Package ‘later’
August 18, 2021

Type     Package
Title    Utilities for Scheduling Functions to Execute Later with Event
          Loops
Version  1.3.0
Description Executes arbitrary R or C functions some time after the current
time, after the R execution stack has emptied. The functions are scheduled
in an event loop.

create_loop

**Description**

Normally, later uses a global event loop for scheduling and running functions. However, in some cases, it is useful to create a *private* event loop to schedule and execute tasks without disturbing the global event loop. For example, you might have asynchronous code that queries a remote data source, but want to wait for a full back-and-forth communication to complete before continuing in your code – from the caller’s perspective, it should behave like synchronous code, and not do anything with the global event loop (which could run code unrelated to your operation). To do this, you would run your asynchronous code using a private event loop.

**Usage**

```r
create_loop(parent = current_loop(), autorun = NULL)

destroy_loop(loop)

exists_loop(loop)

current_loop()

with_temp_loop(expr)

with_loop(loop, expr)

global_loop()
```

**Arguments**

- `parent` The parent event loop for the one being created. Whenever the parent loop runs, this loop will also automatically run, without having to manually call `run_now()` on this loop. If NULL, then this loop will not have a parent event loop that automatically runs it; the only way to run this loop will be by calling `run_now()` on this loop.

- `autorun` This exists only for backward compatibility. If set to `FALSE`, it is equivalent to using `parent=NULL`.

- `loop` A handle to an event loop.

- `expr` An expression to evaluate.
later

Details

create_loop creates and returns a handle to a private event loop, which is useful when for scheduling tasks when you do not want to interfere with the global event loop.
destroy_loop destroys a private event loop.
exists_loop reports whether an event loop exists – that is, that it has not been destroyed.
current_loop returns the currently-active event loop. Any calls to later() or run_now() will use the current loop by default.
with_loop evaluates an expression with a given event loop as the currently-active loop.
with_temp_loop creates an event loop, makes it the current loop, then evaluates the given expression. Afterwards, the new event loop is destroyed.
global_loop returns a handle to the global event loop.

later                              Executes a function later

Description

Schedule an R function or formula to run after a specified period of time. Similar to JavaScript’s setTimeout function. Like JavaScript, R is single-threaded so there’s no guarantee that the operation will run exactly at the requested time, only that at least that much time will elapse.

Usage

later(func, delay = 0, loop = current_loop())

Arguments

func                  A function or formula (see rlang::as_function()).
delay                 Number of seconds in the future to delay execution. There is no guarantee that the function will be executed at the desired time, but it should not execute earlier.
loop                  A handle to an event loop. Defaults to the currently-active loop.

Details

The mechanism used by this package is inspired by Simon Urbanek’s background package and similar code in Rhttpd.

Value

A function, which, if invoked, will cancel the callback. The function will return TRUE if the callback was successfully cancelled and FALSE if not (this occurs if the callback has executed or has been cancelled already).
Note

To avoid bugs due to reentrancy, by default, scheduled operations only run when there is no other R code present on the execution stack; i.e., when R is sitting at the top-level prompt. You can force past-due operations to run at a time of your choosing by calling `run_now()`.

Error handling is not particularly well-defined and may change in the future. `options(error=browser)` should work and errors in `func` should generally not crash the R process, but not much else can be said about it at this point. If you must have specific behavior occur in the face of errors, put error handling logic inside of `func`.

Examples

```r
# Example of formula style
later(~cat("Hello from the past\n"), 3)

# Example of function style
later(function() {
  print(summary(cars))
}, 2)
```

### next_op_secs

**Relative time to next scheduled operation**

**Description**

Returns the duration between now and the earliest operation that is currently scheduled, in seconds. If the operation is in the past, the value will be negative. If no operation is currently scheduled, the value will be `Inf`.

**Usage**

```r
next_op_secs(loop = current_loop())
```

**Arguments**

- `loop` A handle to an event loop.
run_now

execute scheduled operations

Description

Normally, operations scheduled with `later()` will not execute unless/until no other R code is on the stack (i.e. at the top-level). If you need to run blocking R code for a long time and want to allow scheduled operations to run at well-defined points of your own operation, you can call `run_now()` at those points and any operations that are due to run will do so.

Usage

```r
run_now(timeoutSecs = 0L, all = TRUE, loop = current_loop())
```

Arguments

- `timeoutSecs` Wait (block) for up to this number of seconds waiting for an operation to be ready to run. If 0, then return immediately if there are no operations that are ready to run. If Inf or negative, then wait as long as it takes (if none are scheduled, then this will block forever).
- `all` If FALSE, `run_now()` will execute at most one scheduled operation (instead of all eligible operations). This can be useful in cases where you want to interleave scheduled operations with your own logic.
- `loop` A handle to an event loop.Defaults to the currently-active loop.

Details

If one of the callbacks throws an error, the error will not be caught, and subsequent callbacks will not be executed (until `run_now()` is called again, or control returns to the R prompt). You must use your own `tryCatch` if you want to handle errors.

Value

A logical indicating whether any callbacks were actually run.
