Package ‘lattice’

April 5, 2023

Version 0.21-8
Date 2023-04-05
Priority recommended
Title Trellis Graphics for R
Description A powerful and elegant high-level data visualization
system inspired by Trellis graphics, with an emphasis on
multivariate data. Lattice is sufficient for typical graphics needs,
and is also flexible enough to handle most nonstandard requirements.
See ?Lattice for an introduction.

Description

The lattice add-on package is an implementation of Trellis graphics for R. It is a powerful and elegant high-level data visualization system with an emphasis on multivariate data. It is designed to meet most typical graphics needs with minimal tuning, but can also be easily extended to handle most nonstandard requirements.

Details

Trellis Graphics, originally developed for S and S-PLUS at the Bell Labs, is a framework for data visualization developed by R. A. Becker, W. S. Cleveland, et al, extending ideas presented in Cleveland’s 1993 book Visualizing Data. The Lattice API is based on the original design in S, but extends it in many ways.

The Lattice user interface primarily consists of several ‘high-level’ generic functions (listed below in the “See Also” section), each designed to create a particular type of display by default. Although the functions produce different output, they share many common features, reflected in several common arguments that affect the resulting displays in similar ways. These arguments are extensively (sometimes only) documented in the help page for xyplot, which also includes a discussion of the important topics of conditioning and control of the Trellis layout. Features specific to other high-level functions are documented in their respective help pages.
Lattice employs an extensive system of user-controllable settings to determine the look and feel of the displays it produces. To learn how to use and customize the graphical parameters used by lattice, see `trellis.par.set`. For other settings, see `lattice.options`. The default graphical settings are (potentially) different for different graphical devices. To learn how to initialize new devices with the desired settings or change the settings of the current device, see `trellis.device`.

It is usually unnecessary, but sometimes important to be able to plot multiple lattice plots on a single page. Such capabilities are described in the `print.trellis` help page. See `update.trellis` to learn about manipulating a "trellis" object. Tools to augment lattice plots after they are drawn (including `locator`-like functionality) are described in the `trellis.focus` help page.

The online documentation accompanying the package is complete, and effort has been made to present the help pages in a logical sequence, so that one can learn how to use lattice by reading the PDF reference manual available at https://cran.r-project.org/package=lattice. However, the format in which the online documentation is written and the breadth of topics covered necessarily makes it somewhat terse and less than ideal as a first introduction. For a more gentle introduction, a book on lattice is available as part of Springer’s ‘Use R’ series; see the “References” section below.

Note

High-level lattice functions like `xyplot` are different from traditional R graphics functions in that they do not perform any plotting themselves. Instead, they return an object, of class "trellis", which has to be then `print`-ed or `plot`-ted to create the actual plot. Due to R’s automatic printing rule, it is usually not necessary to explicitly carry out the second step, and lattice functions appear to behave like their traditional counterparts. However, the automatic plotting is suppressed when the high-level functions are called inside another function (most often source) or in other contexts where automatic printing is suppressed (e.g., `for` or `while` loops). In such situations, an explicit call to `print` or `plot` is required.

The lattice package is based on the Grid graphics engine and requires the grid add-on package. One consequence of this is that it is not (readily) compatible with traditional R graphics tools. In particular, changing `par()` settings usually has no effect on Lattice plots; lattice provides its own interface for querying and modifying an extensive set of graphical and non-graphical settings.

Bell Lab’s Trellis Page contains several documents outlining the use of Trellis graphics; these provide a holistic introduction to the Trellis paradigm: http://web.archive.org/web/20081020164041/http://cm.bell-labs.com/cm/ms/ departments/sia/project/trellis/display.writing.html
See Also

The following is a list of high-level functions in the **lattice** package and their default displays. In all cases, the actual display is produced by the so-called “panel” function, which has a suitable default, but can be substituted by an user defined function to create customized displays. In many cases, the default panel function will itself have many optional arguments to customize its output. The default panel functions are named as “panel.” followed by the name of the corresponding high-level function; i.e., the default panel function for *xyplot* is *panel.xyplot*, the one for *histogram* is *panel.histogram*, etc. Each default panel function has a separate help page, linked from the help pages of the corresponding high-level function. Although documented separately, arguments to these panel functions can be supplied directly to the high-level functions, which will pass on the arguments appropriately.

**Univariate:**

*barchart*: Bar plots.
*bwplot*: Box-and-whisker plots.
*densityplot*: Kernel density estimates.
*dotplot*: Cleveland dot plots.
*histogram*: Histograms.
*qqmath*: Theoretical quantile plots.
*stripplot*: One-dimensional scatterplots.

**Bivariate:**

*qq*: Quantile plots for comparing two distributions.
*xyplot*: Scatterplots and time-series plots (and potentially a lot more).

**Trivariate:**

*levelplot*: Level plots (similar to *image* plots).
*contourplot*: Contour plots.
*cloud*: Three-dimensional scatter plots.
*wireframe*: Three-dimensional surface plots (similar to *persp* plots).

**Hypervariate:**

*splom*: Scatterplot matrices.
*parallel*: Parallel coordinate plots.

**Miscellaneous:**

*rfs*: Residual and fitted value plots (also see *oneway*).
*td*: Tukey Mean-Difference plots.

In addition, there are several panel functions that do little by themselves, but can be useful components of custom panel functions. These are documented in **panel.functions**. Lattice also provides a collection of convenience functions that correspond to the traditional graphics primitives **lines**, **points**, etc. These are implemented using Grid graphics, but try to be as close to the traditional...
versions as possible in terms of their argument list. These functions have names like \texttt{llines} or \texttt{panel.lines} and are often useful when writing (or porting from S-PLUS code) nontrivial panel functions.

Finally, many useful enhancements that extend the Lattice system are available in the \texttt{latticeExtra} package.

\section*{Examples}

\section*{Description}

This help page documents several commonly used high-level Lattice functions. \texttt{xyplot} produces bivariate scatterplots or time-series plots, \texttt{bwplot} produces box-and-whisker plots, \texttt{dotplot} produces Cleveland dot plots, \texttt{barchart} produces bar plots, and \texttt{stripplot} produces one-dimensional scatterplots. All these functions, along with other high-level Lattice functions, respond to a common set of arguments that control conditioning, layout, aspect ratio, legends, axis annotation, and many other details in a consistent manner. These arguments are described extensively in this help page, and should be used as the reference for other high-level functions as well.

For control and customization of the actual display in each panel, the help page of the respective default panel function will often be more informative. In particular, these help pages describe many arguments commonly used when calling the corresponding high-level function but are specific to them.

\section*{Usage}

\begin{verbatim}
xyplot(x, data, ...)  
dotplot(x, data, ...)  
barchart(x, data, ...)  
stripplot(x, data, ...)  
bwplot(x, data, ...)
\end{verbatim}

\begin{verbatim}
## S3 method for class 'formula'

  aspect = "fill",
  
  ...
Arguments

x

All high-level function in lattice are generic. x is the object on which method dispatch is carried out.

For the "formula" methods, x must be a formula describing the primary variables (used for the per-panel display) and the optional conditioning variables (which define the subsets plotted in different panels) to be used in the plot. Conditioning is described in the “Details” section below.

For the functions documented here, the formula is generally of the form y ~ x | g1 * g2 * ... (or equivalently, y ~ x | g1 + g2 + ...), indicating that plots of y (on the y-axis) versus x (on the x-axis) should be produced conditional on the variables g1, g2, .... Here x and y are the primary variables, and g1, g2, ... are the conditioning variables. The conditioning variables may be omitted to give a formula of the form y ~ x, in which case the plot will consist of a single panel with the full dataset. The formula can also involve expressions, e.g., sqrt(), log(), etc. See the data argument below for rules regarding evaluation of the terms in the formula.

With the exception of xyplot, the functions documented here may also be supplied a formula of the form ~x | g1 * g2 * .... In that case, y defaults to names(x) if x is named, and a factor with a single level otherwise.

Cases where x is not a formula is handled by appropriate methods. The numeric methods are equivalent to a call with no left hand side and no conditioning variables in the formula. For barchart and dotplot, non-trivial methods exist for tables and arrays, documented at barchart.table.

The conditioning variables g1, g2, ... must be either factors or shingles. Shingles provide a way of using numeric variables for conditioning; see the help page of shingle for details. Like factors, they have a "levels" attribute, which is used in producing the conditional plots. If necessary, numeric conditioning
variables are converted to shingles using the shingle function; however, using `equal.count` may be more appropriate in many cases. Character variables are coerced to factors.

**Extended formula interface:** As a useful extension of the interface described above, the primary variable terms (both the LHS `y` and RHS `x`) may consist of multiple terms separated by a `+` sign, e.g., `y1 + y2 ~ x | a * b`. This formula would be taken to mean that the user wants to plot both `y1 ~ x | a * b` and `y2 ~ x | a * b`, but with the `y1 ~ x` and `y2 ~ x` superposed in each panel. The two groups will be distinguished by different graphical parameters. This is essentially what the `groups` argument (see below) would produce, if `y1` and `y2` were concatenated to produce a longer vector, with the `groups` argument being an indicator of which rows come from which variable. In fact, this is exactly what is done internally using the `reshape` function. This feature cannot be used in conjunction with the `groups` argument.

To interpret `y1 + y2` as a sum, one can either set `allow.multiple=FALSE` or use `I(y1+y2)`.

A variation on this feature is when the `outer` argument is set to `TRUE`. In that case, the plots are not superposed in each panel, but instead separated into different panels (as if a new conditioning variable had been added).

**Primary variables:** The `x` and `y` variables should both be numeric in `xyplot`, and an attempt is made to coerce them if not. However, if either is a factor, the levels of that factor are used as axis labels. In the other four functions documented here, exactly one of `x` and `y` should be numeric, and the other a factor or shingle. Which of these will happen is determined by the `horizontal` argument — if `horizontal=TRUE`, then `y` will be coerced to be a factor or shingle, otherwise `x`. The default value of `horizontal` is `FALSE` if `x` is a factor or shingle, `TRUE` otherwise. (The functionality provided by `horizontal=FALSE` is not S-compatible.)

Note that the `x` argument used to be called `formula` in earlier versions (when the high-level functions were not generic and the formula method was essentially the only method). This is no longer allowed. It is recommended that this argument not be named in any case, but instead be the first (unnamed) argument.

**data**

For the `formula` methods, a data frame (or more precisely, anything that is a valid `envir` argument in `eval`, e.g., a list or an environment) containing values for any variables in the formula, as well as `groups` and `subset` if applicable. If not found in `data`, or if `data` is unspecified, the variables are looked for in the environment of the formula. For other methods (where `x` is not a formula), `data` is usually ignored, often with a warning if it is explicitly specified.

**allow.multiple**

Logical flag specifying whether the extended formula interface described above should be in effect. Defaults to `TRUE` whenever sensible.

**outer**

Logical flag controlling what happens with formulas using the extended interface described above (see the entry for `x` for details). Defaults to `FALSE`, except when `groups` is explicitly specified or grouping does not make sense for the default panel function.

**box.ratio**

Applicable to `barchart` and `bwplot`. Specifies the ratio of the width of the rectangles to the inter-rectangle space. See also the `box.width` argument in the respective default panel functions.
horizontal Logical flag applicable to bwplot, dotplot, barchart, and stripplot. Determines which of x and y is to be a factor or shingle (y if TRUE, x otherwise). Defaults to FALSE if x is a factor or shingle, TRUE otherwise. This argument is used to process the arguments to these high-level functions, but more importantly, it is passed as an argument to the panel function, which is expected to use it as appropriate.

A potentially useful component of scales in this case may be abbreviate = TRUE, in which case long labels which would usually overlap will be abbreviated. scales could also contain a minlength argument in this case, which would be passed to the abbreviate function.

**Common arguments:** The following arguments are common to all the functions documented here, as well as most other high-level Trellis functions. These are not documented elsewhere, except to override the usage given here.

panel Once the subset of rows defined by each unique combination of the levels of the grouping variables are obtained (see “Details”), the corresponding x and y variables (or other variables, as appropriate, in the case of other high-level functions) are passed on to be plotted in each panel. The actual plotting is done by the function specified by the panel argument. The argument may be a function object or a character string giving the name of a predefined function. Each high-level function has its own default panel function, named as “panel.” followed by the name of the corresponding high-level function (e.g., panel.xyplot, panel.barchart, etc).

Much of the power of Trellis Graphics comes from the ability to define customized panel functions. A panel function appropriate for the functions described here would usually expect arguments named x and y, which would be provided by the conditioning process. It can also have other arguments. It is useful to know in this context that all arguments passed to a high-level Lattice function (such as xyplot) that are not recognized by it are passed through to the panel function. It is thus generally good practice when defining panel functions to allow a ... argument. Such extra arguments typically control graphical parameters, but other uses are also common. See documentation for individual panel functions for specifics.

Note that unlike in S-PLUS, it is not guaranteed that panel functions will be supplied only numeric vectors for the x and y arguments; they can be factors as well (but not shingles). Panel functions need to handle this case, which in most cases can be done by simply coercing them to numeric.

Technically speaking, panel functions must be written using Grid graphics functions. However, knowledge of Grid is usually not necessary to construct new custom panel functions, as there are several predefined panel functions which can help; for example, panel.grid, panel.loess, etc. There are also some grid-compatible replacements of commonly used traditional graphics functions useful for this purpose. For example, lines can be replaced by llines (or equivalently, panel.lines). Note that traditional graphics functions like lines will not work in a lattice panel function.

One case where a bit more is required of the panel function is when the groups argument is not NULL. In that case, the panel function should also accept arguments named groups and subscripts (see below for details). A useful panel function predefined for use in such cases is panel.superpose, which can be
combined with different panel.groups functions to determine what is plotted for each group. See the “Examples” section for an interaction plot constructed in this way. Several other panel functions can also handle the groups argument, including the default ones for xyplot, barchart, dotplot, and stripplot. Even when groups is not present, the panel function can have subscripts as a formal argument. In either case, the subscripts argument passed to the panel function are the indices of the x and y data for that panel in the original data, BEFORE taking into account the effect of the subset argument. Note that groups remains unaffected by any subsetting operations, so groups[subscripts] gives the values of groups that correspond to the data in that panel.

This interpretation of subscripts does not hold when the extended formula interface is in use (i.e., when allow.multiple is in effect). A comprehensive description would be too complicated (details can be found in the source code of the function latticeParseFormula), but in short, the extended interface works by creating an artificial grouping variable that is longer than the original data frame, and consequently, subscripts needs to refer to rows beyond those in the original data. To further complicate matters, the artificial grouping variable is created after any effect of subset, in which case subscripts may have no relationship with corresponding rows in the original data frame.

One can also use functions called panel.number and packet.number, representing panel order and packet order respectively, inside the panel function (as well as the strip function or while interacting with a lattice display using trellis.focus etc). Both provide a simple integer index indicating which panel is currently being drawn, but differ in how the count is calculated. The panel number is a simple incremental counter that starts with 1 and is incremented each time a panel is drawn. The packet number on the other hand indexes the combination of levels of the conditioning variables that is represented by that panel. The two indices coincide unless the order of conditioning variables is permuted and/or the plotting order of levels within one or more conditioning variables is altered (using perm.cond and index.cond respectively), in which case packet.number gives the index corresponding to the ‘natural’ ordering of that combination of levels of the conditioning variables.

panel.xyplot has an argument called type which is worth mentioning here because it is quite frequently used (and as mentioned above, can be passed to xyplot directly). In the event that a groups variable is used, panel.xyplot calls panel.superpose, arguments of which can also be passed directly to xyplot. Panel functions for bwplot and friends should have an argument called horizontal to account for the cases when x is the factor or shingle.

aspect This argument controls the physical aspect ratio of the panels, which is usually the same for all the panels. It can be specified as a ratio (vertical size/horizontal size) or as a character string. In the latter case, legitimate values are "fill" (the default) which tries to make the panels as big as possible to fill the available space; "xy", which computes the aspect ratio based on the 45 degree banking rule (see banking); and "iso" for isometric scales, where the relation between physical distance on the device and distance in the data scale are forced to be the same for both axes.

If a prepanel function is specified and it returns components dx and dy, these are used for banking calculations. Otherwise, values from the default prepanel
function are used. Not all default prepanel functions produce sensible banking
calculations.

**groups**
A variable or expression to be evaluated in data, expected to act as a group-
ing variable within each panel, typically used to distinguish different groups by
varying graphical parameters like color and line type. Formally, if groups is
specified, then groups along with subscripts is passed to the panel function,
which is expected to handle these arguments. For high level functions where
grouping is appropriate, the default panel functions can handle grouping.

It is very common to use a key (legend) when a grouping variable is specified.
See entries for key, auto.key and simpleKey for how to draw a key.

**auto.key**
A logical, or a list containing components to be used as arguments to simpleKey.
The default can be set using lattice.options.

auto.key = TRUE is equivalent to auto.key = list(), in which case simpleKey
is called with a set of default arguments (which may depend on the relevant high-
level function). Most valid components to the key argument can be specified in
this manner, as simpleKey will simply add unrecognized arguments to the list it
produces.

auto.key is typically used to automatically produce a suitable legend in con-
junction with a grouping variable. If auto.key = TRUE, a suitable legend will
be drawn if a groups argument is also provided, and not otherwise. In list
form, auto.key will modify the default legend thus produced. For example,
auto.key=list(columns = 2) will create a legend split into two columns (columns
is documented in the entry for key).

More precisely, if auto.key is not FALSE, groups is non-null, and there is no
key or legend argument specified in the call, a key is created with simpleKey
with levels(groups) as the first (text) argument. (Note: this may not work
in all high-level functions, but it does work for the ones where grouping makes
sense with the default panel function). If auto.key is provided as a list and
includes a text component, then that is used instead as the text labels in the
key, and the key is drawn even if groups is not specified.

Note that simpleKey uses the default settings (see trellis.par.get) to deter-
mine the graphical parameters in the key, so the resulting legend will be mean-
ingful only if the same settings are used in the plot as well. The par.settings
argument, possibly in conjunction with simpleTheme, may be useful to tem-
porarily modify the default settings for this purpose.

One disadvantage to using key (or even simpleKey) directly is that the graphi-
 cal parameters used in the key are absolutely determined at the time when the
"trellis" object is created. Consequently, if a plot once created is re-plotted
with different settings, the original parameter settings will be used for the
key even though the new settings are used for the actual display. However, with
auto.key, the key is actually created at plotting time, so the settings will match.

**prepanel**
A function that takes the same arguments as the panel function and returns a
list, possibly containing components named xlim, ylim, dx, and dy (and less
frequently, xat and yat). The return value of a user-supplied prepanel func-
tion need not contain all these components; in case some are missing, they are
replaced by the component-wise defaults.
The xlim and ylim components are similar to the high level xlim and ylim arguments (i.e., they are usually a numeric vector of length 2 defining a range, or a character vector representing levels of a factor). If the xlim and ylim arguments are not explicitly specified (possibly as components in scales) in the high-level call, then the actual limits of the panels are guaranteed to include the limits returned by the prepanel function. This happens globally if the relation component of scales is "same", and on a per-panel basis otherwise. The dx and dy components are used for banking computations in case aspect is specified as "xy". See documentation of banking for details. If xlim or ylim is a character vector (which is appropriate when the corresponding variable is a factor), this implicitly indicates that the scale should include the first \( n \) integers, where \( n \) is the length of xlim or ylim, as the case may be. The elements of the character vector are used as the default labels for these \( n \) integers. Thus, to make this information consistent between panels, the xlim or ylim values should represent all the levels of the corresponding factor, even if some are not used within that particular panel. In such cases, an additional component xat or yat may be returned by the prepanel function, which should be a subset of 1:n, indicating which of the \( n \) values (levels) are actually represented in the panel. This is useful when calculating the limits with relation="free" or relation="sliced" in scales. The prepanel function is responsible for providing a meaningful return value when the \( x, y \) (etc.) variables are zero-length vectors. When nothing else is appropriate, values of NA should be returned for the xlim and ylim components.

**strip**

A logical flag or function. If FALSE, strips are not drawn. Otherwise, strips are drawn using the strip function, which defaults to strip.default. See documentation of strip.default to see the arguments that are available to the strip function. This description also applies to the strip.left argument (see ... below), which can be used to draw strips on the left of each panel (useful for wide short panels, e.g., in time-series plots).

**xlab**

Character or expression (or a "grob") giving label(s) for the x-axis. Generally defaults to the expression for \( x \) in the formula defining the plot. Can be specified as NULL to omit the label altogether. Finer control is possible, as described in the entry for main, with the modification that if the label component is omitted from the list, it is replaced by the default xlab.

**ylab**

Character or expression (or "grob") giving label for the y-axis. Generally defaults to the expression for \( y \) in the formula defining the plot. Finer control is possible, see entries for main and xlab.

**scales**

Generally a list determining how the x- and y-axes (tick marks and labels) are drawn. The list contains parameters in name=value form, and may also contain two other lists called x and y of the same form (described below). Components of x and y affect the respective axes only, while those in scales affect both. When parameters are specified in both lists, the values in x or y are used. Note that certain high-level functions have defaults that are specific to a particular axis (e.g., bwplot has alternating=FALSE for the categorical axis only); these can only be overridden by an entry in the corresponding component of scales. As a special exception, scales (or its x and y components) can also be a character string, in which case it is interpreted as the relation component.
The possible components are:

**relation**  A character string that determines how axis limits are calculated for each panel. Possible values are "same" (default), "free" and "sliced". For \texttt{relation="same"}, the same limits, usually large enough to encompass all the data, are used for all the panels. For \texttt{relation="free"}, limits for each panel is determined by just the points in that panel. Behavior for \texttt{relation="sliced"} is similar, except that the length (max - min) of the scales are constrained to remain the same across panels. The determination of what axis limits are suitable for each panel can be controlled by the \texttt{prepanel} function, which can be overridden by \texttt{xlim}, \texttt{ylim} or \texttt{scales$limits} (except when \texttt{relation="sliced"}, in which case explicitly specified limits are ignored with a warning). When \texttt{relation} is "free", \texttt{xlim} or \texttt{ylim} can be a list, in which case it is treated as if its components were the limit values obtained from the \texttt{prepanel} calculations for each panel (after being replicated if necessary).

**tick.number**  An integer, giving the suggested number of intervals between ticks. This is ignored for a factor, shingle, or character vector, for in these cases there is no natural rule for leaving out some of the labels. But see \texttt{xlim}.

**draw**  A logical flag, defaulting to \texttt{TRUE}, that determines whether to draw the axis (i.e., tick marks and labels) at all.

**alternating**  Usually a logical flag specifying whether axis labels should alternate from one side of the group of panels to the other. For finer control, \texttt{alternating} can also be a vector (replicated to be as long as the number of rows or columns per page) consisting of the following numbers
- 0: do not draw tick labels
- 1: bottom/left
- 2: top/right
- 3: both.

\texttt{alternating} applies only when \texttt{relation="same"}. The default is \texttt{TRUE}, or equivalently, \texttt{c(1, 2)}

**limits**  Same as \texttt{xlim} and \texttt{ylim}.

**at**  The location of tick marks along the axis (in native coordinates), or a list as long as the number of panels describing tick locations for each panel.

**labels**  Vector of labels (characters or expressions) to go along with \texttt{at}. Can also be a list like \texttt{at}.

**cex**  A numeric multiplier to control character sizes for axis labels. Can be a vector of length 2, to control left/bottom and right/top labels separately.

**font, fontface, fontfamily**  Specifies the font to be used for axis labels.

**lineheight**  Specifies the line height parameter (height of line as a multiple of the size of text); relevant for multi-line labels. (This is currently ignored for \texttt{cloud}.)

**tck**  Usually a numeric scalar controlling the length of tick marks. Can also be a vector of length 2, to control the length of left/bottom and right/top tick marks separately.

**col**  Color of tick marks and labels.
rot Angle (in degrees) by which the axis labels are to be rotated. Can be a vector of length 2, to control left/bottom and right/top axes separately.

abbreviate A logical flag, indicating whether to abbreviate the labels using the abbreviate function. Can be useful for long labels (e.g., in factors), especially on the x-axis.

minlength Argument passed to abbreviate if abbreviate=TRUE.

log Controls whether the corresponding variable (x or y) will be log transformed before being passed to the panel function. Defaults to FALSE, in which case the data are not transformed. Other possible values are any number that works as a base for taking logarithm, TRUE (which is equivalent to 10), and "e" (for the natural logarithm). As a side effect, the corresponding axis is labeled differently. Note that this is in reality a transformation of the data, not the axes. Other than the axis labeling, using this feature is no different than transforming the data in the formula; e.g., scales=list(x=list(log = 2)) is equivalent to y ~ log2(x).

See entry for equispaced.log below for details on how to control axis labeling.

equispaced.log A logical flag indicating whether tick mark locations should be equispaced when 'log scales' are in use. Defaults to TRUE. Tick marks are always labeled in the original (untransformed) scale, but this makes the choice of tick mark locations nontrivial. If equispaced.log is FALSE, the choice made is similar to how log scales are annotated in traditional graphics. If TRUE, tick mark locations are chosen as ‘pretty’ equispaced values in the transformed scale, and labeled in the form "base^loc", where base is the base of the logarithm transformation, and loc are the locations in the transformed scale.

See also xscale.components.logpower in the latticeExtra package.

format The format to use for POSIXct variables. See strptime for description of valid values.

axs A character string, "r" (default) or "i". In the latter case, the axis limits are calculated as the exact data range, instead of being padded on either side. (May not always work as expected.)

Note that much of the function of scales is accomplished by pscales in splom.

subscripts A logical flag specifying whether or not a vector named subscripts should be passed to the panel function. Defaults to FALSE, unless groups is specified, or if the panel function accepts an argument named subscripts. This argument is useful if one wants the subscripts to be passed on even if these conditions do not hold; a typical example is when one wishes to augment a Lattice plot after it has been drawn, e.g., using panel.identify.

subset An expression that evaluates to a logical or integer indexing vector. Like groups, it is evaluated in data. Only the resulting rows of data are used for the plot. If subscripts is TRUE, the subscripts provided to the panel function will be indices referring to the rows of data prior to the subsetting. Whether levels of factors in the data frame that are unused after the subsetting will be dropped depends on the drop.unused.levels argument.

xlim Normally a numeric vector (or a DateTime object) of length 2 giving left and right limits for the x-axis, or a character vector, expected to denote the levels of
x. The latter form is interpreted as a range containing c(1, length(xlim)), with
the character vector determining labels at tick positions 1:length(xlim).
xlim could also be a list, with as many components as the number of panels (re-
cycled if necessary), with each component as described above. This is meaning-
ful only when scales$x$relation is "free", in which case these are treated
as if they were the corresponding limit components returned by prepanel calcu-
lations.

ylim Similar to xlim, applied to the y-axis.
drop.unused.levels
A logical flag indicating whether the unused levels of factors will be dropped,
usually relevant when a subsetting operation is performed or an interaction is
created. Unused levels are usually dropped, but it is sometimes appropriate to
suppress dropping to preserve a useful layout. For finer control, this argument
could also be list containing components cond and data, both logical, indicating
desired behavior for conditioning variables and primary variables respectively.
The default is given by lattice.getOption("drop.unused.levels"), which
is initially set to TRUE for both components. Note that this argument does not
control dropping of levels of the groups argument.
default.scales A list giving the default values of scales for a particular high-level function.
This is rarely of interest to the end-user, but may be helpful when defining other
functions that act as a wrapper to one of the high-level Lattice functions.
default.prepanel A function or character string giving the name of a function that serves as the
(component-wise) fallback prepanel function when the prepanel argument is
not specified, or does not return all necessary components. The main purpose
of this argument is to enable the defaults to be overridden through the use of
lattice.options.
lattice.options A list that could be supplied to lattice.options. These options are applied
temporarily for the duration of the call, after which the settings revert back to
what they were before. The options are retained along with the object and reused
during plotting. This enables the user to attach options settings to the trellis
object itself rather than change the settings globally. See also the par.settings
argument described below for a similar treatment of graphical settings.

Further arguments, usually not directly processed by the high-level functions
documented here, but instead passed on to other functions. Such arguments can
be broadly categorized into two types: those that affect all high-level Lattice functions in a similar manner, and those that are meant for the specific panel
function being used.
The first group of arguments are processed by a common, unexported function
called trellis.skeleton. These arguments affect all high-level functions, but
are only documented here (except to override the behaviour described here).
All other arguments specified in a high-level call, specifically those neither de-
scribed here nor in the help page of the relevant high-level function, are passed
unchanged to the panel function used. By convention, the default panel function
used for any high-level function is named as “panel.” followed by the name
of the high-level function; for example, the default panel function for bwplot is
panel.bwplot. In practical terms, this means that in addition to the help page of the high-level function being used, the user should also consult the help page of the corresponding panel function for arguments that may be specified in the high-level call.

