Package ‘lba’

Title      Latent Budget Analysis for Compositional Data
Version    2.4.5
Date       2022-05-12
Author     Enio G. Jelihovschi <eniojelihovs@gmail.com> and 
           Ivan Bezerra Allaman <iballaman@uesc.br>
Maintainer Ivan Bezerra Allaman <iballaman@uesc.br>
Depends   R (>= 3.1.0), MASS, alabama, plotrix, scatterplot3d, rgl
Description Latent budget analysis is a method for the analysis of a two-way 
contingency table with an exploratory variable and a response variable. It is 
specially designed for compositional data.

### Description

The goodness of fit results assesses how well the model fits the data. It consists of measures of the resemblance between the observed and the expected data, and the parsimony of the model.

### Usage

```r
goodnessfit(object, ...)
```

## S3 methods

## Default S3 method:
goodnessfit(object, ...)

## S3 method for class 'lba.ls'
goodnessfit(object, ...)

## S3 method for class 'lba.ls.fe'
goodnessfit(object, ...)

## S3 method for class 'lba.ls.logit'
goodnessfit(object, ...)

## S3 method for class 'lba.mle'
goodnessfit(object, ...)

## S3 method for class 'lba.mle.fe'
goodnessfit(object, ...)

## S3 method for class 'lba.mle.logit'
goodnessfit(object, ...)

### Arguments

- **object**: An object of one of following classes: `lba.ls`, `lba.ls.fe`, `lba.ls.logit`, `lba.mle`, `lba.mle.fe`, `lba.mle.logit`
- **...**: Further arguments (required by generic).
### Value

The `goodnessfit` function of the method `lba.mle`, `lba.mle.fe` and `lba.mle.logit` returns a list with the slots:

<table>
<thead>

The Satisfaction with Housing Conditions Study

Description

The housing data frame has 72 rows and 5 columns. The observations were obtained from an investigation of Satisfaction with housing conditions carried out by the Danish Building Research Institute and the Danish Institute of Mental Health Research.

Usage

data(housing)

Format

This data frame contains the following columns:

- **Housing** A factor with levels: Apartment; Atrium; Terraced; Tower.
- **Influence** A factor with levels: hi; low; med.
- **Contact** A factor with levels: high; low.
- **Satisfaction** A factor with levels: hi; low; med.
- **value** The absolute frequencies of which factor.

Description

Latent budget analysis (LBA) is a method for the analysis of contingency tables, from where the compositional data is derived. It is used to understand the relationship between the table rows and columns, where the rows denote the categories of the explanatory variable and the columns denote the categories of the response variable.

Details

The row vectors of the compositional data are called observed budgets which are approximated by the expected budgets. The LBA allows us to find which categories of the response are related to different groups of the explanatory categories. If the table has a product multinomial distribution we can understand the latent budget model (LBM) as explaining the relationship between the explanatory and the response variables assuming that conditioned on the latent variable they are independent. In that sense, the latent budgets, which are categories of a latent variable, are hidden values which explain the relationship between the explanatory and response variables. LBA reduce the dimensionality of the original problem, thus making it easier to understand its hidden relations.

### Arguments

- **obj, formula** The function is generic, accepting some forms of the principal argument for specifying a two-way frequency table. Currently accepted forms are matrix, data frame (coerced to frequency tables), objects of class "xtabs" or "table" and one-sided formulae of the form Col1 + Col2 + ... + Coln ~ Row1 + Row2 + ... + Rown, where Rown and Coln are nth row (the mixing parameters) and column variable (the latent components).

- **data** A data frame containing variables in formula.

- **A** The starting value of a (I x K) matrix containing the mixing parameters, if given. The default is NULL, producing random starting values.

- **B** The starting value of a (J x K) matrix containing the latent components, if given. The default is NULL, producing random starting values.

- **K** Integer giving the number of latent budgets chosen by the user. The default is 1.

- **cA** The value of a (I x K) matrix containing the constraints on the mixing parameters. Fixed constraints are the values themselves which are numbers in the [0,1] interval. The optional equality constraints are indicated by an integer starting from 2, such that parameters that must be equal have the same integer. The default is NULL, indicating no constraints.

