrix to calculate the kernel matrix.
- `z` a suitable vector or matrix
- `k` a suitable vector or matrix
- `a` the squared norm of `x`, e.g., `rowSums(x^2)`
- `blocksize` the kernel expansion computations are done block wise to avoid storing the kernel matrix into memory. `blocksize` defines the size of the computational blocks.

Details

Common functions used during kernel based computations.
The `kernel` parameter can be set to any function, of class `kernel`, which computes the inner product in feature space between two vector arguments. **KERE** provides the most popular kernel functions which can be initialized by using the following functions:

- `rbfdot` Radial Basis kernel function
- `polydot` Polynomial kernel function
- `vanilladot` Linear kernel function
- `tanhdot` Hyperbolic tangent kernel function
- `laplacedot` Laplacian kernel function
- `besseldot` Bessel kernel function
- `anovadot` ANOVA RBF kernel function
- `splinedot` the Spline kernel
kernelFast is mainly used in situations where columns of the kernel matrix are computed per invocation. In these cases, evaluating the norm of each row-entry over and over again would cause significant computational overhead.

Value

kernelMatrix returns a symmetric diagonal semi-definite matrix.
kernelPol returns a matrix.
kernelMult usually returns a one-column matrix.

## calculate kernel matrix
kernelMatrix(rbf, x)

y <- matrix(rnorm(10*1),10,1)

## calculate the quadratic kernel expression
kernelPol(rbf, x, ,y)

## calculate the kernel expansion
kernelMult(rbf, x, ,y)
```

---

**ktd_cv**

Cross validation for tuning the regularization coefficient in the kernel Tweedie model

**Description**

ktd_cv() performs cross-validation to determine the optimal regularization coefficient of the ktweedie model.
**Usage**

```r
ktc_cv(x, y, kern, lambda, nfolds = 5, rho = 1.5, loss = "LL", ...)
```

**Arguments**

- **x**: Covariate matrix.
- **y**: Outcome vector (e.g. insurance cost).
- **kern**: Choice of kernel. See `dots` for details on supported kernel functions.
- **lambda**: A vector of candidate regularization coefficients used in cross-validation.
- **nfolds**: Number of folds in cross-validation. Default is 5.
- **rho**: The power parameter of the Tweedie model. Default is 1.5 and can take any real value between 1 and 2.
- **loss**: Criterion used in cross-validation. "LL" for log likelihood, "RMSE" for root mean squared error, "MAD" for mean absolute difference. Default is "LL".
- **...**: Optional arguments to be passed to `ktc_estimate()`.

**Details**

`ktc_cv()` is a built-in wrapper for cross-validation for the choice of regularization coefficient.

**Value**

A list of two items.

1. LL or RMSE or MAD: a vector of validation error based on the user-specified loss, named by the corresponding lambda values;
2. Best lambda: the lambda value in the pair that generates the best loss;

**See Also**

`ktc_cv2d, ktc_estimate, ktc_predict`

**Examples**

# Provide a sequence of candidate values to the argument lambda.
# ktd_cv() will perform cross-validation to determine which is the best.
```r
( cv1d <- ktd_cv(x = dat$x, y = dat$y,
                 kern = rbf(X = 1e-8),
                 lambda = 10^(4:1),
                 nfolds = 5) )
```
**ktd_cv2d**  
*Cross validation for jointly tuning the regularization coefficient and kernel parameter in the Kernel Tweedie Model*

**Description**

ktd_cv2d() performs 2-dimensional random search from user-specified ranges to determine the optimal pair of regularization coefficient and kernel parameter of the ktweedie model.

**Usage**

