Package ‘lax’

October 13, 2022

Title Loglikelihood Adjustment for Extreme Value Models
Version 1.2.0
Date 2021-07-20

Description Performs adjusted inferences based on model objects fitted, using maximum likelihood estimation, by the extreme value analysis packages 'eva' <https://cran.r-project.org/package=eva>, 'evd' <https://cran.r-project.org/package=evd>, 'evir' <https://cran.r-project.org/package=evir>, 'extRemes' <https://cran.r-project.org/package=extRemes>, 'fExtremes' <https://cran.r-project.org/package=fExtremes>, 'ismev' <https://cran.r-project.org/package=ismev>, 'mev' <https://cran.r-project.org/package=mev>, 'POT' <https://cran.r-project.org/package=POT> and 'texmex' <https://cran.r-project.org/package=texmex>. Adjusted standard errors and an adjusted loglikelihood are provided, using the 'chandwich' package <https://cran.r-project.org/package=chandwich> and the object-oriented features of the 'sandwich' package <https://cran.r-project.org/package=sandwich>. The adjustment is based on a robust sandwich estimator of the parameter covariance matrix, based on the methodology in Chandler and Bate (2007) <doi:10.1093/biomet/asm015>. This can be used for cluster correlated data when interest lies in the parameters of the marginal distributions, or for performing inferences that are robust to certain types of model misspecification. Univariate extreme value models, including regression models, are supported.

alogLik

Loglikelihood adjustment for model fits

Description

This function is generic. It performs adjustment of the loglikelihood associated with fitted model objects, following Chandler and Bate (2007). Certain classes of extreme value model objects are supported automatically. For details see the alogLik help pages for the packages: evd, evir, extRemes, fExtremes, ismev, mev, POT, texmex. User-supplied objects can also be supported: the requirements for these objects are explained in Details.

Usage

alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

Arguments

x A fitted model object with certain associated S3 methods. See Details.
cluster A vector or factor indicating from which cluster the respective loglikelihood contributions from loglik originate. This must have the same length as the vector returned by the logLikVec method for an object like x. If cluster is not supplied (i.e. is NULL) then it is assumed that each observation forms its own cluster. See Details.
use_vcov A logical scalar. Should we use the vcov S3 method for x (if this exists) to estimate the Hessian of the independence loglikelihood to be passed as the argument H to adjust_loglik? Otherwise, H is estimated inside adjust_loglik using optimHess.

... Further arguments to be passed to the functions in the sandwich package meat (if cluster = NULL), or meatCL (if cluster is not NULL).

Details

Object x must have the following S3 methods:

- logLikVec: returns a vector of the contributions to the independence loglikelihood from individual observations;
- coef: returns a vector of model coefficients, see coef;
- nobs: returns the number of (non-missing) observations used in a model fit, see nobs;

and may have the following S3 methods

- vcov: returns the estimated variance-covariance matrix of the (main) parameters of a fitted model, see vcov;
- estfun: returns an \( nxk \) matrix, in which each column gives the derivative of the loglikelihood at each of \( n \) observation with respect to the \( k \) parameters of the model, see estfun.
Loglikelihood adjustment is performed using the `adjust_loglik` function in the `chandwich` package. The relevant arguments to `adjust_loglik`, namely `loglik`, `mle`, `H` and `V`, are created based on the class of the object `x`.

If a `vcov` method is not available, or if `use_vcov = FALSE`, then the variance-covariance matrix of the MLE (from which `H` is calculated) is estimated inside `adjust_loglik` using `optimHess`.

The `sandwich` package is used to estimate the variance matrix `V` of the score vector: `meat` is used if `cluster = NULL`; `meatCL` is used if `cluster` is not `NULL`. If `cluster` is `NULL` then any arguments of `meatCL` present in ... will be ignored. Similarly, if `cluster` is not `NULL` then any arguments of `meat` present in ... will be ignored. `meat` and `meatCL` require an `estfun` method to be available, which, in the current context, provides matrix of score contributions. If a bespoke `estfun` method is not provided then this is constructed by estimating the score contributions using `jacobian`.

**Value**

An object inheriting from class "chandwich". See `adjust_loglik`.