- **cB** The value of a (J x K) matrix containing the constraints on the latent components. Fixed constraints are the values themselves which are numbers in the [0,1] interval. The optional equality constraints are indicated by an integer starting from 2, such that parameters that must be equal have the same integer. The default is NULL, indicating no constraints.

- **logitA** Design (IxS) matrix for row-covariates. The first column contains the one number, indicating a constant covariate. The entries may be continuous or dummy coded values.

- **logitB** Design (JxT) matrix for column-covariates. The entries may be continuous or dummy coded values.

- **omsk** A (SxK) matrix giving the starting values for the multinomial logit parameters of the row covariates. The default is NULL, producing random starting values.
psitk  A (TxK) matrix giving the starting values for the multinomial logit parameters of the column covariates. The default is \texttt{NULL}, producing random starting values.

S  Number of row-covariates. The default is \texttt{NULL}.

T  Number of column-covariates. The default is \texttt{NULL}.

row.weights  A vector with the same number of rows of the matrix of the weighted least squares method. If is \texttt{NULL} (default), the weights are \[ \sqrt{n_{i+}/n_{++}} . \]

col.weights  A vector with the same number of columns of the matrix of the weighted least squares method. If is \texttt{NULL} (default), the weights are \[ 1/\sqrt{n_{+j}/n_{++}} . \]

tolG  A tolerance value for judging when convergence has been reached. It is based on the estimated likelihood ratio statistics G2. The default is \(1e^{-10}\).

tolA  A tolerance value for judging when convergence has been reached. When the one-iteration change in the maximum of the absolute value of the element wise difference of the estimated matrices A is less than tolA. The default is \(1e^{-05}\).

tolB  A tolerance value for judging when convergence has been reached. When the one-iteration change in the maximum of the absolute value of the element wise difference of the estimated matrices B is less than tolB. The default is \(1e^{-05}\).

itmax.unide  Maximum number of iterations performed by the mle or ls method, if convergence is not achieved, before identification parameters. The default is \(1e^{3}\).

itmax.ide  Maximum number of iterations performed by the mle or ls method in the identification process. Is used too when the constrained fixed, equality and logit are required. The default is \(1e^{3}\).

trace.lba  Logical, indicating whether the base function \texttt{optim} and \texttt{constrOptim.nl} from package \texttt{alabama}, will trace their results. The default is \texttt{TRUE}.

toltype  String indicating which kind of tolerance to be used. That is, the EM algorithm stops updating and considers the maximum log-likelihood to have been found. Their types are: "a11" when the one-iteration change in the estimated likelihood ratio statistics G2 is less than tolG, and the one-iteration change in the maximum of the absolute value of the element wise difference of the estimated matrices A is less than tolA and the same for estimated matrices B with respect to tolB; "G2" when the only one-iteration change in the estimated likelihood ratio statistics G2 is less than tolG; "ab" when only the one-iteration change in the maximum of the absolute value of the element wise difference of the estimated matrices A is less than tolA and the same for estimated matrices B with respect to tolB. toltype works only for method = "mle". The default is "a11". The ls method uses only "ab" as tolerance limit.

method  String indicating which kind of estimating method. They are: "ls" when least squares, either weighted or ordinary, method is used; "mle" when maximum likelihood method is used. The default is "ls".
what

String indicating which kind identified solutions for mixing parameters and latent budgets matrices. They are: the "inner" extreme solution and the "outer" extreme solution. The default is "inner".

... Further arguments (required by generic).

Value

The method lba.ls and lba.mle returns a list of class lba.ls and lba.mle respectively with the slots:

- **P**
  - The compositional data matrix which is formed by dividing the raw data matrix by their corresponding total, its rows are called observed budgets.

- **pij**
  - Matrix whose rows are the expected budgets.

- **residual**
  - Residual matrix P - pij.

- **A**
  - (I x K) matrix of the unidentified mixing parameters.

- **B**
  - (J x K) matrix of the unidentified latent components.

- **Aoi**
  - (I x K) matrix of the identified mixing parameters, they may be either the inner extreme values or the outer extreme values.

- **Boi**
  - (J x K) matrix of the identified latent components, they may be either the inner extreme values or the outer extreme values.