The effect of the first group of common arguments are as follows:

`as.table`: A logical flag that controls the order in which panels should be displayed: if `FALSE` (the default), panels are drawn left to right, bottom to top (as in a graph); if `TRUE`, left to right, top to bottom (as in a table).

`between`: A list with components `x` and `y` (both usually 0 by default), numeric vectors specifying the space between the panels (units are character heights). `x` and `y` are repeated to account for all panels in a page and any extra components are ignored. The result is used for all pages in a multi-page display. In other words, it is not possible to use different `between` values for different pages.

`key`: A list that defines a legend to be drawn on the plot. This list is used as an argument to the `draw.key` function, which produces a "grob" (grid object) eventually plotted by the print method for "trellis" objects. The structure of the legend is constrained in the ways described below. Although such a list can be and often is created explicitly, it is also possible to generate such a list using the `simpleKey` function; the latter is more convenient but less flexible. The `auto.key` argument can be even more convenient for the most common situation where legends are used, namely, in conjunction with a grouping variable. To use more than one legend, or to have arbitrary legends not constrained by the structure imposed by `key`, use the `legend` argument.

The position of the key can be controlled in either of two possible ways. If a component called `space` is present, the key is positioned outside the plot region, in one of the four sides, determined by the value of `space`, which can be one of "top", "bottom", "left" and "right". Alternatively, the key can be positioned inside the plot region by specifying components `x`, `y` and `corner`. `x` and `y` determine the location of the corner of the key given by `corner`, which is usually one of `c(0,0)`, `c(1,0)`, `c(1,1)` and `c(0,1)`, which denote the corners of the unit square. Fractional values are also allowed, in which case `x` and `y` determine the position of an arbitrary point inside (or outside for values outside the unit interval) the key. `x` and `y` should be numbers between 0 and 1, giving coordinates with respect to the "display area". Depending on the value of the "legend.bbox" option (see `lattice.getOption`), this can be either the full figure region ("full"), or just the region that bounds the panels and strips ("panel"). The key essentially consists of a number of columns, possibly divided into blocks, each containing some rows. The contents of the key are determined by (possibly repeated) components named "rectangles", "lines", "points" or "text". Each of these must be lists with relevant graphical parameters (see later) controlling their appearance. The key list itself can contain graphical parameters, these would be used if relevant graphical components are omitted from the other components. The length (number of rows) of each such column (except "text"s) is taken to be the largest of the lengths of the graphical components, including the
ones specified outside (see the entry for \texttt{rep} below for details on this). The "text" component must have a character or expression vector as its first component, to be used as labels. The length of this vector determines the number of rows.

The graphical components that can be included in \texttt{key} and also in the components named "text", "lines", "points" and "rectangles" (as appropriate) are:

- \texttt{cex=1} (text, lines, points)
- \texttt{col="black"} (text, rectangles, lines, points)
- \texttt{alpha=1} (text, rectangles, lines, points)
- \texttt{fill="transparent"} (lines, points)
- \texttt{lty=1} (lines)
- \texttt{lwd=1} (lines, points)
- \texttt{font=1} (text, points)
- \texttt{fontface} (text, points)
- \texttt{fontfamily} (text, points)
- \texttt{pch=8} (lines, points)
- \texttt{adj=0} (text)
- \texttt{type="l"} (lines)
- \texttt{size=5} (rectangles, lines)
- \texttt{height=1} (rectangles)
- \texttt{lineheight=1} (text)
- \texttt{angle=0} (rectangles, but ignored)
- \texttt{density=-1} (rectangles, but ignored)

In addition, the component \texttt{border} can be included inside the "rect" component to control the border color of the rectangles; when specified at the top level, \texttt{border} controls the border of the entire key (see below). \texttt{angle} and \texttt{density} are unimplemented. \texttt{size} determines the width of columns of rectangles and lines in character widths. \texttt{type} is relevant for lines; "l" denotes a line, "p" denotes a point, and "b" and "o" both denote both together. \texttt{height} gives heights of rectangles as a fraction of the default.

Other possible components of \texttt{key} are:

- \texttt{reverse.rows} Logical flag, defaulting to \texttt{FALSE}. If \texttt{TRUE}, all components are reversed after being replicated (the details of which may depend on the value of \texttt{rep}). This is useful in certain situations, e.g., with a grouped barchart with \texttt{stack = TRUE} with the categorical variable on the vertical axis, where the bars in the plot will usually be ordered from bottom to top, but the corresponding legend will have the levels from top to bottom unless \texttt{reverse.rows = TRUE}. Note that in this case, unless all columns have the same number of rows, they will no longer be aligned.

- \texttt{between} Numeric vector giving the amount of space (character widths) surrounding each column (split equally on both sides).
- \texttt{title} String or expression giving a title for the key.
rep Logical flag, defaults to TRUE. By default, it is assumed that all columns
in the key (except the "text"s) will have the same number of rows, and
all components are replicated to be as long as the longest. This can be
suppressed by specifying rep=FALSE, in which case the length of each
column will be determined by components of that column alone.

cex.title Zoom factor for the title.
lines.title The amount of vertical space to be occupied by the title in
lines (in multiples of itself). Defaults to 2.
padding.text The amount of space (padding) to be used above and below
each row containing text, in multiples of the default, which is currently
0.2 * "lines". This padding is in addition to the normal height of
any row that contains text, which is the minimum amount necessary to
contain all the text entries.

background Background color for the legend. Defaults to the global back-
ground color.
alpha.background An alpha transparency value between 0 and 1 for the
background.
border Either a color for the border, or a logical flag. In the latter case, the
border color is black if border is TRUE, and no border is drawn if it is
FALSE (the default).
transparent=FALSE Logical flag, whether legend should have a transpar-
ent background.
just A character or numeric vector of length one or two giving horizontal
and vertical justification for the placement of the legend. See grid.layout
for more precise details.
columns The number of column-blocks (drawn side by side) the legend is
to be divided into.
between.columns Space between column blocks, in addition to between.
divide Number of point symbols to divide each line when type is "b" or
"o" in lines.

legend: The legend argument can be useful if one wants to place more than one
key. It also allows the use of arbitrary "grob"s (grid objects) as legends.
If used, legend must be a list, with an arbitrary number of components.
Each component must be named one of "left", "right", "top", "bottom", or "inside". The name "inside" can be repeated, but not the others. This
name will be used to determine the location for that component, and is sim-
lar to the space component of key. If key (or colorkey for levelplot
and wireframe) is specified, their space component must not conflict with
the name of any component of legend.
Each component of legend must have a component called fun. This can be
a "grob", or a function (or the name of a function) that produces a "grob"
when called. If this function expects any arguments, they must be sup-
plied as a list in another component called args. For components named
"inside", there can be additional components called x, y and corner,
which work in the same way as for key.

page: A function of one argument (page number) to be called after drawing
each page. The function must be 'grid-compliant', and is called with the
whole display area as the default viewport.

xlab.top, ylab.right: Labels for the x-axis on top, and y-axis on the right. Similar to xlab and ylab, but less commonly used.

main: Typically a character string or expression describing the main title to be placed on top of each page. Defaults to NULL.

main (as well as xlab, ylab and sub) is usually a character string or an expression that gets used as the label, but can also be a list that controls further details. Expressions are treated as specification of LaTeX-like markup as described in plotmath. The label can be a vector, in which case the components will be spaced out horizontally (or vertically for ylab). This feature can be used to provide column or row labels rather than a single axis label. When main (etc.) is a list, the actual label should be specified as the label component (which may be unnamed if it is the first component). The label can be missing, in which case the default will be used (xlab and ylab usually have defaults, but main and sub do not). Further named arguments are passed on to textGrob; this can include arguments controlling positioning like just and rot as well as graphical parameters such as col and font (see gpar for a full list).

main, sub, xlab, ylab, xlab.top, and ylab.right can also be arbitrary "grob"s (grid graphical objects).

sub: Character string or expression (or a list or "grob") for a subtitle to be placed at the bottom of each page. See entry for main for finer control options.

par.strip.text: A list of parameters to control the appearance of strip text. Notable components are col, cex, font, and lines. The first three control graphical parameters while the last is a means of altering the height of the strips. This can be useful, for example, if the strip labels (derived from factor levels, say) are double height (i.e., contains "\n"-s) or if the default height seems too small or too large.

Additionally, the lineheight component can control the space between multiple lines. The labels can be abbreviated when shown by specifying abbreviate = TRUE, in which case the components minlength and dot (passed along to the abbreviate function) can be specified to control the details of how this is done.

layout: In general, a conditioning plot in Lattice consists of several panels arranged in a rectangular array, possibly spanning multiple pages. layout determines this arrangement.

layout is a numeric vector of length 2 or 3 giving the number of columns, rows, and pages (optional) in a multipanel display. By default, the number of columns is the number of levels of the first conditioning variable and the number of rows is the number of levels of the second conditioning variable. If there is only one conditioning variable, the default layout vector is c(0, n), where n is the number of levels of the given vector. Any time the first value in the layout vector is 0, the second value is used as the desired number of panels per page and the actual layout is computed from this, taking into account the aspect ratio of the panels and the device dimensions (via par("din")). If NA is specified for the number of rows or columns (but not both), that dimension will be filled out according to the number of
panels.
The number of pages is by default set to as many as is required to plot all the panels, and so rarely needs to be specified. However, in certain situations the default calculation may be incorrect, and in that case the number of pages needs to be specified explicitly.

skip: A logical vector (default FALSE), replicated to be as long as the number of panels (spanning all pages). For elements that are TRUE, the corresponding panel position is skipped; i.e., nothing is plotted in that position. The panel that was supposed to be drawn there is now drawn in the next available panel position, and the positions of all the subsequent panels are bumped up accordingly. This may be useful for arranging plots in an informative manner.

strip.left: strip.left can be used to draw strips on the left of each panel, which can be useful for wide short panels, as in time-series (or similar) plots. See the entry for strip for detailed usage.

xlab.default, ylab.default: Fallback default for xlab and ylab when they are not specified. If NULL, the defaults are parsed from the Trellis formula. This is rarely useful for the end-user, but can be helpful when developing new Lattice functions.

xscale.components, yscale.components: Functions that determine axis annotation for the x and y axes respectively. See documentation for xscale.components.default, the default values of these arguments, to learn more.

axis: Function responsible for drawing axis annotation. See documentation for axis.default, the default value of this argument, to learn more.

perm.cond: An integer vector, a permutation of 1:n, where n is the number of conditioning variables. By default, the order in which panels are drawn depends on the order of the conditioning variables specified in the formula. perm.cond can modify this order. If the trellis display is thought of as an n-dimensional array, then during printing, its dimensions are permuted using perm.cond as the perm argument does in aperm.

index.cond: Whereas perm.cond permutes the dimensions of the multidimensional array of panels, index.cond can be used to subset (or reorder) margins of that array. index.cond can be a list or a function, with behavior in each case described below.

The panel display order within each conditioning variable depends on the order of their levels. index.cond can be used to choose a ‘subset’ (in the R sense) of these levels, which is then used as the display order for that variable. If index.cond is a list, it has to be as long as the number of conditioning variables, and the i-th component has to be a valid indexing vector for levels(g_i), where g_i is the i-th conditioning variable in the plot (note that these levels may not contain all levels of the original variable, depending on the effects of the subset and drop.unused.levels arguments). In particular, this indexing may repeat levels, or drop some altogether. The result of this indexing determines the order of panels within that conditioning variable. To keep the order of a particular variable unchanged, the corresponding component must be set to TRUE.

Note that the components of index.cond are interpreted in the order of the conditioning variables in the original call, and is not affected by perm.cond.
Another possibility is to specify index.cond as a function. In this case, this function is called once for each panel, potentially with all arguments that are passed to the panel function for that panel. (More specifically, if this function has a ... argument, then all panel arguments are passed, otherwise, only named arguments that match are passed.) If there is only one conditioning variable, the levels of that variable are then sorted so that these values are in ascending order. For multiple conditioning variables, the order for each variable is determined by first taking the average over all other conditioning variables.

Although they can be supplied in high-level function calls directly, it is more typical to use perm.cond and index.cond to update an existing "trellis" object, thus allowing it to be displayed in a different arrangement without re-calculating the data subsets that go into each panel. In the update.trellis method, both can be set to NULL, which reverts these back to their defaults.

par.settings: A list that could be supplied to trellis.par.set. When the resulting object is plotted, these options are applied temporarily for the duration of the plotting, after which the settings revert back to what they were before. This enables the user to attach some display settings to the trellis object itself rather than change the settings globally. See also the lattice.options argument described above for a similar treatment of non-graphical options.

plot.args: A list containing possible arguments to plot.trellis, which will be used by the plot or print methods when drawing the object, unless overridden explicitly. This enables the user to attach such arguments to the trellis object itself. Partial matching is not performed.

Details

The high-level functions documented here, as well as other high-level Lattice functions, are generic, with the formula method usually doing the most substantial work. The structure of the plot that is produced is mostly controlled by the formula (implicitly in the case of the non-formula methods). For each unique combination of the levels of the conditioning variables g1, g2, ..., a separate "packet" is produced, consisting of the points (x,y) for the subset of the data defined by that combination. The display can be thought of as a three-dimensional array of panels, consisting of one two-dimensional matrix per page. The dimensions of this array are determined by the layout argument. If there are no conditioning variables, the plot produced consists of a single packet. Each packet usually corresponds to one panel, but this is not strictly necessary (see the entry for index.cond above).

The coordinate system used by lattice by default is like a graph, with the origin at the bottom left, with axes increasing to the right and top. In particular, panels are by default drawn starting from the bottom left corner, going right and then up, unless as.table = TRUE, in which case panels are drawn from the top left corner, going right and then down. It is possible to set a global preference for the table-like arrangement by changing the default to as.table=TRUE; this can be done by setting lattice.options(default.args = list(as.table = TRUE)). Default values can be set in this manner for the following arguments: as.table, aspect, between, page, main, sub, par.strip.text, layout, skip and strip. Note that these global defaults are sometimes overridden by individual functions.

The order of the panels depends on the order in which the conditioning variables are specified, with
g1 varying fastest, followed by g2, and so on. Within a conditioning variable, the order depends on the order of the levels (which for factors is usually in alphabetical order). Both of these orders can be modified using the index.cond and perm.cond arguments, possibly using the update (and other related) method(s).

Value

The high-level functions documented here, as well as other high-level Lattice functions, return an object of class "trellis". The update method can be used to subsequently update components of the object, and the print method (usually called by default) will plot it on an appropriate plotting device.

Note

Most of the arguments documented here are also applicable for the other high-level functions in the lattice package. These are not described in any detail elsewhere unless relevant, and this should be considered the canonical documentation for such arguments.

Any arguments passed to these functions and not recognized by them will be passed to the panel function. Most predefined panel functions have arguments that customize its output. These arguments are described only in the help pages for these panel functions, but can usually be supplied as arguments to the high-level plot.

# Not run:
bwplot(decrease ~ treatment, OrchardSprays, groups = rowpos,  
  panel = "panel.superpose",  
  panel.groups = "panel.linejoin",
```

## user defined panel functions

```r
states <- data.frame(state.x77,  
  state.name = dimnames(state.x77)[[1]],  
  state.region = state.region)
xyplot(Murder ~ Population | state.region, data = states,  
  snames = states$state.name,  
  panel = function(x, y, subscripts, snames) {  
    panel.text(x = x, y = y, labels = snames[subscripts], cex = 1,  
               fontfamily = "HersheySans")
  }  
)
```
Description

This function handles time series plotting, including cut-and-stack plots. Examples are given of superposing, juxtaposing and styling different time series.

Usage

```r
## S3 method for class 'ts'
xyplot(x, data = NULL,
   screens = if (superpose) 1 else colnames(x),
   ..., 
   superpose = FALSE,
   cut = FALSE,
   type = "l",
   col = NULL,
   lty = NULL,
   lwd = NULL,
   pch = NULL,
   cex = NULL,
   fill = NULL,
   auto.key = superpose,
   panel = if (superpose) "panel.superpose"
   else "panel.superpose.plain",
   par.settings = list(),
   layout = NULL, as.table = TRUE,
   xlab = "Time", ylab = NULL,
   default.scales = list(y = list(relation =
     if (missing(cut)) "free" else "same")))
```

Arguments

- `x`: an object of class `ts`, which may be multi-variate, i.e. have a matrix structure with multiple columns.
- `data`: not used, and must be left as `NULL`.
- `...`: additional arguments passed to `xyplot`, which may pass them on to `panel.xyplot`.
screens  factor (or coerced to factor) whose levels specify which panel each series is to be plotted in. screens = c(1, 2, 1) would plot series 1, 2 and 3 in panels 1, 2 and 1. May also be a named list, see Details below.

superpose  overlays all series in one panel (via screens = 1) and uses grouped style settings (from trellis.par.get("superpose.line"), etc). Note that this is just a convenience argument: its only action is to change the default values of other arguments.

cut  defines a cut-and-stack plot. cut can be a list of arguments to the function equal.count, i.e. number (number of intervals to divide into) and overlap (the fraction of overlap between cuts, default 0.5). If cut is numeric this is passed as the number argument.

cut = TRUE tries to choose an appropriate number of cuts (up to a maximum of 6), using banking, and assuming a square plot region. This should have the effect of minimising wasted space when aspect = "xy".

type, col, lty, lwd, pch, cex, fill  graphical arguments, which are processed and eventually passed to panel.xyplot. These arguments can also be vectors or (named) lists, see Details for more information.

auto.key  a logical, or a list describing how to draw a key. See the auto.key entry in xyplot. The default here is to draw lines, not points, and any specified style arguments should show up automatically.

panel  the panel function. It is recommended to leave this alone, but one can pass a panel.groups argument which is handled by panel.superpose for each series.

par.settings  style settings beyond the standard col, lty, lwd, etc; see trellis.par.set and simpleTheme.

layout  numeric vector of length 2 specifying number of columns and rows in the plot. The default is to fill columns with up to 6 rows.

as.table  to draw panels from top to bottom. The order is determined by the order of columns in x.

xlab, ylab  X axis and Y axis labels; see xyplot. Note in particular that ylab may be a character vector, in which case the labels are spaced out equally, to correspond to the panels; but NOTE in this case the vector should be reversed OR the argument as.table set to FALSE.

default.scales  scales specification. The default is set to have "free" Y axis scales unless cut is given. Note, users should pass the scales argument rather than default.scales.

Details

The handling of several graphical parameters is more flexible for multivariate series. These parameters can be vectors of the same length as the number of series plotted or are recycled if shorter. They can also be (partially) named list, e.g., list(A = c(1,2), c(3,4)) in which c(3, 4) is the default value and c(1, 2) the value only for series A. The screens argument can be specified in a similar way.

Some examples are given below.
Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

Author(s)

Gabor Grothendieck, Achim Zeileis, Deepayan Sarkar and Felix Andrews <felix@nfrac.org>. The first two authors developed `xyplot.ts` in their `zoo` package, including the screens approach. The third author developed a different `xyplot.ts` for cut-and-stack plots in the `latticeExtra` package. The final author fused these together.

Examples

```r
xyplot(ts(c(1:10,10:1)))
### Figure 14.1 from Sarkar (2008)
xyplot(sunspot.year, aspect = "xy", strip = FALSE, strip.left = TRUE,
cut = list(number = 4, overlap = 0.05))
### A multivariate example; first juxtaposed, then superposed
xyplot(EuStockMarkets, scales = list(y = "same"))
xyplot(EuStockMarkets, superpose = TRUE, aspect = "xy", lwd = 2,
type = c("l","g"), ylim = c(0, max(EuStockMarkets)))
### Examples using screens (these two are identical)
xyplot(EuStockMarkets, screens = c(rep("Continental", 3), "UK"))
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"))
### Automatic group styles
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"), superpose = TRUE)
### Specifying styles for series by name
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"), col = list(DAX = "red", FTSE = "blue", "black"), auto.key = TRUE)
```

```
### Example with simpler data, few data points

```r
set.seed(1)
z <- ts(cbind(a = 1:5, b = 11:15, c = 21:25) + rnorm(5))
xyplot(z, screens = 1)
xyplot(z, screens = list(a = "primary (a)", "other (b & c)"),
type = list(a = c("p", "h"), b = c("p", "s"), "o"),
pch = list(a = 2, c = 3), auto.key = list(type = "o"))
```

---

**B_02_barchart.table**  
*Table methods for barchart and dotplot*

**Description**

Contingency tables are often displayed using bar charts and dot plots. These methods operate directly on tables, bypassing the need to convert them to data frames for use with the formula interface. Matrices and arrays are also supported, by coercing them to tables.

**Usage**

```r
## S3 method for class 'table'
barchart(x, data, groups = TRUE,
       origin = 0, stack = TRUE, ..., horizontal = TRUE)

## S3 method for class 'array'
barchart(x, data, ...)

## S3 method for class 'matrix'
barchart(x, data, ...)

## S3 method for class 'table'
dotplot(x, data, groups = TRUE, ..., horizontal = TRUE)

## S3 method for class 'array'
dotplot(x, data, ...)

## S3 method for class 'matrix'
dotplot(x, data, ...)
```

**Arguments**

- **x** A table, array or matrix object.
- **data** Should not be specified. If specified, will be ignored with a warning.
- **groups** A logical flag, indicating whether to use the last dimension as a grouping variable in the display.
origin, stack
Arguments to panel.barchart. The defaults for the table method are different.

horizontal
Logical flag, indicating whether the plot should be horizontal (with the categorical variable on the y-axis) or vertical.

...
Other arguments, passed to the underlying formula method.

Details
The first dimension is used as the variable on the categorical axis. The last dimension is optionally used as a grouping variable (to produce stacked barcharts by default). All other dimensions are used as conditioning variables. The order of these variables cannot be altered (except by permuting the original argument beforehand using t or aperm). For more flexibility, use the formula method after converting the table to a data frame using the relevant as.data.frame method.

Value
An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

## S3 method for class 'numeric'
densityplot(x, data = NULL, xlab, ...)

do.breaks(endpoints, nint)

**Arguments**

x

The object on which method dispatch is carried out.

For the formula method, x can be a formula of the form \(~ x | g1 * g2 * \ldots\)
indicating that histograms or kernel density estimates of the x variable should
be produced conditioned on the levels of the (optional) variables g1, g2, \ldots. x
should be numeric (or possibly a factor in the case of histogram), and each of
g1, g2, \ldots should be either factors or shingles.

As a special case, the right hand side of the formula can contain more than one
term separated by ‘+’ signs (e.g., \(~ x1 + x2 \mid g1 * g2\)). What happens in this
case is described in the documentation for \texttt{xyplot}. Note that in either form, all
the terms in the formula must have the same length after evaluation.

For the numeric and factor methods, x is the variable whose histogram or
Kernel density estimate is drawn. Conditioning is not allowed in these cases.

data

For the formula method, an optional data source (usually a data frame) in which
variables are to be evaluated (see \texttt{xyplot} for details). data should not be speci-
fied for the other methods, and is ignored with a warning if it is.

type

A character string indicating the type of histogram that is to be drawn. "percent"
and "count" give relative frequency and frequency histograms respectively, and
can be misleading when breakpoints are not equally spaced. "density" pro-
duces a density histogram.

type defaults to "density" when the breakpoints are unequally spaced, and
when breaks is \texttt{NULL} or a function, and to "percent" otherwise.

nint

An integer specifying the number of histogram bins, applicable only when breaks
is unspecified or \texttt{NULL} in the call. Ignored when the variable being plotted is a
factor.

endpoints

A numeric vector of length 2 indicating the range of x-values that is to be cov-
ered by the histogram. This applies only when breaks is unspecified and the
variable being plotted is not a factor. In \texttt{do.breaks}, this specifies the interval
that is to be divided up.

breaks

Usually a numeric vector of length (number of bins + 1) defining the breakpoints
of the bins. Note that when breakpoints are not equally spaced, the only value
of type that makes sense is density.

When breaks is unspecified, the value of \texttt{latticegetOption("histogram.breaks")}
is first checked. If this value is \texttt{NULL}, then the default is to use

\[
\text{breaks} = \text{seq_len}(1 + \text{nlevels(x)}) - 0.5
\]

when x is a factor, and

\[
\text{breaks} = \text{do.breaks(endpoints, nint)}
\]
otherwise. Breakpoints calculated in such a manner are used in all panels. If
the retrieved value is not NULL, or if breaks is explicitly specified, it affects
the display in each panel independently. Valid values are those accepted as the
breaks argument in hist. In particular, this allows specification of breaks
as an integer giving the number of bins (similar to nint), as a character string
denoting a method, or as a function.

When specified explicitly, a special value of breaks is NULL, in which case the
number of bins is determined by nint and then breakpoints are chosen according
to the value of equal.widths.

equal.widths A logical flag, relevant only when breaks=NULL. If TRUE, equally spaced bins
will be selected, otherwise, approximately equal area bins will be selected (typi-
ically producing unequally spaced breakpoints).

n Integer, giving the number of points at which the kernel density is to be eval-
uated. Passed on as an argument to density.

panel A function, called once for each panel, that uses the packet (subset of panel vari-
ables) corresponding to the panel to create a display. The default panel func-
tions panel.histogram and panel.densityplot are documented separately,
and have arguments that can be used to customize its output in various ways.
Such arguments can usually be directly supplied to the high-level function.

allow.multiple, outer
See xyplot.

auto.key See xyplot.

aspect See xyplot.

prepanel See xyplot.

scales See xyplot.

strip See xyplot.

groups See xyplot. Note that the default panel function for histogram does not support
grouped displays, whereas the one for densityplot does.

xlab, ylab See xyplot.

xlim, ylim See xyplot.

drop.unused.levels See xyplot.

lattice.options See xyplot.

default.scales See xyplot.

subscripts See xyplot.

subset See xyplot.

default.prepanel Fallback prepanel function. See xyplot.

weights numeric vector of weights for the density calculations, evaluated in the non-
standard manner used for groups and terms in the formula, if any. If this is
specified, it is subsetted using subscripts inside the panel function to match it
to the corresponding x values.
At the time of writing, weights do not work in conjunction with an extended formula specification (this is not too hard to fix, so just bug the maintainer if you need this feature).

**bw, adjust, width**
Arguments controlling bandwidth. Passed on as arguments to `density`.

**kernel, window**
The choice of kernel. Passed on as arguments to `density`.

**give.Rkern**
Logical flag, passed on as argument to `density`. This argument is made available only for ease of implementation, and will produce an error if TRUE.

**from, to, cut**
Controls range over which density is evaluated. Passed on as arguments to `density`.

**na.rm**
Logical flag specifying whether NA values should be ignored. Passed on as argument to `density`, but unlike in `density`, the default is TRUE.

... Further arguments. See corresponding entry in `xyplot` for non-trivial details.

**Details**
`histogram` draws Conditional Histograms, and `densityplot` draws Conditional Kernel Density Plots. The default panel function uses the `density` function to compute the density estimate, and all arguments accepted by `density` can be specified in the call to `densityplot` to control the output. See documentation of `density` for details.

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

`do.breaks` is an utility function that calculates breakpoints given an interval and the number of pieces to break it into.

**Value**
An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**Note**
The form of the arguments accepted by the default panel function `panel.histogram` is different from that in S-PLUS. Whereas S-PLUS calculates the heights inside `histogram` and passes only the breakpoints and the heights to the panel function, `lattice` simply passes along the original variable `x` along with the breakpoints. This approach is more flexible; see the example below with an estimated density superimposed over the histogram.

Examples

```r
require(stats)
histogram( ~ height | voice.part, data = singer, nint = 17,
    endpoints = c(59.5, 76.5), layout = c(2,4), aspect = 1,
    xlab = "Height (inches)")

histogram(~ height | voice.part, data = singer,
    xlab = "Height (inches)", type = "density",
    panel = function(x, ...) {
        panel.histogram(x, ...)
        panel.mathdensity(dmath = dnorm, col = "black",
                        args = list(mean=mean(x),sd=sd(x))
    }
}
densityplot(~ height | voice.part, data = singer, layout = c(2,4),
    xlab = "Height (inches)", bw = 5)
```

Description

Draw quantile-quantile plots of a sample against a theoretical distribution, possibly conditioned on other variables.

Usage

```r
qqmath(x, data, ...)
```

## S3 method for class 'formula'
```r
qqmath(x,
data,
allow.multiple = is.null(groups) || outer,
outer = !is.null(groups),
distribution = qnorm,
f.value = NULL,
auto.key = lattice.getOption("default.args")$auto.key,
aspect = "fill",
panel = lattice.getOption("panel.qqmath"),
prepanel = NULL,
scales, strip, groups,
xlab, xlim, ylab, ylim,
don.drop.unused.levels = lattice.getOption("drop.unused.levels"),
...,
```
lattice.options = NULL,
default.scales = list(),
default.prepanel = lattice.getOption("prepanel.default.qqmath"),
subscripts,
subset)
## S3 method for class 'numeric'
qqmath(x, data = NULL, ylab, ...)