If `x` is one of the supported models then the class of the returned object is a vector of length 5. The first 3 components are `c("lax", "chandwich", "name_of_package")`, where "name_of_package" is the name of the package from which the input object `x` originated. The remaining 2 components depend on the model that was fitted. See the documentation of the relevant package for details: `evd`, `evir`, `extRemes`, `fExtremes`, `ismev`, `mev`, `POT`, `texmex`.

Otherwise, the class of the returned object is `c("lax", "chandwich", class(x))`.

**Examples**

See the (package-specific) examples in `evd`, `evir`, `extRemes`, `fExtremes`, `ismev`, `mev`, `POT` and `texmex`.

`adjust_loglik` in the `chandwich` package to adjust a user-supplied loglikelihood.

`meat` and `meatCL` in the sandwich package.
Comparison of nested models

Description

anova.lax is a method for objects of class "lax". It compares two or more nested models using the adjusted likelihood ratio test statistic (ALRTS) described in Section 3.5 of Chandler and Bate (2007). The nesting must result from the simple constraint that a subset of the parameters of the larger model is held fixed.

Usage

```r
## S3 method for class 'lax'
anova(object, object2, ...)
```

Arguments

- `object`: An object of class "lax", inheriting from class "chandwich", returned by `alogLik`.
- `object2`: An object of class "lax", inheriting from class "chandwich", returned by `alogLik`.
- `...`: Further objects of class "lax" and/or arguments to be passed to `anova.chandwich`, and then on to `compare_models`, in particular `type`, which chooses the type of adjustment.

Details

The objects of class "lax" need not be provided in nested order: they will be ordered inside `anova.lax` based on the values of `attr(., "p_current")`.

Value

An object of class "anova" inheriting from class "data.frame", with four columns:

- `Model.Df`: The number of parameters in the model
- `Df`: The decrease in the number of parameter compared the model in the previous row
- `ALRTS`: The adjusted likelihood ratio test statistic
- `Pr(>ALRTS)`: The p-value associated with the test that the model is a valid simplification of the model in the previous row.

The row names are the names of the model objects.

}

eva

Loglikelihood adjustment for eva fits

Description

S3 alogLik method to perform loglikelihood adjustment for fitted extreme value model objects returned from the functions gevrFit and gpdFit in the eva package.
### S3 method for class 'gevrFit'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

### S3 method for class 'gpdFit'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

**Arguments**

- **x**: A fitted model object with certain associated S3 methods. See Details.
- **cluster**: A vector or factor indicating from which cluster the respective loglikelihood contributions from loglik originate. This must have the same length as the vector returned by the logLikVec method for an object like x. If cluster is not supplied (i.e. is NULL) then it is assumed that each observation forms its own cluster. See Details.
- **use_vcov**: A logical scalar. Should we use the vcov S3 method for x (if this exists) to estimate the Hessian of the independence loglikelihood to be passed as the argument \( H \) to adjust_loglik? Otherwise, \( H \) is estimated inside adjust_loglik using optimHess.
- **...**: Further arguments to be passed to the functions in the sandwich package meat (if cluster = NULL), or meatCL (if cluster is not NULL).

**Details**

See alogLik for details.

In the stationary case (no covariates) the function gevrFit and gpdFit in the eva package offer standard errors based on the expected information or on the observed information, via the argument information. In contrast, alogLik() always bases calculations on the observed information matrix. Therefore, unadjusted standard errors resulting from alogLik() may be different the corresponding standard errors from gevrFit or gpdFit.

For gevrFit only GEV fits (gumbel = FALSE) are supported.

**Value**

An object inheriting from class "chandwich". See adjust_loglik. class(x) is a vector of length 5. The first 3 components are c("lax", "chandwich", "eva"). The 4th component depends on which model was fitted. "rlarg" if gevrFit was used; "gpd" if gpdFit was used. The 5th component is "stat" if there are no covariates in the mode and "nonstat" otherwise.

                          locform = ~ Trend1 + Trend2*Trend3,
                          scalevars = covs, scaleform = ~ Trend1)
  adj_result2 <- alogLik(result2)
  summary(adj_result2)
S3 \texttt{alogLik} method to perform loglikelihood adjustment for fitted extreme value model objects returned from the functions \texttt{fgev} and \texttt{fpot} in the \texttt{evd} package. If \( x \) is returned from \texttt{fgev} then the call must have used \texttt{prob = NULL}.