- **rescB**
  - (J x K) matrix of the rescaled latent components.

- **pk**
  - Budget proportions.

- **val_func**
  - Value of least squared or likelihood function achieved.

- **iter_unide**
  - Number of unidentified iterations.

- **iter_ide**
  - Number of identified iterations.

The method lba.ls.fe and lba.mle.fe returns a list of class lba.ls.fe and lba.mle.fe respectively with the slots:

- **P**
  - The compositional data matrix which is formed by dividing the raw data matrix by their corresponding row total, its rows are called observed budgets.

- **pij**
  - Matrix whose rows are the expected budgets.

- **residual**
  - Residual matrix P - pij.

- **A**
  - (I x K) matrix of the unidentified mixing parameters.

- **B**
  - (J x K) matrix of the unidentified latent components.

- **rescB**
  - (J x K) matrix of the rescaled latent components.

- **pk**
  - Budget proportions.

- **val_func**
  - Value of least squared or likelihood function achieved.

- **iter_ide**
  - Number of identified iterations.

The method lba.ls.logit and lba.mle.logit returns a list of class lba.ls.logit and lba.mle.logit respectively with the slots:
The compositional data matrix which is formed by dividing the raw data matrix by their corresponding total, its rows are called observed budgets.

$\pi_j$ Matrix whose rows are the expected budgets.

$\text{residual}$ Residual matrix $P - \pi_j$.

$A$ $(I \times K)$ matrix of the unidentified the mixing parameters.

$B$ $(J \times K)$ matrix of the unidentified the latent componentes.

$\text{rescB}$ $(J \times K)$ matrix of the rescaled latent components.

$pk$ Budget proportions.

$\text{val_func}$ Value of least squared or likelihood function achieved.

$\text{iter_ide}$ Number of identified iterations.

$\text{omsk}$ A $(S \times K)$ matrix giving estimated values of the multinomial logit parameters of the row covariates.

$\text{psitk}$ A $(T \times K)$ matrix giving the estimated values for the multinomial logit parameters of the column covariates.

**Note**

The user has two options to entry the data: the raw data and the tabulated data. If the raw data is imported, he may indicate which, among the variables, comprises the row and which the column variable and let the `lba.formula` function make the tabulation. The user may also tabulate the data with the available functions in R. Recalling that if this second option is used, the object must be of the class `xtabs`, `table` or `matrix`. If the user imports the tabulated data, the class is, in general, `data.frame` and so, it is necessary to transform the object data into a `matrix`.

The function `lba` uses EM algorithm to maximise the latent budget model log-likelihood function; the Active Constraints Methods (ACM) to minimise either the weighted least squares (wls), or ordinary least squares (ols) functions; and "BFGS" variable metric method in `constrOptim.nl` function of `alabama` package and in `optim` function of `stats` package used in identification for $K \geq 3$, in constraint algorithm for ls method, in multinomial logit constraints and in some parts of constraining for mle method. Depending on the starting parameters, those algorithms may only locate a local, rather than global, maximum. This becomes more and more of a problem as $K$, the number of latent budgets, increases. It is therefore highly advisable to run `lba` multiple times until you are relatively certain that you have located the global maximum log-likelihood or the global minimum least squares.

# Using LS method (default) with LOGIT constrain
The Midtown Manhattan Study

Description

The MANHATAN data frame has 25 rows and 3 columns. The observations were obtained in a study carried out by the sociologist Leo Srole and describe the cross-classification of 1660 adults in Manhattan, ages 20-59, obtained from a sample of midtown residents.

Usage

data(MANHATAN)
Format

This data frame contains the following columns:

- **health** A factor with levels: Well; Misy; Mosy; Imp.

BEAUTY SALON MANAGEMENT

Description

The PerfMark data frame has 31 rows and 46 columns. The data set is the result of a survey of 47 beauty salons located at the city of Lavras, Brazil, consisting of two types of questions; the first identifies the profile of the owner manager (explanatory variable), the second are questions referring to the degree of professionalism with respect to planning, market and finances (response variable). The data set is already cross-tabulated.