Arguments

x The object on which method dispatch is carried out. For the "formula" method, x should be a formula of the form ~ x | g1 * g2 * ..., where x should be a numeric variable. For the "numeric" method, x should be a numeric vector.
data For the formula method, an optional data source (usually a data frame) in which variables are to be evaluated (see xyplot for details). data should not be specified for the other methods, and is ignored with a warning if it is.
distribution A quantile function that takes a vector of probabilities as argument and produces the corresponding quantiles from a theoretical distribution. Possible values are qnorm, qunif, etc. Distributions with other required arguments need to be provided as user-defined functions (see example with qt).
f.value An optional numeric vector of probabilities, quantiles corresponding to which should be plotted. This can also be a function of a single integer (representing sample size) that returns such a numeric vector. A typical value for this argument is the function ppoints, which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, through the quantile function for the sample, and the function specified as the distribution argument for the theoretical distribution. f.value defaults to NULL, which has the effect of using ppoints for the quantiles of the theoretical distribution, but the exact data values for the sample. This is similar to what happens for qqnorm, but different from the S-PLUS default of f.value=ppoints. For large x, this argument can be used to restrict the number of points plotted. See also the tails.n argument in panel.qqmath.
panel A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel function panel.qqmath is documented separately, and has arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.
allow.multiple, outer
See xyplot.
auto.key See xyplot.
aspect See xyplot.
prepanel See xyplot.
scales See xyplot.
strip See \texttt{xyplot}.
groups See \texttt{xyplot}.
xlab, ylab See \texttt{xyplot}.
xlim, ylim See \texttt{xyplot}.
drop.unused.levels See \texttt{xyplot}.
lattice.options See \texttt{xyplot}.
default.scales See \texttt{xyplot}.
subscripts See \texttt{xyplot}.
subset See \texttt{xyplot}.
default.prepanel Fallback prepanel function. See \texttt{xyplot}.
... Further arguments. See corresponding entry in \texttt{xyplot} for non-trivial details.

\section*{Details}

\texttt{qqmath} produces Q-Q plots of the given sample against a theoretical distribution. The default behaviour of \texttt{qqmath} is different from the corresponding S-PLUS function, but is similar to \texttt{qnorm}. See the entry for \texttt{f.value} for specifics.

The implementation details are also different from S-PLUS. In particular, all the important calculations are done by the panel (and prepanel function) and not \texttt{qqmath} itself. In fact, both the arguments \texttt{distribution} and \texttt{f.value} are passed unchanged to the panel and prepanel function. This allows, among other things, display of grouped Q-Q plots, which are often useful. See the help page for \texttt{panel.qqmath} for further details.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for \texttt{xyplot}, which should be consulted to learn more detailed usage.

\section*{Value}

An object of class "trellis". The \texttt{update} method can be used to update components of the object and the \texttt{print} method (usually called by default) will plot it on an appropriate plotting device.

       aspect = "xy",
       prepanel = prepanel.qqmathline,
       panel = function(x, ...) {
         panel.qqmathline(x, ...)
         panel.qqmath(x, ...)
       })
```

Description

Quantile-Quantile plots for comparing two Distributions

Usage

```r
qq(x, data, ...)  
## S3 method for class 'formula'
qq(x, data, aspect = "fill",  
    panel = lattice.getOption("panel.qq"),
    prepanel, scales, strip,  
    groups, xlab, xlim, ylab, ylim, f.value = NULL,  
    drop.unused.levels = lattice.getOption("drop.unused.levels"),  
    ...,  
    lattice.options = NULL,
    qtype = 7,  
    default.scales = list(),
    default.prepanel = lattice.getOption("prepanel.default.qq"),
    subscripts,  
    subset)
```
Arguments

x  The object on which method dispatch is carried out.
For the "formula" method, x should be a formula of the form \( y \sim x | g1 * g2 * \ldots \), where x should be a numeric variable, and y a factor, shingle, character, or numeric variable, with the restriction that there must be exactly two levels of y, which divide the values of x into two groups. Quantiles for these groups will be plotted against each other along the two axes.

data  For the formula method, an optional data source (usually a data frame) in which variables are to be evaluated (see xyplot for details).

f.value  An optional numeric vector of probabilities, quantiles corresponding to which should be plotted. This can also be a function of a single integer (representing sample size) that returns such a numeric vector. A typical value for this argument is the function ppoints, which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, through the quantile function.

f.value defaults to NULL, which is equivalent to

\[
\text{f.value} = \text{function}(n) \text{ppoints}(n, a = 1)
\]

This has the effect of including the minimum and maximum data values in the computed quantiles. This is similar to what happens for qqplot but different from the default behaviour of qq in S-PLUS.

For large x, this argument can be used to restrict the number of quantiles plotted.

panel  A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel function panel.qq is documented separately, and has arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.

qtype  The type argument for quantile.

aspect  See xyplot.

prepanel  See xyplot.
scales  See xyplot.
strip  See xyplot.
groups  See xyplot.
xlab, ylab  See xyplot.
xlim, ylim  See xyplot.
drop.unused.levels  See xyplot.
lattice.options  See xyplot.
default.scales  See xyplot.
subscripts  See xyplot.
subset  See xyplot.
B_06_levelplot

default.prepanel

Fallback prepanel function. See xyplot.

... Further arguments. See corresponding entry in xyplot for non-trivial details.

Details

qq produces Q-Q plots of two samples. The default behaviour of qq is different from the corresponding S-PLUS function. See the entry for f.value for specifics.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for xyplot, which should be consulted to learn more detailed usage.

Value

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

contourplot(x, data = NULL, aspect = "iso", ..., xlim, ylim)

## S3 method for class 'matrix'
levelplot(x, data = NULL, aspect = "iso",...
Arguments

\texttt{x} \quad \text{for the formula method, a formula of the form \( z \sim x \times y \mid g_1 \times g_2 \times \ldots \), where \( z \) is a numeric response, and \( x, y \) are numeric values evaluated on a rectangular grid. \( g_1, g_2, \ldots \) are optional conditional variables, and must be either factors or shingles if present. Calculations are based on the assumption that all \( x \) and \( y \) values are evaluated on a grid (defined by their unique values). The function will not return an error if this is not true, but the display might not be meaningful. However, the \( x \) and \( y \) values need not be equally spaced.

Both \texttt{levelplot} and \texttt{wireframe} have methods for \texttt{matrix}, \texttt{array}, and \texttt{table} objects, in which case \texttt{x} provides the \( z \) vector described above, while its rows and columns are interpreted as the \( x \) and \( y \) vectors respectively. This is similar to the form used in \texttt{filled.contour} and \texttt{image}. For higher-dimensional arrays and tables, further dimensions are used as conditioning variables. Note that the dimnames may be duplicated; this is handled by calling \texttt{make.unique} to make the names unique (although the original labels are used for the \( x \)- and \( y \)-axes).

\texttt{data} \quad \text{For the formula methods, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated. Usually ignored with a warning in other cases.}

\texttt{row.values, column.values} \quad \text{Optional vectors of values that define the grid when \texttt{x} is a matrix. \texttt{row.values} and \texttt{column.values} must have the same lengths as \texttt{nrow(x)} and \texttt{ncol(x)} respectively. By default, row and column numbers.}

\texttt{panel} \quad \text{panel function used to create the display, as described in \texttt{xyplot}}

\texttt{aspect} \quad \text{For the matrix methods, the default aspect ratio is chosen to make each cell square. The usual default is \texttt{aspect="fill"}, as described in \texttt{xyplot}.}

\texttt{at} \quad \text{A numeric vector giving breakpoints along the range of \( z \). Contours (if any) will be drawn at these heights, and the regions in between would be colored using...}
col.regions. In the latter case, values outside the range of at will not be drawn at all. This serves as a way to limit the range of the data shown, similar to what a zlim argument might have been used for. However, this also means that when supplying at explicitly, one has to be careful to include values outside the range of z to ensure that all the data are shown.

at can have length one only if region=FALSE.

col.regions color vector to be used if regions is TRUE. The general idea is that this should be a color vector of moderately large length (longer than the number of regions. By default this is 100). It is expected that this vector would be gradually varying in color (so that nearby colors would be similar). When the colors are actually chosen, they are chosen to be equally spaced along this vector. When there are more regions than colors in col.regions, the colors are recycled. The actual color assignment is performed by level.colors, which is documented separately.

alpha.regions Numeric, specifying alpha transparency (works only on some devices)

colorkey A logical flag specifying whether a colorkey is to be drawn alongside the plot, or a list describing the colorkey. The list may contain the following components:

- space: location of the colorkey, can be one of "left", "right", "top" and "bottom". Defaults to "right".
- x, y: location, currently unused
- col: A color ramp specification, as in the col.regions argument in level.colors
- at: A numeric vector specifying where the colors change. must be of length 1 more than the col vector.
- tri.lower, tri.upper: Logical or numeric controlling whether the first and last intervals should be triangular instead of rectangular. With the default value (NA), this happens only if the corresponding extreme at values are -Inf or Inf respectively, and the triangles occupy 5% of the total length of the color key. If numeric and between 0 and 0.25, these give the corresponding fraction, which is again 5% when specified as TRUE.
- labels: A character vector for labelling the at values, or more commonly, a list describing characteristics of the labels. This list may include components labels, at, cex, col, rot, font, fontface and fontfamily.
- title: Usually a character vector or expression providing a title for the colorkey, or a list controlling the title in further detail, or an arbitrary "grob". For details of how the list form is interpreted, see the entry for main in xyplot; generally speaking, the actual label should be specified as the label component (which may be unnamed if it is the first component), and the remaining arguments are used as appropriate in a call to textGrob. Further control of the placement of the title is possible through the component title.control. In particular, if a rot component is not specified, its default depends on the value of title.control$side (0 for top or bottom, and 90 for left or right).
- title defaults to NULL, which means no title is drawn.

- title.control: A list providing control over the placement of a title, if specified. Currently two components are honoured: side can take values "top", "bottom", "left", and "right", and specifies the side of the colorkey on
which the title is to be placed. Defaults to the value of the "space" component. padding is a multiplier for the default amount of padding between the title and the colorkey.

tick.number: The approximate number of ticks desired.
tck: A (scalar) multiplier for tick lengths.
corner: Interacts with x, y; currently unimplemented
width: The width of the key
height: The length of key as a fraction of the appropriate side of plot.
raster: A logical flag indicating whether the colorkey should be rendered as a raster image using grid.raster. See also panel.levelplot.raster.
interpolate: Logical flag, passed to rasterGrob when raster=TRUE.
axis.line: A list giving graphical parameters for the color key boundary and tick marks. Defaults to trellis.par.get("axis.line").
axis.text: A list giving graphical parameters for the tick mark labels on the color key. Defaults to trellis.par.get("axis.text").

contour A logical flag, indicating whether to draw contour lines.
cuts The number of levels the range of z would be divided into.
labels Typically a logical indicating whether contour lines should be labelled, but other possibilities for more sophisticated control exists. Details are documented in the help page for panel.levelplot, to which this argument is passed on unchanged. That help page also documents the label.style argument, which affects how the labels are rendered.
pretty A logical flag, indicating whether to use pretty cut locations and labels.
region A logical flag, indicating whether regions between contour lines should be filled as in a level plot.
allow.multiple, outer, prepanel, scales, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels, lattice.options, default.scales, subset
These arguments are described in the help page for xyplot.
default.prepanel
Fallback prepanel function. See xyplot.

... Further arguments may be supplied. Some are processed by levelplot or contourplot, and those that are unrecognized are passed on to the panel function.

useRaster A logical flag indicating whether raster representations should be used, both for the false color image and the color key (if present). Effectively, setting this to TRUE changes the default panel function from panel.levelplot to panel.levelplot.raster, and sets the default value of colorkey$raster to TRUE.
Note that panel.levelplot.raster provides only a subset of the features of panel.levelplot, but setting useRaster=TRUE will not check whether any of the additional features have been requested.
Not all devices support raster images. For devices that appear to lack support, useRaster=TRUE will be ignored with a warning.
Details

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Other useful arguments are mentioned in the help page for the default panel function `panel.levelplot` (these are formally arguments to the panel function, but can be specified in the high level calls directly).

Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

Examples

```r
x <- seq(pi/4, 5 * pi, length.out = 100)
y <- seq(pi/4, 5 * pi, length.out = 100)
r <- as.vector(sqrt(outer(x^2, y^2, "+")))
grid <- expand.grid(x=x, y=y)
grid$z <- cos(r^2) * exp(-r/(pi^3))
levelplot(z ~ x * y, grid, cuts = 50, scales=list(log="e"), xlab="", ylab="", main="Weird Function", sub="with log scales", colorkey = FALSE, region = TRUE)
## triangular end-points in color key, with a title
levelplot(z ~ x * y, grid, col.regions = hcl.colors(10), 
at = c(-Inf, seq(-0.8, 0.8, by = 0.2), Inf))
```

## S-PLUS example

```r
require(stats)
attach(environmental)
ozo.m <- loess((ozone^((1/3))) ~ wind * temperature * radiation, 
parametric = c("radiation", "wind"), span = 1, degree = 2)
w.marginal <- seq(min(wind), max(wind), length.out = 50)
t.marginal <- seq(min(temperature), max(temperature), length.out = 50)
r.marginal <- seq(min(radiation), max(radiation), length.out = 4)
wtr.marginal <- list(wind = w.marginal, temperature = t.marginal, 
radiation = r.marginal)
grid <- expand.grid(wtr.marginal)
```
grid[, "fit"] <- c(predict(ozo.m, grid))
contourplot(fit ~ wind * temperature | radiation, data = grid,
cuts = 10, region = TRUE,
  xlab = "Wind Speed (mph)",
  ylab = "Temperature (F)",
  main = "Cube Root Ozone (cube root ppb)"
) detach()

### 3d Scatter Plot and Wireframe Surface Plot

**Description**

Generic functions to draw 3d scatter plots and surfaces. The "formula" methods do most of the actual work.

**Usage**

```r
cloud(x, data, ...)
wireframe(x, data, ...)
```

```r
## S3 method for class 'formula'
cloud(x,
data,
  allow.multiple = is.null(groups) || outer,
  outer = FALSE,
  auto.key = lattice.getOption("default.args")$auto.key,
  aspect = c(1,1),
  panel.aspect = 1,
  panel = lattice.getOption("panel.cloud"),
  prepanel = NULL,
  scales = list(),
  strip = TRUE,
  groups = NULL,
  xlab, ylab, zlab,
  xlim = if (is.factor(x)) levels(x) else range(x, finite = TRUE),
  ylim = if (is.factor(y)) levels(y) else range(y, finite = TRUE),
  zlim = if (is.factor(z)) levels(z) else range(z, finite = TRUE),
  at,
  drape = FALSE,
  pretty = FALSE,
  drop.unused.levels,
  ...,
  lattice.options = NULL,
  default.scales =
```

## S3 method for class 'table'
cloud(x, data = NULL, groups = FALSE,
    zlab = deparse(substitute(x)),
    type = "h", ...)  

## S3 method for class 'matrix'
wireframe(x, data = NULL,
    zlab = deparse(substitute(x)), aspect, ...,
    xlim, ylim, row.values, column.values)

Arguments

x

The object on which method dispatch is carried out.

For the "formula" methods, a formula of the form `z ~ x * y | g1 * g2 * ...`,
where `z` is a numeric response, and `x`, `y` are numeric values. `g1`, `g2`, ..., if
present, are conditioning variables used for conditioning, and must be either
factors or shingles. In the case of `wireframe`, calculations are based on the
assumption that the `x` and `y` values are evaluated on a rectangular grid defined
by their unique values. The grid points need not be equally spaced.

For `wireframe`, `x`, `y` and `z` may also be matrices (of the same dimension), in
which case they are taken to represent a 3-D surface parametrized on a 2-D grid
(e.g., a sphere). Conditioning is not possible with this feature. See details below.

Missing values are allowed, either as `NA` values in the `z` vector, or missing rows
in the data frame (note however that in that case the `X` and `Y` grids will be
determined only by the available values). For a grouped display (producing
multiple surfaces), missing rows are not allowed, but NA-s in z are.
Both wireframe and cloud have methods for matrix objects, in which case
x provides the z vector described above, while its rows and columns are inter-
preted as the x and y vectors respectively. This is similar to the form used in
persp.
data
for the "formula" methods, an optional data frame in which variables in the
formula (as well as groups and subset, if any) are to be evaluated. data should
not be specified except when using the "formula" method.
row.values, column.values
Optional vectors of values that define the grid when x is a matrix. row.values
and column.values must have the same lengths as nrow(x) and ncol(x) re-
spectively. By default, row and column numbers.
allow.multiple, outer, auto.key, prepanel, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels, lat
These arguments are documented in the help page for xyplot. For the cloud.table
method, groups must be a logical indicating whether the last dimension should
be used as a grouping variable as opposed to a conditioning variable. This is
only relevant if the table has more than 2 dimensions.
type
type of display in cloud (see panel.3dscatter for details). Defaults to "h" for
the matrix method.
aspect, panel.aspect
Unlike other high level functions, aspect is taken to be a numeric vector of
length 2, giving the relative aspects of the y-size/x-size and z-size/x-size of the
enclosing cube. The usual role of the aspect argument in determining the aspect
ratio of the panel (see xyplot for details) is played by panel.aspect, except
that it can only be a numeric value.
For the matrix methods, the default y/x aspect is ncol(x) / nrow(x) and the
z/x aspect is the smaller of the y/x aspect and 1.
panel
panel function used to create the display. See panel.cloud for (non-trivial)
details.
default.prepanel
Fallback prepanel function. See xyplot.
scales
a list describing the scales. As with other high level functions (see xyplot for
details), this list can contain parameters in name=value form. It can also contain
components with the special names x, y and z, which can be similar lists with
axis-specific values overriding the ones specified in scales.
The most common use for this argument is to set arrows=FALSE, which causes
tick marks and labels to be used instead of arrows being drawn (the default).
Both can be suppressed by draw=FALSE. Another special component is distance,
which specifies the relative distance of the axis label from the bounding box. If
specified as a component of scales (as opposed to one of scales$z etc), this
can be (and is recycled if not) a vector of length 3, specifying distances for the
x, y and z labels respectively.
Other components that work in the scales argument of xyplot etc. should also
work here (as long as they make sense), including explicit specification of tick
mark locations and labels. (Not everything is implemented yet, but if you find
something that should work but does not, feel free to bug the maintainer.)
Note, however, that for these functions scales cannot contain information that
is specific to particular panels. If you really need that, consider using the scales.3d
argument of panel.cloud.

### axs.default

Unlike 2-D display functions, cloud does not expand the bounding box to slightly
beyond the range of the data, even though it should. This is primarily be-
cause this is the natural behaviour in wireframe, which uses the same code.
axs.default is intended to provide a different default for cloud. However, this
feature has not yet been implemented.

### zlab

Specifies a label describing the z variable in ways similar to xlab and ylab
(i.e. “grob”, character string, expression or list) in other high level functions.
Additionally, if zlab (and xlab and ylab) is a list, it can contain a component
called rot, controlling the rotation for the label.

### zlim

limits for the z-axis. Similar to xlim and ylim in other high level functions.

### drape

logical, whether the wireframe is to be draped in color. If TRUE, the height of a
facet is used to determine its color in a manner similar to the coloring scheme
used in levelplot. Otherwise, the background color is used to color the facets.
This argument is ignored if shade = TRUE (see panel.3dwire).

### at, col.regions, alpha.regions

these arguments are analogous to those in levelplot. If drape=TRUE, at gives
the vector of cutpoints where the colors change, and col.regions the vec-
tor of colors to be used in that case. alpha.regions determines the alpha-
transparency on supporting devices. These are passed down to the panel func-
tion, and also used in the colorkey if appropriate. The default for col.regions
and alpha.regions is derived from the Trellis setting "regions"

### cuts

if at is unspecified, the approximate number of cutpoints if drape=TRUE

### pretty

whether automatic choice of cutpoints should be prettified

### colorkey

logical indicating whether a color key should be drawn alongside, or a list de-
scribing such a key. See levelplot for details.

... Any number of other arguments can be specified, and are passed to the panel
function. In particular, the arguments distance, perspective, screen and R.mat are very important in determining the 3-D display. The argument shade
can be useful for wireframe calls, and controls shading of the rendered surface.
These arguments are described in detail in the help page for panel.cloud.

Additionally, an argument called zoom may be specified, which should be a nu-
meric scalar to be interpreted as a scale factor by which the projection is magni-
ified. This can be useful to get the variable names into the plot. This argument is
actually only used by the default prepanel function.

### Details

These functions produce three dimensional plots in each panel (as long as the default panel functions
are used). The orientation is obtained as follows: the data are scaled to fall within a bounding box
that is contained in the [-0.5, 0.5] cube (even smaller for non-default values of aspect). The viewing
direction is given by a sequence of rotations specified by the screen argument, starting from the
positive Z-axis. The viewing point (camera) is located at a distance of 1/distance from the origin.
If perspective=FALSE, distance is set to 0 (i.e., the viewing point is at an infinite distance).
cloud draws a 3-D Scatter Plot, while wireframe draws a 3-D surface (usually evaluated on a grid). Multiple surfaces can be drawn by wireframe using the groups argument (although this is of limited use because the display is incorrect when the surfaces intersect). Specifying groups with cloud results in a panel.superpose-like effect (via panel.3dscatter).

wireframe can optionally render the surface as being illuminated by a light source (no shadows though). Details can be found in the help page for panel.3dwire. Note that although arguments controlling these are actually arguments for the panel function, they can be supplied to cloud and wireframe directly.

For single panel plots, wireframe can also plot parametrized 3-D surfaces (i.e., functions of the form \( f(u,v) = (x(u,v), y(u,v), z(u,v)) \), where values of \((u,v)\) lie on a rectangle. The simplest example of this sort of surface is a sphere parametrized by latitude and longitude. This can be achieved by calling wireframe with a formula \( x \) of the form \( z \sim x*y \), where \( x \), \( y \) and \( z \) are all matrices of the same dimension, representing the values of \( x(u,v), y(u,v) \) and \( z(u,v) \) evaluated on a discrete rectangular grid (the actual values of \((u,v)\) are irrelevant).

When this feature is used, the heights used to calculate drape colors or shading colors are no longer the \( z \) values, but the distances of \((x,y,z)\) from the origin.

Note that this feature does not work with groups, subscripts, subset, etc. Conditioning variables are also not supported in this case.

The algorithm for identifying which edges of the bounding box are ‘behind’ the points doesn’t work in some extreme situations. Also, panel.cloud tries to figure out the optimal location of the arrows and axis labels automatically, but can fail on occasion (especially when the view is from ‘below’ the data). This can be manually controlled by the scpos argument in panel.cloud.

These and all other high level Trellis functions have several other arguments in common. These are extensively documented only in the help page for xyplot, which should be consulted to learn more detailed usage.

Value

An object of class “trellis”. The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

Note

There is a known problem with grouped wireframe displays when the \((x, y)\) coordinates represented in the data do not represent the full evaluation grid. The problem occurs whether the grouping is specified through the groups argument or through the formula interface, and currently causes memory access violations. Depending on the circumstances, this is manifested either as a meaningless plot or a crash. To work around the problem, it should be enough to have a row in the data frame for each grid point, with an NA response \((z)\) in rows that were previously missing.

## S3 method for class 'formula'

parallelplot(x,  
data,  
auto.key = lattice.getOption("default.args")$auto.key,  
aspect = "fill",  
between = list(x = 0.5, y = 0.5),  
panel = lattice.getOption("panel.parallel"),  
prepanel,  
scales,  
strip,  
groups,
Arguments

x The object on which method dispatch is carried out.
For the "formula" method, a formula describing the structure of the plot, which
should be of the form ~ x | g1 * g2 * ... , where x is a data frame or matrix.
Each of g1, g2, ... must be either factors or shingles. The conditioning vari-
ables g1, g2, ... may be omitted.
For the data.frame methods, a data frame.
data For the formula methods, an optional data frame in which variables in the for-
formula (as well as groups and subset, if any) are to be evaluated.
aspect aspect ratio of each panel (and subpanel), square by default for splom.
between to avoid confusion between panels and subpanels, the default is to show the
panels of a splom plot with space between them.
panel For parallelplot, this has the usual interpretation, i.e., a function that creates
the display within each panel.
For splom, the terminology is slightly complicated. The role played by the panel
function in most other high-level functions is played here by the superpanel
function, which is responsible for the display for each conditional data subset.
panel is simply an argument to the default superpanel function panel.pairs,
and is passed on to it unchanged. It is used there to create each pairwise display.
See panel.pairs for more useful options.
superpanel function that sets up the splom display, by default as a scatterplot matrix.
pscales a numeric value or a list, meant to be a less functional substitute for the scales
argument in xyplot etc. This argument is passed to the superpanel function,
and is handled by the default superpanel function `panel.pairs`. The help page for the latter documents this argument in more detail.

**varnames**

A character or expression vector or giving names to be used for the variables in `x`. By default, the column names of `x`.

**horizontal.axis**

Logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).

**auto.key, prepanel, scales, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels, lattice.options, default.scales, subset**

See `xyplot`

**default.prepanel**

Fallback prepanel function. See `xyplot`.

**...**

Further arguments. See corresponding entry in `xyplot` for non-trivial details.

**Details**

`splom` produces Scatter Plot Matrices. The role usually played by `panel` is taken over by `superpanel`, which takes a data frame subset and is responsible for plotting it. It is called with the coordinate system set up to have both x- and y-limits from 0.5 to `ncol(z) + 0.5`. The only built-in option currently available is `panel.pairs`, which calls a further panel function for each pair \((i, j)\) of variables in `z` inside a rectangle of unit width and height centered at \(c(i, j)\) (see `panel.pairs` for details).

Many of the finer customizations usually done via arguments to high level function like `xyplot` are instead done by `panel.pairs` for `splom`. These include control of axis limits, tick locations and prepanel calculations. If you are trying to fine-tune your `splom` plot, definitely look at the `panel.pairs` help page. The `scales` argument is usually not very useful in `splom`, and trying to change it may have undesired effects.

`parallelplot` draws Parallel Coordinate Plots. (Difficult to describe, see example.)

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

Examples

```r
super.sym <- trellis.par.get("superpose.symbol")
splom(~iris[1:4], groups = Species, data = iris,
    panel = panel.superpose,
    key = list(title = "Three Varieties of Iris",
               columns = 3,
               points = list(pch = super.sym$pch[1:3],
                              col = super.sym$col[1:3]),
               text = list(c("Setosa", "Versicolor", "Virginica"))))
splom(~iris[1:3]|Species, data = iris,
      layout=c(2,2), pscales = 0,
      varnames = c("Sepal\nLength", "Sepal\nWidth", "Petal\nLength"),
      page = function(...) {
        ltext(x = seq(.6, .8, length.out = 4),
              y = seq(.9, .6, length.out = 4),
              labels = c("Three", "Varieties", "of", "Iris"),
              cex = 2)
      })
parallelplot(~iris[1:4] | Species, iris)
parallelplot(~iris[1:4], iris, groups = Species,
            horizontal.axis = FALSE, scales = list(x = list(rot = 90)))
```

---

**B_09_tmd**

**Tukey Mean-Difference Plot**

**Description**

`tmd` creates Tukey Mean-Difference Plots from a trellis object returned by `xyplot`, `qq` or `qqmath`. The prepanel and panel functions are used as appropriate. The formula method for `tmd` is provided for convenience, and simply calls `tmd` on the object created by calling `xyplot` on that formula.

**Usage**

```r
tmd(object, ...)

## S3 method for class 'trellis'
tmd(object,
    xlab = "mean",
    ylab = "difference",
    panel,
    prepanel,
    ...)
```

```r
prepanel.tmd.qqmath(x,
    f.value = NULL,
    distribution = qnorm,
    qtype = 7,
    groups = NULL,
)```
subscripts, ...)

panel.tmd.qqmath(x,
    f.value = NULL,
    distribution = qnorm,
    qtype = 7,
    groups = NULL,
    subscripts, ...,
    identifier = "tmd")

panel.tmd.default(x, y, groups = NULL, ..., 
    identifier = "tmd")
prepanel.tmd.default(x, y, ...)

Arguments

object An object of class "trellis" returned by xyplot, qq or qqmath.
xlab x label
ylab y label
panel panel function to be used. See details below.
prepanel prepanel function. See details below.
f.value, distribution, qtype
    see panel.qqmath.
groups, subscripts
    see xyplot.
x, y data as passed to panel functions in original call.
... other arguments
identifier A character string that is prepended to the names of grobs that are created by
    this panel function.

Details

The Tukey Mean-difference plot is produced by modifying the (x,y) values of each panel as follows: the new coordinates are given by \(x = (x+y)/2\) and \(y = y-x\), which are then plotted. The default panel function(s) add a reference line at \(y=0\) as well.

tmd acts on the a "trellis" object, not on the actual plot this object would have produced. As such, it only uses the arguments supplied to the panel function in the original call, and completely ignores what the original panel function might have done with this data. tmd uses these panel arguments to set up its own scales (using its prepanel argument) and display (using panel). It is thus important to provide suitable prepanel and panel functions to tmd depending on the original call.