### Usage

```r
# S3 method for class 'evd'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)
```

### Arguments

- \texttt{x} 
  A fitted model object with certain associated S3 methods. See \texttt{Details}.
- \texttt{cluster} 
  A vector or factor indicating from which cluster the respective loglikelihood contributions from \texttt{loglik} originate. This must have the same length as the vector returned by the \texttt{logLikVec} method for an object like \( x \). If \texttt{cluster} is not supplied (i.e. is \texttt{NULL}) then it is assumed that each observation forms its own cluster. See \texttt{Details}.
- \texttt{use_vcov} 
  A logical scalar. Should we use the \texttt{vcov} S3 method for \( x \) (if this exists) to estimate the Hessian of the independence loglikelihood to be passed as the argument \( H \) to \texttt{adjust_loglik}? Otherwise, \( H \) is estimated inside \texttt{adjust_loglik} using \texttt{optimHess}.
- \texttt{...} 
  Further arguments to be passed to the functions in the sandwich package \texttt{meat} (if \texttt{cluster = NULL}), or \texttt{meatCL} (if \texttt{cluster} is not \texttt{NULL}).

### Details

See \texttt{alogLik} for details.

### Value

An object inheriting from class "chandwich". See \texttt{adjust_loglik}. \texttt{class(x)} is a vector of length 5. The first 3 components are \texttt{c(“lax”, “chandwich”, “evd”).} The remaining 2 components depend on the model that was fitted. If \texttt{fgev} was used then these components are \texttt{c(“gev”, “stat”) if nsloc was NULL and \texttt{c(“gev”, “nonstat”) if nsloc was not NULL}. If \texttt{fpot} was used then these components are \texttt{c(“pot”, “gpd”) if model was “gpd” and \texttt{c(“pot”, “pp”) if model was “pp”}}.

if (got_evd) {
  library(evd)
  # An example from the evd::fgev documentation
  set.seed(3082019)
  uvdata <- evd::rgev(100, loc = 0.13, scale = 1.1, shape = 0.2)
  M1 <- evd::fgev(uvdata, nsloc = (-49:50)/100)
  adj_fgev <- alogLik(M1)
  summary(adj_fgev)

  # An example from Chandler and Bate (2007)
  owfit <- fgev(ow$temp, nsloc = ow$loc)
  adj_owfit <- alogLik(owfit, cluster = ow$year)
  summary(adj_owfit)

  # An example from the evd::fpot documentation
  set.seed(3082019)
  uvdata <- evd::rgpd(100, loc = 0, scale = 1.1, shape = 0.2)
  M1 <- fpot(uvdata, 1)
  adj_fpot <- alogLik(M1)
  summary(adj_fpot)

  # Fit using the pp model, rather than the gpd
  M1 <- fpot(uvdata, 1, model = "pp", npp = 365)
  adj_fpot <- alogLik(M1)
  summary(adj_fpot)
}
```

**evir**  
*Loglikelihood adjustment for evir fits*

Description

S3 `alogLik` method to perform loglikelihood adjustment for fitted extreme value model objects returned from the functions `gev`, `gpd` and `pot` in the evir package. If `x` was returned from `pot` then the model will need to be re-fitted using `pot_refit`. 
Usage

## S3 method for class 'gev'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

## S3 method for class 'gpd'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

## S3 method for class 'potd'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

Arguments

x
A fitted model object with certain associated S3 methods. See Details.

cluster
A vector or factor indicating from which cluster the respective loglikelihood contributions from loglik originate. This must have the same length as the vector returned by the logLikVec method for an object like x. If cluster is not supplied (i.e. is NULL) then it is assumed that each observation forms its own cluster. See Details.

use_vcov
A logical scalar. Should we use the vcov S3 method for x (if this exists) to estimate the Hessian of the independence loglikelihood to be passed as the argument H to adjust_loglik? Otherwise, H is estimated inside adjust_loglik using optimHess.

... Further arguments to be passed to the functions in the sandwich package meat (if cluster = NULL), or meatCL (if cluster is not NULL).

Details

See alogLik for details.

If pot was used then x does not contain the raw data that alogLik needs. The model will need to be re-fitted using pot_refit and the user will be prompted to do this by an error message produced by alogLik.

Value

An object inheriting from class "chandwich". See adjust_loglik. class(x) is a vector of length 5. The first 3 components are c("lax", "chandwich", "evir"). The remaining 2 components depend on the model that was fitted. If gev was used then these components are c("gev", "stat"). If gpd was used then these components are c("gpd", "stat"). If pot_refit was used then these components are c("potd", "stat").

extRemes | Loglikelihood adjustment for extRemes fits

Description

S3 alogLik method to perform loglikelihood adjustment for fitted extreme value model objects returned from the function fevd in the extRemes package. The model must have been fitted using maximum likelihood estimation.

Usage

