Package ‘lessR’

June 11, 2020

Version 3.9.6
Date 2020-06-09
Title Less Code, More Results
Author David Gerbing, The School of Business, Portland State University
Maintainer David W. Gerbing <gerbing@pdx.edu>
Depends R (>= 2.15.0)
Imports graphics, grDevices, stats, utils, methods, lattice,
    latticeExtra, robustbase, ellipse, leaps, openxlsx, triangle,
    colorspace, viridisLite, knitr
Suggests KernSmooth, rmarkdown, wesanderson, haven
VignetteBuilder knitr
Description Each function accomplishes the work of several or more standard R functions. For example, two function calls, Read() and CountAll(), read the data and generate summary statistics for all variables in the data frame, plus histograms and bar charts as appropriate. Other functions provide for descriptive statistics, a comprehensive regression analysis, analysis of variance and t-test, plotting including the introduced here Violin/Box/Scatter plot for a numerical variable, bar chart, histogram, box plot, density curves, calibrated power curve, reading multiple data formats with the same function call, variable labels, color themes, Trellis graphics and a built-in help system. Also includes a confirmatory factor analysis of multiple indicator measurement models, pedagogical routines for data simulation such as for the Central Limit Theorem, and generation and rendering of R markdown instructions for interpretative output.

Function: for Selecting Rows/Columns with base R Extract

Description

Using the base R Extract function, with the unobtrusive function name, ., express a subsetting operation as
dl.(rows), .(cols)]
for a less annoying experience. With . to express a logical criterion to select rows, do not append
the data frame name and $ to variable names in expressions as otherwise required by Extract. Can
also do a random selection of rows. For columns, no need to quote variable names, can include
variable ranges defined by a colon, :, and add - to exclude designated columns. Also does not list
rows missing data when not requested as does Extract.

Usage

. (x, ...)

Arguments

x       Logical expression to subset rows or columns.
...     Allows multiple expressions when selecting columns.
Details

Eliminates the need to prepend the data frame name and a `\$` to each variable name in the specified logical expression to select rows. For columns, no quoting variables, allow variable ranges.

Can create a character string called `rows` that expresses the logic of row selection. Can create a character string called `cols` that expresses the logic of column (variable) selection. To negate the `rows` expression, `.(!(rows))`. Use `-.(cols)` to exclude designated variables.

Select a random selection of rows with the containing function `random(n)`, where `n` is the specified number of random rows to select from the full data frame.

Value

The row or columns names of the rows of data or columns of data that satisfy the specified logical conditions.

Author(s)

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

Extract subset.

Examples

```r
# see vignette

d <- Read("Employee", quiet=TRUE)

# no data frame name attached to variable names
# as variables assumed in the data frame
d[.(Gender=="M" & Post>90), ]

# include first three rows and only the specified variables
# variable range permitted
d[1:3, .(Years:Salary, Post)]

# include first three rows and delete the specified variables
# because of the default for the base R Extract function [ ],
# if only one variable retained,
# then add drop=FALSE to retain the result as a data frame
d[1:3, .(Salary), drop=FALSE]

# rows and columns
d[.(Gender="M" & Post>90), .(Years:Salary, Post)]

# define character string arguments
cols <- "Gender:Salary, Post"
rows <- "Gender=="M" & Post>93"
```
ANOVA

\[
\begin{align*}
\text{d} &\left[ .(\text{rows}), .(\text{cols}) \right] \\
& \quad \# \text{ negate} \\
\text{d} &\left[ .!(\text{rows}), -.\left(\text{cols}\right) \right] \\
& \quad \# \text{ random selection of 4 rows, retain all variables} \\
\text{d} &\left[ .\left(\text{random}(4)\right), \right]
\end{align*}
\]

\text{ANOVA} \quad \text{Analysis of Variance}

\textbf{Description}

Abbreviation: av, av\_brief

Analysis of variance from the R \texttt{aov} function plus graphics and effect sizes. Included designs are one-way between groups, two-way between groups and randomized blocks with one treatment factor with one observation for each treatment and block combination.

Output is generated into distinct segments by topic, organized and displayed in sequence by default. When the output is assigned to an object, such as in \texttt{a <- \text{reg}(Y ~ X)}, the full or partial output can be accessed for later analysis and/or viewing. A primary such analysis is with \texttt{knitr} for dynamic report generation. The input instructions to \texttt{knitr} are written comments and interpretation with embedded R code, called R-Markdown. Generate a complete, though preliminary at this time, R Markdown document from the Rmd option ready to knit. Simply specify the option with a file name, run the ANOVA function to create the file. Then open the newly created .Rmd file in RStudio and click the knit button to create a formatted document that consists of the statistical results and interpretative comments. See the sections arguments, value and examples for more information.

\textbf{Usage}

\begin{verbatim}
ANOVA(my_formula, data=d, rows=NULL, 
brief=getOption("brief"), digits_d=NULL, 
Rmd=NULL, graphics=TRUE, 
rb_points=TRUE, res_rows=NULL, res_sort=c("zresid", "fitted", "off"), 
pdf=FALSE, width=5, height=5, fun_call, ...) 
\end{verbatim}

\begin{verbatim}
av(...) 
av\_brief(..., brief=TRUE)
\end{verbatim}

\textbf{Arguments}

\begin{tabular}{ll}
\texttt{my\_formula} & Standard R \texttt{formula} for specifying a model. \\
\texttt{data} & The default name of the data frame that contains the data for analysis is d, otherwise explicitly specify. \\
\texttt{rows} & A logical expression that specifies a subset of rows of the data frame to analyze. \\
\texttt{brief} & If set to TRUE, reduced text output with no Tukey multiple comparison of means and no residuals. Can change system default with \texttt{style} function. \\
\end{tabular}
**digits_d**  For the Basic Analysis, it provides the number of decimal digits. For the rest of the output, it is a suggestion only.

**Rmd**  File name for the file of R Markdown instructions to be written, if specified. The file type is .Rmd, which automatically opens in RStudio, but it is a simple text file that can be edited with any text editor, including RStudio.

**graphics**  Produce graphics. Default is TRUE. In Rmd can be useful to set to FALSE so that regPlot can be used to place the graphics within the output file.

**rb_points**  For a randomized block design, a plot of the fitted value for each cell is obtained as well as the individual data values. Set to FALSE to suppress the data values.

**res_rows**  Default is 20, which lists the first 20 rows of data and residuals sorted by the specified sort criterion. To disable residuals, specify a value of 0. To see the residuals output for all observations, specify a value of "all".

**res_sort**  Default is "zresid", for specifying standardized residuals as the sort criterion for the display of the rows of data and associated residuals. Other values are “fitted” for the fitted values and "off" to not sort the rows of data.

**pdf**  Indicator as to if the graphic files should be saved as pdf files instead of directed to the standard graphics windows.

**width**  Width of the pdf file in inches.

**height**  Height of the pdf file in inches.

**fun_call**  Function call. Used with Rmd to pass the function call when obtained from the abbreviated function call av.

**...**  Other parameter values for R function lm which provides the core computations.

---

**Details**

**OVERVIEW**
The one-way ANOVA with Tukey HSD and corresponding plot is based on the R functions aov, TukeyHSD, and provides summary statistics for each level. Two-factor ANOVA also provides an interaction plot of the means with interaction.plot as well as a table of means and other summary statistics. The two-factor analysis can be between groups or a randomized blocked design. Residuals are displayed by default. Tukey HSD comparisons and residuals are not displayed if brief=TRUE.

The rows parameter subsets rows (cases) of the input data frame according to a logical expression. Use the standard R operators for logical statements as described in Logic such as & for and, | for or and ! for not, and use the standard R relational operators as described in Comparison such as == for logical equality, != for not equals, and > for greater than. See the Examples.

**MODEL SPECIFICATION**
In the following specifications, Y is the response variable, X is a treatment variable and Blocks is the blocking variable. The distinction between the one-way randomized blocks and the two-way between groups models is not the variable names, but rather the delimiter between the variable names. Use * to indicate a two-way crossed between groups design and + for a randomized blocks design.

one-way between groups: ANOVA(Y ~ X)

one-way randomized blocks: ANOVA(Y ~ X + Blocks)
two-way between groups: \( \text{ANOVA}(Y \sim X1 \times X2) \)

For more complex designs, use the standard R function `aov` upon which ANOVA depends.

**BALANCED DESIGN**

The design for the two-factor analyses must be balanced. A check is performed and processing ceases if not balanced. For unbalanced designs, consider the function `lmer` in the `lme4` package.

**DECIMAL DIGITS**

The number of decimal digits displayed on the output is, by default, the maximum number of decimal digits for all the data values of the response variable. Or, this value can be explicitly specified with the `digits_d` parameter.

---

**Value**

The output can optionally be returned and saved into an R object, otherwise it simply appears at the console. The components of this object are redesigned in `lessR` version 3.3.5 into (a) pieces of text that form the readable output and (b) a variety of statistics. The readable output are character strings such as tables amenable for viewing and interpretation. The statistics are numerical values amenable for further analysis, such as to be referenced in a subsequent R Markdown document.

The motivation of these two types of output is to facilitate R markdown documents, as the name of each piece, preceded by the name of the saved object followed by a $, can be inserted into the R markdown document (see examples).

**TEXT OUTPUT**

- `out_background`: variables in the model, rows of data and retained
- `out_descriptive`: descriptive stats
- 1-predictor: `out_cell.n`: cell sample size
- 2-predictors: `out_cell.means`: cell means
- 2-predictors: `out_cell.marginals`: marginal means
- 2-predictors: `out_cell.gm`: grand mean
- 2-predictors: `out_cell.sd`: cell standard deviations
- `out_anova`: analysis of variance summary table
- `out_effects`: effect sizes
- `out_hsd`: Tukey’s honestly significant different analysis
- `out_res`: residuals
- `out_plots`: list of plots generated if more than one

Separated from the rest of the text output are the major headings, which can then be deleted from custom collations of the output.