Such functions currently exist for xyplot, qq (the ones with default in their name) and qqmath, as listed in the usage section above. These assume the default displays for the corresponding high-level call. If unspecified, the prepanel and panel arguments default to suitable choices.

tmd uses the update method for "trellis" objects, which processes all extra arguments supplied to tmd.
Value

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

B_10_rfs

Residual and Fit Spread Plots

Description

Plots fitted values and residuals (via qqmath) on a common scale for any object that has methods for fitted values and residuals.

Usage

rfs(model, layout=c(2, 1), xlab="f-value", ylab=NULL,
   distribution = qunif,
   panel, prepanel, strip, ...)

Arguments

model    a fitted model object with methods fitted.values and residuals. Can be the value returned by oneway
layout    default layout is c(2,1)
xlab    defaults to "f.value"
distribution    the distribution function to be used for qqmath

ylab, panel, prepanel, strip
   See xyplot

...    other arguments, passed on to qqmath.

Value

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.
**Description**

Fits a One-way model to univariate data grouped by a factor, the result often being displayed using `rfs`

**Arguments**

- **formula**: formula of the form `y ~ x` where `y` is the numeric response and `x` is the grouping factor
- **data**: data frame in which the model is to be evaluated
- **location**: function or numeric giving the location statistic to be used for centering the observations, e.g. `median`, 0 (to avoid centering).
- **spread**: function or numeric giving the spread statistic to be used for scaling the observations, e.g. `sd`, 1 (to avoid scaling).

**Value**

A list with components

- `location`: vector of locations for each group.
- `spread`: vector of spreads for each group.
- `fitted.values`: vector of locations for each observation.
- `residuals`: residuals (`y - fitted.values`).
- `scaled.residuals`: residuals scaled by `spread` for their group

C_01_trellis.device  Initializing Trellis Displays

Description
   Initialization of a display device with appropriate graphical parameters.

Usage
   trellis.device(device = getOption("device"),
                   color = !(dev.name == "postscript"),
                   theme = lattice.getOption("default.theme"),
                   new = TRUE,
                   retain = FALSE,
                   ...)  

Arguments
   device  function (or the name of one as a character string) that starts a device. Admis-
            sible values depend on the platform and how R was compiled (see Devices),
            but usually "pdf", "postscript", "png", "jpeg" and at least one of "X11",
            "windows" and "quartz" will be available.
   color   logical, whether the initial settings should be color or black and white. Defaults
            to FALSE for postscript devices, TRUE otherwise. Note that this only applies to
            the initial choice of colors, which can be overridden using theme or subsequent
            calls to trellis.par.set (and by arguments supplied directly in high level
            calls for some settings).
   theme   list of components that changes the settings of the device opened, or, a function
            that when called produces such a list. The function name can be supplied as a
            quoted string. These settings are only used to modify the default settings
            (determined by other arguments), and need not contain all possible parameters.
            A possible use of this argument is to change the default settings by specifying
            lattice.options(default.theme = "col.whitebg"). For back-compatibility,
            this is initially (when lattice is loaded) set to getOption(lattice.theme).
            If theme is a function, it will not be supplied any arguments, however, it is
            guaranteed that a device will already be open when it is called, so one may use
            .Device inside the function to ascertain what device has been opened.
   new     logical flag indicating whether a new device should be started. If FALSE, the
            options for the current device are changed to the defaults determined by the
            other arguments.
   retain  logical. If TRUE and a setting for this device already exists, then that is used
            instead of the defaults for this device. By default, pre-existing settings are over-
            written (and lost).
name
... additional parameters to be passed to the device function, most commonly file for non-screen devices, as well as height, width, etc. See the help file for individual devices for admissible arguments.

Details
The `trellis.device` function sets up an R graphics device for use with lattice graphics, by opening the device if necessary, and defining a set of associated graphical parameters (colors, line types, fonts, etc.).

Even if a device is opened without calling `trellis.device`, for example, by calling a device function directly, `trellis.device` is still called automatically when a "trellis" object is plotted. The default graphical settings used in this case can be customized using `lattice.options`. It is therefore rarely necessary for the user to call `trellis.device` explicitly.

Value
None; `trellis.device` is called for the side effect of opening a device and / or setting associated graphical parameters.

Note
Earlier versions of `trellis.device` had a `bg` argument to set the background color, but this is no longer supported. If supplied, the `bg` argument will be passed on to the device function; however, this will have no effect on the Trellis settings. It is rarely meaningful to change the background alone; if you feel the need to change the background, consider using the `theme` argument instead.

Author(s)
Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

References

See Also
`Lattice` for an overview of the lattice package.
`Devices` for valid choices of device on your platform.
`standard.theme` for the default theme and alternatives.
Description

Built-in graphical parameter settings. These mainly differ in their choice of colors.

Usage

\begin{verbatim}
standard.theme(name, color = TRUE,
    symbol = palette.colors(palette = "Okabe-Ito")[:c(6, 2, 4, 7, 3, 5, 8)],
    fill = NULL,
    region = hcl.colors(14, palette = "YlGnBu", rev = TRUE),
    reference = "gray90",
    bg = "transparent",
    fg = "black",
    ...
)
canonical.theme(...)
custom_theme(symbol, fill, region,
    reference = "gray90", bg = "transparent", fg = "black",
    strip.bg = rep("gray95", 7), strip.fg = rep("gray70", 7),
    ...
)
classic.theme(name, color)
col.whitebg()
\end{verbatim}

Arguments

- **name**: character string giving the name of the device for which the setting is required, as returned by `.Device`. This is only used by `classic.theme` to allow device-specific setting. It is retained in `standard.theme` for back-compatibility, but its use is not recommended.
- **color**: logical, whether the initial settings should be color or black and white.
- **symbol**: vector of colors to be used for symbols and lines.
- **fill**: vector of colors to be used as fill colors, e.g., in bar charts and histograms. The default of `NULL` in `standard.theme` results in lightened versions of the symbol colors to be used.
- **region**: vector of colors to be used to create a color ramp, typically used by `levelplot`.
- **reference**: color, to be used for reference lines.
- **fg**: color, to be used for foreground elements such as axes and labels.
- **bg**: color, to be used as background.
- **strip.bg**: color, to be used as strip background.
- **strip.fg**: color, to be used as strip foreground.
additional arguments, passed on to other functions as appropriate. In particular, additional arguments provided to standard.theme will be passed on to custom_theme, and these may include non-color parameters that will be used to modify the resulting theme via simpleTheme.

Details

Trellis Graphics functions obtain the default values of various graphical parameters (colors, line types, fonts, etc.) from a customizable “settings” list (see trellis.par.set for details). This functionality is analogous to par for standard R graphics and, together with lattice.options, mostly supplants it (par settings are mostly ignored by Lattice). Unlike par, Trellis settings can be controlled separately for each different device type (but not concurrently for different instances of the same device).

The functions documented in this page produce such graphical settings (a.k.a. themes), usually to be used with trellis.device or trellis.par.set.

classic.theme and col.whitebg produce predefined themes that are not recommended for routine use but retained for compatibility.

The classic.theme function was intended to provide device specific settings (e.g. light colors on a grey background for screen devices, dark colors or black and white for print devices) and was used to obtain defaults prior to R 2.3.0. However, these settings are not always appropriate, due to the variety of platforms and hardware settings on which R is used, as well as the fact that a plot created on a particular device may be subsequently used in many different ways. For this reason, common device-agnostic defaults were used for all devices from R 2.3.0 onwards. The earlier behaviour can be reinstated by setting classic.theme as the default theme argument, e.g. by putting lattice.options(default.theme = "classic.theme") in a startup script (see the entry for theme in trellis.device for details).

Since R 2.4.3, a new set of defaults given by standard.theme is used. The defaults are based on HCL palettes, but customization of the palettes is allowed.

custom_theme is the workhorse function called by standard.theme. canonical.theme is an alias for standard.theme.

Value

A list of components defining graphical parameter settings for Lattice displays. It is used internally in trellis.device, and can also be used as the theme argument to trellis.par.set.

col.whitebg returns a similar (but smaller) list that is suitable as the theme argument to trellis.device and trellis.par.set. It contains settings values which provide colors suitable for plotting on a white background. Note that the name col.whitebg is somewhat of a misnomer, since it actually sets the background to transparent rather than white.

Lattice for an overview of the lattice package.

Devices for valid choices of device on your platform.

trellis.par.get and trellis.par.set can be used to query and modify the settings after a
device has been initialized. The par.settings argument to high level functions, described in
xyplot, can be used to attach transient settings to a "trellis" object.

Description

Functions used to query, display and modify graphical parameters for fine control of Trellis displays.
Modifications are made to the settings for the currently active device only.

Usage

trellis.par.set(name, value, ..., theme, warn = TRUE, strict = FALSE)
trellis.par.get(name = NULL)
show.settings(x = NULL)

Arguments

name 
A character string giving the name of a component. If unspecified in trellis.par.get(),
the return value is a named list containing all the current settings (this can be
used to get the valid values for name).

value 
a list giving the desired value of the component. Components that are already
defined as part of the current settings but are not mentioned in value will remain
unchanged.

theme 
a list describing how to change the settings, similar to what is returned by trellis.par.get().
This is purely for convenience, allowing multiple calls to trellis.par.set to
be condensed into one. The name of each component must be a valid name as
described above, with the corresponding value a valid value as described above.
As in trellis.device, theme can also be a function that produces such a list
when called. The function name can be supplied as a quoted string.

... 
Multiple settings can be specified in name = value form. Equivalent to calling
with theme = list(...) 

warn 
A logical flag, indicating whether a warning should be issued when trellis.par.get
is called when no graphics device is open.

strict 
Usually a logical flag, indicating whether the value should be interpreted strictly.
Usually, assignment of value to the corresponding named component is fuzzy in
the sense that sub-components that are absent from value but not currently NULL
are retained. By specifying strict = TRUE, such values will be removed.
An even stricter interpretation is allowed by specifying strict as a numeric
value larger than 1. In that case, top-level components not specified in the call
will also be removed. This is primarily for internal use.
optional list of components that change the settings (any valid value of theme). These are used to modify the current settings (obtained by `trellis.par.get`) before they are displayed.

Details

The various graphical parameters (color, line type, background etc) that control the look and feel of Trellis displays are highly customizable. Also, R can produce graphics on a number of devices, and it is expected that a different set of parameters would be more suited to different devices. These parameters are stored internally in a variable named `lattice.theme`, which is a list whose components define settings for particular devices. The components are identified by the name of the device they represent (as obtained by `.Device`), and are created as and when new devices are opened for the first time using `trellis.device` (or Lattice plots are drawn on a device for the first time in that session).

The initial settings for each device defaults to values appropriate for that device. In practice, this boils down to three distinct settings, one for screen devices like `x11` and `windows`, one for black and white plots (mostly useful for `postscript`) and one for color printers (color `postscript`, `pdf`).

Once a device is open, its settings can be modified. When another instance of the same device is opened later using `trellis.device`, the settings for that device are reset to its defaults, unless otherwise specified in the call to `trellis.device`. But settings for different devices are treated separately, i.e., opening a postscript device will not alter the `x11` settings, which will remain in effect whenever an `x11` device is active.

The functions `trellis.par.*` are meant to be interfaces to the global settings. They always apply on the settings for the currently ACTIVE device.

`trellis.par.get`, called without any arguments, returns the full list of settings for the active device. With the `name` argument present, it returns that component only. `trellis.par.get` sets the value of the `name` component of the current active device settings to `value`.

`trellis.par.get` is usually used inside Trellis functions to get graphical parameters before plotting. Modifications by users via `trellis.par.set` is traditionally done as follows:

```
add.line <- trellis.par.get("add.line")
add.line$col <- "red"
trellis.par.set("add.line", add.line)
```

More convenient (but not S compatible) ways to do this are

```
trellis.par.set(list(add.line = list(col = "red")))
```

and

```
trellis.par.set(add.line = list(col = "red"))
```

The actual list of the components in `trellis.settings` has not been finalized, so I’m not attempting to list them here. The current value can be obtained by `print(trellis.par.get())`. Most names should be self-explanatory.

`show.settings` provides a graphical display summarizing some of the values in the current settings.

Value

`trellis.par.get` returns a list giving parameters for that component. If `name` is missing, it returns the full list.
Most of the settings are graphical parameters that control various elements of a lattice plot. For details, see the examples below. The more unusual settings are described here.

grid.pars  Grid graphical parameters that are in effect globally unless overridden by specific settings.

fontsize  A list of two components (each a numeric scalar), text and points, for text and symbols respectively.

clip  A list of two components (each a character string, either "on" or "off"), panel and strip.

axis.components  A list with four components (left, top, right, bottom), each a list giving numeric multipliers named tck, pad1, and pad2 for corresponding grid layout units.

layout.heights  A list with numeric multipliers for grid layout heights.

layout.widths  A list with numeric multipliers for grid layout widths.

Note

In some ways, trellis.par.get and trellis.par.set together are a replacement for the par function used in traditional R graphics. In particular, changing par settings has little (if any) effect on lattice output. Since lattice plots are implemented using Grid graphics, its parameter system does have an effect unless overridden by a suitable lattice parameter setting. Such parameters can be specified as part of a lattice theme by including them in the grid.pars component (see gpar for a list of valid parameter names).

  },
  xlab = "Graphical parameters",
  ylab = "Setting names")

---

### C_03_simpleTheme

Function to generate a simple theme

---

**Description**

Simple interface to generate a list appropriate as a theme, typically used as the `par.settings` argument in a high level call.

**Usage**

```r
simpleTheme(col, alpha,
            cex, pch, lty, lwd, font, fill, border,
            col.points, col.line,
            alpha.points, alpha.line)
```

**Arguments**

- `col, col.points, col.line`
  - A color specification. `col` is used for components "plot.symbol", "plot.line", "plot.polygon", "superpose.symbol", "superpose.line", and "superpose.polygon". `col.points` overrides `col`, but is used only for "plot.symbol" and "superpose.symbol". Similarly, `col.line` overrides `col` for "plot.line" and "superpose.line". The arguments can be vectors, but only the first component is used for scalar targets (i.e., the ones without "superpose" in their name).

- `alpha, alpha.points, alpha.line`
  - A numeric alpha transparency specification. The same rules as `col`, etc., apply.

- `cex, pch, font`
  - Parameters for points. Applicable for components `plot.symbol` (for which only the first component is used) and `superpose.symbol` (for which the arguments can be vectors).

- `lty, lwd`
  - Parameters for lines. Applicable for components `plot.line` (for which only the first component is used) and `superpose.line` (for which the arguments can be vectors).

- `fill`
  - Fill color, applicable for components `plot.symbol`, `plot.polygon`, `superpose.symbol`, and `superpose.polygon`.

- `border`
  - Border color, applicable for components `plot.polygon` and `superpose.polygon`.
Details

The appearance of a lattice display depends partly on the “theme” active when the display is plotted (see `trellis.device` for details). This theme is used to obtain defaults for various graphical parameters, and in particular, the `auto.key` argument works on the premise that the same source is used for both the actual graphical encoding and the legend. The easiest way to specify custom settings for a particular display is to use the `par.settings` argument, which is usually tedious to construct as it is a nested list. The `simpleTheme` function can be used in such situations as a wrapper that generates a suitable list given parameters in simple `name=value` form, with the nesting made implicit. This is less flexible, but straightforward and sufficient in most situations.

Value

A list that would work as the `theme` argument to `trellis.device` and `trellis.par.set`, or as the `par.settings` argument to any high level lattice function such as `xyplot`.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>, based on a suggestion from John Maindonald.

See Also

`trellis.device`, `xyplot`, `Lattice`

Examples

```r
str(simpleTheme(pch = 16))

dotplot(variety ~ yield | site, data = barley, groups = year,
auto.key = list(space = "right"),
par.settings = simpleTheme(pch = 16),
xlab = "Barley Yield (bushels/acre) ",
aspect=0.5, layout = c(1,6))
```

Description

Functions to handle settings used by lattice. Their main purpose is to make code maintenance easier, and users normally should not need to use these functions. However, fine control at this level maybe useful in certain cases.

Usage

```r
lattice.options(...)
lattice.getOption(name)
```
Arguments

name character giving the name of a setting

... new options can be defined, or existing ones modified, using one or more arguments of the form name = value or by passing a list of such tagged values. Existing values can be retrieved by supplying the names (as character strings) of the components as unnamed arguments.

Details

These functions are modeled on options and getOption, and behave similarly for the most part. Some of the available components are documented here, but not all. The purpose of the ones not documented are either fairly obvious, or not of interest to the end-user.

panel.error A function, or NULL. If the former, every call to the panel function will be wrapped inside tryCatch with the specified function as an error handler. The default is to use the panel.error function. This prevents the plot from failing due to errors in a single panel, and leaving the grid operations in an unmanageable state. If set to NULL, errors in panel functions will not be caught using tryCatch.

save.object Logical flag indicating whether a "trellis" object should be saved when plotted for subsequent retrieval and further manipulation. Defaults to TRUE.

layout.widths, layout.heights Controls details of the default space allocation in the grid layout created in the course of plotting a "trellis" object. Each named component is a list of arguments to the grid function unit (x, units, and optionally data).

Usually not of interest to the end-user, who should instead use the similarly named component in the graphical settings, modifiable using trellis.par.set.

drop.unused.levels A list of two components named cond and data, both logical flags. The flags indicate whether the unused levels of factors (conditioning variables and primary variables respectively) will be dropped, which is usually relevant when a subsetting operation is performed or an 'interaction' is created. See xyplot for more details. Note that this does not control dropping of levels of the 'groups' argument.

legend.bbox A character string, either "full" or "panel". This determines the interpretation of x and y when space="inside" in key (determining the legend; see xyplot): either the full figure region ("full"), or just the region that bounds the panels and strips ("panel").

default.args A list giving default values for various standard arguments: as.table, auto.key, aspect, between, grid, skip, strip, xscale.components, yscale.components, and axis.

highlight.gpar A list giving arguments to gpar used to highlight a viewport chosen using trellis.focus.

banking The banking function. See banking.

axis.padding List with components named "numeric" and "factor", both scalar numbers. Panel limits are extended by this amount, to provide padding for numeric and factor scales respectively. The value for numeric is multiplicative, whereas factor is additive.

skip.boundary.labels Numeric scalar between 0 and 1. Tick marks that are too close to the limits are not drawn unless explicitly requested. The limits are contracted by this proportion, and anything outside is skipped.

interaction.sep The separator for creating interactions with the extended formula interface (see xyplot).
optimize.grid Logical flag, FALSE by default. Complicated grid unit calculations can be slow. Sometimes these can be optimized at the cost of potential loss of accuracy. This option controls whether such optimization should be applied.

axis.units List determining default units for axis components. Should not be of interest to the end-user.

In addition, there is an option for the default prepanel and panel function for each high-level function; e.g., \texttt{panel.xypplot} and \texttt{prepanel.default.xypplot} for \texttt{xypplot}. The options for the others have similarly patterned names.

Value

\texttt{lattice.getOption} returns the value of a single component, whereas \texttt{lattice.options} always returns a list with one or more named components. When changing the values of components, the old values of the modified components are returned by \texttt{lattice.options}. If called without any arguments, the full list is returned.

  lattice.options(default.args = list(as.table = TRUE,
                                    grid = TRUE,
                                    auto.key = TRUE))

  ## End(Not run)
\end{verbatim}
## S3 method for class 'trellis'
plot(x, position, split,
     more = FALSE, newpage = TRUE,
     packet.panel = packet.panel.default,
     draw.in = NULL,
     panel.height = lattice.getOption("layout.heights")$panel,
     panel.width = lattice.getOption("layout.widths")$panel,
     save.object = lattice.getOption("save.object"),
     panel.error = lattice.getOption("panel.error"),
     prefix,
     ...)  
## S3 method for class 'trellis'
print(x, ...)  
## S3 method for class 'trellis'
summary(object, ...)  
## S3 method for class 'trellis'
dim(x)  
## S3 method for class 'trellis'
dimnames(x)  
panel.error(e)

### Arguments

- **x, object**
  
  An object of class "trellis"

- **position**
  
  A vector of 4 numbers, typically c(xmin, ymin, xmax, ymax) that give the lower-left and upper-right corners of a rectangle in which the Trellis plot of x is to be positioned. The coordinate system for this rectangle is [0-1] in both the x and y directions.

- **split**
  
  A vector of 4 integers, c(x,y,nx,ny), that says to position the current plot at the x,y position in a regular array of nx by ny plots. (Note: this has origin at top left)

- **more**
  
  A logical specifying whether more plots will follow on this page.

- **newpage**
  
  A logical specifying whether the plot should be on a new page. This option is specific to lattice, and is useful for including lattice plots in an arbitrary grid viewport (see the details section).

- **packet.panel**
  
  A function that determines which packet (data subset) is plotted in which panel. Panels are always drawn in an order such that columns vary the fastest, then rows and then pages. This function determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. By default, the association is determined by matching panel order with packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. This association rule is encoded in the
default, namely the function `packet.panel.default`, whose help page details the arguments supplied to whichever function is specified as the `packet.panel` argument.

draw.in

An optional (grid) viewport (used as the name argument in `downViewport`) in which the plot is to be drawn. If specified, the `newpage` argument is ignored. This feature is not well-tested.

panel.width, panel.height

lists with 2 components, that should be valid x and units arguments to `unit()` (the `data` argument cannot be specified currently, but can be considered for addition if needed). The resulting `unit` object will be the width/height of each panel in the Lattice plot. These arguments can be used to explicitly control the dimensions of the panel, rather than letting them expand to maximize available space. Vector widths are allowed, and can specify unequal lengths across rows or columns.

Note that this option should not be used in conjunction with non-default values of the `aspect` argument in the original high level call (no error will be produced, but the resulting behaviour is undefined).

save.object

logical, specifying whether the object being printed is to be saved. The last object thus saved can be subsequently retrieved. This is an experimental feature that should allow access to a panel’s data after the plot is done, making it possible to enhance the plot after the fact. This also allows the user to invoke the `update` method on the current plot, even if it was not assigned to a variable explicitly. For more details, see `trellis.focus`.

panel.error

a function, or a character string naming a function, that is to be executed when an error occurs during the execution of the panel function. The error is caught (using `tryCatch`) and supplied as the only argument to `panel.error`. The default behaviour (implemented as the `panel.error` function) is to print the corresponding error message in the panel and continue. To stop execution on error, use `panel.error = stop`.

Normal error recovery and debugging tools are unhelpful when `tryCatch` is used. `tryCatch` can be completely bypassed by setting `panel.error` to `NULL`.

prefix

A character string acting as a prefix identifying the plot of a "trellis" object, primarily used in constructing viewport and grob names, to distinguish similar viewports if a page contains multiple plots. The default is based on the serial number of the current plot on the current page (specifically, "plot_01", "plot_02", etc.). If supplied explicitly, this must be a valid R symbol name (briefly, it must start with a letter or a period followed by a letter) and must not contain the grid path separator (currently "::").

e

an error condition caught by `tryCatch`

... extra arguments, ignored by the print method. All arguments to the `plot` method are passed on to the `print` method.

Details

This is the default print method for objects of class "trellis", produced by calls to functions like `xyplot`, `bwplot` etc. It is usually called automatically when a trellis object is produced. It can also be called explicitly to control plot positioning by means of the arguments `split` and `position`. 
When `newpage = FALSE`, the current grid viewport is treated as the plotting area, making it possible to embed a Lattice plot inside an arbitrary grid viewport. The `draw.in` argument provides an alternative mechanism that may be simpler to use.

The print method uses the information in `x` (the object to be printed) to produce a display using the Grid graphics engine. At the heart of the plot is a grid layout, of which the entries of most interest to the user are the ones containing the display panels.

Unlike in older versions of Lattice (and Grid), the grid display tree is retained after the plot is produced, making it possible to access individual viewport locations and make additions to the plot. For more details and a lattice level interface to these viewports, see `trellis.focus`.

**Note**

Unlike S-PLUS, trying to position a multipage display (using `position` and/or `split`) will mess things up.

**Examples**

```r
p11 <- histogram(~height | voice.part, data = singer, xlab="Height")
p12 <- densityplot(~height | voice.part, data = singer, xlab = "Height")
p2 <- histogram(~height, data = singer, xlab = "Height")

## simple positioning by split
print(p11, split=c(1,1,1,2), more=TRUE)
print(p2, split=c(1,2,1,2))

## Combining split and position:
print(p11, position = c(0,0,.75,.75), split=c(1,1,1,2), more=TRUE)
print(p12, position = c(0,0,.75,.75), split=c(1,2,1,2), more=TRUE)
print(p2, position = c(.5,.75,1,1), more=FALSE)

## Using seekViewport
## repeat same plot, with different polynomial fits in each panel
xyplot(Armed.Forces ~ Year, longley, index.cond = list(rep(1, 6)),
       layout = c(3, 2),
       panel = function(x, y, ...)
       {
       panel.xyplot(x, y, ...)
       fm <- lm(y ~ poly(x, panel.number()))
       llines(x, predict(fm))
       })
```
Retrieve and Update Trellis Object

**Description**

Update method for objects of class "trellis", and a way to retrieve the last printed trellis object (that was saved).

**Usage**

```r
## S3 method for class 'trellis'
update(object,
panel,
aspect,
as.table,
between,
key,
auto.key,
legend,
layout,
main,
page,
par.strip.text,
```

```r
```
C_06_update.trellis

prepanel, scales, skip, strip, strip.left, sub, xlab, ylab, xlab.top, ylab.right, xlim, ylim, xscale.components, yscale.components, axis, par.settings, plot.args, lattice.options, index.cond, perm.cond, ...

## S3 method for class 'trellis'

\texttt{t(x)}

## S3 method for class 'trellis'

\texttt{x[i, j, \ldots, \text{drop} = \text{FALSE}]}

trellis.last.object(\ldots, \text{prefix})

Arguments

- \texttt{object, x} The object to be updated, of class "trellis".
- \texttt{i, j} indices to be used. Names are not currently allowed.
- \texttt{drop} logical, whether dimensions with only one level are to be dropped. Currently ignored, behaves as if it were \texttt{FALSE}.
- panel, aspect, as.table, between, key, auto.key, legend, layout, main, page, par.strip.text, prepanel, scales, ... arguments that will be used to update \texttt{object}. See details below.
- \texttt{prefix} A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed. See \texttt{trellis.focus}.

Details

All high level lattice functions such as \texttt{xyplot} produce an object of (S3) class "trellis", which is usually displayed by its \texttt{print} method. However, the object itself can be manipulated and modified
to a large extent using the update method, and then re-displayed as needed.

Most arguments to high level functions can also be supplied to the update method as well, with some exceptions. Generally speaking, anything that would needs to change the data within each panel is a no-no (this includes the formula, data, groups, subscripts and subset). Everything else is technically game, though might not be implemented yet. If you find something missing that you wish to have, feel free to make a request.

Not all arguments accepted by a Lattice function are processed by update, but the ones listed above should work. The purpose of these arguments are described in the help page for `xyplot`. Any other argument is added to the list of arguments to be passed to the panel function. Because of their somewhat special nature, updates to objects produced by `cloud` and `wireframe` do not work very well yet.

The "[" method is a convenient shortcut for updating `index.cond`. The t method is a convenient shortcut for updating `perm.cond` in the special (but frequent) case where there are exactly two conditioning variables, when it has the effect of switching ('transposing') their order.

The print method for "trellis" objects optionally saves the object after printing it. If this feature is enabled, `trellis.last.object` can retrieve it. By default, the last object plotted is retrieved, but if multiple objects are plotted on the current page, then others can be retrieved using the appropriate prefix argument. If `trellis.last.object` is called with arguments, these are used to update the retrieved object before returning it.