```r
## S3 method for class 'fevd'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)
```

Arguments

- `x` A fitted model object with certain associated S3 methods. See Details.
- `cluster` A vector or factor indicating from which cluster the respective loglikelihood contributions from loglik originate. This must have the same length as the vector returned by the logLikVec method for an object like x. If cluster is not

---

# We need the evir package
got_evir <- requireNamespace("evir", quietly = TRUE)
if (got_evir) {
  library(evir)
  # An example from the evir::gev documentation
  data(bmw)
  out <- gev(bmw, "month")
  adj_out <- alogLik(out)
  summary(adj_out)

  # An example from the evir::gpd documentation
  data(danish)
  out <- gpd(danish, 10)
  adj_out <- alogLik(out)
  summary(adj_out)

  # An example from the evir::pot documentation
  # We use lax::pot_refit() to return the input data
  out <- pot_refit(danish, 10)
  adj_out <- alogLik(out)
  summary(adj_out)
}
supplied (i.e. is NULL) then it is assumed that each observation forms its own
cluster. See Details.

use_vcov

A logical scalar. Should we use the vcov S3 method for x (if this exists) to
estimate the Hessian of the independence loglikelihood to be passed as the ar-
gument H to adjust_loglik? Otherwise, H is estimated inside adjust_loglik
using optimHess.

... Further arguments to be passed to the functions in the sandwich package meat
(if cluster = NULL), or meatCL (if cluster is not NULL).

Details

See alogLik for details.

Value

An object inheriting from class "chandwich". See adjust_loglik. class(x) is a vector of length
5. The first 3 components are c("lax", "chandwich", "extRemes"). The remaining 2 compo-
nents depend on the model that was fitted. The 4th component is: "gev" if x$type = "GEV" or
x$type = "Gumbel"; "gp" if x$type = "GP" or x$type = "Exponential"; "pp" if x$type = "PP".
The 5th component is "stat" if is.fixedfevd = TRUE and "nonstat" if is.fixedfevd = FALSE.

fExtremes

Loglikelihood adjustment for fExtremes fits

Description

S3 alogLik method to perform loglikelihood adjustment for fitted extreme value model objects returned from the functions gevFit, gumbelFit and gpdFit in the fExtremes package. The model must have been fitted using maximum likelihood estimation.

Usage

## S3 method for class 'fGEVFIT'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

## S3 method for class 'fGPDFIT'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

Arguments

x
A fitted model object with certain associated S3 methods. See Details.

cluster
A vector or factor indicating from which cluster the respective loglikelihood contributions from loglik originate. This must have the same length as the vector returned by the logLikVec method for an object like x. If cluster is not supplied (i.e. is NULL) then it is assumed that each observation forms its own cluster. See Details.

use_vcov
A logical scalar. Should we use the vcov S3 method for x (if this exists) to estimate the Hessian of the independence loglikelihood to be passed as the argument H to adjust_loglik? Otherwise, H is estimated inside adjust_loglik using optimHess.

...
Further arguments to be passed to the functions in the sandwich package meat (if cluster = NULL), or meatCL (if cluster is not NULL).

Details

See alogLik for details.

Value

An object inheriting from class "chandwich". See adjust_loglik. class(x) is a vector of length 5. The first 3 components are c("lax", "chandwich", "fExtremes"). The remaining 2 components depend on the model that was fitted. If gevFit or gumbelFit was used then these components are c("gev", "stat"). If gpdFit was used then these components are c("gpd", "stat").

  # An example from the fExtremes::gpdFit documentation
  # Simulate GP data
  x <- fExtremes::gpdSim(model = list(xi = 0.25, mu = 0, beta = 1), n = 1000)
  fit <- fExtremes::gpdFit(x, u = min(x))
  adj_fit <- alogLik(fit)
  summary(adj_fit)
}
```

