Package ‘leidenAlg’

March 3, 2022

Type Package

Title Implements the Leiden Algorithm via an R Interface

Version 1.0.2

Description
An R interface to the Leiden algorithm, an iterative community detection algorithm on networks. The algorithm is designed to converge to a partition in which all subsets of all communities are locally optimally assigned, yielding communities guaranteed to be connected. The implementation proves to be fast, scales well, and can be run on graphs of millions of nodes (as long as they can fit in memory). The original implementation was constructed as a python interface `leidenalg` found here: <https://github.com/vtraag/leidenalg>. The algorithm was originally described in Traag, V.A., Waltman, L. & van Eck, N.J. “From Louvain to Leiden: guaranteeing well-connected communities”. Sci Rep 9, 5233 (2019) <doi:10.1038/s41598-019-41695-z>.

NeedsCompilation yes
**as.dendrogram.fakeCommunities**

Returns pre-calculated dendrogram

### Description

Returns pre-calculated dendrogram

### Usage

```r
## S3 method for class 'fakeCommunities'
as.dendrogram(object, ...)
```

### Arguments

- **object**: fakeCommunities object
- **...**: further parameters for generic

### Value

- **dendrogram**
Examples

```r
rLeidenComm = suppressWarnings(rleiden.community(exampleGraph, n.cores=1))
as.dendrogram.fakeCommunities(rLeidenComm)
```

### Description

**Conos graph**

**Usage**

```r
eexampleGraph
```

**Format**

An object of class `igraph` of length 10.

### find_partition

**Finds the optimal partition using the Leiden algorithm**

**Description**

Finds the optimal partition using the Leiden algorithm

**Usage**

```r
find_partition(graph, edge_weights, resolution = 1, niter = 2L)
```

**Arguments**

- `graph`: The igraph graph to define the partition on
- `edge_weights`: Vector of edge weights. In weighted graphs, a real number is assigned to each (directed or undirected) edge. Refer to igraph, weighted graphs.
- `resolution`: Integer resoluiton parameter controlling communities detected (default=1.0) Higher resolutions lead to more communities, while lower resolutions lead to fewer communities.
- `niter`: Number of iterations that the algorithm should be run for (default=2)

**Value**

A vector of membership values
Examples

```r
library(igraph)
library(leidenAlg)

g <- make_star(10)
E(g)$weight <- seq(ecount(g))
find_partition(g, E(g)$weight)
```

leiden.community  
Leiden algorithm community detection
Detect communities using Leiden algorithm (implementation copied from https://github.com/vtraag/leidenalg)

Description

Leiden algorithm community detection
Detect communities using Leiden algorithm (implementation copied from https://github.com/vtraag/leidenalg)

Usage

```
leiden.community(graph, resolution = 1, n.iterations = 2)
```

Arguments

- **graph**: graph on which communities should be detected
- **resolution**: resolution parameter (default=1.0) - higher numbers lead to more communities
- **n.iterations**: number of iterations that the algorithm should be run for (default=2)

Value

a fakeCommunities object that returns membership and dendrogram

Examples

```
leiden.community(exampleGraph)
```
membership.fakeCommunities

Returns pre-calculated membership factor

Description

Returns pre-calculated membership factor

Usage

```r
# S3 method for class 'fakeCommunities'
membership(object, ...)
```

Arguments

- `object`: fakeCommunities object
- `...`: further parameters for generic

Value

membership factor

Examples

```r
leidenComm = leiden.community(exampleGraph)
membership.fakeCommunities(leidenComm)
```

rleiden.community

Recursive leiden communities Constructs an n-step recursive clustering, using leiden.community

Description

Recursive leiden communities Constructs an n-step recursive clustering, using leiden.community

Usage

```r
rleiden.community(
  graph,
  max.depth = 2,
  n.cores = parallel::detectCores(logical = FALSE),
  min.community.size = 10,
  verbose = FALSE,
  resolution = 1,
  cur.depth = 1,
```
hierarchical = TRUE,
...
)

Arguments

- **graph**
  - graph

- **max.depth**
  - Recursive depth (default=2)

- **n.cores**
  - integer Number of cores to use (default = parallel::detectCores(logical=FALSE)). If logical=FALSE, uses the number of physical CPUs/cores. If logical=TRUE, uses the logical number of CPUs/cores. See parallel::detectCores()

- **min.community.size**
  - integer Minimal community size parameter for the walktrap communities—Communities smaller than that will be merged (default=10)

- **verbose**
  - boolean Whether to output progress messages (default=FALSE)

- **resolution**
  - resolution parameter passed to leiden.community (either a single value, or a value equivalent to max.depth) (default=1)

- **cur.depth**
  - integer Current depth of clustering (default=1)

- **hierarchical**
  - boolean If TRUE, calculate hierarchy on the multilevel clusters (default=TRUE)

Value

- a fakeCommunities object that returns membership and dendrogram

Examples

- rleiden.community(exampleGraph, n.cores=1)