Value

An object of class `trellis`, by default plotted by `print.trellis`. `trellis.last.object` returns `NULL` if no saved object is available.

       scales = list(x = list(alternating = 2)),
       main = "Average Yearly Sunspots")
update(trellis.last.object(), aspect = "xy")
trellis.last.object(xlab = "Year")
lattice.options(old.options)
```
Description

Functions to handle shingles

Usage

shingle(x, intervals=sort(unique(x)))
equal.count(x, ...)
as.shingle(x)
is.shingle(x)

## S3 method for class 'shingle'
plot(x, panel, xlab, ylab, ...)

## S3 method for class 'shingle'
print(x, showValues = TRUE, ...)

## S3 method for class 'shingleLevel'
as.character(x, ...)

## S3 method for class 'shingleLevel'
print(x, ...)

## S3 method for class 'shingle'
summary(object, showValues = FALSE, ...)

## S3 method for class 'shingle'
x[subset, drop = FALSE]
as.factorOrShingle(x, subset, drop)

Arguments

x numeric variable or R object, shingle in plot.shingle and x[]. An object (list of intervals) of class "shingleLevel" in print.shingleLevel
object shingle object to be summarized
showValues logical, whether to print the numeric part. If FALSE, only the intervals are printed
intervals numeric vector or matrix with 2 columns
subset logical vector
drop whether redundant shingle levels are to be dropped
panel, xlab, ylab

standard Trellis arguments (see `xyplot`)

... other arguments, passed down as appropriate. For example, extra arguments to `equal.count` are passed on to `co.intervals`. Graphical parameters can be passed as arguments to the `plot` method.

Details

A shingle is a data structure used in Trellis, and is a generalization of factors to ‘continuous’ variables. It consists of a numeric vector along with some possibly overlapping intervals. These intervals are the ‘levels’ of the shingle. The `levels` and `nlevels` functions, usually applicable to factors, also work on shingles. The implementation of shingles is slightly different from S.

There are print methods for shingles, as well as for printing the result of `levels()` applied to a shingle. For use in labelling, the `as.character` method can be used to convert levels of a shingle to character strings.

`equal.count` converts x to a shingle using the equal count algorithm. This is essentially a wrapper around `co.intervals`. All arguments are passed to `co.intervals`.

`shingle` creates a shingle using the given intervals. If `intervals` is a vector, these are used to form 0 length intervals.

`as.shingle` returns `shingle(x)` if x is not a shingle.

`is.shingle` tests whether x is a shingle.

`plot.shingle` displays the ranges of shingles via rectangles. `print.shingle` and `summary.shingle` describe the shingle object.

Value

`x$intervals` for `levels.shingle(x)`, logical for `is.shingle`, an object of class "trellis" for `plot` (printed by default by `print.trellis`), and an object of class "shingle" for the others.

print(z)
print(levels(z))
```
D_draw.colorkey  Produce a colorkey typically for levelplot

Description

Creates (and optionally draws) a grid frame grob representing a color key that can be placed in other grid-based plots. Primarily used by levelplot when a color key is requested.

Usage

draw.colorkey(key, draw = FALSE, vp = NULL)

Arguments

key A list determining the key. See documentation for levelplot, in particular the section describing the colorkey argument, for details.
draw A scalar logical, indicating whether the grob is to be drawn.
vp The viewport in which to draw the grob, if applicable.

Value

A grid frame object (that inherits from "grob")

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

xyplot, levelplot

D_draw.key  Produce a Legend or Key

Description

Produces (and possibly draws) a Grid frame grob which is a legend (aka key) that can be placed in other Grid plots.

Usage

draw.key(key, draw=FALSE, vp=NULL, ...)

Arguments

- **key**: A list determining the key. See documentation for `xyplot`, in particular the section describing the key argument, for details.
- **draw**: logical, whether the grob is to be drawn.
- **vp**: viewport
- **...**: ignored

Value

A Grid frame object (that inherits from 'grob').

`xyplot`

---

**D_level.colors**  
*A function to compute false colors representing a numeric or categorical variable*

Description

Calculates false colors from a numeric variable (including factors, using their numeric codes) given a color scheme and breakpoints.

Usage

```r
level.colors(x, at, col.regions, colors = TRUE, ...)
```

Arguments

- **x**: A numeric or `factor` variable.
- **at**: A numeric variable of breakpoints defining intervals along the range of `x`.
- **col.regions**: A specification of the colors to be assigned to each interval defined by `at`. This could be either a vector of colors, or a function that produces a vector of colors when called with a single argument giving the number of colors. See details below.
- **colors**: logical indicating whether colors should be computed and returned. If FALSE, only the indices representing which interval (among those defined by `at`) each value in `x` falls into is returned.
- **...**: Extra arguments, ignored.
Details

If `at` has length n, then it defines n-1 intervals. Values of x outside the range of at are not assigned to an interval, and the return value is NA for such values.

Colors are chosen by assigning a color to each of the n-1 intervals. If `col.regions` is a palette function (such as `topo.colors`, or the result of calling `colorRampPalette`), it is called with n-1 as an argument to obtain the colors. Otherwise, if there are exactly n-1 colors in `col.regions`, these get assigned to the intervals. If there are fewer than n-1 colors, `col.regions` gets recycled. If there are more, a more or less equally spaced (along the length of `col.regions`) subset is chosen.

Value

A vector of the same length as x. Depending on the `colors` argument, this could be either a vector of colors (in a form usable by R), or a vector of integer indices representing which interval the values of x fall in.

Author(s)

Deepayan Sarkar <deepayan.sarkar@r-project.org>

See Also

`levelplot`, `colorRampPalette`.

Examples

```r
depth.col <-
  with(quakes,
    level.colors(depth, at = do.breaks(range(depth), 30),
      col.regions = hcl.colors))
```

```r
xyplot(lat ~ long | equal.count(stations), quakes,
  strip = strip.custom(var.name = "Stations"),
  colours = depth.col,
  panel = function(x, y, colours, subscripts, ...) {
    panel.xyplot(x, y, pch = 21, col = "transparent",
                 fill = colours[subscripts], ...)
  })
```

Description

Combines two or more vectors, possibly of different lengths, producing a data frame with a second column indicating which of these vectors that row came from. This is mostly useful for getting data into a form suitable for use in high level Lattice functions.
Usage

make.groups(…)

Arguments

… one or more vectors of the same type (coercion is attempted if not), or one or more data frames with similar columns, with possibly differing number of rows.

Value

When all the input arguments are vectors, a data frame with two columns

data all the vectors supplied, concatenated
which factor indicating which vector the corresponding data value came from

When all the input arguments are data frames, the result of rbind applied to them, along with an additional which column as described above.

Usage

simpleKey(text, points = TRUE, 
           rectangles = FALSE, 
           lines = FALSE, 
           col, cex, alpha, font, 
           fontface, fontfamily, 
           lineheight, ...)

---

**D_simpleKey**  
*Function to generate a simple key*

Description

Simple interface to generate a list appropriate for draw.key

Usage

simpleKey(text, points = TRUE, 
           rectangles = FALSE, 
           lines = FALSE, 
           col, cex, alpha, font, 
           fontface, fontfamily, 
           lineheight, ...)
Arguments

- **text**: character or expression vector, to be used as labels for levels of the grouping variable
- **points**: logical
- **rectangles**: logical
- **lines**: logical
- **col, cex, alpha, font, fontface, fontfamily, lineheight**: Used as top-level components of the list produced, to be used for the text labels. Defaults to the values in `trellis.par.get("add.text")`
- **...**: further arguments added to the list, eventually passed to `draw.key`

Details

A lattice plot can include a legend (key) if an appropriate list is specified as the key argument to a high level Lattice function such as `xyplot`. This key can be very flexible, but that flexibility comes at a cost: this list needs to be fairly complicated even in simple situations. `simpleKey` is designed as a useful shortcut in the common case of a key drawn in conjunction with a grouping variable, using the default graphical settings.

The `simpleKey` function produces a suitable key argument using a simpler interface. The resulting list will use the `text` argument as a text component, along with at most one set each of points, rectangles, and lines. The number of entries (rows) in the key will be the length of the `text` component. The graphical parameters for the additional components will be derived from the default graphical settings (wherein lies the simplification, as otherwise these would have to be provided explicitly).

Calling `simpleKey` directly is usually unnecessary. It is most commonly invoked (during the plotting of the "trellis" object) when the `auto.key` argument is supplied in a high-level plot with a `groups` argument. In that case, the `text` argument of `simpleKey` defaults to `levels(groups)`, and the defaults for the other arguments depend on the relevant high-level function. Note that these defaults can be overridden by supplying `auto.key` as a list containing the replacement values.

Value

A list that would work as the key argument to `xyplot`, etc.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

`Lattice`, `draw.key`, `trellis.par.get`, and `xyplot`, specifically the entry for `auto.key`. 
**D_strip.default**  
*Default Trellis Strip Function*

**Description**

`strip.default` is the function that draws the strips by default in Trellis plots. Users can write their own strip functions, but most commonly this involves calling `strip.default` with a slightly different arguments. `strip.custom` provides a convenient way to obtain new strip functions that differ from `strip.default` only in the default values of certain arguments.

**Usage**

```r
strip.default(which.given,  
 which.panel,  
 var.name,  
 factor.levels,  
 shingle.intervals,  
 strip.names = c(FALSE, TRUE),  
 strip.levels = c(TRUE, FALSE),  
 sep = " : ",  
 style = 1,  
 horizontal = TRUE,  
 bg = trellis.par.get("strip.background")$col[which.given],  
 fg = trellis.par.get("strip.shingle")$col[which.given],  
 par.strip.text = trellis.par.get("add.text"))
```

**Arguments**

- `which.given` integer index specifying which of the conditioning variables this strip corresponds to.
- `which.panel` vector of integers as long as the number of conditioning variables. The contents are indices specifying the current levels of each of the conditioning variables (thus, this would be unique for each distinct packet). This is identical to the return value of `which.packet`, which is a more accurate name.
- `var.name` vector of character strings or expressions as long as the number of conditioning variables. The contents are interpreted as names for the conditioning variables. Whether they are shown on the strip depends on the values of `strip.names` and `style` (see below). By default, the names are shown for shingles, but not for factors.
- `factor.levels` vector of character strings or expressions giving the levels of the conditioning variable currently being drawn. For more than one conditioning variable, this will vary with `which.given`. Whether these levels are shown on the strip depends on the values of `strip.levels` and `style` (see below). `factor.levels` may be specified for both factors and shingles (despite the name), but by default they are shown only for factors. If shown, the labels may optionally be abbreviated by specifying suitable components in `par.strip.text` (see `xyplot`)
shingle.intervals
if the current strip corresponds to a shingle, this should be a 2-column matrix
giving the levels of the shingle. (of the form that would be produced by printing
levels(shingle)). Otherwise, it should be NULL.

strip.names
a logical vector of length 2, indicating whether or not the name of the condition-
inging variable that corresponds to the strip being drawn is to be written on the
strip. The two components give the values for factors and shingles respectively.
This argument is ignored for a factor when style is not one of 1 and 3.

strip.levels
a logical vector of length 2, indicating whether or not the level of the condition-
inging variable that corresponds to the strip being drawn is to be written on the
strip. The two components give the values for factors and shingles respectively.

sep
character or expression, serving as a separator if the name and level are both to
be shown.

style
integer, with values 1, 2, 3, 4 and 5 currently supported, controlling how the cur-
rent level of a factor is encoded. Ignored for shingles (actually, when shingle.intervals
is non-null).
The best way to find out what effect the value of style has is to try them out.
Here is a short description: for a style value of 1, the strip is colored in the
background color with the strip text (as determined by other arguments) centered
on it. A value of 3 is the same, except that a part of the strip is colored in the
foreground color, indicating the current level of the factor. For styles 2 and 4, the
part corresponding to the current level remains colored in the foreground color,
however, for style = 2, the remaining part is not colored at all, whereas for 4, it
is colored with the background color. For both these, the names of all the levels
of the factor are placed on the strip from left to right. Styles 5 and 6 produce
the same effect (they are subtly different in S, this implementation corresponds
to 5), they are similar to style 1, except that the strip text is not centered, it is
instead positioned according to the current level.
Note that unlike S-PLUS, the default value of style is 1. strip.names and
strip.levels have no effect if style is not 1 or 3.

horizontal
logical, specifying whether the labels etc should be horizontal. horizontal=FALSE
is useful for strips on the left of panels using strip.left=TRUE.

par.strip.text
list with parameters controlling the text on each strip, with components col,
cex, font, etc.

bg
strip background color.

fg
strip foreground color.

... arguments to be passed on to strip.default, overriding whatever value it
would have normally assumed.

Details
default strip function for trellis functions. Useful mostly because of the style argument — non-
default styles are often more informative, especially when the names of the levels of the factor x are
small. Traditional use is as strip = function(…) strip.default(style=2,…), though this
can be simplified by the use of strip.custom.
D_trellis.object

Value

strip.default is called for its side-effect, which is to draw a strip appropriate for multi-panel Trellis conditioning plots. strip.custom returns a function that is similar to strip.default, but with different defaults for the arguments specified in the call.

Examples

## Traditional use
xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = function(..., style) strip.default(..., style = 4))

## equivalent call using strip.custom
xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = strip.custom(style = 4))

xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = FALSE,
       strip.left = strip.custom(style = 4, horizontal = FALSE))

---

D_trellis.object A Trellis Plot Object

Description

This class of objects is returned by high level lattice functions, and is usually plotted by default by its print method.

Details

A trellis object, as returned by high level lattice functions like xyplot, is a list with the "class" attribute set to "trellis". Many of the components of this list are simply the arguments to the high level function that produced the object. Among them are: as.table, layout, page, panel, prepanel, main, sub, par.strip.text, strip, skip, xlab, ylab, par.settings, lattice.options and plot.args. Some other typical components are:

formula the Trellis formula used in the call
index.cond list with index for each of the conditioning variables
perm.cond permutation of the order of the conditioning variables
aspect.fill logical, whether aspect is "fill"
aspect.ratio numeric, aspect ratio to be used if aspect.fill is False
call call that generated the object.
condlevels list with levels of the conditioning variables
legend list describing the legend(s) to be drawn
panel.args a list as long as the number of panels, each element being a list itself, containing the arguments in named form to be passed to the panel function in that panel.
panel.args.common a list containing the arguments common to all the panel functions in name=value form
x.scales list describing x-scale, can consist of several other lists, paralleling panel.args, if x-relation is not "same"
y.scales list describing y-scale, similar to x.scales
x.between numeric vector of interpanel x-space
y.between numeric vector of interpanel y-space
x.limits numeric vector of length 2 or list, giving x-axis limits
y.limits similar to x.limits
packet.sizes array recording the number of observations in each packet

Lattice, xyplot, print.trellis

Description
The classic Trellis paradigm is to plot the whole object at once, without the possibility of interacting with it afterwards. However, by keeping track of the grid viewports where the panels and strips are drawn, it is possible to go back to them afterwards and enhance them one panel at a time. These functions provide convenient interfaces to help in this. Note that these are still experimental and the exact details may change in future.

Usage
panel.identify(x, y = NULL,
    subscripts = seq_along(x),
    labels = subscripts,
    n = length(x), offset = 0.5,
    threshold = 18, ## in points, roughly 0.25 inches
    panel.args = trellis.panelArgs(),
panel.identify.qqmath(x, distribution, groups, subscripts, labels,
    panel.args = trellis.panelArgs(),
    ...)  
panel.identify.cloud(x, y, z, subscripts,
    perspective, distance,
    xlim, ylim, zlim,
    screen, R.mat, aspect, scales.3d,
    ...
    panel.3d.identify,
    n = length(subscripts),
    offset = 0.5,
    threshold = 18,
    labels = subscripts,
    panel.args = trellis.panelArgs())
panel.link.splom(threshold = 18, verbose = getOption("verbose"), ...)
panel.brush.splom(threshold = 18, verbose = getOption("verbose"), ...)

trellis.vpname(name = c("position", "split", "split.location", "toplevel",
    "figure", "panel", "strip", "strip.left",
    "legend", "legend.region", "main", "sub",
    "xlab", "ylab", "xlab.top", "ylab.right", "page"),
    column, row,
    side = c("left", "top", "right", "bottom", "inside"),
    clip.off = FALSE, prefix)
trellis.grobnname(name,
    type = c("", "panel", "strip", "strip.left",
    "key", "colorkey"),
    group = 0,
    which.given = lattice.getStatus("current.which.given",
    prefix = prefix),
    which.panel = lattice.getStatus("current.which.panel",
    prefix = prefix),
    column = lattice.getStatus("current.focus.column",
    prefix = prefix),
    row = lattice.getStatus("current.focus.row",
    prefix = prefix),
    prefix = lattice.getStatus("current.prefix"))
trellis.focus(name, column, row, side, clip.off,
    highlight = interactive(), ..., prefix,
    guess = TRUE, verbose = getOption("verbose"))
trellis.switchFocus(name, side, clip.off, highlight, ..., prefix)
trellis.unfocus()
trellis.panelArgs(x, packet.number)
Arguments

x, y, z  
variables defining the contents of the panel. In the case of `trellis.panelArgs`, a "trellis" object.

n  
the number of points to identify by default (overridden by a right click)

subscripts  
an optional vector of integer indices associated with each point. See details below.

labels  
an optional vector of labels associated with each point. Defaults to subscripts.

distribution, groups  
typical panel arguments of `panel.qqmath`. These will usually be obtained from `panel.args`.

offset  
the labels are printed either below, above, to the left or to the right of the identified point, depending on the relative location of the mouse click. The offset specifies (in "char" units) how far from the identified point the labels should be printed.

threshold  
threshold in grid’s "points" units. Points further than these from the mouse click position are not considered.

panel.args  
list that contains components names x (and usually y), to be used if x is missing. Typically, when called after `trellis.focus`, this would appropriately be the arguments passed to that panel.

perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, scales.3d  
arguments as passed to `panel.cloud`. These are required to recompute the relevant three-dimensional projections in `panel.identify.cloud`.

panel.3d.identify  
the function that is responsible for the actual interaction once the data rescaling and rotation computations have been done. By default, an internal function similar to `panel.identify` is used.

name  
A character string indicating which viewport or grob we are looking for. Although these do not necessarily provide access to all viewports and grobs created by a lattice plot, they cover most of the ones that end-users may find interesting. `trellis.vpname` and `trellis.focus` deal with viewport names only, and only accept the values explicitly listed above. `trellis.grobname` is meant to create names for grobs, and can currently accept any value.

If name, as well as column and row is missing in a call to `trellis.focus`, the user can click inside a panel (or an associated strip) to focus on that panel. Note however that this assumes equal width and height for each panel, and may not work when this is not true.

When name is "panel", "strip", or "strip.left", column and row must also be specified. When name is "legend", side must also be specified.

column, row  
integers, indicating position of the panel or strip that should be assigned focus in the Trellis layout. Rows are usually calculated from the bottom up, unless the plot was created with `as.table=TRUE`.

guess  
logical. If TRUE, and the display has only one panel, that panel will be automatically selected by a call to `trellis.focus`.
side

clip.off

type

group

which.given, which.panel

prefix

highlight

packet.number

verbose

...
Although it is possible to call it as part of the panel function, it is more typical to use it to identify points after plotting the whole object, in which case a call to `trellis.focus` first is necessary.

`panel.link.splom` is meant for use with `splom`, and requires a panel to be chosen using `trellis.focus` before it is called. Clicking on a point causes that and the corresponding projections in other pairwise scatter plots to be highlighted. `panel.brush.splom` is a (misnamed) alias for `panel.link.splom`, retained for back-compatibility.

`panel.identify.qqmath` is a specialized wrapper meant for use with the display produced by `qqmath`. `panel.identify.qqmath` is a specialized wrapper meant for use with the display produced by `cloud`. It would be unusual to call them except in a context where default panel function arguments are available through `trellis.panelArgs` (see below).

One way in which `panel.identify` etc. are different from `identify` is in how it uses the `subscripts` argument. In general, when one identifies points in a panel, one wants to identify the origin in the data frame used to produce the plot, and not within that particular panel. This information is available to the panel function, but only in certain situations. One way to ensure that `subscripts` is available is to specify `subscripts = TRUE` in the high level call such as `xyplot`. If `subscripts` is not explicitly specified in the call to `panel.identify`, but is available in `panel.args`, then those values will be used. Otherwise, they default to `seq_along(x)`. In either case, the final return value will be the subscripts that were marked.

The process of printing (plotting) a Trellis object builds up a grid layout with named viewports which can then be accessed to modify the plot further. While full flexibility can only be obtained by using grid functions directly, a few lattice functions are available for the more common tasks.

`trellis.focus` can be used to move to a particular panel or strip, identified by its position in the array of panels. It can also be used to focus on the viewport corresponding to one of the labels or a legend, though such usage would be less useful. The exact viewport is determined by the name along with the other arguments, not all of which are relevant for all names. Note that when more than one object is plotted on a page, `trellis.focus` will always go to the plot that was created last.

For more flexibility, use grid functions directly (see note below).

After a successful call to `trellis.focus`, the desired viewport (typically panel or strip area) will be made the ‘current’ viewport (plotting area), which can then be enhanced by calls to standard lattice panel functions as well as grid functions.

It is quite common to have the layout of panels chosen when a “trellis” object is drawn, and not before then. Information on the layout (specifically, how many rows and columns, and which packet belongs in which position in this layout) is retained for the last “trellis” object plotted, and is available through `trellis.currentLayout`.

`trellis.unfocus` unsets the focus, and makes the top level viewport the current viewport.

`trellis.switchFocus` is a convenience function to switch from one viewport to another, while preserving the current row and column. Although the rows and columns only make sense for panels and strips, they would be preserved even when the user switches to some other viewport (where row/column is irrelevant) and then switches back.

Once a panel or strip is in focus, `trellis.panelArgs` can be used to retrieve the arguments that were available to the panel function at that position. In this case, it can be called without arguments as

```r
trellis.panelArgs()
```
This usage is also allowed when a "trellis" object is being printed, e.g. inside the panel functions or the axis function (but not inside the prepanel function). trellis.panelArgs can also retrieve the panel arguments from any "trellis" object. Note that for this usage, one needs to specify the packet.number (as described under the panel entry in xyplot) and not the position in the layout, because a layout determines the panel only after the object has been printed.

It is usually not necessary to call trellis.vpname and trellis.grobname directly. However, they can be useful in generating appropriate names in a portable way when using grid functions to interact with the plots directly, as described in the note below.

Value

panel.identify returns an integer vector containing the subscripts of the identified points (see details above). The equivalent of identify with pos=TRUE is not yet implemented, but can be considered for addition if requested.

trellis.panelArgs returns a named list of arguments that were available to the panel function for the chosen panel.

trellis.vpname and trellis.grobname return character strings.

trellis.focus has a meaningful return value only if it has been used to focus on a panel interactively, in which case the return value is a list with components col and row giving the column and row positions respectively of the chosen panel, unless the choice was cancelled (by a right click), in which case the return value is NULL. If click was outside a panel, both col and row are set to 0.

Note

The viewports created by lattice are accessible to the user through trellis.focus as described above. Functions from the grid package can also be used directly. For example, current.vpTree can be used to inspect the current viewport tree and seekViewport or downViewport can be used to navigate to these viewports. For such usage, trellis.vpname and trellis.grobname provides a portable way to access the appropriate viewports and grobs by name.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>. Felix Andrews provided initial implementations of panel.identify.qqmath and support for focusing on panels interactively.

**F_1_panel.barchart**  
*Default Panel Function for barchart*

**Description**

Default panel function for `barchart`.

**Usage**

```
panel.barchart(x, y, box.ratio = 1, box.width,
               horizontal = TRUE,
               origin = NULL, reference = TRUE,
               stack = FALSE,
               groups = NULL,
               col = if (is.null(groups)) plot.polygon$col
               else superpose.polygon$col,
               border = if (is.null(groups)) plot.polygon$border
               else superpose.polygon$border,
               lty = if (is.null(groups)) plot.polygon$lty
               else superpose.polygon$lty,
               lwd = if (is.null(groups)) plot.polygon$lwd
               else superpose.polygon$lwd,
               ..., identifier = "barchart")
```

**Arguments**

- `x`  
  Extent of Bars. By default, bars start at left of panel, unless `origin` is specified, in which case they start there.

- `y`  
  Horizontal location of bars. Possibly a factor.

- `box.ratio`  
  Ratio of bar width to inter-bar space.

- `box.width`  
  Thickness of bars in absolute units; overrides `box.ratio`. Useful for specifying thickness when the categorical variable is not a factor, as use of `box.ratio` alone cannot achieve a thickness greater than 1.

- `horizontal`  
  Logical flag. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of `x` and `y` are switched. `x` is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of `bwplot` for a fuller explanation.
origin  The origin for the bars. For grouped displays with stack = TRUE, this argument is ignored and the origin set to 0. Otherwise, defaults to NULL, in which case bars start at the left (or bottom) end of a panel. This choice is somewhat unfortunate, as it can be misleading, but is the default for historical reasons. For tabular (or similar) data, origin = 0 is usually more appropriate; if not, one should reconsider the use of a bar chart in the first place (dot plots are often a good alternative).

reference  Logical, whether a reference line is to be drawn at the origin.

stack  logical, relevant when groups is non-null. If FALSE (the default), bars for different values of the grouping variable are drawn side by side, otherwise they are stacked.

groups  Optional grouping variable.

col, border, lty, lwd  Graphical parameters for the bars. By default, the trellis parameter plot.polygon is used if there is no grouping variable, otherwise superpose.polygon is used. col gives the fill color, border the border color, and lty and lwd the line type and width of the borders.

...  Extra arguments will be accepted but ignored.

identifier  A character string that is prepended to the names of grobs that are created by this panel function.

Details

A barchart is drawn in the panel. Note that most arguments controlling the display can be supplied to the high-level barchart call directly.

Examples

barchart(yield ~ variety | site, data = barley,  
groups = year, layout = c(1,6), origin = 0,  
ylab = "Barley Yield (bushels/acre)",  
scales = list(x = list(abbreviate = TRUE,  
        minlength = 5))))
**F_1_panel.bwplot**

Default Panel Function for bwplot

Description

This is the default panel function for bwplot.

Usage

```
panel.bwplot(x, y, box.ratio = 1,
box.width = box.ratio / (1 + box.ratio),
horizontal = TRUE,
pch, col, alpha, cex,
font, fontfamily, fontface,
fill, varwidth = FALSE,
notch = FALSE, notch.frac = 0.5,
..., levels.fos,
stats = boxplot.stats,
coef = 1.5,
do.out = TRUE,
identifier = "bwplot")
```

Arguments

- `x, y` numeric vector or factor. Boxplots drawn for each unique value of `y` (`x`) if `horizontal` is TRUE (FALSE)
- `box.ratio` ratio of box thickness to inter box space
- `box.width` thickness of box in absolute units; overrides `box.ratio`. Useful for specifying thickness when the categorical variable is not a factor, as use of `box.ratio` alone cannot achieve a thickness greater than 1.
- `horizontal` logical. If FALSE, the plot is 'transposed' in the sense that the behaviours of `x` and `y` are switched. `x` is now the 'factor'. Interpretation of other arguments change accordingly. See documentation of `bwplot` for a fuller explanation.
- `pch, col, alpha, cex, font, fontfamily, fontface` graphical parameters controlling the dot. `pch="|"` is treated specially, by replacing the dot with a line (similar to `boxplot`)
- `fill` color to fill the boxplot
- `varwidth` logical. If TRUE, widths of boxplots are proportional to the number of points used in creating it.
- `notch` if `notch` is TRUE, a notch is drawn in each side of the boxes. If the notches of two plots do not overlap this is 'strong evidence' that the two medians differ (Chambers et al., 1983, p. 62). See `boxplot.stats` for the calculations used.
- `notch.frac` numeric in (0,1). When `notch=TRUE`, the fraction of the box width that the notches should use.
stats a function, defaulting to `boxplot.stats`, that accepts a numeric vector and returns a list similar to the return value of `boxplot.stats`. The function must accept arguments `coef` and `do.out` even if they do not use them (a ... argument is good enough). This function is used to determine the box and whisker plot.

coeff, `do.out` passed to `stats`

levels.fos numeric values corresponding to positions of the factor or shingle variable. For internal use.

... further arguments, ignored.

identifier A character string that is prepended to the names of grobs that are created by this panel function.

Details

Creates Box and Whisker plot of `x` for every level of `y` (or the other way round if `horizontal=FALSE`). By default, the actual boxplot statistics are calculated using `boxplot.stats`. Note that most arguments controlling the display can be supplied to the high-level `bwplot` call directly.

Although the graphical parameters for the dot representing the median can be controlled by optional arguments, many others can not. These parameters are obtained from the relevant settings parameters ("box.rectangle" for the box, "box.umbrella" for the whiskers and "plot.symbol" for the outliers).

Default Panel Function for cloud

Description

Default panel functions controlling cloud and wireframe displays.