- `out_title_bck`: BACKGROUND
- `out_title_des`: DESCRIPTIVE STATISTICS
- `out_title_basic`: BASIC ANALYSIS
- `out_title_res`: RESIDUALS

**STATISTICS**

- `call`: function call that generated the analysis
- `formula`: model formula that specifies the model
- `n.vars`: number of variables in the model
- `n.obs`: number of rows of data submitted for analysis
- `n.keep`: number of rows of data retained in the analysis
- `residuals`: residuals
fitted: fitted values

Although not typically needed for analysis, if the output is assigned to an object named, for example, `a`, then the complete contents of the object can be viewed directly with the `unclass` function, here as `unclass(a)`. Invoking the `class` function on the saved object reveals a class of `out_all`. The class of each of the text pieces of output is `out`.

p5,2,1,2,3
p6,5,5,6,8
p7,2,3,2,4")
```
```r
# reshape data from wide form to long form
# do not need the row names
d <- reshape(d, direction="long",
   idvar="Person", v.names="Reps",
   varying=list(2:5), timevar="Supplement")
rownames(data) <- NULL

ANOVA(Reps ~ Supplement + Person)
```

---

### BarChart

#### Bar Chart for One or Two Variables

**Description**

Abbreviation: bc

Plots a bar chart, one categorical variable, x against one numeric variable y, as well as an optional second categorical variable by with a provided legend. One option is to enter the reduced data table, which consists of each level of x paired with the corresponding numerical value of y, with the number of rows the number of levels. Or, transform the full data table of original measurements. If no value of y is specified, by default the numeric variable is the computed frequency of values in each category, with default colors for one or two variables, which can be replaced with custom color scales. Or, if a y variable is specified, obtain the reduced data table from which the bar chart is computed by summarizing the value of y at each level of x, such as the mean or a variety of other summary statistics.

Also displays the frequency table for one or two variables, Cramer’s V association, and the corresponding chi-square inferential analysis. For two variables, the frequencies include the joint and marginal frequencies. To activate Trellis graphics specify a by1 variable. If the provided object to analyze is a set of multiple variables, including an entire data frame, then a bar chart is calculated for each non-numeric variable in the data frame.

**Usage**

```r
BarChart(x=NULL, y=NULL, by=NULL, data=d, rows=NULL,
stat=NULL, n_cat=getOption("n_cat"), one_plot=NULL,
by1=NULL, n_row=NULL, n_col=NULL, aspect="fill",
horiz=FALSE, beside=FALSE, stack100=FALSE,
gap=NULL, scale_y=NULL,
theme=getOption("theme"),
fill=NULL,
color=getOption("bar_color_discrete"),
trans=getOption("trans_bar_fill"),
fill_split=NULL,

legend_title=NULL, legend_position="right_margin",
```

BarChart

legend_labels=NULL, legend_horiz=FALSE,
legend_size=NULL,

value_labels=NULL,
rotate_x=getOption("rotate_x"),

pad_y_min=0, pad_y_max=0,

add=NULL, x1=NULL, y1=NULL, x2=NULL, y2=NULL,

eval_df=NULL, quiet=getOption("quiet"),
width=6.5, height=6, pdf=FALSE, ...)

c(...)

Arguments

x Variable(s) to analyze. Can be a single variable, either within a data frame or as a vector in the users workspace, or multiple variables in a data frame such as designated with the c function, or an entire data frame. If not specified, then defaults to all non-numerical variables in the specified data frame, by default. To manage large category values, unless brake_x is FALSE, any space in each category value is converted to new line for the corresponding axis label in the plot. To keep two (small) words on the same line, replace the space that separates them with an underscore, which is converted to a blank for the corresponding axis label.

y Numeric variable for which the values are displayed on the vertical axis. If specified, then data frame is summary data (i.e., aggregated). See later example to create with R link{aggregate} function. If not specified, then its value is automatically tabulated as the frequency of each category or joint category.

by A categorical variable to provide a bar chart for each level of the numeric primary variables x and y on the same plot, which applies to the panels of a Trellis plot if by1 is specified.

data Optional data frame that contains the variables of interest. Can contain data from which frequencies are computed for the y-values, or can contain values to
plot on the y-axis instead of counts.

**rows**  
A logical expression that specifies a subset of rows of the data frame to analyze.

**stat**  
Statistical transformation of the data. If no \( y \) variable, then "count" or "proportion", otherwise "mean", "sd", etc.

**n_cat**  
When analyzing all the variables in a data frame, specifies the largest number of unique values of variable of a numeric data type for which the variable will be analyzed as a categorical. Default is 0.

**one_plot**  
For bar charts of multiple \( x \)-variables, indicates if a bar plot is produced for each \( x \)-variable, or all are combined into a single plot, such as for items that all share common responses such as survey data with a common Likert scale across variables. Default is if variables share a common response scale set to TRUE, otherwise FALSE.

**by1**  
A categorical variable called a conditioning variable that activates Trellis graphics, from the lattice package, to provide a separate bar chart (panel) of numeric primary variables \( x \) and \( y \) for each level of the variable.

**n_row**  
Optional specification for the number of rows in the layout of a multi-panel display with Trellis graphics. Need not specify \( n\_col \).

**n_col**  
Optional specification for the number of columns in the layout of a multi-panel display with Trellis graphics. Need not specify \( n\_row \). If set to 1, then the strip that labels each group locates to the left of each plot instead of the top.

**aspect**  
Lattice parameter for the aspect ratio of the panels in a Trellis plot (multi-panel display), defined as height divided by width. The default value is "fill" to have the panels expand to occupy as much space as possible. Set to 1 for square panels. Set to "xy" to specify a ratio calculated to "bank" to 45 degrees, that is, with the line slope approximately 45 degrees.

**horiz**  
By default the value is FALSE so bars are vertical, unless one_plot is TRUE.

**beside**  
For a two variable plot, set to TRUE for the levels of the first variable to be plotted as adjacent bars instead of stacked on each other.

**stack100**  
100% stacked bar chart when a \( by \) variable is present, also activated by setting stat to "proportion" with a \( by \) variable.

**gap**  
Gap between bars. Provides the value of the space option from the standard R `barplot` function with a default of 0.2 unless two variables are plotted and beside=TRUE, in which case the default is \( c(.1,1) \).

**scale_y**  
If specified, a vector of three values that define the numerical values of the y-axis, the numerical axis, within the bounds of plot region: starting value, ending value, and number of intervals.

**theme**  
Color theme for this analysis. Make persistent across analyses with `style`.

**fill**  
Fill color of the bars, override the default with a vector of colors: names, rgb, hex or hcl and many other possibilities from palettes such as viridis. Can generate these colors with pre-defined qualitative, sequential and divergent palettes generated by lessR `getColors`, such as "blues". Or set to the name of \( y \) to
map the values of bar fill into the fill colors. Specified the name of \( y \) as \((\text{count})\) if tabulated from the data, or \((\text{count.v})\) for viridis palette. See the details and examples sections. Default is \texttt{bar\_color\_discrete} from the lessR \texttt{style} function except sequential ordered factors.

\textbf{color}  
Border color of the bars, can be a vector to customize the color for each bar. Default is \texttt{bar\_color\_discrete} from the lessR \texttt{style} function.

\textbf{trans}  
Transparency factor of the area of each slice from 0, no transparency to 1, full transparency. Default is \texttt{trans\_bar\_fill} from the lessR \texttt{style} function.

\textbf{fill\_split}  
The value of the numeric variable \( y \) for which bars that correspond to values of \( y \leq \text{fill\_split} \) are displayed in the first fill color and other values displayed in the second fill color, or as specified by a vector of exactly two fill colors.

\textbf{legend\_title}  
Title of the legend, which is usually set by default except when raw counts are entered as a matrix. Then a title must be specified to generate a legend.

\textbf{legend\_position}  
When plotting two variables, location of the legend, with the default in the right margin. Additional options from standard R are "topleft", "top", "topright" and others as shown in the help for the \texttt{legend} function.

\textbf{legend\_labels}  
When plotting two variables, labels for the legend, which by default are the levels for the second or by variable.

\textbf{legend\_horiz}  
By default the legend is vertical, but can be changed to horizontal.

\textbf{legend\_size}  
Size of legend text.

\textbf{value\_labels}  
For factors, default is the factor labels, and for character variables, default is the character values. Or, provide labels for the \( x \)-axis on the graph to override these values. If the variable is a factor and \texttt{value\_labels} is not specified (is \texttt{NULL}), then the value\_labels are set to the factor levels with each space replaced by a new line character. If \( x \) and \( y \)-axes have the same scale, they also apply to the \( y \)-axis. Control the plotted size with \texttt{axis\_cex} and \texttt{axis\_x\_cex} from the lessR \texttt{style} function.

\textbf{rotate\_x}  
Degrees that the axis values for the category values axis are rotated, usually to accommodate longer values, typically used in conjunction with \texttt{offset}. When equal 90 the value labels are perpendicular to the \( x \)-axis and a different algorithm places the labels so that \texttt{offset} is not needed.

\textbf{offset}  
The amount of spacing between the axis values and the axis. Default is 0.5. Larger values such as 1.0 create space for the label when longer axis value names are rotated.

\textbf{break\_x}  
Replace spaces in the category values with a new line and replace underscores with a blank. By default, \texttt{TRUE} for vertical bar charts with \texttt{rotate\_x} set to 0, and \texttt{FALSE} otherwise.

\textbf{sort}  
Sort the categories by their frequency for one variable and by the column sums if a by variable. Not applicable to Trellis plots. By default "0" for no sort, or sort descending "-" or ascending "+", unless \texttt{one\_plot} is \texttt{TRUE}, then is set to "*".
label_max

To improve readability, the maximum size of the value labels before the labels are abbreviated for text output only. Not a literal maximum as preserving unique values may require a larger number of characters than specified.

out_size

To improve the readability of the frequency distribution of a single variable displayed at the console, the maximum number of characters on a line of output at the console for one variable before the frequency distribution is written vertically.

values

If not "off", adds the numerical results to the plot according to the default "%" for tabulated counts and "input" for the input values for a y-variable explicitly provided, unless there are more than 15 levels or y is present and non-integer in which case the default is "off". For tabulated counts, "prop" is also available for proportions as well as "input".

values_color

Color of the plotted text. Could be a vector to specify a unique color for each value. If fewer colors are specified than the number of categories, the colors are recycled.

values_size

Character expansion factor, the size, of the plotted text, for which the default value is 0.95, or 0.9 of value if beside is TRUE and values_position is "in" because bars are narrower.

values_digits

Number of decimal digits for which to display the values. Default is 0, round to the nearest integer for "\%", 2 for "prop", and if "input" and y is entered directly, display the literal value unless > 9999, in which case set to 0.

values_position

Position of the plotted text. Default is inside the bar, or, if "out", as part of the label for each value outside of the bar.

values_cut

Threshold for displaying the value. If values_position equals "out", then default is 0.028 unless there is a by variable or multiple x-variables on the same plot, then default is 0.040

xlab

Label for x-axis. If xlab is not specified, then the label becomes the name of the corresponding variable label if it exists, or, if not, the variable name. If xy_ticks is FALSE, then no label is displayed. If no y variable is specified, then xlab is set to Index unless xlab has been specified.

ylab

Label for y-axis. If xlab is not specified, then the label becomes the name of the corresponding variable label if it exists, or, if not, the variable name. If xy_ticks is FALSE, then no label displayed.

main

Label for the title of the graph. Can set size with main_cex and color with main_color from the lessR style function.

sub

Sub-title of graph, below xlab.

lab_adj

Two-element vector – x-axis label, y-axis label – adjusts the position of the axis labels in approximate inches. + values move the labels away from plot edge. Not applicable to Trellis graphics.

margin_adj

Four-element vector – top, right, bottom and left – adjusts the margins of the plotted figure in approximate inches. + values move the corresponding margin away from plot edge. Not applicable to Trellis graphics.
pad_y_min  Proportion of padding added to the left side of the y-axis. Value from 0 to 1.

pad_y_max  Proportion of padding added to the right side of the y-axis. Value from 0 to 1.

add  **Draw one or more objects**, text or a geometric figures, on the plot. Possible values are any text to be written, the first argument, which is "text", or, to indicate a figure, "rect" (rectangle), "line", "arrow", "v.line" (vertical line), and "h.line" (horizontal line). The value "means" is short-hand for vertical and horizontal lines at the respective means. Does not apply to Trellis graphics. Customize with parameters such as add_fill and add_color from the style function.

x1  First x coordinate to be considered for each object. All coordinates vary from -1 to 1.

y1  First y coordinate to be considered for each object.

x2  Second x coordinate to be considered for each object. Only used for "rect", "line" and arrow.

y2  Second y coordinate to be considered for each object. Only used for "rect", "line" and arrow.

eval_df  Determines if to check for existing data frame and specified variables. By default is TRUE unless the shiny package is loaded then set to FALSE so that Shiny will run. Needs to be set to FALSE if using the pipe %>% notation.

quiet  If set to TRUE, no text output. Can change system default with style function.

width  Width of the plot window in inches, defaults to 4.5.

height  Height of the plot window in inches, defaults to 4.5.

pdf  If TRUE, indicate to direct pdf graphics for each specified variable to a pdf file named BarChart_name.pdf where name is the variable name.

...  Other parameter values for graphics as defined by barplot, legend, and par including xlim and ylim for setting the range of the x and y-axes
cex.main for the size of the title
col.main for the color of the title
"dotted", "dotdash"
sub and col.sub for a subtitle and its color
las=3 to reorient vertical axis labels
space for one variable only

**Details**

**OVERVIEW**
Plot a bar chart with default colors for one or two categorical variables, that is, with a relatively small number of values for each variable. By default, colors are selected for the bars, background and grid lines, all of which can be customized. The basic computations of the chart are provided with the standard R functions barplot, chisq.test and, for two variables, legend. Horizontal bar charts, specified by horiz=TRUE, list the value labels horizontally and automatically extend the left margin to accommodate both the value labels and the variable label.
DATA
Ultimately the bar chart is constructed from a simple table in which each row consists of a level of the categorical variable \( x \) paired with the corresponding value of the numerical variable, \( y \), with as many rows as the number of levels of \( x \). A data table of this form can be read by specifying the variable \( x \) and the variable \( y \). Alternatively, read a data table in the form in which the data are typically gathered, with many replications of the levels of the categorical variable \( x \). In this situation, with just the specification of the variable \( x \), the corresponding numerical variable is the tabulation of the counts of the number of occurrences for each level of \( x \). Or, specify a numerical variable from a data table of this form and reduce to the smaller data table via statistical transformation of the values of \( y \) for each level of \( x \), such as the mean.

The data may either be a vector from the global environment, the user’s workspace, as illustrated in the examples below, or a variable in a data frame. The default input data frame is \( d \). Specify a different data frame name with the `data` option. Regardless of its name, the variables in the data frame are referenced directly by their names.

If the name of the vector is in the global environment and of a variable in the input data frame has the same name, the vector from the global environment is analyzed, unless the data name frame is explicitly provided, not relying upon the default \( d \). If two variables are specified, both variables should be in the data frame, or one of the variables is in the data frame and the other in the global environment.

To obtain a bar chart of each categorical variable in the \( d \) data frame, invoke `BarChart()` . Or, for a data frame with a different name, insert the data frame name between the parentheses as the first listed parameter value. To analyze a subset of the variables in a data frame, specify the variable list with either a `:` or the `c` function, such as `m01:m03` or `c(m01,m02,m03)`.

The `rows` parameter subsets rows (cases) of the input data frame according to a logical expression. Use the standard R operators for logical statements as described in `Logic` such as `&` for and, `|` for or and `!` for not. Use the standard R relational operators as described in `Comparison`. Examples include `==` for logical equality, `!=` for not equals, and `>` for greater than. See the Examples.

The form of the entered data, the first variable, categorical \( x \), and optionally a second variable, numerical \( y \), is flexible. The data may be entered as factors, numeric values, characters, or a matrix. The data may be entered and the resulting frequencies computed, or the frequencies can be entered directly. The most natural type of data to enter, when entering the variables, is to enter factors.

STATISTICAL TRANSFORMATIONS
Ultimately the bar plot is constructed from a small table of data values with each row a level of the categorical variable \( x \) paired with the corresponding value of the numerical variable \( y \), with as many rows as values of \( x \). It is also possible to plot transformations of the values of \( y \) for each level of categorical variable \( x \) from a full data table with many replications of each value of \( x \) and corresponding \( y \). Then reduce the larger data table down to the summary table with one of following transformations.