**ismev**  
*Loglikelihood adjustment for ismev fits*

Description

S3 alogLik method to perform loglikelihood adjustment for fitted extreme value model objects returned from the functions `gev.fit`, `gpd.fit`, `pp.fit` and `rlarg.fit` in the ismev package. If regression modelling is used then the model will need to be re-fitted, see ismev_refits.
Usage

## S3 method for class 'gev.fit'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

## S3 method for class 'pp.fit'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

## S3 method for class 'gpd.fit'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

## S3 method for class 'rlarg.fit'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

Arguments

x A fitted model object with certain associated S3 methods. See Details.

cluster A vector or factor indicating from which cluster the respective loglikelihood contributions from loglik originate. This must have the same length as the vector returned by the logLikVec method for an object like x. If cluster is not supplied (i.e. is NULL) then it is assumed that each observation forms its own cluster. See Details.

use_vcov A logical scalar. Should we use the vcov S3 method for x (if this exists) to estimate the Hessian of the independence loglikelihood to be passed as the argument H to adjust_loglik? Otherwise, H is estimated inside adjust_loglik using optimHess.

... Further arguments to be passed to the functions in the sandwich package meat (if cluster = NULL), or meatCL (if cluster is not NULL).

Details

See alogLik for details.

If regression modelling is used then the ismев functions gev.fit, gpd.fit, pp.fit and rlarg.fit return residuals but alogLik needs the raw data. The model will need to be re-fitted, using one of the functions in ismев_refits, and the user will be prompted to do this by an error message produced by alogLik.

Value

An object inheriting from class "chandwich". See adjust_loglik. class(x) is a vector of length 5. The first 3 components are c("lax", "chandwich", "ismev"). The remaining 2 components depend on the model that was fitted. The 4th component is: "gev" if gev.fit (or gev_refit) was used; "gpd" if gpd.fit (or gpd_refit) was used; "pp" pp.fit (or pp_refit) was used; "rlarg" rlarg.fit (or rlarg_refit) was used. The 5th component is "stat" if x$trans = FALSE and "nonstat" if x$trans = TRUE.

lax

lax: Loglikelihood Adjustment for Extreme Value Models

Description

Performs adjusted inferences based on model objects fitted, using maximum likelihood estimation, by the extreme value analysis packages eva, evd, evir, extReRemes, fExtremes, ismev, mev, POT and texmex. Univariate extreme value models, including regression models, are supported. Adjusted standard errors and an adjusted loglikelihood are provided, using the chandwich package and the object-oriented features of the sandwich package.
Details

The adjustment is based on a robust sandwich estimator of the parameter covariance matrix, based on the methodology in Chandler and Bate (2007). This can be used for cluster correlated data when interest lies in the parameters of the marginal distributions, or for performing inferences that are robust to certain types of model misspecification.

The main function is `alogLik`, which works in an object-oriented way, operating on fitted model objects. This function performs the loglikelihood adjustments using `adjust_loglik`. See the following package-specific help pages for details and examples: `eva`, `evd`, `evir`, `extRemes`, `fExtremes`, `ismev`, `mev`, `POT`, `texmex`.

See vignette("lax-vignette", package = "lax") for an overview of the package.

**logLik.logLikVec**

*Sum loglikelihood contributions from individual observations*

**Description**

S3 logLik method for logLikVec objects

**Usage**

```r
## S3 method for class 'logLikVec'
logLik(object, ...)
```

**Arguments**

- `object` An object of class "logLikVec" return from a logLikVec method.
- `...` Further arguments.

---

**logLikVec**

*Evaluate loglikelihood contributions from specific observations*

**Description**

Generic function for calculating loglikelihood contributions from individual observations for a fitted model.

**Usage**

```r
logLikVec(object, ...)
```

**Arguments**

- `object` A fitted model object.
- `...` Further arguments.
Loglikelihood adjustment for mev fits

Description

S3 alogLik method to perform loglikelihood adjustment for fitted extreme value model objects returned from the functions fit.gev, fit.gpd, and fit.pp and fit.rlarg in the mev package.