Usage

panel.cloud(x, y, subscripts, z, 
groups = NULL, 
perspective = TRUE, 
distance = if (perspective) 0.2 else 0, 
xlim, ylim, zlim, 
panel.3d.cloud = "panel.3dscatter", 
panel.3d.wireframe = "panel.3dwire", 
screen = list(z = 40, x = -60), 
R.mat = diag(4), aspect = c(1, 1), 
par.box = NULL, 
xlab, ylab, zlab, 
xlab.default, ylab.default, zlab.default, 
scales.3d, 
proportion = 0.6, 
wireframe = FALSE, 
srpos, 
..., 
identifier = "cloud")

panel.wireframe(...)

panel.3dscatter(x, y, z, rot.mat, distance, 
groups, type = "p", 
xlim, ylim, zlim, 
xlim.scaled, ylim.scaled, zlim.scaled, 
zero.scaled, 
col, col.point, col.line, 
lty, lwd, cex, pch, fill, 
cross, ..., .scale = FALSE, subscripts, 
identifier = "3dscatter")

panel.3dwire(x, y, z, rot.mat = diag(4), distance, 
shade = FALSE, 
shade.colors.palette = trellis.par.get("shade.colors")$palette, 
light.source = c(0, 0, 1000), 
xlim, ylim, zlim, 
xlim.scaled, 
ylim.scaled, 
zlim.scaled, 
col = if (shade) "transparent" else "black", 
...
lty = 1, lwd = 1,
alpha,
col.groups = superpose.polygon$col,
polynum = 100,
..., .scale = FALSE,
drape = FALSE,
at,
col.regions = regions$col,
alpha.regions = regions$alpha,
identifier = "3dwire")

makeShadePalette(col.regions, ..., min = 0.05, pref = 0.75)

Arguments

x, y, z numeric (or possibly factors) vectors representing the data to be displayed. The interpretation depends on the context. For panel.cloud these are essentially the same as the data passed to the high level plot (except if formula was a matrix, the appropriate x and y vectors are generated). By the time they are passed to panel.3dscatter and panel.3dwire, they have been appropriately subsetted (using subscripts) and scaled (to lie inside a bounding box, usually the [-0.5, 0.5] cube).

Further, for panel.3dwire, x and y are shorter than z and represent the sorted locations defining a rectangular grid. Also in this case, z may be a matrix if the display is grouped, with each column representing one surface. In panel.cloud (called from wireframe) and panel.3dwire, x, y and z could also be matrices (of the same dimension) when they represent a 3-D surface parametrized on a 2-D grid.

subscripts index specifying which points to draw. The same x, y and z values (representing the whole data) are passed to panel.cloud for each panel. subscripts specifies the subset of rows to be used for the particular panel.

groups specification of a grouping variable, passed down from the high level functions.

perspective logical, whether to plot a perspective view. Setting this to FALSE is equivalent to setting distance to 0
distance numeric, between 0 and 1, controls amount of perspective. The distance of the viewing point from the origin (in the transformed coordinate system) is 1 / distance. This is described in a little more detail in the documentation for cloud

screen A list determining the sequence of rotations to be applied to the data before being plotted. The initial position starts with the viewing point along the positive z-axis, and the x and y axes in the usual position. Each component of the list should be named one of "x", "y" or "z" (repetitions are allowed), with their values indicating the amount of rotation about that axis in degrees.

R.mat initial rotation matrix in homogeneous coordinates, to be applied to the data before screen rotates the view further.

par.box graphical parameters for box, namely, col, lty and lwd. By default obtained from the parameter box.3d.
xlim, ylim, zlim
limits for the respective axes. As with other lattice functions, these could each be a numeric 2-vector or a character vector indicating levels of a factor.

panel.3d.cloud, panel.3d.wireframe
functions that draw the data-driven part of the plot (as opposed to the bounding box and scales) in cloud and wireframe. This function is called after the ‘back’ of the bounding box is drawn, but before the ‘front’ is drawn.
Any user-defined custom display would probably want to change these functions. The intention is to pass as much information to this function as might be useful (not all of which are used by the defaults). In particular, these functions can expect arguments called xlim, ylim, zlim which give the bounding box ranges in the original data scale and xlim.scaled, ylim.scaled, zlim.scaled which give the bounding box ranges in the transformed scale. More arguments can be considered on request.

aspect
aspect as in cloud

xlab, ylab, zlab
Labels, have to be lists. Typically the user will not manipulate these, but instead control this via arguments to cloud directly.

xlab.default for internal use
ylab.default for internal use
zlab.default for internal use

scales.3d list defining the scales

proportion numeric scalar, gives the length of arrows as a proportion of the sides

scpos A list with three components x, y and z (each a scalar integer), describing which of the 12 sides of the cube the scales should be drawn. The defaults should be OK. Valid values are: x: 1, 3, 9, 11; y: 8, 5, 7, 6 and z: 4, 2, 10, 12. (See comments in the source code of panel.cloud to see the details of this enumeration.)

wireframe logical, indicating whether this is a wireframe plot

drape logical, whether the facets will be colored by height, in a manner similar to levelplot. This is ignored if shade=TRUE.

at When drape = TRUE in wireframe, the facets defining the surface are colored as a function of (average) height, similar to levelplot. at is a numeric vector giving the breakpoints along the z-axis where colors change.

col.regions vector of colors to be used in conjunction with at when drape = TRUE.

In makeShadePalette, which can be used to define a shading palette (see below), col.regions is an initial vector defining the base color (as a function of height) that is then adjusted according to irradiance and reflectance.

alpha.regions numeric scalar controlling transparency when drape = TRUE.

rot.mat 4x4 transformation matrix in homogeneous coordinates. This gives the rotation matrix combining the screen and R.mat arguments to panel.cloud

type Character vector, specifying type of cloud plot. Can include one or more of "p", "l", "h" or "b". "p" and "l" mean ‘points’ and ‘lines’ respectively, and "b" means ‘both’. "h" stands for ‘histogram’, and causes a line to be drawn from each point to the X-Y plane (i.e., the plane representing z = 0), or the lower (or upper) bounding box face, whichever is closer.
xlim.scaled, ylim.scaled, zlim.scaled
axis limits (after being scaled to the bounding box)

zero.scaled  z-axis location (after being scaled to the bounding box) of the X-Y plane in the original data scale, to which lines will be dropped (if within range) from each point when type = "h"

cross      logical, defaults to TRUE if pch = "+". panel.3dscatter can represent each point by a 3d ‘cross’ of sorts (it’s much easier to understand looking at an example than from a description). This is different from the usual pch argument, and reflects the depth of the points and the orientation of the axes. This argument indicates whether this feature will be used.

This is useful for two reasons. It can be set to FALSE to use "+" as the plotting character in the regular sense. It can also be used to force this feature in grouped displays.

shade      logical, indicating whether the surface is to be colored using an illumination model with a single light source

shade.colors.palette
a function (or the name of one) that is supposed to calculate the color of a facet when shading is being used. Three pieces of information are available to the function: first, the cosine of the angle between the incident light ray and the normal to the surface (representing foreshortening); second, the cosine of half the angle between the reflected ray and the viewing direction (useful for non-Lambertian surfaces); and third, the scaled (average) height of that particular facet with respect to the total plot z-axis limits.

All three numbers should be between 0 and 1. The shade.colors.palette function should return a valid color. The default function is obtained from the trellis settings using makeShadePalette.

min    numeric, between 0 and 1, giving a minimum saturation in makeShadePalette

pref    numeric, giving a power that is applied to reflectance value before it is used to ‘darken’ the colors.

light.source    a 3-vector representing (in cartesian coordinates) the light source. This is relative to the viewing point being (0, 0, 1/distance) (along the positive z-axis), keeping in mind that all observations are bounded within the [-0.5, 0.5] cube

polynum    quadrilateral faces are drawn in batches of polynum at a time. Drawing too few at a time increases the total number of calls to the underlying grid.polygon function, which affects speed. Trying to draw too many at once may be unnecessarily memory intensive. This argument controls the trade-off.

col.groups    colors for different groups

col, col.point, col.line, lty, lwd, cex, pch, fill, alpha
Graphical parameters. Some other arguments (such as lex for line width) may also be passed through the ... argument.

...    other parameters, passed down when appropriate

.scale    Logical flag, indicating whether x, y, and z should be assumed to be in the original data scale and hence scaled before being plotted. x, y, and z are usually already scaled. However, setting .scale=TRUE may be helpful for calls to panel.3dscatter and panel.3dwire in user-supplied panel functions.
identifier A character string that is prepended to the names of grobs that are created by this panel function.

Details

These functions together are responsible for the content drawn inside each panel in cloud and wireframe. `panel.wireframe` is a wrapper to `panel.cloud`, which does the actual work.

`panel.cloud` is responsible for drawing the content that does not depend on the data, namely, the bounding box, the arrows/scales, etc. At some point, depending on whether `wireframe` is TRUE, it calls either `panel.3d.wireframe` or `panel.3d.cloud`, which draws the data-driven part of the plot.

The arguments accepted by these two functions are different, since they have essentially different purposes. For cloud, the data is unstructured, and \( x, y \) and \( z \) are all passed to the `panel.3d.cloud` function. For wireframe, on the other hand, \( x \) and \( y \) are increasing vectors with unique values, defining a rectangular grid. \( z \) must be a matrix with \( \text{length}(x) \times \text{length}(y) \) rows, and as many columns as the number of groups.

`panel.3dscatter` is the default `panel.3d.cloud` function. It has a `type` argument similar to `panel.xyplot`, and supports grouped displays. It tries to honour depth ordering, i.e., points and lines closer to the camera are drawn later, overplotting more distant ones. (Of course there is no absolute ordering for line segments, so an ad hoc ordering is used. There is no hidden point removal.)

`panel.3dwire` is the default `panel.3d.wireframe` function. It calculates polygons corresponding to the facets one by one, but waits till it has collected information about `polynum` facets, and draws them all at once. This avoids the overhead of drawing `grid.polygon` repeatedly, speeding up the rendering considerably. If `shade = TRUE`, these attempt to color the surface as being illuminated from a light source at `light.source`. `palette.shade` is a simple function that provides the default shading colors.

Multiple surfaces are drawn if `groups` is non-null in the call to `wireframe`, however, the algorithm is not sophisticated enough to render intersecting surfaces correctly.

```r
wireframe(volcano, shade = TRUE,
  shade.colors.palette = makeShadePalette(hcl.colors(10, "Inferno"),
  pref = 0.2))
wireframe(volcano, shade = TRUE,
  shade.colors.palette = makeShadePalette(hcl.colors(10, "Dark Mint"),
  pref = 0.2))
wireframe(volcano, shade = TRUE,
  shade.colors.palette = makeShadePalette(hcl.colors(10, "Harmonic"),
  pref = 0.2))
```
F_1_panel.densityplot  Default Panel Function for densityplot

Description

This is the default panel function for densityplot.

Usage

panel.densityplot(x, darg, plot.points = "jitter", ref = FALSE, 
groups = NULL, weights = NULL, jitter.amount, type, ..., 
grid = lattice.getOption("default.args")$grid, identifier = "density")

Arguments

x  data points for which density is to be estimated

darg  list of arguments to be passed to the density function. Typically, this should be a list with zero or more of the following components: bw, adjust, kernel, window, width, give.Rkern, n, from, to, cut, na.rm (see density for details)

plot.points  logical specifying whether or not the data points should be plotted along with the estimated density. Alternatively, a character string specifying how the points should be plotted. Meaningful values are "rug", in which case panel.rug is used to plot a 'rug', and "jitter", in which case the points are jittered vertically to better distinguish overlapping points.

ref  logical, whether to draw x-axis

groups  an optional grouping variable. If present, panel.superpose will be used instead to display each subgroup

weights  numeric vector of weights for the density calculations. If this is specified, the ... part must also include a subscripts argument that matches the weights to x.

jitter.amount  when plot.points="jitter", the value to use as the amount argument to jitter.

type  type argument used to plot points, if requested. This is not expected to be useful, it is available mostly to protect a type argument, if specified, from affecting the density curve.

...  extra graphical parameters. Note that additional arguments to panel.rug cannot be passed on through panel.densityplot.
grid A logical flag, character string, or list specifying whether and how a background grid should be drawn. In its general form, grid can be a list of arguments to be supplied to panel.grid, which is called with those arguments. Three shortcuts are available:

- TRUE: roughly equivalent to list(h = -1, v = -1)
- "h": roughly equivalent to list(h = -1, v = 0)
- "v": roughly equivalent to list(h = 0, v = -1)

No grid is drawn if grid = FALSE.

identifier A character string that is prepended to the names of grobs that are created by this panel function.

densityplot, jitter

Default Panel Function for dotplot

Description

Default panel function for dotplot.

Usage

panel.dotplot(x, y, horizontal = TRUE,
              pch, col, lty, lwd, col.line,
              levels.fos,
              groups = NULL,
              ...,
              grid = lattice.getOption("default.args")$grid,
              identifier = "dotplot")

Arguments

- x, y variables to be plotted in the panel. Typically y is the 'factor'
- horizontal logical. If FALSE, the plot is 'transposed' in the sense that the behaviours of x and y are switched. x is now the 'factor'. Interpretation of other arguments change accordingly. See documentation of bwplot for a fuller explanation.
- pch, col, lty, lwd, col.line graphical parameters
- levels.fos locations where reference lines will be drawn
groups grouping variable (affects graphical parameters)
... extra parameters, passed to panel.xyplot which is responsible for drawing the
foreground points (panel.dotplot only draws the background reference lines).
grid A logical flag, or list specifying whether and how a background grid should
be drawn. In its general form grid can be a list of arguments to be sup-
plied to panel.grid, which is called with those arguments. If FALSE, no grid
lines are drawn. grid = TRUE is roughly equivalent to list(h = 0, v = -1) if
horizontal = TRUE and list(h = -1, v = 0) if horizontal = FALSE. In other
words, grid lines are drawn only for the numeric axis, as reference lines for the
categorical axis are drawn regardless of the value of grid.
identifier A character string that is prepended to the names of grobs that are created by
this panel function.

Details

Creates (possibly grouped) Dotplot of x against y or vice versa

dotplot

panel.histogram(x, breaks, equal.widths = TRUE, type = "density",
nint = round(log2(length(x)) + 1), alpha, col, border, lty, lwd,
..., identifier = "histogram")
Arguments

- **x**: The data points for which the histogram is to be drawn
- **breaks**: The breakpoints for the histogram
- **equal.widths**: logical used when `breaks==NULL`
- **type**: Type of histogram, possible values being "percent", "density" and "count"
- **nint**: Number of bins for the histogram
- **alpha**, **col**, **border**, **lty**, **lwd**: graphical parameters for bars; defaults are obtained from the `plot.polygon` settings.
- **...**: other arguments, passed to `hist` when deemed appropriate
- **identifier**: A character string that is prepended to the names of grobs that are created by this panel function.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

- `histogram`

Description

These are the default panel functions for levelplot and contourplot. Also documented is an alternative raster-based panel function for use with levelplot.

Usage

```R
panel.levelplot(x, y, z,
    subscripts, at = pretty(z), shrink, labels,
    label.style = c("mixed", "flat", "align"),
    contour = FALSE, region = TRUE,
    col = add.line$col,
    lty = add.line$lty,
    lwd = add.line$lwd,
    border = "transparent",
    border.lty = 1,
    border.lwd = 0.1,
)```
\[
\text{region.type} = \text{c("grid", "contour")},
\text{col.regions} = \text{regions$col},
\text{alpha.regions} = \text{regions$alpha},
\text{identifier} = \text{"levelplot"})
\]

\[
\text{panel.contourplot}(\ldots)
\]

\[
\text{panel.levelplot.raster}(x, y, z,
\text{subscripts},
\text{at} = \text{pretty(z)},
\ldots,
\text{col.regions} = \text{regions$col},
\text{alpha.regions} = \text{regions$alpha},
\text{interpolate} = \text{FALSE},
\text{identifier} = \text{"levelplot"})
\]

**Arguments**

- **x, y, z** Variables defining the plot.
- **subscripts** Integer vector indicating what subset of x, y and z to draw.
- **at** Numeric vector giving breakpoints along the range of z. See `levelplot` for details.
- **shrink** Either a numeric vector of length 2 (meant to work as both x and y components), or a list with components x and y which are numeric vectors of length 2. This allows the rectangles to be scaled proportional to the z-value. The specification can be made separately for widths (x) and heights (y). The elements of the length 2 numeric vector gives the minimum and maximum proportion of shrinkage (corresponding to min and max of z).
- **labels** Either a logical scalar indicating whether the labels are to be drawn, or a character or expression vector giving the labels associated with the at values. Alternatively, labels can be a list with the following components:
  - **labels**: a character or expression vector giving the labels. This can be omitted, in which case the defaults will be used.
  - **col, cex, alpha**: graphical parameters for label texts
  - **fontfamily, fontface, font**: font used for the labels
- **label.style** Controls how label positions and rotation are determined. A value of "flat" causes the label to be positioned where the contour is flattest, and the label is not rotated. A value of "align" causes the label to be drawn as far from the boundaries as possible, and the label is rotated to align with the contour at that point. The default is to mix these approaches, preferring the flattest location unless it is too close to the boundaries.
- **contour** A logical flag, specifying whether contour lines should be drawn.
- **region** A logical flag, specifying whether inter-contour regions should be filled with appropriately colored rectangles.
- **col, lty, lwd** Graphical parameters for contour lines.
border
  Border color for rectangles used when region=TRUE.
border.lty, border.lwd
  Graphical parameters for the border
...
  Extra parameters.
region.type
  A character string, one of "grid" and "contour". The former (the default) uses a grid of rectangles to display the colors for the level plot; the latter uses a grid of polygons, mimicking the behavior of `filled.contour`, which gives a smoother appearance at the cost of increased processing time.
  The "contour" option requires x and y to be complete, in the sense that it must include all possible combinations in the underlying grid. However, z values are allowed to be missing.
col.regions
  A vector of colors, or a function to produce a vector of colors, to be used if region=TRUE. Each interval defined by at is assigned a color, so the number of colors actually used is one less than the length of at. See `level.colors` for details on how the color assignment is done.
alpha.regions
  numeric scalar controlling transparency of facets
interpolate
  logical, passed to `grid.raster`.
identifier
  A character string that is prepended to the names of grobs that are created by this panel function.

Details

The same panel function is used for both `levelplot` and `contourplot` (which differ only in default values of some arguments). `panel.contourplot` is a simple wrapper to `panel.levelplot`.

When contour=TRUE, the `contourLines` function is used to calculate the contour lines.

`panel.levelplot.raster` is an alternative panel function that uses the raster drawing abilities in R 2.11.0 and higher (through `grid.raster`). It has fewer options (e.g., can only render data on an equispaced grid), but can be more efficient. When using `panel.levelplot.raster`, it may be desirable to render the color key in the same way. This is possible, but must be done separately; see `levelplot` for details.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>.

The functionality of `region.type = "contour"` is based on code borrowed from the `gridGraphics` package, written by Zhijian (Jason) Wen and Paul Murrell and ported to lattice by Johan Larsson.

F_1_panel.pairs  Default Superpanel Function for splom

Description

This is the default superpanel function for splom.

Usage

panel.pairs(z,
    panel = lattice.getOption("panel.splom"),
    lower.panel = panel,
    upper.panel = panel,
    diag.panel = "diag.panel.splom",
    as.matrix = FALSE,
    groups = NULL,
    panel.subscripts,
    subscripts,
    pscales = 5,
    prepanel.limits = scale_limits,
    varnames = colnames(z),
    varname.col, varname.cex, varname.font,
    varname.fontfamily, varname.fontface,
    axis.text.col, axis.text.cex, axis.text.font,
    axis.text.fontfamily, axis.text.fontface,
    axis.text.lineheight,
    axis.line.col, axis.line.lty, axis.line.lwd,
    axis.line.alpha, axis.line.tck,
    ...
)

diag.panel.splom(x = NULL,
    varname = NULL, limits, at = NULL, labels = NULL,
    draw = TRUE, tick.number = 5,
    varname.col, varname.cex,
    varname.lineheight, varname.font,
    varname.fontfamily, varname.fontface,
    axis.text.col, axis.text.alpha,
axis.text.cex, axis.text.font, 
axis.text.fontfamily, axis.text.fontface, 
axis.text.lineheight, 
axis.line.col, axis.line.alpha, 
axis.line.lty, axis.line.lwd, 
axis.line.tck, 
...

Arguments

z The data frame used for the plot.

panel, lower.panel, upper.panel
The panel function used to display each pair of variables. If specified, lower.panel and upper.panel are used for panels below and above the diagonal respectively. In addition to extra arguments not recognized by panel.pairs, the list of arguments passed to the panel function also includes arguments named i and j, with values indicating the row and column of the scatterplot matrix being plotted.

diag.panel
The panel function used for the diagonals. See arguments to diag.panel.splom to know what arguments this function is passed when called. Use diag.panel=NULL to suppress plotting on the diagonal panels.

as.matrix logical. If TRUE, the layout of the panels will have origin on the top left instead of bottom left (similar to pairs). This is in essence the same functionality as provided by as.table for the panel layout

groups
Grouping variable, if any

panel.subscripts
logical specifying whether the panel function accepts an argument named subscripts.

subscripts
The indices of the rows of z that are to be displayed in this (super)panel.

pscales
Controls axis labels, passed down from splom. If pscales is a single number, it indicates the approximate number of equally-spaced ticks that should appear on each axis. If pscales is a list, it should have one component for each column in z, each of which itself a list with the following valid components:

- at: a numeric vector specifying tick locations
- labels: character vector labels to go with at
- limits: numeric 2-vector specifying axis limits (should be made more flexible at some point to handle factors)

These are specifications on a per-variable basis, and used on all four sides in the diagonal cells used for labelling. Factor variables are labelled with the factor names. Use pscales=0 to suppress the axes entirely.

prepanel.limits
A function to calculate suitable axis limits given a single argument x containing a data vector. The return value of the function should be similar to the xlim or ylim argument documented in xyplot: that is, it should be a numeric or Date/Time vector of length 2 defining a range, or a character vector representing levels of a factor.

Most high-level lattice plots (such as xyplot) use the prepanel function for deciding on axis limits from data. This function serves a similar function by
calculating the per-variable limits. These limits can be overridden by the corresponding limits component in the `pscales` list.

**x**
- data vector corresponding to that row / column (which will be the same for diagonal `panels`).

**varname**
- (scalar) character string or expression that is to be written centred within the panel

**limits**
- numeric of length 2, or, vector of characters, specifying the scale for that panel (used to calculate tick locations when missing)

**at**
- locations of tick marks

**labels**
- optional labels for tick marks

**draw**
- A logical flag specifying whether to draw the tick marks and labels. If `FALSE`, variable names are shown but axis annotation is omitted.

**tick.number**
- A numeric scalar giving the suggested number of tick marks.

**varnames**
- A character or expression vector or giving names to be used for the variables in `x`. By default, the column names of `x`.

**varname.col**
- Color for the variable name in each diagonal panel. See `gpar` for details on this and the other graphical parameters listed below.

**varname.cex**
- Size multiplier for the variable name in each diagonal panel.

**varname.lineheight**
- Line height for the variable name in each diagonal panel.

**varname.font, varname.fontfamily, varname.fontface**
- Font specification for the variable name in each diagonal panel.

**axis.text.col**
- Color for axis label text.

**axis.text.cex**
- Size multiplier for axis label text.

**axis.text.font, axis.text.fontfamily, axis.text.fontface**
- Font specification for axis label text.

**axis.text.lineheight**
- Line height for axis label text.

**axis.text.alpha**
- Alpha-transparency for axis label text.

**axis.line.col**
- Color for the axes.

**axis.line.lty**
- Line type for the axes.

**axis.line.lwd**
- Line width for the axes.

**axis.line.alpha**
- Alpha-transparency for the axes.

**axis.line.tck**
- A numeric multiplier for the length of tick marks in diagonal panels.

**...**
- Further arguments, passed on to `panel`, `lower.panel`, `upper.panel`, and `diag.panel` from `panel.pairs`. Currently ignored by `diag.panel.splom`.

**Details**

`panel.pairs` is the function that is actually used as the panel function in a "trellis" object produced by `splom`.
**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

splom

**Examples**

```r
Cmat <- outer(1:6, 1:6, 
    function(i,j) hcl.colors(11)[i+j-1]) ## rainbow(11, start=.12, end=.5)[i+j-1])

splom(~diag(6), as.matrix = TRUE, 
    panel = function(x, y, i, j, ...) { 
        panel.fill(Cmat[i,j]) 
        panel.text(.5,.5, paste("("i","",j")",sep=""))
    })
```

---

**F_1_panel.parallel**

*Default Panel Function for parallel*

**Description**

This is the default panel function for parallel.

**Usage**