```
Transformation
"sum"
"mean"
"sd"
"dev"
"min"
"median"
```
The other statistical transformation is simply counting the number of occurrences of each level of \( x \), which does not involve a value of \( y \) read from the data. Instead the value of \( y \) for each level of \( x \) is tabulated.

COLORS

For a one variable plot, set the default color of the bars by the current color theme according to \( \text{bar\_fill\_discrete} \) argument of the function \( \text{style} \), which includes the default color theme "hues" that defines a qualitative HCL color scale, or set the bar color with the \( \text{fill} \) parameter, which references a specified vector of color specifications, such as generated by the lessR \( \text{getColors} \) function.

Set \( \text{fill} \) to a single color or a color palette, of which there are many possibilities. Define a qualitative color palette with "hues" that provides HCL colors of the same chroma (saturation) and luminance (brightness). Also available are the pre-specified R color palettes "rainbow", "terrain", and "heat". Pre-defined sequential and divergent color ranges are available as implicit calls to \( \text{getColors} \). The full list of pre-defined color ranges (defined in 30 degree increments around the HCL color wheel): "reds", "rusts", "browns", "olives", "greens", "emeralds", "turquoises", "aquas", "blues", "purples", "violets", "magentas", and "grays".

Define the default qualitative color scale with a \( \text{fill} \) set to "hues". Define a sequential color scale with single value of \( \text{fill} \) for a pre-defined palette such as "blues". Define a divergent color scale with value of \( \text{fill} \) that consists of a vector of two such pre-defined ranges, such as \( \text{c("purples","rusts")} \). Divergent color palettes are applicable in particular for plotting multiple bar charts on the same plot such as for a set of Likert response items, all on a common response scale. Or, manually specify colors. For example, for a two-level by variable, could set \( \text{fill} \) to \( \text{c("coral3","seagreen3")} \), where the specified colors are not pre-defined color ranges.

For the pre-defined color scales can obtain more control over the obtained color palettes with an explicit call to \( \text{getColors} \) for the argument to \( \text{fill} \). Here the value of chroma \( (c) \) and luminance \( (l) \) can be explicitly manipulated in conjunction with the specification of a pre-defined color range. Or, create a custom color range for any value of hue \( (h) \). See \( \text{getColors} \) for more information.

The values of another variable can be mapped into the fill color of the bars. To do so, set \( \text{fill} \) to the value of the variable, which would usually be the name of the \( y \) variable if explicitly given. Or, if \( y \) is tabulated, refer to the variable name as \( (\text{count}) \). The larger the count for a level of \( x \), the darker the bar.

LEGEND

When two variables are plotted, a legend is produced, with values for each level of the second or by variable. By default, the location is placed in the right margin of the plot. This position can be changed with the \( \text{legend\_position} \) option, which, in addition to the \text{lessR} option of \( \text{right\_margin} \), accepts any valid value consistent with the standard R \( \text{legend} \) function, used to generate the legend_

If the default right margin is retained, variable labels are also accommodated for the legend title. To conserve horizontal space, the variable label is listed in multiple lines if needed. The legend title is constructed by forming lines of maximum length of 12 characters, with multiple words per line if possible. Any single word in the label of more than 12 characters is abbreviated to 12 characters with the R \( \text{abbreviate} \) function. Also, any value labels are abbreviated to a maximum of 6 characters.

If the legend is not in the right margin, sometimes bars from the graph may intrude into the legend_. One response is to re-run the analysis with the legend in a new location. Another response is to
invoke the `add_top` option to place more space between the top bar in the graph and the top of the graph. This option only applies for the default vertical bars. Also, the legend is displayed vertically by default, but can be changed to horizontal with the `legend_horiz` option.

LONG CATEGORY NAMES
For many plots, the names of the categories are too long. To adjust the plot for these long names, they can be rotated using the `rotate_x` and `rotate_y` parameters, in conjunction with `offset`. The `offset` parameter moves the category name out from the axis to compensate for the rotation. The changes can also be specified from `style` to persist until further changes. To reset to the default after obtaining an analysis, use `style()`. Also, the following codes are used to adjust line spacing:
1. Any space in a category name is converted to a new line.
2. If the space should not be converted to a new line, then replace with a tilde, ~, which will display as a space without a line break.

For the text output at the console, can specify the maximum number of characters in a label with `labels.max`. Longer value names are abbreviated to the specified length. This facilitates reading cross-tab tables. Also, a provided table pairs the abbreviated names with the actual names. For one variable frequency distributions, `out_size` provides the maximum number of characters for the text output before the horizontal display of the frequency distribution is shifted to a vertical presentation.

MULTIPLE BAR CHARTS ON THE SAME PANEL (PLOT)
For multiple x-variables, set the parameter `one_plot` to `TRUE` to specify that each bar chart should be produced on the same panel as all other bars. This is most meaningful when all items have the same set of responses, such as a common Likert scale found in survey data. By default the one panel plot is produced when a common response scale is detected.

The algorithm to detect if the response scale is common first identifies the first variable with the largest set of responses, then checks the responses of all other variables. If all responses to all other variables are contained within the set of responses to the reference variable, then the response scales are the same. This means that on a Likert scale, for example, some items may not contain all possible responses, such as no one selects Strongly Disagree for an item. However, for the response scales to be deemed the same, at least one item (variable) must contain all possible responses.

Regardless, the `one_plot` parameter can be set to either `TRUE` or `FALSE` regardless of the commonality of responses. Setting this parameter explicitly saves some CPU time as the algorithm to evaluate the communality of responses need not be activated.

ENTER NUMERIC VARIABLE DIRECTLY
Instead of calculating the counts from the data, the values of any numerical variable, including the counts, can be entered directly as the y-variable, in addition to the categorical x-variable, and perhaps a categorical by-variable. See the examples below, under “bar chart directly from data”.

Or, include the already tabulated counts as the data which is read into R, either as a matrix or a data frame.

STATISTICS
In addition to the bar chart, descriptive and optional inferential statistics are also presented. First, the frequency table for one variable or the joint frequency table for two variables is displayed. Second, the corresponding Cramer’s V and chi-square test are also displayed by default.

VARIABLE LABELS
If variable labels exist, then the corresponding variable label is listed as the label for the horizontal
axis unless xlab is specified in the function call. If there are two variables to plot, the title of the resulting plot is based on the two variable labels, unless a specific title is listed with the main option. The variable label is also listed in the text output, next to the variable name. If the analysis is for two variables, then labels for both variables are included.

PDF OUTPUT
To obtain pdf output, set the pdf option to TRUE, perhaps with the optional width and height options. These files are written to the default working directory, which can be explicitly specified with the R setwd function.

ONLY VARIABLES ARE REFERENCED
The referenced variable in a lessR function can only be a variable name (or list of variable names). This referenced variable must exist in either the referenced data frame, such as the default d, or in the user’s workspace, more formally called the global environment. That is, expressions cannot be directly evaluated. For example:

```r
> BarChart(cut(rnorm(50), breaks=seq(-5,5))) # does NOT work
```

Instead, do the following:

```r
> Y <- cut(rnorm(50), breaks=seq(-5,5)) # create vector Y in user workspace
> BarChart(Y) # directly reference Y
```

Value
The output can optionally be saved into an R object, otherwise it only appears in the console (unless quiet is set to TRUE). Two different types of components are provided: the pieces of readable output, and a variety of statistics. The readable output are character strings such as tables amenable for display. The statistics are numerical values amenable for further analysis. The motivation of these types of output is to facilitate R markdown documents, as the name of each piece, preceded by the name of the saved object and a $, can be inserted into the R~Markdown document (see examples), interspersed with explanation and interpretation.

Tabulated numerical variable y

corCFA  Confirmatory Factor Analysis of a Multiple Indicator Measurement Model

Description

Abbreviation: cfa

A multiple indicator measurement model partitions a set of indicators, such as items on a survey, into mutually exclusive groups with one common factor per group of indicators. From the input correlation matrix of the indicator variables, this procedure uses iterated centroid estimation to estimate the coefficients of the model, the factor pattern and factor-factor correlations, as well as the correlations of each factor with each indicator. The analysis is an adaptation and extension of John Hunter’s program PACKAGE (Hunter and Cohen, 1969).

Corresponding scale reliabilities are provided, as well as the residuals, the difference between the indicator correlations and those predicted by the model. To visualize the relationships, a heat map of the re-ordered correlation matrix is also provided, with indicator communalities in the diagonal. To understand the meaning of each factor, the corresponding indicator content is displayed for each factor if the indicators have been read as variable labels. Also provides the code to obtain the maximum likelihood solution of the corresponding multiple indicator measurement model (MIMM) with the cfa function from the lavaan package.

The scales is a wrapper that retains 1’s in the diagonal of the indicator correlation matrix, so provides scale reliabilities and observed indicator-scale and scale-scale correlations.

Output is generated into distinct pieces by topic, organized and displayed in sequence by default. When the output is assigned to an object, such as f in f <- cfa(Fac ~ X1 + X2 + X3), the full or partial output can be accessed for later analysis and/or viewing. A primary such analysis is with knitr for dynamic report generation, run from, for example, RStudio. The input instructions written to the R–Markdown file are written comments and interpretation with embedded R code. Doing a knitr analysis is to “knit” these comments and subsequent output together so that the R output is embedded in the resulting document, either html, pdf or Word, by default with explanation.
and interpretation. Generate a complete R~Markdown set of instructions ready to knit from the Rmd option. Simply specify the option and create the file and then open in RStudio and click the knit button to create a formatted document that consists of the statistical results and interpretative comments. See the following sections arguments, value and examples for more information.

Usage

corCFA(mimm=NULL, x=mycor, data=d, fac.names=NULL, 
        Rmd=NULL, explain=getOption("explain"), 
        interpret=getOption("interpret"), results=getOption("results"), 
        labels=c("include", "exclude", "only"), 
        min_cor=.10, min_res=.05, iter=50, grid=TRUE, 
        resid=TRUE, item_cor=TRUE, sort=TRUE, 
        main=NULL, heat_map=TRUE, bottom=3, right=3, 
        pdf_file=NULL, width=5, height=5,

        F6=NULL, F7=NULL, F8=NULL, F9=NULL, F10=NULL, 
        F11=NULL, F12=NULL, F13=NULL, F14=NULL, F15=NULL, 
        F16=NULL, F17=NULL, F18=NULL, F19=NULL, F20=NULL, 
        fun_call=NULL, ...) 

cfa(...) 

scales(..., iter=0, resid=FALSE, item_cor=FALSE, sort=FALSE, heat_map=FALSE) 

Arguments

**mimm**  
Multiple indicator measurement model, a character string with the specification of each factor on a separate line: the factor name, an equals sign, and the indicators separated by plus signs. Each indicator is assigned to only one factor.

**x**  
Correlation matrix to be analyzed.

**data**  
Data frame of the original data to be checked for any variable labels, usually indicator (item) content. This is not to calculate correlations, which is separately provided for by the lessR function *Correlation*.

**fac.names**  
Optional factor names for the original, non-lavaan model specification.

**Rmd**  
File name for the file of R Markdown instructions to be written, if specified. The file type is .Rmd, which automatically opens in RStudio, but it is a simple text file that can be edited with any text editor, including RStudio.

**explain**  
If set to FALSE the explanations of the results are not provided in the R~Markdown file. Set globally with options(explain=FALSE).
### Options

- **interpret**
  - If set to FALSE the interpretations of the results are not provided in the R-Markdown file. Set globally with options(interpret=FALSE).

- **results**
  - If set to FALSE the results are not provided in the R-Markdown file, relying upon the interpretations. Set globally with options(results=FALSE).

- **labels**
  - If "include" or "exclude" then variable labels are displayed (if available) or not, organized by the items within each factor. If "only" then no data analysis performed, only the display of the labels by factor.

- **min_cor**
  - Minimum correlation to display. To display all, set to 0.

- **min_res**
  - Minimum residual to display. To display all, set to 0.

- **iter**
  - Number of iterations for communality estimates.

- **grid**
  - If TRUE, then separate items in different factors by a grid of horizontal and vertical lines in the output correlation matrix.

- **resid**
  - If TRUE, then calculate and print the residuals.

- **item_cor**
  - If TRUE, display the indicator correlations.

- **sort**
  - If TRUE, re-order the output correlation matrix so that indicators within each factor are sorted by their factor loadings on their own factor.

- **main**
  - Graph title of heat map. Set to main="" to turn off.

- **heat_map**
  - If TRUE, display a heat map of the indicator correlations with indicator communalities in the diagonal.

- **bottom**
  - Number of lines of bottom margin of heat map.

- **right**
  - Number of lines of right margin of heat map.

- **pdf_file**
  - Name of the pdf file to which graphics are redirected.

- **width**
  - Width of the pdf file in inches.

- **height**
  - Height of the pdf file in inches.

- **F1**
  - Variables that define Factor 1.

- **F2**
  - Variables that define Factor 2.

- **F3**
  - Variables that define Factor 3.

- **F4**
  - Variables that define Factor 4.

- **F5**
  - Variables that define Factor 5.

- **F6**
  - Variables that define Factor 6.

- **F7**
  - Variables that define Factor 7.

- **F8**
  - Variables that define Factor 8.

- **F9**
  - Variables that define Factor 9.

- **F10**
  - Variables that define Factor 10.

- **F11**
  - Variables that define Factor 11.

- **F12**
  - Variables that define Factor 12.

- **F13**
  - Variables that define Factor 13.

- **F14**
  - Variables that define Factor 14.

- **F15**
  - Variables that define Factor 15.
Variables that define Factor 16.

Variables that define Factor 17.

Variables that define Factor 18.

Variables that define Factor 19.

Variables that define Factor 20.

Function call. Used internally with knitr to pass the function call when obtained from the abbreviated function call cfa. Not usually invoked by the user.

Details

OVERVIEW
A multiple indicator measurement model defines one or more latent variables, called factors, in terms of mutually exclusive sets of indicator variables, such as items from a questionnaire or survey. That is, each factor is defined by a unique set or group of indicators, and each indicator only contributes to the definition of one factor. Two sets of parameters are estimated by the model, the factor pattern coefficients, the lambda’s, and the factor-factor correlations, the phi’s. Also estimated here are the correlations of each indicator with the other factors.

INPUT
Unless labels="only", the analysis requires the correlation matrix of the indicators and the specification of the groups of indicators, each of which defines a factor in the multiple indicator measurement model. The default name for the indicator correlation matrix is mycor, which is also the default name of the matrix produced by the lessR function Correlation that computes the correlations from the data, as well as the name of the matrix read by the lessR function corRead that reads the already computed correlation matrix from an external file.

For versions of lessR after 3.3, the correlation matrix computed by Correlation is now a list element called R within the returned list. For example, mycor$R from mycor <- cr(d). The function corCFA automatically finds this correlation matrix from just entering the entire list name of the returned list, mycor, or the specific location, mycor$R, or as a stand-alone numerical matrix as done in versions of lessR previous to 3.3.

The data frame from which the correlation matrix was computed is required only if any associated variable labels are listed, organized by the items within each factor. By default, labels="include", these labels are listed as part of the analysis if they are available.

Define the constituent variables, the indicators, of each factor with a listing of each variable by its name in the correlation matrix. Each of the up to 20 factors is named by default F1, F2, etc. If the specified variables of a factor are in consecutive order in the input correlation matrix, the list can be specified by listing the first variable, a colon, and then the last variable. To specify multiple variables, a single variable or a list, separate each by a comma, then invoke the R combine or c function, preceded by the factor’s name and an equals sign. For example, if the first factor is defined by variables in the input correlation matrix from m02 through m05, and the variable Anxiety, then define the factor in the corCFA function call according to F1=c(m02:m05,Anxiety).

OUTPUT