Usage

```r
## S3 method for class 'mev_gev'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

## S3 method for class 'mev_pp'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

## S3 method for class 'mev_gpd'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

## S3 method for class 'mev_egp'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

## S3 method for class 'mev_rlarg'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)
```

Arguments

- **x**: A fitted model object with certain associated S3 methods. See Details.
- **cluster**: A vector or factor indicating from which cluster the respective loglikelihood contributions from loglik originate. This must have the same length as the vector returned by the logLikVec method for an object like x. If cluster is not supplied (i.e. is NULL) then it is assumed that each observation forms its own cluster. See Details.
- **use_vcov**: A logical scalar. Should we use the vcov S3 method for x (if this exists) to estimate the Hessian of the independence loglikelihood to be passed as the argument H to adjust_loglik? Otherwise, H is estimated inside adjust_loglik using optimHess.
- **...**: Further arguments to be passed to the functions in the sandwich package meat (if cluster = NULL), or meatCL (if cluster is not NULL).

Details

See alogLik for details.

If x was returned from fit.pp then the data xdat supplied to fit.pp must contain all the data, both threshold exceedances and non-exceedances.
Value

An object inheriting from class "chandwich". See adjust_loglik. class(x) is a vector of length 5. The first 3 components are c("lax", "chandwich", "mev"). The 4th component depends on which model was fitted. "gev" if fit.gev was used; "gpd" if fit.gpd was used; "pp" if fit.pp was used; "egp" if fit.egp was used; "rlarg" if fit.rlarg was used; The 5th component is "stat" (for stationary).

Oxford and Worthing annual maximum temperatures

Description

Annual maximum temperatures at Oxford and Worthing (England), for the period 1901 to 1980.

Usage

ow

Format

A dataframe with 80 rows and 4 columns.

- Column 1, temp: annual maximum temperatures in degrees Fahrenheit.
- Column 2, year: year in which the maximum was recorded.
- Column 3, name: name of location, "oxford" or "worthing"
- Column 4, loc: location: 1 for "oxford", -1 for "worthing"

References

plot.retlev

Plot diagnostics for a retlev object

Description

plot method for an objects of class c("retlev", "lax").

Usage

## S3 method for class 'retlev'
plot(x, y = NULL, level = NULL, legend = TRUE, digits = 3, plot = TRUE, ...)

Arguments

x an object of class c("retlev", "lax"). a result of a call to return_level, using prof = TRUE.

y Not used.

level A numeric scalar in (0, 1). The confidence level required for the confidence interval for the m-year return level. If level is not supplied then x$level is used. level must be no larger than x$level.

legend A logical scalar. Should we add a legend (in the top right of the plot) that gives the approximate values of the MLE and 100level% confidence limits?

digits An integer. Passed to signif to round the values in the legend.

plot A logical scalar. If TRUE then the plot is produced. Otherwise, it is not, but the MLE and confidence limits are returned.

... Further arguments to be passed to plot.

Details

Plots the profile loglikelihood for a return level, provided that x returned by a call to return_level using prof = TRUE. Horizontal lines indicate the values of the maximised loglikelihood and the critical level used to calculate the confidence limits. If level is smaller than x$level then approximate 100level% confidence limits are recalculated based on the information contained in x$for_plot.

Value

A numeric vector of length 3 containing the lower 100level% confidence limit, the MLE and the upper 100level% confidence limit.

Examples

See the examples in return_level.

See Also

return_level to perform inferences about return levels.
Loglikelihood adjustment for POT fits

Description

S3 alogLik method to perform loglikelihood adjustment for fitted extreme value model objects returned from fitGPD function in the POT package. The model must have been fitted using maximum likelihood estimation.

Usage

```r
# S3 method for class 'uvpot'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)
```

Arguments

- `x`: A fitted model object with certain associated S3 methods. See Details.
- `cluster`: A vector or factor indicating from which cluster the respective loglikelihood contributions from loglik originate. This must have the same length as the vector returned by the logLikVec method for an object like x. If cluster is not supplied (i.e. is NULL) then it is assumed that each observation forms its own cluster. See Details.
- `use_vcov`: A logical scalar. Should we use the vcov S3 method for x (if this exists) to estimate the Hessian of the independence loglikelihood to be passed as the argument H to adjust_loglik? Otherwise, H is estimated inside adjust_loglik using optimHess.
- `...`: Further arguments to be passed to the functions in the sandwich package meat (if cluster = NULL), or meatCL (if cluster is not NULL).

