Package ‘labeling’

October 20, 2020

Type Package
Title Axis Labeling
Version 0.4.2
Date 2020-10-15
Author Justin Talbot,
Maintainer Nuno Sempere <nuno.semperelh@gmail.com>
Description Functions which provide a range of axis labeling algorithms.
License MIT + file LICENSE | Unlimited
Collate 'labeling.R'
NeedsCompilation no
Imports stats, graphics
Repository CRAN

Description

Functions for positioning tick labels on axes

Details

Package: labeling
Type: Package
Version: 0.2
Date: 2011-04-01
License: Unlimited
LazyLoad: yes

Implements a number of axis labeling schemes, including those compared in An Extension of Wilkinson’s Algorithm for Positioning Tick Labels on Axes by Talbot, Lin, and Hanrahan, InfoVis 2010.

Author(s)

Justin Talbot <justintalbot@gmail.com>

An Extension of Wilkinson’s Algorithm for Position Tick Labels on Axes

Description

extended is an enhanced version of Wilkinson’s optimization-based axis labeling approach. It is described in detail in our paper. See the references.

Usage

extended(dmin, dmax, m, Q = c(1, 5, 2, 2.5, 4, 3),
               only.loose = FALSE, w = c(0.25, 0.2, 0.5, 0.05))

Arguments

dmin minimum of the data range
dmax maximum of the data range
m number of axis labels
Q set of nice numbers
only.loose if true, the extreme labels will be outside the data range
w weights applied to the four optimization components (simplicity, coverage, density, and legibility)

Value

vector of axis label locations

Author(s)

Justin Talbot <justintalbot@gmail.com>

References

**extended.figures**

*Generate figures from An Extension of Wilkinson’s Algorithm for Position Tick Labels on Axes*

**Description**
Generates Figures 2 and 3 from our paper.

**Usage**
```
extended.figures(samples = 100)
```

**Arguments**
- **samples**: number of samples to use (in the paper we used 10000, but that takes awhile to run).

**Value**
produces plots as a side effect

**Author(s)**
Justin Talbot <justintalbot@gmail.com>

---

**gnuplot**

*gnuplot’s labeling algorithm*

**Description**

*gnuplot’s labeling algorithm*

**Usage**
```
gnuplot(dmin, dmax, m)
```

**Arguments**
- **dmin**: minimum of the data range
- **dmax**: maximum of the data range
- **m**: number of axis labels
heckbert

Value
vector of axis label locations

Author(s)
Justin Talbot <justintalbot@gmail.com>

References

Description
Heckbert's labeling algorithm

Usage
heckbert(dmin, dmax, m)

Arguments
- dmin: minimum of the data range
- dmax: maximum of the data range
- m: number of axis labels

Value
vector of axis label locations

Author(s)
Justin Talbot <justintalbot@gmail.com>

References
Matplotlib's labeling algorithm

**Description**
Matplotlib's labeling algorithm

**Usage**
```r
matplotlib(dmin, dmax, m)
```

**Arguments**
- `dmin`: minimum of the data range
- `dmax`: maximum of the data range
- `m`: number of axis labels

**Value**
- vector of axis label locations

**Author(s)**
Justin Talbot <justintalbot@gmail.com>

Nelder's labeling algorithm

**Description**
Nelder's labeling algorithm

**Usage**
```r
nelder(dmin, dmax, m,
       Q = c(1, 1.2, 1.6, 2, 2.5, 3, 4, 5, 6, 8, 10))
```

**Arguments**
- `dmin`: minimum of the data range
- `dmax`: maximum of the data range
- `m`: number of axis labels
- `Q`: set of nice numbers
Value

vector of axis label locations

Author(s)

Justin Talbot <justintalbot@gmail.com>

rpretty

R's pretty algorithm implemented in R

Description

R's pretty algorithm implemented in R

Usage

rpretty(dmin, dmax, m = 6, n = floor(m) - 1,
       min.n = n%/%3, shrink.sml = 0.75, high.u.bias = 1.5,
       u5.bias = 0.5 + 1.5 * high.u.bias)

Arguments

dmin minimum of the data range
dmax maximum of the data range
m number of axis labels
n number of axis intervals (specify one of \emph{m} or \emph{n})
min.n nonnegative integer giving the minimal number of intervals. If \emph{min.n} == 0, \emph{pretty(.)} may return a single value.
shrink.sml positive numeric by a which a default scale is shrunk in the case when \texttt{range(x)} is very small (usually 0).
high.u.bias non-negative numeric, typically > 1. The interval unit is determined as \{1, 2, 5, 10\} times b, a power of 10. Larger \texttt{high.u.bias} values favor larger units.
u5.bias non-negative numeric multiplier favoring factor 5 over 2. Default and 'optimal': \texttt{u5.bias} = .5 + 1.5*\texttt{high.u.bias}.

Value

vector of axis label locations
Sparks’ labeling algorithm

Usage

sparks(dmin, dmax, m)

Arguments

- **dmin**: minimum of the data range
- **dmax**: maximum of the data range
- **m**: number of axis labels

Value

vector of axis label locations

Author(s)

Justin Talbot <justintalbot@gmail.com>

References

thayer

Thayer and Storer's labeling algorithm

Usage

thayer(dmin, dmax, m)

Arguments

  dmin  minimum of the data range
  dmax  maximum of the data range
  m     number of axis labels

Value

vector of axis label locations

Author(s)

Justin Talbot <justintalbot@gmail.com>

References

wilkinson

Wilkinson’s labeling algorithm

Usage

wilkinson(dmin, dmax, m,
Q = c(1, 5, 2, 2.5, 3, 4, 1.5, 7, 6, 8, 9),
mincoverage = 0.8,
 mrange = max(floor(m/2), 2):ceiling(6 * m))
Arguments

dmin minimum of the data range
dmax maximum of the data range
m number of axis labels
Q set of nice numbers
mincoverage minimum ratio between the the data range and the labeling range, controlling the whitespace around the labeling (default = 0.8)
mrange range of m, the number of tick marks, that should be considered in the optimization search

Value

vector of axis label locations

Note

Ported from Wilkinson’s Java implementation with some changes. Changes: 1) m (the target number of ticks) is hard coded in Wilkinson’s implementation as 5. Here we allow it to vary as a parameter. Since m is fixed, Wilkinson only searches over a fixed range 4-13 of possible resulting ticks. We broadened the search range to max(floor(m/2),2) to ceiling(6*m), which is a larger range than Wilkinson considers for 5 and allows us to vary m, including using non-integer values of m. 2) Wilkinson’s implementation assumes that the scores are non-negative. But, his revised granularity function can be extremely negative. We tweaked the code to allow negative scores. We found that this produced better labelings. 3) We added 10 to Q. This seemed to be necessary to get steps of size 1. It is possible for this algorithm to find no solution. In Wilkinson’s implementation, instead of failing, he returns the non-nice labels spaced evenly from min to max. We want to detect this case, so we return NULL. If this happens, the search range, mrange, needs to be increased.