The result of the analysis is the correlation matrix of the indicator variables and resulting factors, plus the reliability analysis of the observed total scores or scale that corresponds to each factor. Each scale is defined as an unweighted composite. The corresponding code to analyze the model with
the cfa function from the lavaan package is also provided with the default maximum likelihood estimation procedure. The comparable lavaan solution appears in the column that represents the fully standardized solution, factors and indicators, Std.all, the last column of the solution output. If the lavaan library is loaded, then explicitly refer to the lessR function cfa with lessR::cfa and the corresponding lavaan function with lavaan::cfa.

VARIABLE LABELS
To display the indicator content, first read the indicators as variable labels with the lessR function `Read`. If this labels data frame exists, then the corresponding variable labels, such as the actual items on a survey, are listed by factor. For more information, see `Read`.

HEAT MAP
To help visualize the overall patterning of the correlations, the corresponding heat map of the item correlation matrix with communalities is produced when heat_map=TRUE, the default. As is true of the output correlation matrix, the correlations illustrated in the heat map are also sorted by their ordering within each factor. The corresponding color scheme is dictated by the system setting, according to the lessR function `style`. The default color scheme is blue.

ESTIMATION PROCEDURE
The estimation procedure is centroid factor analysis, which defines each factor, parallel to the definition of each scale score, as the unweighted composite of the corresponding items for that scale. The latent variables are obtained by replacing the 1’s in the diagonal of the indicator variable correlation matrix with communality estimates. These estimates are obtained by iterating the solution to the specified number of iterations according to iter, which defaults to 50.

A communality is the percentage of the item’s correlation attributable to, in this situation of a multiple indicator measurement model, its one underlying factor. As such, the communality is comparable to the item correlations for items within the same factor, which are also due only to the influence of the one common, underlying factor. A value of 0 for iter implies that the 1’s remain in the observed variable correlation matrix, which then means that there are no latent factors defined. Instead the resulting correlation matrix is of the observed scale scores and the component items.

Value

TEXT OUTPUT
out_labels: variables in the model
out_reliability: reliability analysis with alpha and omega
out_indicators: solution in terms of the analysis of each indicator
out_solution: full solution
out_residuals: residuals
out_res_stats: stats for residuals
out_lavaan: lavaan model specification

Separated from the rest of the text output are the major headings, which can then be deleted from custom collations of the output. out_title_scales: scales
out_title_rel: reliability analysis
out_title_solution: solution
out_title_residuals: residual analysis
out_title_lavaan: lavaan specification
STATISTICS
Returns a list of six components.
1. ff.cor: matrix of the factor correlations
2. if.cor: matrix of the indicator-factor correlations that includes the estimated pattern coefficients of the model that link a factor to its indicators
3. diag.cor: the indicator communalities
4. alpha: coefficient alpha for each set of indicators
5. omega: if a factor analysis with communality estimates (iter > 0), contains coefficient omega for each set of indicators
6. pred: matrix of correlations predicted by the model and its estimates
7. resid: matrix of raw indicator residuals defined as the observed correlation minus that predicted by the model and its estimates

Exploratory Factor Analysis and Multiple Indicator Measurement Model

Description

Abbreviation: efa

A maximum likelihood exploratory factor analysis of an input correlation matrix, provided by the standard R exploratory factor analysis factanal, which requires the specified number of factors as an input to the analysis. Then constructs the code to run the corresponding multiple indicator measurement model (MIMM) suggested by the exploratory factor analysis loadings in terms of both the lessR corCFA and the cfa function from the lavaan package.

Usage

corEFA(x=mycor, n_factors, rotate=c("promax", "varimax", "none"), min_loading=.2, sort=TRUE, Rmd=NULL, ...)

efa(...)

Arguments

  x            Correlation matrix.
  n_factors    Number of factors.
rotates the input variables by their highest factor loadings (but only first just list those items with loadings larger than 0.5).

min_loading Minimum loading to include in suggested factor for confirmatory analysis and for the display of the loadings for the exploratory analysis. To ignore, set to 0.

sort Sort the input variables by their highest factor loadings (but only first just list those items with loadings larger than 0.5).

Rmd File name for the file of R markdown to be written, if specified. The file type is .Rmd, which automatically opens in RStudio, but it is a simple text file that can be edited with any text editor, including RStudio.

Details

Only the loadings from the exploratory factor analysis are provided, with either an oblique (promax), by default, or an orthogonal (varimax) rotation. If more information is desired, run factanal directly.

Also provides the associated multiple indicator measurement model suggested by the exploratory factor analysis. Each MIMM factor is defined by the items that have the highest loading on the corresponding exploratory factor.

For versions of lessR after 3.3, the correlation matrix computed by Correlation is now a list element called R within the returned list. For example, mycor$R from mycor <-cr(d). The function corEFA automatically finds this correlation matrix from just entering the entire list name of the returned list, mycor, or the specific location, mycor$R, or as a stand-alone numerical matrix as done in versions of lessR previous to 3.3.

Value

The output can optionally be returned and saved into an R object, otherwise it simply appears at the console. The components of this object are redesigned in lessR version 3.3 into three different types: pieces of text that form the readable output, a variety of statistics, and R markdown instructions. The readable output are character strings such as tables amenable for viewing and interpretation. The statistics are numerical values amenable for further analysis, such as to be referenced in a subsequent R markdown document. The R-Markdown input is available for entry direct into knitr, such as in RStudio. The motivation of these three types of output is to facilitate R markdown documents, as the name of each piece, preceded by the name of the saved object followed by a $, can be inserted into the R markdown document (see examples).

READABLE OUTPUT
out_title: Variables in the model, rows of data and retained
out_loadings: Estimated coefficients, hypothesis tests and confidence intervals
out_sum_squares: Fit indices
out_cfa_title: Analysis of variance
out_ice: Correlations among all variables in the model
out_lavaan: Collinearity analysis
out_deleted: R squared adjusted for all (or many) possible subsets

STATISTICS
Rmd: Instructions to run through knitr, such as copy and paste, to obtain output in the form of a
web file, pdf document or Word document. Can also obtain these instructions with the \texttt{Rmd} option, which writes them directly to the specified text file. Obtain a less detailed \texttt{Rmd} file by setting \texttt{explain=FALSE}.

Although not typically needed for analysis, if the output is assigned to an object named, for example, \texttt{fa}, then the complete contents of the object can be viewed directly with the \texttt{unclass} function, here as \texttt{unclass(fa)}. Invoking the \texttt{class} function on the saved object reveals a class of out\_all. The class of each of the text pieces of output is out.

0.144,0.108,0.072,0.480,1.000,0.240, 
0.096,0.072,0.048,0.320,0.240,1.000))

colnames(mycor) <- c("X1", "X2", "X3", "X4", "X5", "X6")
rownames(mycor) <- colnames(mycor)

# default factor analysis of default correlation matrix mycor
# with two factors extracted

corEFA(n_factors=2)

# abbreviated form
# use all items to construct the MIMM, regardless of their loadings
# and show all loadings
# show the initial factor extraction

efa(n_factors=2, min_loading=0, show_initial=TRUE)
\end{verbatim}
Description

Abbreviation: prop

In the population, indicators of the same factor or latent variable have parallel correlations with all other variables. Of course, in the presence of sampling error, this parallelism will only be approximate. To assess this parallelism, proportionality coefficients are computed for each pair of variables in the input correlation matrix. Also output is a heat map of the resulting matrix of proportionality coefficients. Each graph is based on a default color theme. The original default is lightbronze, but other color palettes can be generated as well.

Usage

corProp(R=mycor,
   main=NULL, heat_map=TRUE, bottom=3, right=3,
   pdf_file=NULL, width=5, height=5, ...)

   prop(...)

Arguments

R          Correlation matrix.
main       Graph title. Set to main="" to turn off.
heat_map   If TRUE, display a heat map of the item correlations with the diagonal ignored.
bottom     Number of lines of bottom margin.
right      Number of lines of right margin.
pdf_file   Name of the pdf file to which graphics are redirected.
width      Width of the pdf file in inches.
height     Height of the pdf file in inches.
...        Parameter values_

Details

Proportionality coefficients indicate the extent of proportionality between two variables. Perfect proportionality of two variables is consistent with both variables being indicators of the same latent variable or factor and indicators of no other factor.

In the current version the diagonal of the input correlation matrix is ignored. To maintain parallelism, the diagonal element of 1.00 would need to be replaced the corresponding communalities, which first requires a factor analysis.

```

---

**corRead**

*Read Specified Correlation Matrix*

**Description**

Abbreviation: rd.cor

A wrapper for base-R `read.table`. Read a correlation matrix into R. All coefficients for each variable must be on one physical row. No variable names are in the file to be read.