Usage

data(PerfMark)

Format

This data frame contains the following columns referring the absolute frequencies to each row variable:

Planning variables:

- **PA14** What is the dependence of the owner to function properly?.
- **PA20** What are your plans towards next year? only a dream.
- **PA21** What are your plans towards next year? vague goals. Marketing variables:

Marketing variables:

- **MA11** Your business tries to systematically assess the customer satisfaction and use that as a basis for management decisions. Alternative 1.

plotcorr

Plot lba objects using the correspondence analysis approach as suggested by Jelihovschi (2011).

Description

S3 methods for lba objects.

Usage

plotcorr(x, ...)

## S3 method for class 'lba.1d'
plotcorr(x,
          xlim = NULL,
          ylim = NULL,
plotcorr

xlab = NULL,
ylab = NULL,
metrics = TRUE,
radius = rep(0.5,2),
col.points = NULL,
height.points = NULL,
labels.points = NULL,
pch.points = NULL,
pos.points = NULL,
args.legend = NULL,
height.budget = NULL,
labels.budget = NULL,
pch.budget = NULL,
pos.budget = NULL,
cex.budget = NULL,
col.budget = NULL,
with.ml = c("mix","lat"),
...

## S3 method for class 'lba.2d'
plotcorr(x,
  dim   = c(1,2), #only K = 3
  xlim  = NULL,
  ylim  = NULL,
  xlab  = NULL,
  ylab  = NULL,
  args.legend = NULL,
  col.points = NULL,
  labels.points = NULL,
  pch.points = NULL,
  pos.points = NULL,
  labels.budget = NULL,
  pch.budget = NULL,
  pos.budget = NULL,
  cex.budget = NULL,
  col.budget = NULL,
  with.ml = c("mix","lat"),
  ...
)

## S3 method for class 'lba.3d'
plotcorr(x,
  rgl.use = FALSE,
  dim   = c(1,2,3), #only K >= 3
  xlim  = NULL,
  ylim  = NULL,
  zlim  = NULL,
  xlab  = NULL,
  ylab  = NULL,
plotcorr

zlab = NULL,
args.legend = NULL, #only rgl.use=FALSE
col.points = NULL,
labels.points = NULL,
pch.points = NULL,
pos.points = NULL,
labels.budget = NULL,
pch.budget = NULL,
pos.budget = NULL,
cex.budget = NULL,
col.budget = NULL,
with.ml = c("mix","lat"),
...

Arguments

x
A object of lba class.
dim
The dimention to be plotted. The default is c(1,2) to K = 2 and c(1,2,3) to K = 3.
xlim
The x limits (x1, x2) of the plot.
ylim
The y limits of the plot.
zlim
The z limits of the plot.
xlab
A label for the x axis, defaults to a description of "x".
ylab
A label for the y axis, defaults to a description of "y".
zlab
A label for the z axis, defaults to a description of "z".
rgl.use
A logical value. If TRUE the 3d scatter will be done with the rgl environment, in another way the scatterplot3d will be used.
metrics
Logical. If TRUE (default), the radius is plotted.
radius
A arbitrary number to choose the groups. The default is 0.5. See details.
col.points
The color points to be used, possibly vectors. The default is NULL. See datails.
height.points
Points label height in relation to the y-coordinate. The default is NULL.
labels.points
A character label or expression specifying the _text_ to be written. The default is NULL.
pch.points
A symbols to use. O default is NULL.
pos.points
A position specifier for the text. If specified this overrides any "adj" value given. Values of "1", "2", "3" and "4", respectively indicate positions below, to the left of, above and to the right of the specified coordinates.
args.legend
List of additional arguments to be passed to legend; names of the list are used as argument names. Only used if K=2. The default is NULL.
pch.budget
A symbols to use. O default is NULL.
pos.budget
A position specifier for the text. If specified this overrides any "adj" value given. Values of "1", "2", "3" and "4", respectively indicate positions below, to the left of, above and to the right of the specified coordinates.
plotcorr

height.budget  Budget label height in relation to the y-coordinate. The default is NULL.
labels.budget  A character vector or expression specifying the _text_ to be written. The default is NULL.
cex.budget  The size of text. The default is NULL.
col.budget  The color budget to be used, possibly vectors. The default is NULL.
with.ml  Vector of two character strings specifying the parameters of the plot. Set "mix" to plot the mixing parameters and "lat" to plot the latent components. The default is "mix".
...  Further graphical parameters.