```r
ktd_cv2d(
  x, 
  y, 
  kernfunc, 
  lambda, 
  sigma, 
  ncoefs, 
  nfolds = 5, 
  rho = 1.5, 
  loss = "LL", 
  ...
)
```

**Arguments**

- `x`: Covariate matrix.
- `y`: Outcome vector (e.g. insurance cost).
- `kernfunc`: Choice of kernel function. See dots for details on supported kernel functions.
- `lambda`: A vector of length two indicating the lower and upper bound from which candidate regularization coefficient values are sampled uniformly on the log scale.
- `sigma`: A vector of length two indicating the lower and upper bound from which candidate kernel parameter values are sampled uniformly on the log scale.
- `ncoefs`: The number of candidate lambda and sigma pairs to be evaluated.
- `nfolds`: Number of folds in cross-validation. Default is 5.
- `rho`: The power parameter of the Tweedie model. Default is 1.5 and can take any real value between 1 and 2.
- `loss`: Criterion used in cross-validation. "LL" for log likelihood, "RMSE" for root mean squared error, "MAD" for mean absolute difference. Default is "LL".
- `...`: Optional arguments to be passed to ktd_estimate().

**Details**

ktd_cv2d() is a built-in wrapper for 2D random search for the regularization coefficient and kernel parameter. For kernel functions with greater than one parameters, ktd_cv2d() supports the tuning of the first one.
**Value**

A list of three items.

1. LL or RMSE or MAD: a vector of validation error based on the user-specified loss, named by the corresponding lambda and sigma values;
2. Best_lambda: the lambda value in the pair that generates the best loss;
3. Best_sigma: the sigma value in the pair that generates the best loss.

**See Also**

ktd_cv, ktd_estimate, ktd_predict

**Examples**

```r
### Cross-validation
# Provide the kernel function name (e.g. rbfdot) to the argument kernfunc,
# NOT the kernel function object, e.g. rbfdot(sigma = 1).
# Provide ranges where the candidate lambdas and sigmas are drawn from
# to the arguments lambda and sigma.
# The number of pairs of candidates to select from is specified by ncoefs.
(cv2d <- ktd_cv2d(x = dat$x, y = dat$y,
    kernfunc = rbfdot,
    lambda = c(1e-3, 1e0),
    sigma = c(1e-3, 1e0),
    ncoefs = 10))

### Followed by fitting
fit <- ktd_estimate(x = dat$x, y = dat$y,
    kern = rbfdot(sigma = cv2d$Best_sigma),
    lam1 = cv2d$Best_lambda)
```

---

**ktd_estimate**

*Estimate kernel Tweedie model coefficients*

**Description**

ktd_estimate() estimates the coefficients of the kernel Tweedie model ktweedie and the sparse kernel Tweedie model sktweedie. The log of the expected Tweedie mean is modeled by a function in the reproducing kernel Hilbert space. The sktweedie has an integrated feature selection component that induces sparsity by applying weights on the features and penalizing the weights.

**Usage**

```r
ktd_estimate(
    x,
    y,
    kern,
    lam1,
    rho = 1.5,
```
ftol = 1e-08,
partol = 1e-08,
abstol = 0,
maxit = 1e+06,
sparsity = FALSE,
lam2 = 0,
innerpartol = 1e-06,
innermaxit = 1e+06,
verbose = FALSE
)

Arguments

x  Covariate matrix.
y  Outcome vector (e.g. insurance cost).
kern  Choice of kernel. See dots for details on supported kernel functions.
lam1  A vector of regularization coefficients.
rho  The power parameter of the Tweedie model. Default is 1.5 and can take any real value between 1 and 2.
ftol  Stopping criterion based on objective function value. Default is 1e-8. See Details.
partol  Stopping criterion based on the coefficient values. Default is 1e-8. See Details.
abstol  Stopping criterion based on absolute value of the objective function. Default is 0.
maxit  Maximum number of iterations.
sparsity  Logical If true, the sktweedie model with variable selection will be used. Default is false, for the ktweedie model.
lam2  Regularization coefficient for the sparsity-inducing penalty in the sktweedie model.
innerpartol  Stopping criterion for the inner loops that update kernel parameters and weights based on the coefficient values. See Details.
innermaxit  Maximum number of iterations for the inner loops that update kernel parameters and variable weights. See Details.
verbose  Logical indicating whether to show details of each update.

Details

ktd_estimate() stops when the absolute difference between the objective function values of the last two updates is smaller than ftol, or the sum of absolute differences between the coefficients of the last two updates is smaller than partol, or the objective function values is below abstol, before maxit is reached. For the sktweedie model, there are inner loops for the update of kernel regression coefficients and regularization weights. The innerpartol and innermaxit arguments are the counterparts of partol and maxit for the inner loops.
**ktd_predict**

**Value**

A list of three items.

1. estimates: a list containing the final objective function values and kernel Tweedie regression coefficients for each `lam1`.
2. data: stores the inputs, including the predictor matrix, the kernel function used in the fitting and `lam1`.
3. sparsity: a logical variable indicating whether the ktweedie or sktweedie is fitted.

**See Also**

`ktd_cv`, `ktd_cv2d`, `ktd_predict`, `rbfdot`

**Examples**