**Usage**

```r
corRead(from=NULL, var_names=NULL, ...)
```

```r
dc.cor(...)```
corRead

Arguments

from       File reference, either omitted to browse for the data file, or a full path name or web URL, included in quotes. A URL begins with http://.
var_names  The names of the variables in the matrix.

Details

Read a correlation, or any square, matrix into R. All coefficients for each variable must be on one row. No variable names are in the file to be read. The coefficients within each row, that is, for a single variable, are delimited by a white space, such as one or more blanks.

The standard R function that reads the matrix is read.table.

By default the variables are named X1, X2, etc. If the var_names option is invoked, then the specified names refer to the respective rows and columns of the matrix. Here it may be convenient to name the variables with the lessR function to.

The alternative is to calculate the correlations from the data, such as with the lessR function Correlation or the standard R function cor.

# mycor <- rd.cor(var_names=c("m06","m07","m09","m10"))
corReflect  

Reflect Specified Variables in a Correlation Matrix

Description

Abbreviation: reflect

Reflects the specified variables by multiplying each correlation of the variable by -1. Usually a prelude to a factor analysis, such as provided by corCFA.

Usage

```r
corReflect(R=mcory, vars,
           main=NULL, heat_map=TRUE, bottom=3, right=3,
           pdf_file=NULL, width=5, height=5, ...)
```

```r
reflect(...)
```

Arguments

- `R`  
  Correlation matrix.

- `vars`  
  List of the re-ordered variables, each variable listed by its ordinal position in the input correlation matrix.

- `main`  
  Graph title. Set to `main=""` to turn off.

- `heat_map`  
  If `TRUE`, display a heat map of the item correlations with item communalities in the diagonal.

- `bottom`  
  Number of lines of bottom margin.

- `right`  
  Number of lines of right margin.

- `pdf_file`  
  Name of the pdf file to which graphics are redirected.

- `width`  
  Width of the pdf file in inches.

- `height`  
  Height of the pdf file in inches.

- `...`  
  Parameter values

Details

Reflects the specified variables by multiplying each correlation of the variable by -1. The original data from which the correlations are computed is unmodified unless the output of the function is written into the input correlation matrix, by default `mcory`.

Define the constituent variables, the items, with a listing of each variable by its name in the correlation matrix. If the specified variables are in consecutive order in the input correlation matrix, the list can be specified by listing the first variable, a colon, and then the last variable. To specify multiple variables, a single variable or a list, separate each by a comma, then invoke the R combine or `c` function. For example, if the list of variables in the input correlation matrix is from m02 through m05, and the variable Anxiety, then define the list in the corReflect function call according to `vars=c(m02:m05,Anxiety)`.

mycor <- reflect(vars=c(V4,V5,V6))

Correlation Analysis

Description

Abbreviation: cr, cr_brief

For two variables yields the correlation coefficient with hypothesis test and confidence interval. For a data frame or list of variables from a data frame, yields the correlation matrix. The default computed coefficient(s) are the standard Pearson’s product-moment correlation, with Spearman and Kendall coefficients available. For the default missing data technique of pairwise deletion, an analysis of missing data for each computed correlation coefficient is provided. For a correlation matrix a statistical summary of the missing data across all cells is provided.

Versions of this function from lessR 3.3 or earlier returned just a correlation matrix. Now other values are returned as well so that the correlation matrix is now stored as part of a returned list in R, directly available, for example, as mycor$R from mycor <- cr(d). This revision is automatically adjusted for in the lessR routines that read the subsequent correlation matrix, so all pre-existing code continues to work. That is, the input into any of these routines could be, for example, mycor, mycor$R or a stand-alone correlation matrix such as in pre-lessR 3.3.
Correlation

Usage

Correlation(x, y, data=d, miss=c("pairwise", "listwise", "everything"), fill_low=NULL, fill_hi=NULL, show_n=NULL, brief=FALSE, digits_d=NULL, heat_map=TRUE, main=NULL, bottom=3, right=3, pdf=FALSE, width=5, height=5, ...)

cr_brief(..., brief=TRUE)

cr(...)

Arguments

x
First variable, or list of variables for a correlation matrix.

y
Second variable or not specified if the first argument is a list.

data
Optional data frame that contains the variables of interest, default is d.

miss
Basis for deleting missing data values.

fill_low
Starting color for a custom sequential palette.

fill_hi
Ending color for a custom sequential palette.

show_n
For pairwise deletion, show the matrix of sample sizes for each correlation coefficient, regardless of sample size.

brief
Pertains to a single correlation coefficient analysis. If FALSE, then the sample covariance and number of non-missing and missing observations are displayed.

digits_d
Specifies the number of decimal digits to display in the output.

heat_map
If TRUE, generate a heat map.

main
Graph title of heat map. Set to main="" to turn off.

bottom
Number of lines of bottom margin of heat map.

right
Number of lines of right margin of heat map.

pdf
If TRUE, generate the heat map and write to pdf files.

width
Width of the pdf file in inches.

height
Height of the pdf file in inches.

...
Other parameter values for internally called functions, which include method="spearman" and method="kendall" and also alternative="less" and alternative="more".

Details

When two variables are specified, both x and y, the output is the correlation coefficient with hypothesis test, for a null hypothesis of 0, and confidence interval. Also displays the sample covariance. Based on R functions cor, cor.test, cov.

In place of two variables x and y, x can be a complete data frame, either specified with the name of a data frame, or blank to rely upon the default data frame d. Or, x can be a list of variables from the
input data frame. In these situations y is missing. Any non-numeric variables in the data frame or specified variable list are automatically deleted from the analysis.

When heat_map=TRUE, generate a heat map to standard graphics windows. Set pdf=TRUE to generate these graphics but have them directed to their respective pdf files.

For treating missing data, the default is pairwise, which means that an observation is deleted only for the computation of a specific correlation coefficient if one or both variables are missing the value for the relevant variable(s). For listwise deletion, the entire observation is deleted from the analysis if any of its data values are missing. For the more extreme everything option, any missing data values for a variable result in all correlations for that variable reported as missing.

Value

From versions of lessR of 3.3 and earlier, if a correlation matrix is computed, the matrix is returned. Now more values are returned, so the matrix is embedded in a list of returned elements.

READABLE OUTPUT

single coefficient
out_background: Variables in the model, any variable labels
out_describe: Estimated coefficients
out_inference: Hypothesis test and confidence interval estimated coefficient

matrix
out_background: Variables in the model, any variable labels
out_missing: Missing values analysis
out_cor: Correlations

STATISTICS

single coefficient
r: Model formula that specifies the model
tvalue: t-statistic of estimated value of null hypothesis of no relationship
df: Degrees of freedom of hypothesis test pvalue: Number of rows of data submitted for analysis
lb: Lower bound of confidence interval
ub: Upper bound of confidence interval

matrix
R: Correlations

Usually assign the name of mycor to the output matrix, as in following examples. This matrix is ready for input into any of the lessR functions that analyze correlational data, including confirmatory factor analysis by corCFA and also exploratory factor analysis, either the standard R function factanal or the lessR function corEFA

```

corReorder

Reorder Variables in a Correlation Matrix
**corReorder**

**Description**

Abbreviation: reord

Re-arranges the order of the variables in the input correlation matrix. If no variable list is specified then the variables are re-ordered according to hierarchical clustering or the Hunter (1973) chain method in which the first variable is the variable with the largest sum of squared correlations of all the variables, then the variable that has the highest correlation with the first variable, and so forth.

**Usage**

```
corReorder(R=mycor, order=c("hclust", "chain", "manual"),
            hclust_type = c("complete", "ward.D", "ward.D2", "single",
                             "average", "mcquitty", "median", "centroid"),
            dist_type=c("R", "dist"),
            n_clusters=NULL, vars=NULL, chain_first=0,
            heat_map=TRUE, diagonal_new=TRUE,
            main=NULL, bottom=3, right=3,
            pdf_file=NULL, width=5, height=5, ...)
```

`reord(...)`

**Arguments**

- **R** Correlation matrix.
- **order** Source of ordering (seriation): Hierarchical cluster matrix, Hunter(1973) chain method, or manually specified with `vars`.
- **hclust_type** Type of hierarchical cluster analysis.
- **dist_type** Default is a correlation matrix of similarities, otherwise a distance matrix.
- **n_clusters** For a hierarchical cluster analysis, get the cluster membership for the specified number of clusters.
- **vars** List of the re-ordered variables, each variable listed by its ordinal position in the input correlation matrix. If this is set, then `order` set to "manual".
- **chain_first** The first variable listed in the ordered matrix with the chain method.
- **main** Graph title. Set to `main=""` to turn off.
- **heat_map** If TRUE, display a heat map of the item correlations.
- **diagonal_new** If TRUE, replace diagonal for the heat map only with an average of the correlation of item on the diagonal with the two adjacent items.
- **bottom** Number of lines of bottom margin.
- **right** Number of lines of right margin.
- **pdf_file** Name of the pdf file to which graphics are redirected.
- **width** Width of the pdf file in inches.
- **height** Height of the pdf file in inches.
- **...** Parameter values_
Details

Reorder and/or delete variables in the input correlation matrix.

Define the constituent variables, the items, with a listing of each variable by its name in the correlation matrix. If the specified variables are in consecutive order in the input correlation matrix, the list can be specified by listing the first variable, a colon, and then the last variable. To specify multiple variables, a single variable or a list, separate each by a comma, then invoke the R combine or c function. For example, if the list of variables in the input correlation matrix is from m02 through m05, and the variable Anxiety, then define the list in the corReorder function call according to vars=c(m02:m05,Anxiety).

Or, define the ordering with a hierarchical cluster analysis from the base R function hclust(). The same default type of "complete" is provided, though this can be changed with the parameter hclust_type according to hclust. Default input is a correlation matrix, converted to a matrix of dissimilarities by subtracting each element from 1.

Or, use the Hunter (1973) chain method. Define the ordering of the variables according to the following algorithm. If no variable list is specified then the variables are re-ordered such that the first variable is that which has the largest sum of squared correlations of all the variables, then the variable that has the highest correlation with the first variable, and so forth.

In the absence of a variable list, the first variable in the re-ordered matrix can be specified with the chain_first option.

# can also reorder with index position of each variable
mycor <- corReorder(vars=c(4, 5, 6, 1, 2, 3))

corScree

**Eigenvalue Plot of a Correlation Matrix**

**Description**

Abbreviation: scree

Plots the successive eigenvalues of an input correlation matrix. Also plots the successive differences of the eigenvalues. The purpose is usually to help determine the number of factors that explain the correlations in a correlation matrix. So usually a prelude to an exploratory factor analysis, such as provided by the lessR function corEFA. This program relies upon the standard R exploratory factor analysis factanal, which requires the specified number of factors as an input to the analysis.