Details

See alogLik for details.

Value

An object inheriting from class "chandwich". See adjust_loglik.

class(x) is c("lax", "chandwich", "POT", "pot", "gpd").

References

pot_refit

See Also

alogLik: loglikelihood adjustment for model fits.

Examples

# We need the POT package
got_POT <- requireNamespace("POT", quietly = TRUE)

if (got_POT) {
  library(POT)
  # An example from the POT::fitgpd documentation.
  set.seed(4082019)
  x <- POT::rgpd(200, 1, 2, 0.25)
  fit <- fitgpd(x, 1, "mle")
  adj_fit <- alogLik(fit)
}

pot_refit  Fits a Poisson point process to the data, an approach sometimes known
as peaks over thresholds (POT), and returns an object of class "potd".

Description

This is a slightly modified versions of the pot function in the evir package. The main modification is to add to the returned object the argument data supplied by the user. This is added to the returned (list) object with the name input_data.

Usage

pot_refit(data, threshold = NA, nextremes = NA, run = NA, picture = TRUE, ...)

Arguments

data        numeric vector of data, which may have a times attribute containing (in an object of class "POSIXct", or an object that can be converted to that class; see as.POSIXct) the times/dates of each observation. If no times attribute exists, the data are assumed to be equally spaced.
threshold   a threshold value (either this or nextremes must be given but not both).
nextremes   the number of upper extremes to be used (either this or threshold must be given but not both).
run         if the data are to be declustered the run length parameter for the runs method (see decluster) should be entered here.
picture     whether or not a picture should be drawn if declustering is performed.
...         arguments passed to optim.
References

Examples

# We need the evir package
got_evir <- requireNamespace("evir", quietly = TRUE)
if (got_evir) {
  library(evir)
data(danish)
  out <- pot(danish, 10)
  ls(out)
  out <- pot_refit(danish, 10)
  ls(out)
}

print.retlev

Print method for retlev object

Description

print method for an objects of class c("retlev", "lax").

Usage

## S3 method for class 'retlev'
print(x, digits = max(3L,getOption("digits") - 3L), ...)

Arguments

x
  an object of class c("retlev", "lax"), a result of a call to return_level.
digits
  The argument digits to print.default.
...
  Additional arguments. None are used in this function.

Details

Prints the call to return_level and the estimates and 100x$level% confidence limits for the x$m-observation return level.

Value

The argument x, invisibly, as for all print methods.

Examples

See the examples in return_level.
See Also

return_level.
return_level

Return Level Inferences for Stationary Extreme Value Models

Description

Calculates point estimates and confidence intervals for \( m \)-observation return levels for \texttt{stationary} extreme value fitted model objects returned from \texttt{alogLik}. Two types of interval may be returned: (a) intervals based on approximate large-sample normality of the maximum likelihood estimator for return level, which are symmetric about the point estimate, and (b) profile likelihood-based intervals based on an (adjusted) loglikelihood.

Usage

\begin{verbatim}
return_level(
  x, 
  m = 100, 
  level = 0.95, 
  npy = 1, 
  prof = TRUE, 
  inc = NULL, 
  type = c("vertical", "cholesky", "spectral", "none")
)
\end{verbatim}

Arguments

- \texttt{x} \hspace{1cm} An object inheriting from class \texttt{"lax"} returned from \texttt{alogLik}.
- \texttt{m} \hspace{1cm} A numeric scalar. The return period, in units of the number of observations. See \texttt{Details} for information.
- \texttt{level} \hspace{1cm} A numeric scalar in \((0, 1)\). The confidence level required for confidence interval for the \( m \)-observation return level.
- \texttt{npy} \hspace{1cm} A numeric scalar. The
- \texttt{prof} \hspace{1cm} A logical scalar. Should we calculate intervals based on profile loglikelihood?
- \texttt{inc} \hspace{1cm} A numeric scalar. Only relevant if \texttt{prof = TRUE}. The increment in return level by which we move upwards and downwards from the MLE for the return level in the search for the lower and upper confidence limits. If this is not supplied then \texttt{inc} is set to one hundredth of the length of the symmetric confidence interval for return level.
- \texttt{type} \hspace{1cm} A character scalar. The argument \texttt{type} to the function returned by \texttt{adjust_loglik}, that is, the type of adjustment made to the independence loglikelihood function in creating an adjusted loglikelihood function. See \texttt{Details} and \texttt{Value} in \texttt{adjust_loglik}.
Details

At present return_level only supports GEV models.