Details

The plotcorr suggested by Jelihovschi et all (2011), has a graphical display which uses the correspondence analysis graphics of the mixing parameters and latent components matrices. In this case, a graphic display is possible for K >= 2.

The argument radius was featured in order to help the user as he or she needs do decide which are the points belonging to a certain latent budget. Only the points to the right or left of LB1 and LB2 but always towards the center of the graphic (the zero of x axis) were taken in account, since those in opposite direction automatically belong to the closest latent budget. This argument only works for K = 2. It’s should be of size two.

The argument col.points takes in account the argument radius in order to color the groups which either belong or not to a certain budget, therefore, the size of the vector of this argument must be equal to the number of formed groups.

**plotlba**

_Plotba objects using the approach suggested by van der Ark (1999)._

**Description**

S3 methods for lba objects.

**Usage**

```r
## S3 method for class 'lba.1d'
plotlba(x,
    height.line = NULL,
    xlab = NULL,
    ylab = NULL,
    ylim = NULL,
    args.legend = NULL,
    rgl.use = FALSE)```

```r
plotlba(x,
    height.line = NULL,
    xlab = NULL,
    ylab = NULL,
    ylim = NULL,
    args.legend = NULL,
    rgl.use = TRUE)```
plotlba

labels.points = NULL,
col.points = par('col'),
col.lines = par('col'),
lty.lines = par('lty'),
lwd.lines = par('lwd'),
pch.budget = par('pch'),
col.budget = par('fg'),
lty.budget = par('lty'),
lwd.budget = par('lwd'),
colline.budget = NULL,
with.ml = c("mix","lat"),
...

## S3 method for class 'lba.2d'
plotlba(x,
axis.labels = NULL,
labels.points = NULL,
col.points = par('fg'),
pch.budget = par('pch'),
col.budget = par('fg'),
lty.budget = par('lty'),
lwd.budget = par('lwd'),
colline.budget = par('fg'),
args.legend = NULL,
with.ml = c("mix","lat"),
...

Arguments

x A object of lba class.
height.line Is a vector with the lines height when K = 2.
xlab A title for the x axis.
ylab A title for the y axis.
ylim The y limits of the plot.
args.legend List of additional arguments to be passed to legend; names of the list are used as argument names. The default is NULL.
axis.labels Labels for the three axes in the order left, right, bottom. Defaults to the column names.
labels.points A character vector or expression specifying the text to be written. The default is NULL.
col.points A vector of colour representing the points of the mixing parameters. The default is par('fg').
col.lines A vector of colour representing the lines of the mixing parameters. The default is par('fg').
lty.lines A vector of line types representing the mixing parameters. The default is par('lty').
lwd.lines  A vector of line width representing the mixing parameters. The default is par('lwd').
pch.budget A vector of plotting characters or symbols representing the budget proportion. The default is par('pch').
col.budget  A vector of colour representing the budget proportion. The default is par('fg').
lty.budget   A vector of line types representing the budget proportion. The default is par('lty').
lwd.budget   A vector of line width representing the budget proportion. The default is par('lwd').
colline.budget  The colors for line budget. The default is par('fg').
with.ml      What’s parameters do you like to plot? The default is mixing parameters ('mix').
...          Other graphical parameters may also be passed as arguments to these functions.

Details

The plotlba function, was suggested at de Leeuw et all (1990) and at van der Ark (1999) thesis. Those types of plots have only graphical views for $K = 2$ and $K = 3$. When $K = 2$, either the latent budgets or the mixing parameters are displayed on a (one dimensional) line segment. When $K = 3$, either the latent budgets or the mixing parameters are displayed in a equilateral triangle using a barycentric coordinate system where the budgets are represented by the vertices and the plot is made with help of triax.plot and triax.points function of plotrix package.

        lwd.budget = 3,
        colline.budget = 3,
        axis.labels = c('Lba1','Lba2','Lba3'))
The postmater data frame has 13 rows and 8 columns. The raw data refers to a political and social survey across Europe that is conducted twice a year.