```r
panel.parallel(x, y, z, subscripts, 
    groups = NULL, 
    col, lwd, lty, alpha, 
    common.scale = FALSE, 
    lower, 
    upper, 
    ..., 
    horizontal.axis = TRUE, 
    identifier = "parallel")
```

**Arguments**

- **x, y**
  
  dummy variables, ignored.

- **z**
  
  The data frame used for the plot. Each column will be coerced to numeric before being plotted, and an error will be issued if this fails.

- **subscripts**
  
  The indices of the rows of z that are to be displayed in this panel.

- **groups**
  
  An optional grouping variable. If specified, different groups are distinguished by use of different graphical parameters (i.e., rows of z in the same group share parameters).
col, lwd, lty, alpha

Graphical parameters (defaults to the settings for `superpose.line`). If `groups` is non-null, these parameters used one for each group. Otherwise, they are recycled and used to distinguish between rows of the data frame `z`.

**common.scale**

Logical, whether a common scale should be used columns of `z`. Defaults to `FALSE`, in which case the horizontal range for each column is different (as determined by `lower` and `upper`).

**lower, upper**

Numeric vectors replicated to be as long as the number of columns in `z`. Determines the lower and upper bounds to be used for scaling the corresponding columns of `z` after coercing them to numeric. Defaults to the minimum and maximum of each column. Alternatively, these could be functions (to be applied on each column) that return a scalar.

... other arguments (ignored)

**horizontal.axis**

Logical indicating whether the parallel axes should be laid out horizontally (`TRUE`) or vertically (`FALSE`).

**identifier**

A character string that is prepended to the names of grobs that are created by this panel function.

**Details**

Produces parallel coordinate plots, which are easier to understand from an example than through a verbal description. See example for `parallel`.

### F_1_panel.qqmath

**Default Panel Function for qqmath**

**Description**

This is the default panel function for `qqmath`. 
Usage

panel.qqmath(x, f.value = NULL,
             distribution = qnorm,
             qtype = 7,
             groups = NULL, ...,
             tails.n = 0,
             identifier = "qqmath")

Arguments

x      vector (typically numeric, coerced if not) of data values to be used in the panel.
f.value, distribution  Defines how quantiles are calculated. See qqmath for details.
qtype  The type argument to be used in quantile
groups  An optional grouping variable. Within each panel, one Q-Q plot is produced for every level of this grouping variable, differentiated by different graphical parameters.
...  Further arguments, often graphical parameters, eventually passed on to panel.xyplot. Arguments grid and abline of panel.xyplot may be particularly useful.
tails.n  number of data points to represent exactly on each tail of the distribution. This reproduces the effect of f.value = NULL for the extreme data values, while approximating the remaining data. It has no effect if f.value = NULL. If tails.n is given, qtype is forced to be 1.
identifier  A character string that is prepended to the names of grobs that are created by this panel function.

Details

Creates a Q-Q plot of the data and the theoretical distribution given by distribution. Note that most of the arguments controlling the display can be supplied directly to the high-level qqmath call.

Examples

set.seed(0)
x <- rt(10000, df = 10)
qqmath(~ x, pch = "+", distribution = qnorm,
       grid = TRUE, abline = c(0, 1),
       xlab.top = c("raw", "ppoints(100)", "tails.n = 50"),
       panel = function(..., f.value) {
         switch(panel.number(),
panel.qqmath(..., f.value = NULL),
panel.qqmath(..., f.value = ppoints(100)),
panel.qqmath(..., f.value = ppoints(100), tails.n = 50))
}

Description
This is the default panel function for stripplot. Also see panel.superpose

Usage
panel.stripplot(x, y, jitter.data = FALSE,
factor = 0.5, amount = NULL,
horizontal = TRUE, groups = NULL,
..., grid = lattice.getOption("default.args")$grid,
identifier = "stripplot")

Arguments
x, y coordinates of points to be plotted
jitter.data whether points should be jittered to avoid overplotting. The actual jittering is
performed inside panel.xyplot, using its jitter.x or jitter.y argument (depending on the value of horizontal).
factor, amount amount of jittering, see jitter
horizontal logical. If FALSE, the plot is 'transposed' in the sense that the behaviours of
x and y are switched. x is now the 'factor'. Interpretation of other arguments change accordingly. See documentation of bwplot for a fuller explanation.
groups optional grouping variable
... additional arguments, passed on to panel.xyplot
grid A logical flag, character string, or list specifying whether and how a background
grid should be drawn. In its general form, grid can be a list of arguments to be
supplied to panel.grid, which is called with those arguments. Three shortcuts
are available:
TRUE: roughly equivalent to list(h = -1, v = -1)
"h": roughly equivalent to list(h = -1, v = 0)
"v": roughly equivalent to list(h = 0, v = -1)
No grid is drawn if grid = FALSE.
identifier A character string that is prepended to the names of grobs that are created by
this panel function.
Details

Creates stripplot (one dimensional scatterplot) of \( x \) for each level of \( y \) (or vice versa, depending on the value of horizontal).

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

stripplot, jitter

Usage

\[
\text{panel.xyplot}(x, y, \text{type} = \text{"p"}, \\
\quad \text{groups = NULL,} \\
\quad \text{pch, col, col.line, col.symbol,} \\
\quad \text{font, fontfamily, fontface,} \\
\quad \text{lty, cex, fill, lwd,} \\
\quad \text{horizontal = FALSE, ...,} \\
\quad \text{smooth = NULL,} \\
\quad \text{grid = lattice.getOption("default.args")$grid,} \\
\quad \text{abline = NULL,} \\
\quad \text{jitter.x = FALSE, jitter.y = FALSE,} \\
\quad \text{factor = 0.5, amount = NULL,} \\
\quad \text{identifier = "xyplot")} \\
\]

\[\text{panel.splom}(..., \text{identifier = "splom")} \]

\[\text{panel.qq}(..., \text{identifier = "qq")} \]

Arguments

\( x, y \)

variables to be plotted in the scatterplot

\( \text{type} \)

character vector controlling how \( x \) and \( y \) are to be plotted. Can consist of one or more of the following: "p", "l", "h", "b", "o", "s", "S", "g", "r", "a", "smooth", and "spline". If \( \text{type} \) has more than one element, an attempt is made to combine the effect of each of the components.

The behaviour if any of the first five are included in \( \text{type} \) is similar to the effect of the corresponding type in \text{plot}: "p" and "l" stand for points and lines.
respectively; "b" and "o" (for 'overlay') plot both; "h" draws vertical (or horizontal if horizontal = TRUE) line segments from the points to the origin. Types "s" and "S" are like "l" in the sense that they join consecutive points, but instead of being joined by a straight line, points are connected by a vertical and a horizontal segment forming a 'step', with the vertical segment coming first for "s", and the horizontal segment coming first for "S". Types "s" and "S" sort the values along one of the axes (depending on horizontal); this is unlike the behavior in plot. For the latter behavior, use type = "s" with panel = panel.points.

Type "g" adds a reference grid using panel.grid in the background, but using the grid argument is now the preferred way to do so.

The remaining values of type lead to various types of smoothing. This can also be achieved using the smooth argument, or by calling the relevant panel functions directly. The panel functions provide finer control over graphical and other parameters, but using smooth or type is convenient for simple usage. Using smooth is recommended, but type is also supported for backwards compatibility.

Type "r" adds a linear regression line, "smooth" adds a loess fit, "spline" adds a cubic smoothing spline fit, and "a" draws line segments joining the average y value for each distinct x value. See smooth for details.

See example(xyplot) and demo(lattice) for examples.

groups an optional grouping variable. If present, panel.superpose will be used instead to display each subgroup.

col, col.line, col.symbol
default colours are obtained from plot.symbol and plot.line using trellis.par.get.

font, fontface, fontfamily
font used when pch is a character.

pch, lty, cex, lwd, fill
other graphical parameters. fill serves the purpose of bg in points for certain values of pch.

horizontal A logical flag controlling the orientation for certain type's, e.g., "h", "s", ans "S" and the result of smoothing.

... Extra arguments, if any, for panel.xyplot. Usually passed on as graphical parameters to low level plotting functions, or to the panel functions performing smoothing, if applicable.

smooth If specified, indicates the type of smooth to be added. Can be a character vector containing one or more values from "lm", "loess", "spline", and "average". Can also be a logical flag; TRUE is interpreted as "loess". Each of these result in calling a corresponding panel function as described below; the smooth argument simply provides a convenient shortcut.

"lm" adds a linear regression line (same as panel.lmline, except for default graphical parameters). "loess" adds a loess fit (same as panel.loess). "spline" adds a cubic smoothing spline fit (same as panel.spline). "average" has the effect of calling panel.average, which in conjunction with a groups argument can be useful for creating interaction plots.
Normally, smoothing is performed with the \( y \) variable as the response and the \( x \) variable as the predictor. However, the roles of \( x \) and \( y \) are reversed if `horizontal = TRUE`.

**grid**
A logical flag, character string, or list specifying whether and how a background grid should be drawn. This provides the same functionality as `type="g"`, but is the preferred alternative as the effect `type="g"` is conceptually different from that of other type values (which are all data-dependent). Using the `grid` argument also allows more flexibility. Most generally, `grid` can be a list of arguments to be supplied to `panel.grid`, which is called with those arguments. Three shortcuts are available:
- `TRUE`: roughly equivalent to `list(h = -1, v = -1)`
- "h": roughly equivalent to `list(h = -1, v = 0)`
- "v": roughly equivalent to `list(h = 0, v = -1)`

No grid is drawn if `grid = FALSE`.

**abline**
A numeric vector or more generally a list containing arguments that are used to call `panel.abline`. If specified as a numeric vector, `abline` is used as the first unnamed argument to `panel.abline`. This allows arguments of the form `abline = c(0, 1)`, which adds the diagonal line, or `abline = coef(fm)` to fit the regression line from a fitted mode. Use the list form for finer control; e.g., `abline = list(h = 0, v = 0, col = "grey")`. For more flexibility, use `panel.abline` directly.

**jitter.x, jitter.y**

- logical, whether the data should be jittered before being plotted.
- factor, amount controls amount of jittering.
- identifier A character string that is prepended to the names of grobs that are created by this panel function.

**Details**
Creates scatterplot of \( x \) and \( y \), with various modifications possible via the type argument. `panel.qq` draws a 45 degree line before calling `panel.xyplot`.

Note that most of the arguments controlling the display can be supplied directly to the high-level (e.g. `xyplot`) call.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**Examples**

```r

types.plain <- c("p", "l", "o", "r", "g", "s", "S", "h", "a", "smooth")
types.horiz <- c("s", "S", "h", "a", "smooth")
```
horiz <- rep(c(FALSE, TRUE), c(length(types.plain), length(types.horiz)))

types <- c(types.plain, types.horiz)

x <- sample(seq(-10, 10, length.out = 15), 30, TRUE)
y <- x + 0.25 * (x + 1)^2 + rnorm(length(x), sd = 5)

xyplot(y ~ x | gl(1, length(types)),
      xlab = "type",
      ylab = list(c("horizontal=TRUE", "horizontal=FALSE"), y = c(1/6, 4/6)),
      as.table = TRUE, layout = c(5, 3),
      between = list(y = c(0, 1)),
      strip = function(...) {
        panel.fill(trellis.par.get("strip.background")$col[1])
        type <- types[panel.number()]
        grid::grid.text(label = sprintf("\"%s\"", type),
                        x = 0.5, y = 0.5)
        grid::grid.rect()
      },
      scales = list(alternating = c(0, 2), tck = c(0, 0.7), draw = FALSE),
      par.settings =
      list(layout.widths = list(strip.left = c(1, 0, 0, 0, 0))),
      panel = function(...) {
        type <- types[panel.number()]
        horizontal <- horiz[panel.number()]
        panel.xyplot(...,
                     type = type,
                     horizontal = horizontal)
      })[rep(1, length(types))]

F_2_2llines

Replacements of traditional graphics functions

Description
These functions are intended to replace common low level traditional graphics functions, primarily for use in panel functions. The originals can not be used (at least not easily) because lattice panel functions need to use grid graphics. Low level drawing functions in grid can be used directly as well, and is often more flexible. These functions are provided for convenience and portability.

Usage

lplot.xy(xy, type, pch, lty, col, cex, lwd,
        font, fontfamily, fontface,
        col.line, col.symbol, alpha, fill,
        origin = 0, ..., identifier, name.type)

llines(x, ...)
lpoints(x, ...)
ltext(x, ...)

## Default S3 method:
llines(x, y = NULL, type = "l",
col, alpha, lty, lwd, ..., identifier, name.type)
## Default S3 method:
lpoints(x, y = NULL, type = "p", col, pch, alpha, fill,
font, fontfamily, fontface, cex, ..., identifier, name.type)
## Default S3 method:
ltext(x, y = NULL, labels = seq_along(x),
col, alpha, cex, srt = 0,
lineheight, font, fontfamily, fontface,
adj = c(0.5, 0.5), pos = NULL, offset = 0.5, ..., identifier, name.type)

lsegments(x0, y0, x1, y1, x2, y2,
col, alpha, lty, lwd,
font, fontface, ..., identifier, name.type)
lrect(xleft, ybottom, xright, ytop,
x = (xleft + xright) / 2,
y = (ybottom + ytop) / 2,
width = xright - xleft,
height = ytop - ybottom,
col = "transparent",
border = "black",
lty = 1, lwd = 1, alpha = 1,
just = "center",
hjust = NULL, vjust = NULL,
font, fontface,
..., identifier, name.type)
larrows(x0 = NULL, y0 = NULL, x1, y1, x2 = NULL, y2 = NULL,
angle = 30, code = 2, length = 0.25, unit = "inches",
ends = switch(code, "first", "last", "both"),
type = "open",
col = add.line$col,
alpha = add.line$alpha,
lty = add.line$lty,
lwd = add.line$lwd,
fill = NULL,
font, fontface,
..., identifier, name.type)
lpolygon(x, y = NULL,
border = "black", col = "transparent", fill = NULL,
font, fontface, ..., identifier, name.type)

panel.lines(...)
panel.points(...)
panel.segments(....)
panel.text(...)
panel.rect(...)
panel.arrows(...)
panel.polygon(...)

Arguments

\(x, y, x0, y0, x1, y1, x2, y2, xy\)
locations. \(x2\) and \(y2\) are available for for S compatibility.

length, unit
determines extent of arrow head. length specifies the length in terms of unit,
which can be any valid grid unit as long as it doesn’t need a data argument. unit
defaults to inches, which is the only option in the base version of the function, arrows.

angle, code, type, labels, srt, adj, pos, offset
arguments controlling behaviour. See respective base functions for details. For
larrows and panel.larrows, type is either "open" or "closed", indicating
the type of arrowhead.

eventserves the same function as code, using descriptive names rather than integer
codes. If specified, this overrides code.

col, alpha, lty, lwd, fill, pch, cex, lineheight, font, fontfamily, fontface, col.line, col.symbol, border

... graphical parameters. fill applies to points when \(pch\) is in \(21:25\) and specifies
the fill color, similar to the bg argument in the base graphics function \texttt{points}.
For devices that support alpha-transparency, a numeric argument \texttt{alpha} between
0 and 1 can controls transparency. Be careful with this, since for devices that
do not support alpha-transparency, nothing will be drawn at all if this is set to
anything other than 0.

fill, font and fontface are included in \texttt{lrect}, \texttt{larrows}, \texttt{lpolygon}, and
\texttt{lsegments} only to ensure that they are not passed down (as \texttt{gpar} does not like
them).

origin
for type="h" or type="H", the value to which lines drop down.
xleft, ybottom, xright, ytop
see \texttt{rect}

width, height, just, hjust, vjust
finer control over rectangles, see \texttt{grid.rect}

... extra arguments, passed on to lower level functions as appropriate.

identifier
A character string that is prepended to the name of the grob that is created.

name.type
A character value indicating whether the name of the grob should have panel or
strip information added to it. Typically either "panel", "strip", "strip.left",
or "" (for no extra information).

Details

These functions are meant to be grid replacements of the corresponding base R graphics functions,
to allow existing Trellis code to be used with minimal modification. The functions panel.* are
essentially identical to the \texttt{l*} versions, are recommended for use in new code (as opposed to ported
code) as they have more readable names.

See the documentation of the base functions for usage. Not all arguments are always supported. All
these correspond to the default methods only.
Note

There is a new type="H" option wherever appropriate, which is similar to type="h", but with horizontal lines.

**F_2_panel.functions**  
*Useful Panel Function Components*

**Description**

These are predefined panel functions available in lattice for use in constructing new panel functions (often on-the-fly).

**Usage**

```r
panel.abline(a = NULL, b = 0,
            h = NULL, v = NULL,
            reg = NULL, coef = NULL,
            col, col.line, lty, lwd, alpha, type,
            ..., reference = FALSE,
            identifier = "abline")

panel.refline(...)

panel.curve(expr, from, to, n = 101,
            curve.type = "l",
            col, lty, lwd, type,
            ..., identifier = "curve")

panel.rug(x = NULL, y = NULL,
          regular = TRUE,
          start = if (regular) 0 else 0.97,
          end = if (regular) 0.03 else 1,
          x.units = rep("npc", 2),
          y.units = rep("npc", 2),
          col, col.line, lty, lwd, alpha,
          ..., identifier = "rug")

panel.average(x, y, fun = mean, horizontal = TRUE,
```
lwd, lty, col, col.line, type,
..., identifier = "linejoin")
panel.linejoin(x, y, fun = mean, horizontal = TRUE,
lwd, lty, col, col.line, type,
..., identifier = "linejoin")

panel.fill(col, border, ..., identifier = "fill")
panel.grid(h=3, v=3, col, col.line, lty, lwd, x, y, ..., identifier = "grid")
panel.lmline(x, y, ..., identifier = "lmline")
panel.mathdensity(dmath = dnorm, args = list(mean=0, sd=1),
n = 50, col, col.line, lwd, lty, type,
..., identifier = "mathdensity")

Arguments

x, y    Variables defining the contents of the panel. In panel.grid these are optional and are used only to choose an appropriate method of pretty.
a, b    Coefficients of the line to be added by panel.abline. a can be a vector of length 2, representing the coefficients of the line to be added, in which case b should be missing. a can also be an appropriate ‘regression’ object, i.e., an object which has a coef method that returns a length 2 numeric vector. The corresponding line will be plotted. The reg argument overrides a if specified.
_coef  Coefficients of the line to be added as a vector of length 2.
reg    A (linear) regression object, with a coef method that gives the coefficients of the corresponding regression line.
h, v    For panel.abline, these are numeric vectors giving locations respectively of horizontal and vertical lines to be added to the plot, in native coordinates. For panel.grid, these usually specify the number of horizontal and vertical reference lines to be added to the plot. Alternatively, they can be negative numbers. h=-1 and v=-1 are intended to make the grids aligned with the axis labels. This doesn’t always work; all that actually happens is that the locations are chosen using pretty, which is also how the label positions are chosen in the most common cases (but not for factor variables, for instance). h and v can be negative numbers other than -1, in which case -h and -v (as appropriate) is supplied as the n argument to pretty.
If x and/or y are specified in panel.grid, they will be used to select an appropriate method for pretty. This is particularly useful while plotting date-time objects.
reference A logical flag determining whether the default graphical parameters for panel.abline should be taken from the “reference.line” parameter settings. The default is to take them from the “add.line” settings. The panel.refline function is a wrapper around panel.abline that calls it with reference = TRUE.
expr  An expression considered as a function of \( x \), or a function, to be plotted as a curve.

n  The number of points to use for drawing the curve.

from, to  optional lower and upper x-limits of curve. If missing, limits of current panel are used

curve.type  Type of curve ("p" for points, etc), passed to \texttt{llines}

regular  A logical flag indicating whether the ‘rug’ is to be drawn on the ‘regular’ side (left / bottom) or not (right / top).

start, end  endpoints of rug segments, in normalized parent coordinates (between 0 and 1). Defaults depend on value of regular, and cover 3% of the panel width and height.

x.units, y.units  Character vectors, replicated to be of length two. Specifies the (grid) units associated with \( \text{start} \) and \( \text{end} \) above. \texttt{x.units} and \texttt{y.units} are for the rug on the x-axis and y-axis respectively (and thus are associated with \text{start} and \text{end} values on the y and x scales respectively).

col, col.line, lty, lwd, alpha, border  Graphical parameters.

type  Usually ignored by the panel functions documented here; the argument is present only to make sure an explicitly specified type argument (perhaps meant for another function) does not affect the display.

fun  The function that will be applied to the subset of \( x \) values (or \( y \) if \texttt{horizontal} is \texttt{FALSE}) determined by the unique values of \( y \) (\( x \)).

horizontal  A logical flag. If \texttt{FALSE}, the plot is ‘transposed’ in the sense that the roles of \( x \) and \( y \) are switched; \( x \) is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of \texttt{bwplot} for a fuller explanation.

dmath  A vectorized function that produces density values given a numeric vector named \( x \), e.g., \texttt{dnorm}.

args  A list giving additional arguments to be passed to \texttt{dmath}.

...  Further arguments, typically graphical parameters, passed on to other low-level functions as appropriate. Color can usually be specified by \texttt{col}, \texttt{col.line}, and \texttt{col.symbol}, the last two overriding the first for lines and points respectively.

identifier  A character string that is prepended to the names of grobs that are created by this panel function.

**Details**

\texttt{panel.abline} adds a line of the form \( y = a + b \times x \), or vertical and/or horizontal lines. Graphical parameters are obtained from the “add.line” settings by default. \texttt{panel.refline} is similar, but uses the “reference.line” settings for the defaults.

\texttt{panel.grid} draws a reference grid.

\texttt{panel.curve} adds a curve, similar to what \texttt{curve} does with \texttt{add = TRUE}. Graphical parameters for the curve are obtained from the “add.line” setting.
panel.average treats one of x and y as a factor (according to the value of horizontal), calculates fun applied to the subsets of the other variable determined by each unique value of the factor, and joins them by a line. Can be used in conjunction with panel.xyplot, and more commonly with panel.superpose to produce interaction plots.

panel.linejoin is an alias for panel.average. It is retained for back-compatibility, and may go away in future.

panel.mathdensity plots a (usually theoretical) probability density function. This can be useful in conjunction with histogram and densityplot to visually assess goodness of fit (note, however, that qqmath is more suitable for this).

panel.rug adds a rug representation of the (marginal) data to the panel, much like rug. panel.lmline(x, y) is equivalent to panel.abline(lm(y ~ x)).

Examples

## Interaction Plot

bwplot(yield ~ site, barley, groups = year, 
  panel = function(x, y, groups, subscripts, ...) {
    panel.grid(h = -1, v = 0)
    panel.stripplot(x, y, ..., jitter.data = TRUE, grid = FALSE, 
      groups = groups, subscripts = subscripts)
    panel.superpose(x, y, ..., panel.groups = panel.average, grid = FALSE, 
      groups = groups, subscripts = subscripts)
  },
  auto.key = list(points = FALSE, lines = TRUE, columns = 2))

## Superposing a fitted normal density on a Histogram

histogram(~ height | voice.part, data = singer, layout = c(2, 4),
  type = "density", border = "transparent", col.line = "grey60",
  xlab = "Height (inches)",
  ylab = "Density Histogram \n with Normal Fit",
  panel = function(x, ...) {
    panel.histogram(x, ...)
    panel.mathdensity(dmath = dnorm,
      args = list(mean = mean(x), sd = sd(x)), ...)
  })
Panel Function to Add a LOESS Smooth

Description

A predefined panel function that can be used to add a LOESS smooth based on the provided data.

Usage

panel.loess(x, y, span = 2/3, degree = 1,
               family = c("symmetric", "gaussian"),
               evaluation = 50,
               lwd, lty, col, col.line, type,
               horizontal = FALSE,
               ..., identifier = "loess")

Arguments

x, y Variables defining the data to be used.

lwd, lty, col, col.line Graphical parameters for the added line. col.line overrides col.

type Ignored. The argument is present only to make sure that an explicitly specified type argument (perhaps meant for another function) does not affect the display.

span, degree, family, evaluation Arguments to loess.smooth, for which panel.loess is essentially a wrapper.

horizontal A logical flag controlling which variable is to be treated as the predictor (by default x) and which as the response (by default y). If TRUE, the plot is ‘transposed’ in the sense that y becomes the predictor and x the response. (The name ‘horizontal’ may seem an odd choice for this argument, and originates from similar usage in bwplot).

... Extra arguments, passed on to panel.lines.

identifier A character string that is prepended to the names of grobs that are created by this panel function.

Value

The object returned by loess.smooth.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

Lattice, loess.smooth, prepanel.loess
Useful panel function with `qqmath`. Draws a line passing through the points (usually) determined by the .25 and .75 quantiles of the sample and the theoretical distribution.

```r
panel.qqmathline(x, y=x, 
distribution = qnorm, 
probs = c(0.25, 0.75), 
qtype = 7, 
groups = NULL, 
..., 
identifier = "qqmathline")
```

**Arguments**

- `x` The original sample, possibly reduced to a fewer number of quantiles, as determined by the `f.value` argument to `qqmath`
- `y` an alias for `x` for backwards compatibility
- `distribution` quantile function for reference theoretical distribution.
- `probs` numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.
- `qtype` the type of quantile computation used in `quantile`
- `groups` optional grouping variable. If non-null, a line will be drawn for each group.
- `...` other arguments.
- `identifier` A character string that is prepended to the names of grobs that are created by this panel function.

`prepanel.qqmathline, qqmath, quantile`
F_2_panel.smoothScatter

Lattice panel function analogous to smoothScatter

Description

This function allows the user to place smoothScatter plots in lattice graphics.

Usage

panel.smoothScatter(x, y = NULL, 
nbin = 64, cuts = 255, 
bandwidth, 
col.regions, 
colramp, 	nrpoints = 100, 
transformation = function(x) x^0.25, 
pch = ".", 
cex = 1, col="black", 
rangep.x, 
..., 
raster = FALSE, 
subscripts, 
identifier = "smoothScatter")

Arguments

x Numeric vector containing x-values or n by 2 matrix containing x and y values.
y Numeric vector containing y-values (optional). The length of x must be the same as that of y.
nbin Numeric vector of length 1 (for both directions) or 2 (for x and y separately) containing the number of equally spaced grid points for the density estimation.
cuts number of cuts defining the color gradient
bandwidth Numeric vector: the smoothing bandwidth. If missing, these functions come up with a more or less useful guess. This parameter then gets passed on to the function bkde2D.
col.regions character vector of colors, or a function producing such a vector. Defaults to the col component of the regions setting of the current theme.
colramp Function accepting an integer n as an argument and returning n colors. If missing, the default is derived from col.regions with the following modification: if col.regions is a vector of colors, it is prepended by "white" before being converted into a function using colorRampPalette.
nrpoints Numeric vector of length 1 giving number of points to be superimposed on the density image. The first nrpoints points from those areas of lowest regional densities will be plotted. Adding points to the plot allows for the identification of outliers. If all points are to be plotted, choose nrpoints = Inf.
transformation  Function that maps the density scale to the color scale.
pch, cex      graphical parameters for the nrpoints “outlying” points shown in the display
range.x      see bkde2d for details.
col          points color parameter
...          Further arguments that are passed on to panel.levelplot.
raster       logical; if TRUE, panel.levelplot.raster is used, making potentially smaller output files.
subscripts    ignored, but necessary for handling of ... in certain situations. Likely to be removed in future.
identifier   A character string that is prepended to the names of grobs that are created by this panel function.

Details

This replicates the display part of the smoothScatter function by replacing standard graphics calls by grid-compatible ones.

Value

The function is called for its side effects, namely the production of the appropriate plots on a graphics device.

Author(s)

Deepayan Sarkar <deepayan.sarkar@r-project.org>

Examples

ddf <- as.data.frame(matrix(rnorm(40000), ncol = 4) + 1.5 * rnorm(10000))
ddf[, c(2,4)] <- (-ddf[, c(2,4)])
xyplot(V1 ~ V2 + V3, ddf, outer = TRUE,
       panel = panel.smoothScatter, aspect = "iso")
## argument to panel.levelplot
xyplot(V1 ~ V2, ddf, panel = panel.smoothScatter, cuts = 10,
       region.type = "contour")
splom(ddf, panel = panel.smoothScatter, nbin = 64, raster = TRUE)
F_2_panel.spline

Panel Function to Add a Spline Smooth

Description
A predefined panel function that can be used to add a spline smooth based on the provided data.

Usage
panel.spline(x, y, npoints = 101, lwd = plot.line$lwd, lty = plot.line$lty, col, col.line = plot.line$col, type, horizontal = FALSE, ..., keep.data = FALSE, identifier = "spline")

Arguments
x, y Variables defining the data to be used.
npoints The number of equally spaced points within the range of the predictor at which the fitted model is evaluated for plotting.
lwd, lty, col, col.line Graphical parameters for the added line. col.line overrides col.
type Ignored. The argument is present only to make sure that an explicitly specified type argument (perhaps meant for another function) does not affect the display.
horizontal A logical flag controlling which variable is to be treated as the predictor (by default x) and which as the response (by default y). If TRUE, the plot is ‘transposed’ in the sense that y becomes the predictor and x the response. (The name ‘horizontal’ may seem an odd choice for this argument, and originates from similar usage in bwplot).
keep.data Passed on to smooth.spline. The default here (FALSE) is different, and results in the original data not being retained in the fitted spline model. It may be useful to set this to TRUE if the return value of panel.spline, which is the fitted model as returned by smooth.spline, is to be used for subsequent computations.
... Extra arguments, passed on to smooth.spline and panel.lines as appropriate.
identifier A character string that is prepended to the names of grobs that are created by this panel function.

Value
The fitted model as returned by smooth.spline.

F_2_panel.superpose  Panel Function for Display Marked by groups

Description

These are panel functions for Trellis displays useful when a grouping variable is specified for use within panels. The x (and y where appropriate) variables are plotted with different graphical parameters for each distinct value of the grouping variable.

Usage

panel.superpose(x, y = NULL, subscripts, groups, 
    panel.groups = "panel.xyplot", 
    ..., 
    col, col.line, col.symbol, 
    pch, cex, fill, font, 
    fontface, fontfamily, 
    lty, lwd, alpha, 
    type = "p", 
    grid = lattice.getOption("default.args")$grid, 
    distribute.type = FALSE)
panel.superpose.2(..., distribute.type = TRUE)

panel.superpose.plain(..., 
    col, col.line, col.symbol, 
    pch, cex, fill, font, 
    fontface, fontfamily, 
    lty, lwd, alpha)

Arguments

x, y  Coordinates of the points to be displayed. Usually numeric.

panel.groups  The panel function to be used for each subgroup of points. Defaults to panel.xyplot. To be able to distinguish between different levels of the originating group inside panel.groups, it will be supplied two special arguments called group.number and group.value which will hold the numeric code and factor level corresponding to the current level of groups. No special care needs to be taken when writing a panel.groups function if this feature is not used.
subscripts

An integer vector of subscripts giving indices of the x and y values in the original data source. See the corresponding entry in `xyplot` for details.

groups

A grouping variable. Different graphical parameters will be used to plot the subsets of observations given by each distinct value of `groups`. The default graphical parameters are obtained from the "superpose.symbol" and "superpose.line" settings using `trellis.par.get` wherever appropriate.

type

Usually a character vector specifying how each group should be drawn. Formally, it is passed on to the `panel.groups` function, which must know what to do with it. By default, `panel.groups` is `panel.xyplot`, whose help page describes the admissible values.

The functions `panel.superpose` and `panel.superpose.2` differ only in the default value of `distribute.type`, which controls the way the `type` argument is interpreted. If `distribute.type = FALSE`, then the interpretation is the same as for `panel.xyplot` for each of the unique groups. In other words, if `type` is a vector, all the individual components are honoured concurrently. If `distribute.type = TRUE`, `type` is replicated to be as long as the number of unique values in `groups`, and one component used for the points corresponding to the each different group. Even in this case, it is possible to request multiple types per group, specifying `type` as a list, each component being the desired type vector for the corresponding group.

If `distribute.type = FALSE`, any occurrence of "g" in `type` causes a grid to be drawn, and all such occurrences are removed before `type` is passed on to `panel.groups`.

grid

Logical flag specifying whether a background reference grid should be drawn. See `panel.xyplot` for details.

col

A vector color specification. See Details.

col.line

A vector color specification. See Details.

col.symbol

A vector color specification. See Details.

pch

A vector plotting character specification. See Details.

cex

A vector size factor specification. See Details.

fill

A vector fill color specification. See Details.

font, fontface, fontfamily

A vector color specification. See Details.

lty

A vector color specification. See Details.

lwd

A vector color specification. See Details.

alpha

A vector alpha-transparency specification. See Details.

...

Extra arguments. Passed down to `panel.superpose` from `panel.superpose.2`, and to `panel.groups` from `panel.superpose`.

distribute.type

Logical controlling interpretation of the `type` argument.
Details

panel.superpose divides up the x (and optionally y) variable(s) by the unique values of groups[subscripts], and plots each subset with different graphical parameters. The graphical parameters (col, symbol, pch, etc.) are usually supplied as suitable atomic vectors, but can also be lists. When panel.groups is called for the i-th level of groups, the corresponding element of each graphical parameter is passed to it. In the list form, the individual components can themselves be vectors.

The actual plot for each subgroup is created by the panel.groups function. With the default panel.groups, the col argument is overridden by col.line and col.symbol for lines and points respectively, which default to the "superpose.line" and "superpose.symbol" settings. However, col will still be supplied as an argument to panel.groups functions that make use of it, with a default of "black". The defaults of other graphical parameters are also taken from the "superpose.line" and "superpose.symbol" settings as appropriate. The alpha parameter takes it default from the "superpose.line" setting.

panel.superpose and panel.superpose.2 differ essentially in how type is interpreted by default. The default behaviour in panel.superpose is the opposite of that in S, which is the same as that of panel.superpose.2.

panel.superpose.plain is the same as panel.superpose, except that the default settings for the style arguments are the same for all groups and are taken from the default plot style. It is used in xyplot.ts.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org> (panel.superpose.2 originally contributed by Neil Klepeis)

See Also

Different functions when used as panel.groups gives different types of plots, for example panel.xyplot, panel.dotplot and panel.average (This can be used to produce interaction plots).

See Lattice for an overview of the package, and xyplot for common arguments (in particular, the discussion of the extended formula interface and the groups argument).

F_2_panel.violin  Panel Function to create Violin Plots

Description

This is a panel function that can create a violin plot. It is typically used in a high-level call to bwplot.

Usage

panel.violin(x, y, box.ratio = 1, box.width,
            horizontal = TRUE,
            alpha, border, lty, lwd, col,
Arguments

x, y  numeric vector or factor. Violin plots are drawn for each unique value of y (x) if horizontal is TRUE (FALSE)

box.ratio  ratio of the thickness of each violin and inter violin space

box.width  thickness of the violins in absolute units; overrides box.ratio. Useful for specifying thickness when the categorical variable is not a factor, as use of box.ratio alone cannot achieve a thickness greater than 1.

horizontal  logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of x and y are switched. x is now the ‘factor’. See documentation of bwplot for a fuller explanation.

alpha, border, lty, lwd, col  graphical parameters controlling the violin. Defaults are taken from the "plot.polygon" settings.

varwidth  logical. If FALSE, the densities are scaled separately for each group, so that the maximum value of the density reaches the limit of the allocated space for each violin (as determined by box.ratio). If TRUE, densities across violins will have comparable scale.

bw, adjust, kernel, window, width, n, from, to, cut, na.rm  arguments to density, passed on as appropriate

...  arguments passed on to density.

identifier  A character string that is prepended to the names of grobs that are created by this panel function.

Details

Creates Violin plot of x for every level of y. Note that most arguments controlling the display can be supplied to the high-level (typically bwplot) call directly.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

bwplot, density
Examples

bwplot(voice.part ~ height, singer,
panel = function(..., box.ratio) {
  panel.violin(..., col = "transparent",
              varwidth = FALSE, box.ratio = box.ratio)
  panel.bwplot(..., fill = NULL, box.ratio = .1)
})

Default Prepanel Functions

Description

These prepanel functions are used as fallback defaults in various high level plot functions in Lattice. These are rarely useful to normal users but may be helpful in developing new displays.

Usage

prepanel.default.bwplot(x, y, horizontal, nlevels, origin, stack, ...)
prepanel.default.histogram(x, breaks, equal.widths, type, nint, ...)
prepanel.default.qq(x, y, ...)
prepanel.default.xyplot(x, y, type, subscripts, groups, ...)
prepanel.default.cloud(perspective, distance,
                      xlim, ylim, zlim,
                      screen = list(z = 40, x = -60),
                      R.mat = diag(4),
                      aspect = c(1, 1), panel.aspect = 1,
                      ..., zoom = 0.8)
prepanel.default.levelplot(x, y, subscripts, ...)
prepanel.default.qqmath(x, f.value, distribution, qtype,
                        groups, subscripts, ..., tails.n = 0)
prepanel.default.densityplot(x, darg, groups, weights, subscripts, ...)
prepanel.default.parallel(x, y, z, ..., horizontal.axis)
prepanel.default.splom(z, ...)

Arguments

x, y  x and y values, numeric or factor
horizontal  logical, applicable when one of the variables is to be treated as categorical (factor or shingle).
horizontal.axis  logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).
nlevels number of levels of such a categorical variable.
origin, stack for barcharts or the type="h" plot type
breaks, equal.widths, type, nint
details of histogram calculations. type has a different meaning in prepanel.default.xyplot
(see panel.xyplot)
groups, subscripts
See xyplot. Whenever appropriate, calculations are done separately for each
group and then combined.
weights numeric vector of weights for the density calculations. If this is specified, it is
subsetted by subscripts to match it to x.
perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, panel.aspect, zoom
see panel.cloud
f.value, distribution, tails.n
see panel.qqmath
darg list of arguments passed to density
z see panel.parallel and panel.pairs
qtype type of quantile
... other arguments, usually ignored

Value
A list with components xlim, ylim, dx and dy, and possibly xat and yat, the first two being used
to calculate panel axes limits, the last two for banking computations. The form of these components
are described in the help page for xyplot.

Author(s)
Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also
xyplot, banking, Lattice. See documentation of corresponding panel functions for more details
about the arguments.
Usage

prepanel.lmline(x, y, ...)
prepanel.qqmathline(x, y = x, distribution = qnorm,
    probs = c(0.25, 0.75), qtype = 7,
    groups, subscripts,
    ...)
prepanel.loess(x, y, span, degree, family, evaluation,
    horizontal = FALSE, ...)
prepanel.spline(x, y, npoints = 101,
    horizontal = FALSE, ..., keep.data = FALSE)

Arguments

x, y x and y values, numeric or factor
distribution quantile function for theoretical distribution. This is automatically passed in
    when this is used as a prepanel function in qqmath.
qtype type of quantile
probs numeric vector of length two, representing probabilities. If used with aspect="xy",
    the aspect ratio will be chosen to make the line passing through the correspond-
    ing quantile pairs as close to 45 degrees as possible.
span, degree, family, evaluation
    Arguments controlling the underlying loess smooth.
horizontal, npoints
    See documentation controlling for underlying loess smooth.
keep.data Ignored. Present to capture argument of the same name in smooth.spline.
groups, subscripts
    See xypplot. Whenever appropriate, calculations are done separately for each
    group and then combined.
...
    Other arguments. These are passed on to other functions if appropriate (in par-
    ticular, smooth.spline), and ignored otherwise.

Details

All these prepanel functions compute the limits to be large enough to contain all points as well as
the relevant smooth.

In addition, prepanel.lmline computes the dx and dy such that it reflects the slope of the linear
regression line; for prepanel.qqmathline, this is the slope of the line passing through the quanti-
tile pairs specified by_probs_. For prepanel.loess and prepanel.spline, dx and dy reflect the
piecewise slopes of the nonlinear smooth.

Value

usually a list with components xlim, ylim, dx and dy, the first two being used to calculate panel
axes limits, the last two for banking computations. The form of these components are described
under `xyplot`. There are also several prepanel functions that serve as the default for high level functions, see `prepanel.default.xyplot`

### G_axis.default

**Default axis annotation utilities**

### Description

Lattice functions provide control over how the plot axes are annotated through a common interface. There are two levels of control. The `xscale.components` and `yscale.components` arguments can be functions that determine tick mark locations and labels given a packet. For more direct control, the `axis` argument can be a function that actually draws the axes. The functions documented here are the defaults for these arguments. They can additionally be used as components of user written replacements.

### Usage