Care must be taken in specifying the input value of m, taking into account the parameterisation of the original fit.

For GEV models it is common for each observation to relate to a year. In this event the m-observation return level is an m-year return level.

For details about the definition and estimation of return levels see Chapter 3 and 4 of Coles (2001). The profile likelihood-based intervals are calculated by reparameterising in terms of the m-year return level and estimating the values at which the (adjusted) profile loglikelihood reaches the critical value \( \logLik(x) - 0.5 * \text{stats::qchisq(level, 1)} \). This is achieved by calculating the profile loglikelihood for a sequence of values of this return level as governed by inc. Once the profile loglikelihood drops below the critical value the lower and upper limits are estimated by interpolating linearly between the cases lying either side of the critical value. The smaller inc the more accurate (but slower) the calculation will be.

Value

A object (a list) of class "retlev", "lax" with the components

- rl_sym, rl_prof
  Named numeric vectors containing the respective lower 100level1% limit, the MLE and the upper 100level1% limit for the return level. If prof = FALSE then rl_prof will be missing.

- rl_se
  Estimated standard error of the return level.

- max_loglik, crit, for_plot
  If prof = TRUE then these components will be present, containing respectively: the maximised loglikelihood; the critical value and a matrix with return levels in the first column (ret_levs) and the corresponding values of the (adjusted) profile loglikelihood (prof_loglik).

- m, level
  The input values of m and level.

- call
  The call to return_level.

References

See Also

plot.retlev for plotting the profile loglikelihood for a return level.

Examples

got_evd <- requireNamespace("evd", quietly = TRUE)
if (got_evd) {
  library(evd)
summary.retlev

Summary method for a "retlev" object

Description

summary method for an objects of class c("retlev", "lax").

Usage

## S3 method for class 'retlev'
summary(object, digits, ...)

Arguments

object an object of class c("retlev", "lax"). a result of a call to return_level.
digits An integer. Used for number formatting with signif. If digits is not specified (i.e. missing) then signif() will not be called (i.e. no rounding will be performed).
... Additional arguments. None are used in this function.

Value

Returns a list containing the list element object$call and a numeric matrix matrix containing the MLE and estimated SE of the return level.
Examples

See the examples in return_level.

return_level.

texmex  

Loglikelihood adjustment of texmex fits

Description

S3 alogLik method to perform loglikelihood adjustment of fitted extreme value model objects returned from the evm function in the texmex package. The model must have been fitted using maximum likelihood estimation.

Usage

## S3 method for class 'evmOpt'
alogLik(x, cluster = NULL, use_vcov = TRUE, ...)

Arguments

x  

A fitted model object with certain associated S3 methods. See Details.

cluster  

A vector or factor indicating from which cluster the respective loglikelihood contributions from loglik originate. This must have the same length as the vector returned by the logLikVec method for an object like x. If cluster is not supplied (i.e. is NULL) then it is assumed that each observation forms its own cluster. See Details.

use_vcov  

A logical scalar. Should we use the vcov S3 method for x (if this exists) to estimate the Hessian of the independence loglikelihood to be passed as the argument H to adjust_loglik? Otherwise, H is estimated inside adjust_loglik using optimHess.

...  

Further arguments to be passed to the functions in the sandwich package meat (if cluster = NULL), or meatCL (if cluster is not NULL).

Details

See alogLik for details.

Value

An object inheriting from class "chandwich". See adjust_loglik. class(x) is a vector of length 5. The first 3 components are c("lax", "chandwich", "texmex"). The remaining 2 components depend on the model that was fitted. The 4th component is: "gev" if x$family$name = "GEV"; "gpd" if x$family$name = "GPD"; "egp3" if x$family$name = "EGP3". The 5th component is "stat" if there are no covariates in the mode and "nonstat" otherwise.