**Usage**

```r
corScree(x=mycor,
  main=NULL, pdf=FALSE, width=5, height=5, ...)

scree(...)
```
Arguments

- **x**  Correlation matrix.
- **main**  Graph title, which is blank by default.
- **pdf**  Indicator as to if the graphic files should be saved as pdf files instead of directed to the standard graphics windows.
- **width**  Width of the pdf file in inches.
- **height**  Height of the pdf file in inches.
- **...**  Parameter values_

Details

Interpretation of the scree plot to assist in the assessment of the number of factors that account for the structure of a correlation matrix depends primarily on the analysis of the differences between the successive eigenvalues. The differences begin to diminish where the "scree" begins, analogous to the debris that falls off of a hill top. Accordingly both the scree plot itself, the plot of the successive eigenvalues, and the plot of the differences of the successive eigenvalues are presented.

**PDF OUTPUT**

Because of the customized graphic windowing system that maintains a unique graphic window for the Help function, the standard graphic output functions such as `pdf` do not work with the `lessR` graphics functions. Instead, to obtain pdf output, use the `pdf_file` option, perhaps with the optional `width` and `height` options. These files are written to the default working directory, which can be explicitly specified with the R `setwd` function.

If the two plots, of the population and sample distributions respectively, are written to pdf files, according to `pdf=TRUE`, they are named Scree.pdf and ScreeDiff.pdf. Their names and the directory to which they are written are provided as part the console output.

CountAll

Description

Automatically call the following functions in this package: SummaryStats, Histogram and BarChart. The result is set of summary statistics for every variable in the data frame, by default called d, a histogram for each numerical variable and a bar chart for each categorical variable.

Usage

CountAll(x=d, quiet=FALSE, ...)

c("

Arguments

x
quiet
...

Data frame that contains the variables to analyze, by default d.
Suppress text output if TRUE.
Other parameter values for graphics.

Details

CountAll is designed to work in conjunction with the lessR function Read, which reads a csv or other formatted data file into the data frame d. All the bar charts and associated summary statistics are written to one file and all the histograms and associated summary statistics for the numerical variables are written to another file.

### Description

1993 New Car Data.

### Usage

```r
data(dataCars93)
```

### Format

A data table with 93 observations and 25 variables.

#### Variables

- **Make**: Model
- **Type**: Small, Sporty, Compact, Midsize, Large
- **MinPrice**: Minimum Price (in $1,000) - Price for basic version of this model
- **MidPrice**: Midrange Price (in $1,000) - Average of Min and Max prices
- **MaxPrice**: Maximum Price (in $1,000) - Price for a premium version
- **MPGcity**: City MPG
- **MPGhiway**: Highway MPG
- **Airbags**: 0 = none, 1 = driver only, 2 = driver & passenger
- **DriveTrain**: 0 = rear wheel drive, 1 = front wheel drive, 2 = all wheel drive
- **Cylinders**: Number of cylinders
- **Engine**: Engine size (liters)
- **HP**: maximum Horsepower
- **RPM**: revolutions per minute at maximum horsepower
- **RevMile**: Engine revolutions per mile in highest gear
- **Manual**: Manual transmission available, 0 = No, 1 = Yes
- **FuelCap**: Fuel tank capacity (gallons)
- **PassCap**: Passenger capacity (persons)
- **Length**: Length (inches)
- **Wheelbase**: Wheelbase (inches)
- **Width**: Width (inches)
- **Uturn**: U-turn space (feet)
- **RearSeat**: Rear seat room (inches)
- **LugCap**: Luggage capacity (cu. ft.)
- **Weight**: Weight (pounds)
- **Source**: 0=non-USA manufacturer, 1=USA manufacturer

VariableLabels: Mach4 Data Set

Description

For the data of 351 responses to the 20-item Mach IV scale.

Usage

data(dataMach4_lbl)

Format

Variable labels, the items of the Christie and Geiss Mach IV Scale

m01: Never tell anyone the real reason you did something unless it is useful to do so
m02: The best way to handle people is to tell them what they want to hear
m03: One should take action only when sure it is morally right
m04: Most people are basically good and kind
m05: It is safest to assume that all people have a vicious streak and it will come out when they are given a chance
m06: Honesty is the best policy in all cases
m07: There is no excuse for lying to someone else
m08: Generally speaking, people won’t work hard unless they’re forced to do so
m09: All in all, it is better to be humble and honest than to be important and dishonest
m10: When you ask someone to do something for you, it is best to give the real reasons for wanting it rather than giving reasons which carry more weight
m11: Most people who get ahead in the world lead clean, moral lives
m12: Anyone who completely trusts anyone else is asking for trouble
m13: The biggest difference between most criminals and other people is that the criminals are stupid enough to get caught
m14: Most people are brave
m15: It is wise to flatter important people
m16: It is possible to be good in all respects
m17: Barnum was wrong when he said that there’s a sucker born every minute
m18: It is hard to get ahead without cutting corners here and there
m19: People suffering from incurable diseases should have the choice of being put painlessly to death
m20: Most people forget more easily the death of a parent than the loss of their property

dataStockPrice  

Data: Stock price of Apple, IBM and Intel from 1980 through January of 2019

Description

Usage

data(dataStockPrice)

Format

A data table in tidy format with three variables: month, Company and Price. The variable month is a date expression expressed as a four digit year, followed by a month, then a day, separated by either dashes. A total of 1374 rows, 458 rows per company.
Density Curves from Data plus Histogram

Description

Abbreviation: \texttt{dn}

Plots a normal density curve and/or a general density curve superimposed over a histogram, all estimated from the data. Also reports the Shapiro-Wilk normality test and summary statistics.

If the provided object to analyze is a set of multiple variables, including an entire data frame, then each non-numeric variable in the data frame is analyzed and the results written to the current graphics device or to a pdf file in the current working directory. The name of each output pdf file that contains a bar chart and its path are specified in the output.

When output is assigned into an object, such as \texttt{dn(Y)}, the pieces of output can be accessed for later analysis. A primary such analysis is \texttt{knitr} for dynamic report generation from an R markdown document in which R output is embedded in documents, facilitated by the \texttt{Rmd} option. See value below.

Usage

\begin{verbatim}
Density(x, data=d, rows=NULL, 
n_cat=getOption("n_cat"), Rmd=NULL, 
 bw=NULL, type=c("general", "normal", "both"), 
 histogram=TRUE, bin_start=NULL, bin_width=NULL, 
 color_nrm="gray20", color_gen="gray20", 
 fill_nrm=NULL, fill_gen=NULL, 
 rotate_x=0, rotate_y=0, offset=0.5, 
 x.pt=NULL, xlab=NULL, main=NULL, sub=NULL, y_axis=FALSE, 
 x.min=NULL, x.max=NULL, 
 rug=FALSE, color_rug="black", size_rug=0.5, 
 eval_df=NULL, digits_d=NULL, quiet=getOption("quiet"), 
 width=4.5, height=4.5, pdf=FALSE, 
 fun_call=NULL, ...)

dn(...)\end{verbatim}
Arguments

x
Variable(s) to analyze. Can be a single numerical variable, either within a data frame or as a vector in the user’s workspace, or multiple variables in a data frame such as designated with the `c` function, or an entire data frame. If not specified, then defaults to all numerical variables in the specified data frame, `d` by default.

data
Optional data frame that contains the variable(s) of interest, default is `d`.

rows
A logical expression that specifies a subset of rows of the data frame to analyze.

n_cat
For the analysis of multiple variables, such as a data frame, specifies the largest number of unique values of variable of a numeric data type for which the variable will be analyzed as categorical. Default is 0.

Rmd
File name for the file of R markdown to be written, if specified. The file type is `.Rmd`, which automatically opens in RStudio, but it is a simple text file that can be edited with any text editor, including RStudio.

bw
Bandwidth of kernel estimation. Initial value is "nrd0", but unless specified, then may be iterated upward to create a smoother curve.

type
Type of density curve plotted. By default, the general density is plotted, though can request the normal density and both densities.

histogram
If TRUE overlay the density plot over a histogram.

bin_start
Optional specified starting value of the bins.

bin_width
Optional specified bin width, which can be specified with or without a `bin_start` value.

color_nrm
Color of the normal curve.

color_gen
Color of the general density curve.

fill_nrm
Fill color for the estimated normal curve, with a partially transparent blue as the default, and transparent for the gray theme.

fill_gen
Fill color for the estimated general density curve, with a partially transparent light red as the default, and a light transparent gray for the gray theme.

rotate_x
Degrees that the x-axis values are rotated, usually to accommodate longer values, typically used in conjunction with `offset`.

rotate_y
Degrees that the y-axis values are rotated.

offset
The amount of spacing between the axis values and the axis. Default is 0.5. Larger values such as 1.0 are used to create space for the label when longer axis value names are rotated.

x.pt
Value of the point on the x-axis for which to draw a unit interval around illustrating the corresponding area under the general density curve. Only applies when requesting type=general.

xlab
Label for x-axis. Defaults to variable name unless variable labels are present, the defaults to also include the corresponding variable label. Can style with the lessR `style` function.
main  Label for the title of the graph. Can set size with `main_cex` and color with `main_color` from the lessR `style` function.

sub  Sub-title of graph, below `xlab`.

`y_axis`  Specifies if the y-axis, the density axis, should be included.

`x.min`  Smallest value of the variable x plotted on the x-axis.

`x.max`  Largest value of the variable x plotted on the x-axis.

`rug`  If `TRUE`, add a rug plot, a direct display of density in the form of a narrow band beneath the density curve.

`color_rug`  Color of the rug ticks.

`size_rug`  Line width of the rug ticks.

`eval_df`  Determines if to check for existing data frame and specified variables. By default is `TRUE` unless the shiny package is loaded then set to `FALSE` so that Shiny will run. Needs to be set to `FALSE` if using the pipe `%>%` notation.

`digits_d`  Number of significant digits for each of the displayed summary statistics.

`quiet`  If set to `TRUE`, no text output. Can change system default with `style` function.

`width`  Width of the plot window in inches, defaults to 4.5.

`height`  Height of the plot window in inches, defaults to 4.5.

`pdf`  If `TRUE`, graphics are to be redirected to a pdf file.

`fun_call`  Function call. Used with `knitr` to pass the function call when obtained from the abbreviated function call `dn`.

...  Other parameter values for graphics as defined processed by `plot`, including `xlim`, `ylim`, `lwd` and `lab_cex`, `color_main`, `color_lab`, `sub`, `color_sub`, and `color_ticks` to specify the color of the ticks used to label the axis values, density, for the general density calculations, can set bandwidth with the standard `bw`.