Usage

data(postmater)

Format

This data frame contains the following columns:

- **country**: A factor with levels: F France; B Belgium; NL Netherlands; D Germany; I Italy; L Luxembourg; DK Denmark; IRL Ireland; GB Great Britain; NIRL Northern Ireland; GR Greece; E Spain; P Portugal.
- **m..**: The absolute frequencies of materialist factor in the respect country. The degree of ranking of this index is ++.
- **m.**: The absolute frequencies of materialist factor in the respect country. The degree of ranking of this index is +.
- **m**: The absolute frequencies of materialist factor in the respect country. The degree of ranking of this index is below of the "m.".
- **m_pm**: The absolute frequencies of materialist/post-materialist factor in the respect country. The degree of ranking of this index is below of the "m".
- **pm**: The absolute frequencies of post-materialist factor in the respect country. The degree of ranking of this index is below of the "m_pm".
- **pm.**: The absolute frequencies of post-materialist factor in the respect country. The degree of ranking of this index is below of the "pm".
- **pm..**: The absolute frequencies of post-materialist factor in the respect country. The degree of ranking of this index is below of the "pm.".

Description

The pregnancy matrix has 16 rows and 5 columns. The raw data refers to California pregnancy-related deaths from 2002-2005.

Usage

data(pregnancy)

Format

This matrix contains the following columns:

- **Pre.E**  Preeclampsia/eclampsia
- **OH**  Obstetric hemorrhage
- **CVD**  Cardiovascular diseases
- **DVTPE**  Deep vein thrombosis - pulmonary embolism
- **AFE**  Amniotic fluid embolism

The rows refers to:

- **Hfob**  Hispanic, foreign-born
- **Husb**  Hispanic, us-born
- **Wnh**  White, non-hispanic
- **Bnh**  Black, non-hispanic
- **$<30^a$**  Maternal age
- **$30-40^a$**  Maternal age
- **$>40^a$**  Maternal age
- **$<30^b$**  Maternal age
- **$30-40^b$**  Maternal age
- **$>40^b$**  Maternal age
- **$<32^w$**  Gestational age at delivery
- **$32-36^w$**  Gestational age at delivery
- **$>37^w$**  Gestational age at delivery

**print.goodnessfit**  
Print Method for goodnessfit objects.

### Description
Returns (and prints) a summary list for goodnessfit objects.

### Usage
```r
## S3 method for class 'goodnessfit.lba.ls'
print(x, digits=3L, ...)

## S3 method for class 'goodnessfit.lba.ls.fe'
print(x, digits=3L, ...)

## S3 method for class 'goodnessfit.lba.ls.logit'
print(x, digits=3L, ...)

## S3 method for class 'goodnessfit.lba.mle'
print(x, digits=3L, ...)

## S3 method for class 'goodnessfit.lba.mle.fe'
print(x, digits=3L, ...)

## S3 method for class 'goodnessfit.lba.mle.logit'
print(x, digits=3L, ...)
```

### Arguments
- **digits**: A non-null value for digits specifies the minimum number of significant digits to be printed in values. The default is 3.
- **...**: Further arguments (require by generic).
print.lba

print.lba

Print Method for lba objects.

Description

Returns (and prints) a summary list for objects of class lba.ls, lba.ls.fe, lba.ls.logit, lba.mle, lba.mle.fe, and lba.mle.logit.

Usage

## S3 method for class 'lba.ls'
print(x, digits = 3L, ...)

## S3 method for class 'lba.ls.fe'
print(x, digits = 3L, ...)

## S3 method for class 'lba.ls.logit'
print(x, digits = 3L, ...)

## S3 method for class 'lba.mle'
print(x, digits = 3L, ...)

## S3 method for class 'lba.mle.fe'
print(x, digits = 3L, ...)

## S3 method for class 'lba.mle.logit'
print(x, digits = 3L, ...)
Arguments

x A given object of the class lba, lba.ls.fe, lba.mle.fe, lba.ls.logit and lba.mle.logit.
digits Number of decimal digits in the results. The default is 3.
...
Further arguments (require by generic).