```
####### ktweedie #######
# Provide a sequence of candidate values to the argument lam1.
# Provide a kernel object to the argument kern.
lam1.seq <- c(1e-5, 1e-4, 1e-3, 1e-2, 1e-1, 1e0, 1e1)
fit.ktd <- ktd_estimate(x = dat$x, y = dat$y,
                        kern = rbfdot(sigma = 1e-8),
                        lam1 = lam1.seq)

####### sktweedie #######
# Set sparsity to TRUE and a lam2 to control the level of sparsity
# Decrease lam2 if "WARNING: All weights are zero..."
fit.sktd <- ktd_estimate(x = dat$x,
                         y = dat$y,
                         kern = rbfdot(sigma = 0.1),
                         lam1 = 5,
                         sparsity = TRUE,
                         lam2 = 1)
# variables with fitted weight equal to 0 are not selected
```

---

**ktd_predict**

*Predict outcome using fitted kernel Tweedie model*

**Description**

`ktd_predict()` predicts the outcome with fitted ktweedie or sktweedie model at the user supplied new data.

**Usage**

```
ktd_predict(model, newdata, which.lam1 = 1, type = "link")
```
Arguments

model  Fitted model from `ktd_estimate`
newdata New x matrix for the prediction. If not provided, it will be the x matrix used to fit model.
which.lam1 The index of the lam1 in model used in the prediction. Default is 1.
type The type of prediction to be made - "link" for the linear predictor and "response" for the predicted outcome. Default is "link".

Details

`ktd_predict()` uses the fitted model from `ktd_estimate` to estimate the mean outcome for new data points.

Value

A list named prediction containing the vector of predicted outcomes.

See Also

`ktd_estimate`, `ktd_cv`, `ktd_cv2d`

Examples

```r
# Fit a ktweedie model
fit <- ktd_estimate(x = dat$x, y = dat$y,
     kern = rbfdot(sigma = 1e-6),
     lam1 = 10^(-5:1))
# Generate newx at which predictions are to be made.
# The newdata should have the same dimension as the original training data.
newx <- matrix(rnorm(10 * ncol(dat$x)), nrow = 10)
pred <- ktd_predict(model = fit, newdata = newx,
     which.lam1 = 3, type = "link")
```

Description

Kernel-based Tweedie compound Poisson gamma model using high-dimensional covariates for the analyses of zero-inflated response variables. The package features built-in estimation, prediction and cross-validation tools and supports choice of different kernel functions.

Details

The ktweedie package includes functions `ktd_estimate`, `ktd_cv`, `ktd_cv2d` and `ktd_predict`. 
Functions

- **ktd_estimate** Estimation of Tweedie model coefficients.
- **ktd_cv** Wrapper for cross-validation for regularization parameter tuning.
- **ktd_cv2d** Wrapper for cross-validation for simultaneous regularization and kernel parameter tuning.
- **ktd_predict** Prediction of Tweedie model outcomes.