```r
xscale.components.default(lim, 
    packet.number = 0, 
    packet.list = NULL, 
    top = TRUE, 
    ...
)
yscale.components.default(lim, 
    packet.number = 0, 
    packet.list = NULL, 
    right = TRUE, 
    ...
)
axis.default(side = c("top", "bottom", "left", "right"), 
    scales, components, as.table, 
    labels = c("default", "yes", "no"), 
    ticks = c("default", "yes", "no"), 
    ..., prefix)
```

### Arguments

- **`lim`**: the range of the data in that packet (data subset corresponding to a combination of levels of the conditioning variable). The range is not necessarily numeric; e.g. for factors, they could be character vectors representing levels, and for the various date-time representations, they could be vectors of length 2 with the corresponding class.
G_axis.default

packet.number which packet (counted according to the packet order, described in print.trellis) is being processed. In cases where all panels have the same limits, this function is called only once (rather than once for each packet), in which case this argument will have the value 0.

packet.list list, as long as the number of packets, giving all the actual packets. Specifically, each component is the list of arguments given to the panel function when and if that packet is drawn in a panel. (This has not yet been implemented.)

top, right the value of the top and right components of the result, as appropriate. See below for interpretation.

side on which side the axis is to be drawn. The usual partial matching rules apply.

scales the appropriate component of the scales argument supplied to the high level function, suitably standardized.

components list, similar to those produced by xscale.components.default and yscale.components.default.

as.table the as.table argument in the high level function.

labels whether labels are to be drawn. By default, the rules determined by scales are used.

ticks whether labels are to be drawn. By default, the rules determined by scales are used.

... many other arguments may be supplied, and are passed on to other internal functions.

prefix A character string identifying the plot being drawn (see print.trellis). Used to retrieve location of current panel in the overall layout, so that axes can be drawn appropriately.

Details

These functions are part of a new API introduced in lattice 0.14 to provide the user more control over how axis annotation is done. While the API has been designed in anticipation of use that was previously unsupported, the implementation has initially focused on reproducing existing capabilities, rather than test new features. At the time of writing, several features are unimplemented. If you require them, please contact the maintainer.

Value

xscale.components.default and yscale.components.default return a list of the form suitable as the components argument of axis.default. Valid components in the return value of xscale.components.default are:

num.limit A numeric limit for the box.

bottom A list with two elements, ticks and labels. ticks must be a list with components at and tck which give the location and lengths of tick marks. tck can be a vector, and will be recycled to be as long as at. labels must be a list with components at, labels, and check.overlap. at and labels give the location and labels of the tick labels; this is usually the same as the location of the ticks, but is not required to be so. check.overlap is a logical flag indicating whether overlapping of labels should be avoided by omitting some of the labels while rendering.
top This can be a logical flag; if TRUE, top is treated as being the same as bottom; if FALSE, axis annotation for the top axis is omitted. Alternatively, top can be a list like bottom.

Valid components in the return value of yscale.components.default are left and right. Their interpretations are analogous to (respectively) the bottom and top components described above.

**G_banking**

**Banking**

**Description**

Calculates banking slope
Usage

banking(dx, dy)

Arguments

dx, dy  vector of consecutive x, y differences.

Details

banking is the banking function used when aspect = "xy" in high level Trellis functions. It is usually not very meaningful except with xyplot. It considers the absolute slopes (based on dx and dy) and returns a value which when adjusted by the panel scale limits will make the median of the above absolute slopes correspond to a 45 degree line.

This function was inspired by the discussion of banking in the documentation for Trellis Graphics available at Bell Labs’ website (see Lattice), but is most likely identical to an algorithm described by Cleveland et al (see below). It is not clear (to the author) whether this is the algorithm used in S-PLUS. Alternative banking rules, implemented as a similar function, can be used as a drop-in replacement by suitably modifying lattice.options("banking").

               scales = list(x = list(alternating = 2)),
               main = "Yearly Sunspots")
print(plot, position = c(0,.3,1,.9), more = TRUE)
print(update(plot, aspect = "xy", main = "", xlab = "Year"),
       position = c(0, 0, 1, .3))

## cut-and-stack plot (see also xyplot.ts)

xyplot(sunspot.year ~ time(sunspot.year) | equal.count(time(sunspot.year)),
       xlab = "", type = "l", aspect = "xy", strip = FALSE,
       scales = list(x = list(alternating = 2, relation = "sliced")),
       as.table = TRUE, main = "Yearly Sunspots")
**G_latticeParseFormula**  
*Parse Trellis formula*

**Description**

This function is used by high level Lattice functions like `xyplot` to parse the formula argument and evaluate various components of the data.

**Usage**

```r
latticeParseFormula(model, data, dimension = 2,  
                     subset = TRUE, groups = NULL,  
                     multiple, outer,  
                     subscripts,  
                     drop)
```

**Arguments**

- `model` the model/formula to be parsed. This can be in either of two possible forms, one for 2d and one for 3d formulas, determined by the `dimension` argument. The 2d formulas are of the form `y ~ x | g1 * ... * gn`, and the 3d formulas are of the form `z ~ x * y | g1 * ... * gn`. In the first form, `y` may be omitted. The conditioning variables `g1, ..., gn` can be omitted in either case.
- `data` the environment/dataset where the variables in the formula are evaluated.
- `dimension` dimension of the model, see above
- `subset` index for choosing a subset of the data frame
- `groups` the grouping variable, if present
- `multiple, outer` logicals, determining how a `+` in the `y` and `x` components of the formula are processed. See `xyplot` for details
- `subscripts` logical, whether subscripts are to be calculated
- `drop` logical or list, similar to the `drop.unused.levels` argument in `xyplot`, indicating whether unused levels of conditioning factors and data variables that are factors are to be dropped.

**Value**

Returns a list with several components including `left, right, left.name, right.name, condition` for 2-D, and `left, right.x, right.y, left.name, right.x.name, right.y.name, condition` for 3-D. Other possible components are `groups, subscr`

**Author(s)**

Saikat DebRoy, Deepayan Sarkar <Deepayan.Sarkar@R-project.org>
G_packet.panel.default

Associating Packets with Panels

Description

When a "trellis" object is plotted, panels are always drawn in an order such that columns vary the fastest, then rows and then pages. An optional function can be specified that determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. The function documented here implements the default behaviour, which is to match panel order with packet order, determined by varying the first conditioning variable the fastest, then the second, and so on. This matching is performed after any reordering and/or permutation of the conditioning variables.

Usage

```r
packet.panel.default(layout, condlevels, page, row, column,
                     skip, all.pages.skip = TRUE)
```

Arguments

- `layout`: the layout argument in high level functions, suitably standardized.
- `condlevels`: a list of levels of conditioning variables, after relevant permutations and/or re-ordering of levels
- `page`, `row`, `column`: the location of the panel in the coordinate system of pages, rows and columns.
- `skip`: the skip argument in high level functions
- `all.pages.skip`: whether skip should be replicated over all pages. If FALSE, skip will be replicated to be only as long as the number of positions on a page, and that template will be used for all pages.

Value

A suitable combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable. Specifically, if the return value is `p`, then the `i`-th conditioning variable will have level `condlevels[[i]][p[i]]`.

HP <- equal.count(mtcars$hp, 6)
p <-
  xyplot(mpg ~ disp | HP * factor(cyl),
         mtcars, layout = c(0, 6, 1))
print(p, packet.panel = packet.panel.page(1))
print(p, packet.panel = packet.panel.page(2))
```

---

**G_panel.axis**  
**Panel Function for Drawing Axis Ticks and Labels**

**Description**

`panel.axis` is the function used by lattice to draw axes. It is typically not used by users, except those wishing to create advanced annotation. Keep in mind issues of clipping when trying to use it as part of the panel function. `current.panel.limits` can be used to retrieve a panel’s x and y limits.

**Usage**

```r
panel.axis(side = c("bottom", "left", "top", "right"),
           at,
           labels = TRUE,
           draw.labels = TRUE,
           check.overlap = FALSE,
           outside = FALSE,
           ticks = TRUE,
           half = !outside,
           which.half,
           tck = as.numeric(ticks),
           ...)```
```
rot = if (is.logical(labels)) 0 else c(90, 0),
text.col, text.alpha, text.cex, text.font,
text.fontfamily, text.fontface, text.lineheight,
line.col, line.lty, line.lwd, line.alpha)

current.panel.limits(unit = "native")

Arguments

side A character string indicating which side axes are to be drawn on. Partial specification is allowed.
at Numeric vector giving location of labels. Can be missing, in which case they are computed from the native coordinates of the active viewport.
labels The labels to go along with at, as a character vector or a vector of expressions. This only makes sense provided at is explicitly specified, as otherwise the provided labels may not match the computed at values. Alternatively, labels can be a logical flag: If TRUE, the labels are derived from at, otherwise, labels are empty.
draw.labels A logical indicating whether labels are to be drawn.
check.overlap A logical, whether to check for overlapping of labels. This also has the effect of removing at values that are ‘too close’ to the limits.
outside A logical flag, indicating whether to draw the labels outside the panel or inside. Note that outside=TRUE will only have a visible effect if clipping is disabled for the viewport (panel).
ticks Logical flag, whether to draw the tickmarks.
half Logical flag, indicating whether only around half the scales will be drawn for each side. This is primarily used for axis labeling in splom.
which.half Character string, either "lower" or "upper", indicating which half is to be used for tick locations if half = TRUE. Defaults to whichever is suitable for splom.
tck A numeric scalar multiplier for tick length. Can be negative, in which case the ticks point inwards.
rot Rotation angle(s) for labels in degrees. Can be a vector of length 2 for x- and y-axes.
text.col Color for the axis label text. See gpar for more details on this and the other graphical parameters listed below.
text.alpha Alpha-transparency value for the axis label text.
text.cex Size multiplier for the axis label text.
text.font, text.fontfamily, text.fontface Font for the axis label text.
text.lineheight Line height for the axis label text.
line.col Color for the axis label text.
line.lty Color for the axis.
line.lwd Color for the axis.
line.alpha Alpha-transparency value for the axis.
unit Which grid unit the values should be in.
Details

panel.axis can draw axis tick marks inside or outside a panel (more precisely, a grid viewport). It honours the (native) axis scales. Used in panel.pairs for splom, as well as for all the usual axis drawing by the print method for “trellis” objects. It can also be used to enhance plots ‘after the fact’ by adding axes.

Value

current.panel.limits returns a list with components xlim and ylim, which are both numeric vectors of length 2, giving the scales of the current panel (viewport). The values correspond to the unit system specified by unit, by default “native”.

Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

See Also

Lattice, xyplot, trellis.focus, unit

Description

Control over lattice plots are provided through a collection of user specifiable functions that perform various tasks during the plotting. Not all information is available to all functions. The functions documented here attempt to provide a consistent interface to access relevant information from within these user specified functions, namely those specified as the panel, strip and axis functions. Note that this information is not available to the prepanel function, which is executed prior to the actual plotting.

Usage

current.row(prefix)
current.column(prefix)
panel.number(prefix)
packet.number(prefix)
which.packet(prefix)
trellis.currentLayout(which = c(“packet”, “panel”), prefix)
Arguments

which  whether return value (a matrix) should contain panel numbers or packet numbers, which are usually, but not necessarily, the same (see below for details).

prefix  A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed. See `trellis.focus`.

Value

trellis.currentLayout returns a matrix with as many rows and columns as in the layout of panels in the current plot. Entries in the matrix are integer indices indicating which packet (or panel; see below) occupies that position, with 0 indicating the absence of a panel. current.row and current.column return integer indices specifying which row and column in the layout are currently active. panel.number returns an integer counting which panel is being drawn (starting from 1 for the first panel, a.k.a. the panel order). packet.number gives the packet number according to the packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. which.packet returns the combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable.

Note

The availability of these functions make redundant some features available in earlier versions of lattice, namely optional arguments called panel.number and packet.number that were made available to panel and strip. If you have written such functions, it should be enough to replace instances of panel.number and packet.number by the corresponding function calls. You should also remove panel.number and packet.number from the argument list of your function to avoid a warning.

If these accessor functions are not enough for your needs, feel free to contact the maintainer and ask for more.

G_Rows  Extract rows from a list

Description

Convenience function to extract subset of a list. Usually used in creating keys.
Usage

\texttt{Rows(x, which)}

Arguments

\texttt{x} \hspace{1cm} \texttt{list} with each member a vector of the same length
\texttt{which} \hspace{1cm} \texttt{index} for members of \texttt{x}

Value

A list similar to \texttt{x}, with each \texttt{x[[i]]} replaced by \texttt{x[[i]][which]}

\texttt{G\_utilities.3d} \hspace{1cm} \textit{Utility functions for 3-D plots}

Description

These are (related to) the default panel functions for cloud and wireframe.

Usage

\texttt{ltransform3dMatrix(screen, R.mat)}
\texttt{ltransform3dto3d(x, R.mat, dist)}

Arguments

\texttt{x} \hspace{1cm} \texttt{x} can be a numeric matrix with 3 rows for \texttt{ltransform3dto3d}
\texttt{screen} \hspace{1cm} \texttt{list}, as described in \texttt{panel.cloud}
\texttt{R.mat} \hspace{1cm} \texttt{4x4} transformation matrix in homogeneous coordinates
\texttt{dist} \hspace{1cm} \texttt{controls} transformation to account for perspective viewing
H_barley

Details

ltransform3dMatrix and ltransform3dto3d are utility functions to help in computation of projections. These functions are used inside the panel functions for cloud and wireframe. They may be useful in user-defined panel functions as well.

The first function takes a list of the form of the screen argument in cloud and wireframe and a R.mat, a 4x4 transformation matrix in homogeneous coordinates, to return a new 4x4 transformation matrix that is the result of applying R.mat followed by the rotations in screen. The second function applies a 4x4 transformation matrix in homogeneous coordinates to a 3xn matrix representing points in 3-D space, and optionally does some perspective computations. (There has been no testing with non-trivial transformation matrices, and my knowledge of the homogeneous coordinate system is very limited, so there may be bugs here.)

H_barley  
Yield data from a Minnesota barley trial

Description

Total yield in bushels per acre for 10 varieties at 6 sites in each of two years.

Usage

barley

Format

A data frame with 120 observations on the following 4 variables.

yield  Yield (averaged across three blocks) in bushels/acre.

year  Factor with levels 1932, 1931

site  Factor with 6 levels: "Grand Rapids", "Duluth", "University Farm", "Morris", "Crookston", "Waseca"
Details

These data are yields in bushels per acre, of 10 varieties of barley grown in 1/40 acre plots at University Farm, St. Paul, and at the five branch experiment stations located at Waseca, Morris, Crookston, Grand Rapids, and Duluth (all in Minnesota). The varieties were grown in three randomized blocks at each of the six stations during 1931 and 1932, different land being used each year of the test.

Immer et al. (1934) present the data for each Year*Site*Variety*Block. The data here is the average yield across the three blocks.

Immer et al. (1934) refer (once) to the experiment as being conducted in 1930 and 1931, then later refer to it (repeatedly) as being conducted in 1931 and 1932. Later authors have continued the confusion.

Cleveland (1993) suggests that the data for the Morris site may have had the years switched.

Author(s)

Documentation contributed by Kevin Wright.

References

See Also

`immer` in the MASS package for data from the same experiment (expressed as total yield for 3 blocks) for a subset of varieties.

Examples

```r
# Graphic suggesting the Morris data switched the years 1931 and 1932
# Figure 1.1 from Cleveland
dotplot(variety ~ yield | site, data = barley, groups = year,
    key = simpleKey(levels(barley$year), space = "right"),
    xlab = "Barley Yield (bushels/acre) ",
    aspect=0.5, layout = c(1,6), ylab=NULL)
```
**H_environmental**

*Atmospheric environmental conditions in New York City*

**Description**

**Usage**

`environmental`

**Format**

A data frame with 111 observations on the following 4 variables.

- **ozone**: Average ozone concentration (of hourly measurements) of in parts per billion.
- **radiation**: Solar radiation (from 08:00 to 12:00) in langleys.
- **temperature**: Maximum daily temperature in degrees Fahrenheit.
- **wind**: Average wind speed (at 07:00 and 10:00) in miles per hour.

**Author(s)**

Documentation contributed by Kevin Wright.

**Source**

**References**

**Examples**

```r
# Scatter plot matrix with loess lines
splom(~environmental, 
    panel=function(x,y){
        panel.xyplot(x,y) 
        panel.loess(x,y) 
    })

# Conditioned plot similar to figure 5.3 from Cleveland 
attach(environmental)
```
H_ethanol

Ethanol fuel was burned in a single-cylinder engine. For various settings of the engine compression and equivalence ratio, the emissions of nitrogen oxides were recorded.

Usage

ethanol

Format

A data frame with 88 observations on the following 3 variables.

NOx  Concentration of nitrogen oxides (NO and NO2) in micrograms/J.

C    Compression ratio of the engine.

E    Equivalence ratio—a measure of the richness of the air and ethanol fuel mixture.

Author(s)

Documentation contributed by Kevin Wright.

})
```

```
H_melanoma                  Melanoma skin cancer incidence

Description

These data from the Connecticut Tumor Registry present age-adjusted numbers of melanoma skin-cancer incidences per 100,000 people in Connecticut for the years from 1936 to 1972.

Usage

melanoma
**Format**

A data frame with 37 observations on the following 2 variables.

- **year** Years 1936 to 1972.
- **incidence** Rate of melanoma cancer per 100,000 population.

**Note**

This dataset is not related to the `melanoma` dataset in the `boot` package with the same name.

The S-PLUS 6.2 help for the melanoma data says that the incidence rate is per million, but this is not consistent with data found at the National Cancer Institute (https://www.cancer.gov/).

**Author(s)**

Documentation contributed by Kevin Wright.

**Source**

**References**

**Examples**

```r
# Time-series plot. Figure 3.64 from Cleveland.
xyplot(incidence ~ year,
data = melanoma,
aspect = "xy",
panel = function(x, y)
panel.xyplot(x, y, type="o", pch = 16),
ylim = c(0, 6),
mlab = "Year",
ylab = "Incidence")
```

---

**H_singer**  
*Heights of New York Choral Society singers*

**Description**

Heights in inches of the singers in the New York Choral Society in 1979. The data are grouped according to voice part. The vocal range for each voice part increases in pitch according to the following order: Bass 2, Bass 1, Tenor 2, Tenor 1, Alto 2, Alto 1, Soprano 2, Soprano 1.

**Usage**

singer
Format

A data frame with 235 observations on the following 2 variables.

**height**  Height in inches of the singers.

**voice.part** (Unordered) factor with levels "Bass 2", "Bass 1", "Tenor 2", "Tenor 1", "Alto 2", "Alto 1", "Soprano 2", "Soprano 1".

Author(s)

Documentation contributed by Kevin Wright.

References

Examples

```r
# Separate histogram for each voice part (Figure 1.2 from Cleveland)
histogram(~ height | voice.part,
data = singer,
aspect = 1,
layout = c(2, 4),
nint = 15,
xlab = "Height (inches)"
)

# Quantile-Quantile plot (Figure 2.11 from Cleveland)
qqmath(~ height | voice.part,
data = singer,
aspect = 1,
layout = c(2,4),
prepanel = prepanel.qqmathline,
panel = function(x, ...) {
  panel.grid()
  panel.qqmathline(x, ...)
  panel.qqmath(x, ..., grid = FALSE)
},
xlab = "Unit Normal Quantile",
ylab="Height (inches)"
)`
**Description**

These datasets record mortality rates across all ages in the USA by cause of death, sex, and rural/urban status, 2011–2013. The two datasets represent the national aggregate rates and the region-wise rates for each administrative region under the Department of Health and Human Services (HHS).

**Usage**

- USMortality
- USRegionalMortality

**Format**

**USRegionalMortality** is a data frame with 400 observations on the following 6 variables.

- **Region**: A factor specifying HHS Region. See details.
- **Status**: A factor with levels Rural and Urban
- **Sex**: A factor with levels Female and Male
- **Cause**: Cause of death. A factor with levels Alzheimers, Cancer, Cerebrovascular diseases, Diabetes, Flu and pneumonia, Heart disease, Lower respiratory, Nephritis, Suicide, and Unintentional injuries
- **Rate**: Age-adjusted death rate per 100,000 population
- **SE**: Standard error for the rate

**USMortality** is a data frame with 40 observations, containing the same variables with the exception of Region.

**Details**

The region-wise data give estimated rates separately for each of 10 HHS regions. The location of the regional offices and their coverage area, available from [https://www.hhs.gov/about/agencies/tea/regional-offices/index.html](https://www.hhs.gov/about/agencies/tea/regional-offices/index.html), is given below.

- **HHS Region 01 - Boston**: Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont
- **HHS Region 02 - New York**: New Jersey, New York, Puerto Rico, and the Virgin Islands
- **HHS Region 03 - Philadelphia**: Delaware, District of Columbia, Maryland, Pennsylvania, Virginia, and West Virginia
- **HHS Region 04 - Atlanta**: Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, and Tennessee
- **HHS Region 05 - Chicago**: Illinois, Indiana, Michigan, Minnesota, Ohio, and Wisconsin
HHS Region 06 - Dallas: Arkansas, Louisiana, New Mexico, Oklahoma, and Texas
HHS Region 07 - Kansas City: Iowa, Kansas, Missouri, and Nebraska
HHS Region 08 - Denver: Colorado, Montana, North Dakota, South Dakota, Utah, and Wyoming
HHS Region 09 - San Francisco: Arizona, California, Hawaii, Nevada, American Samoa, Commonwealth of the Northern Mariana Islands, Federated States of Micronesia, Guam, Marshall Islands, and Republic of Palau
HHS Region 10 - Seattle: Alaska, Idaho, Oregon, and Washington

I_lset

Interface to modify Trellis Settings - Defunct

Description

A (hopefully) simpler alternative to trellis.par.get/set. This is deprecated, and the same functionality is now available with trellis.par.set

Usage

lset(theme = col.whitebg())

Arguments

theme  
a list describing how to change the settings of the current active device. Valid components are those in the list returned by trellis.par.get(). Each component must itself be a list, with one or more of the appropriate components (need not have all components). Changes are made to the settings for the currently active device only.