Details

OVERVIEW
Results are based on the standard `dnorm` function and `density` R functions for estimating densities from data, as well as the `hist` function for calculating a histogram. Colors are provided by default and can also be specified.

The default histogram can be modified with the `bin_start` and `bin_width` options. Use the `Histogram` function in this package for more control over the parameters of the histogram.

The limits for the axes are automatically calculated so as to provide sufficient space for the density curves and histogram, and should generally not require user intervention. Also, the curves are centered over the plot window so that the resulting density curves are symmetric even if the underlying histogram is not. The estimated normal curve is based on the corresponding sample mean and standard deviation.

If `x.pt` is specified, then `type` is set to general and `y_axis` set to `TRUE`. 
DATA
The data may either be a vector from the global environment, the user’s workspace, as illustrated in the examples below, or one or more variable’s in a data frame, or a complete data frame. The default input data frame is \(d\). Can specify the source data frame name with the \texttt{data} option. If multiple variables are specified, only the numerical variables in the list of variables are analyzed. The variables in the data frame are referenced directly by their names, that is, no need to invoke the standard R mechanisms of the \texttt{d$name} notation, the \texttt{with} function or the \texttt{attach} function. If the name of the vector in the global environment and of a variable in the input data frame are the same, the vector is analyzed.

The \texttt{rows} parameter subsets rows (cases) of the input data frame according to a logical expression. Use the standard R operators for logical statements as described in \texttt{Logic} such as & for and, | for or and ! for not, and use the standard R relational operators as described in \texttt{Comparison} such as == for logical equality != for not equals, and > for greater than.

COLOR THEME
Individual colors in the plot can be manipulated with options such as \texttt{color_bars} for the color of the histogram bars. A color theme for all the colors can be chosen for a specific plot with the \texttt{colors} option with the \texttt{lessR} function \texttt{style}. The default color theme is blue, but a gray scale is available with "gray", and other themes are available as explained in \texttt{style}, such as "red" and "green". Use the option \texttt{style(sub_theme="black")} for a black background and partial transparency of plotted colors.

VARIABLE LABELS
If variable labels exist, then the corresponding variable label is by default listed as the label for the horizontal axis and on the text output. For more information, see \texttt{Read}.

PDF OUTPUT
To obtain pdf output, use the \texttt{pdf} option, perhaps with the optional \texttt{width} and \texttt{height} options. These files are written to the default working directory, which can be explicitly specified with the R \texttt{setwd} function.

ONLY VARIABLES ARE REFERENCED
The referenced variable in a \texttt{lessR} function can only be a variable name (or list of variable names). This referenced variable must exist in either the referenced data frame, such as the default \(d\), or in the user’s workspace, more formally called the global environment. That is, expressions cannot be directly evaluated. For example:

\[
> \text{Density(rnorm(50)) \# does NOT work}
\]

Instead, do the following:

\[
> Y \leftarrow \text{rnorm(50)} \quad \# \text{create vector } Y \text{ in user workspace}
> \text{Density}(Y) \quad \# \text{directly reference } Y
\]

Value
The output can optionally be saved into an R object, otherwise it simply appears in the console. Redesigned in \texttt{lessR} version 3.3 to provide two different types of components: the pieces of readable output, and a variety of statistics. The readable output are character strings such as tables amenable for reading. The statistics are numerical values amenable for further analysis. The motivation of these types of output is to facilitate R markdown documents, as the name of each piece, preceded by the name of the saved object and a $, can be inserted into the R~Markdown document (see \texttt{examples}).
Density

READABLE OUTPUT

codeout_title: Title of output
codeout_stats: Statistics
codeout_file: Name and location of optional R markdown file

STATISTICS

codebw: Bandwidth parameter
coden: Number of data values analyzed
coden.miss: Number of missing data values
codeW: W statistic for Shapiro-Wilk normality test
codepvalue: p-value for W statistic

Although not typically needed, if the output is assigned to an object named, for example, h, then the contents of the object can be viewed directly with the unclass function, here as unclass(h).

Density(c(X,Y))

details

Display Contents of a Data File and Optional Variable Labels

Description

Abbreviation: db

Provides feedback regarding a data frame which includes the variable names, the dimensions of the resulting data frame, the data type for each variable, and the values of the variables in the data file for the first and last rows of the data. In addition, an analysis of missing data is provided, listing the number of missing values for each variable and for each observation.

Usage

details(data=d, n_mcut=1, miss_zero=FALSE, max_lines=30,  
miss_show=30, miss_matrix=FALSE, brief=getOption("brief"))

db(..., brief=TRUE)
Arguments

data
n_mcut
miss_zero
max_lines
miss_show
miss_matrix
brief
...

Details

MISSING DATA
By default, details provides a list of each variable and each row with the display of the number of associated missing values, indicated by the standard R missing value code NA. To not list the variable name or row name of variables or rows without missing data, invoke the miss_zero=FALSE option, which can appreciably reduce the amount of output for large data sets. To view the entire data table in terms of 0's and 1's for non-missing and missing data, respectively, invoke the miss_matrix=TRUE option.

VARIABLE LABELS
Standard R does not provide for variable labels, but lessR does. Variable labels can be provided for some or all of the variables in the data frames. One way to enter the variable labels is to read them from their own file with details with labels set to the full path name or URL of the labels file, or just the file name if the labels file is in the same directory as the data file. Another method is to include the labels directly in the data file. To to this, specify the file of variable labels with the label="row2" option. The web survey application Qualtrics downloads csv files in this format. For a file that contains only labels, each row of the file, including the first row, consists of the variable name, a comma, and then the label, that is, standard csv format such as obtained with the csv option from a standard worksheet application such as Microsoft Excel or LibreOffice Calc. Not all variables in the data frame that contains the data, usually d, need have a label, and the variables with their corresponding labels can be listed in any order. An example follows.
I2,This instructor presents material in a clear and organized manner.
I4,Overall, this instructor was highly effective in this class.
I1,This instructor has command of the subject.
I3,This instructor relates course materials to real world situations.

If there is a comma in the variable label, then the label needs to be enclosed in quotes.
The lessR functions that provide analysis, such as Histogram for a histogram, automatically include the variable labels in their output, such as the title of a graph. Standard R functions can also
use these variable labels by invoking the `label` function, such as setting `main=label(I4)` to put the variable label for a variable named `I4` in the title of a graph.

**Author(s)**

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

**See Also**

Read.

**Examples**

```r
# read the built-in data set datEmployee
# this provides an automatic call to details
d <- Read("Employee")

# manually request the details for d
details()

# manually request just variable names, labels for d
db()
```

---

**factors**

Create Factor Variables Across a Sequential Range or Vector of Variables

**Description**

Creates factors for many variables. Specify a range from a given start variable and end variable. Applies only to variables in a data frame, `d` by default, and outputs the entire data frame including the factor transformation.

**Usage**

```r
factors(x, levels, labels=NULL, data=d, ordered=FALSE,
        new=FALSE, suffix="_f", var_labels=FALSE, ...)
```

**Arguments**

- `x` Name of variable(s) to convert to a factor. List a single variable or a vector
- `levels` Levels for which to define the factor.
- `labels` Value labels to assign to the levels. If not present then assumes the character version of the levels.
- `data` The data frame of interest.
- `ordered` If FALSE, factor levels are not ordered.
new

If FALSE, original variables are replaced, otherwise new factor variables are created.

suffix

The appended suffix to newly created variables from the original variable names when new is TRUE.

var_labels

Just create new variable labels for newly created factor variables, without doing a factor conversion, presumably after a previous run with factors converted to new factor variables.

Details

Returns the entire data frame if applied to one or more variables in a data frame, including the new factors.

Examples

# get the data, variables Gender plus m01 through m20, 20 Mach IV items
# coded as integers from 0 to 5 on 6-pt Likert scales
d <- rd("Mach4", quiet=TRUE)

# single variable converted to a factor
d <- factors(Gender, 0:1, c("Male", "Female"))

# Define the labels
LikertCats <- c("Strongly Disagree", "Disagree", "Slightly Disagree", "Slightly Agree", "Agree", "Strongly Agree")

# Convert the integer responses to factors for the 20 Mach IV items
d <- factors(m01:m20, levels=0:5, labels=LikertCats)

# read the data again and this time also the variable labels
d <- rd("Mach4", quiet=TRUE)
l <- rd("Mach4_lbl")

# convert specified variables to factors according to the given vector
# of three variables only
# leave the original variables unmodified, create new variables
d <- factors(c(m06, m07, m20), levels=0:5, labels=LikertCats, new=TRUE)
# now copy the variable labels from the original integer variables to the
# newly created factor variables
l <- factors(c(m06, m07, m20), var_labels=TRUE)
getColors

Hue, Chroma, Luminance (HCL) Color Wheel or Specified Colors

**Description**

Generates vectors colors including HCL colors for qualitative and sequential color scales and displays colors, both those generated and also arbitrary colors manually specified. To avoid bias in the comparison of differently colored regions of a visualization, generates HCL colors by default with fixed values of chroma (saturation) and luminance (brightness) for a range of hues, by default ordered so that adjacent colors are as separated as possible. Also generates a sequence of HCL colors according to any chosen hue value in which chroma and luminance can be varied by implicit calls to Zeileis's et al. `sequential_hcl` function from Ihaka's et al. `colorspace` package, and also with pre-defined values such as "blues". Also processes any arbitrarily specified set of colors that are specified, or generated from a custom range according to a beginning and ending specified color, and includes color palettes from the viridis and wesanderson packages.

In terms of workflow, use the function by itself to select a set of colors from the resulting color rectangle/wheel. The function outputs the colors so that the function call can serve as an argument to parameters in other functions that require a sequence of one or more colors as input, in which case the visualization of the color wheel or rectangle is not generated. So after the colors are selected, pass to an argument for a visualization function such as for the `fill` parameter.

**Usage**

```r
getColors(pal=NULL, end_pal=NULL, n=12, h=0, h2=NULL, c=NULL, l=NULL, trans=0, in_order=NULL, fixup=TRUE, power=NULL, shape=c("rectangle", "wheel"), radius=0.9, border="lightgray", main=NULL, labels=NULL, labels_cex=0.8, lty="solid", output=NULL, quiet=getOption("quiet"), ...)
```

**Arguments**

- **pal**: Palette of optional specified colors to plot. If a set of specified colors, then the following parameters are not relevant. Can also be pre-defined color codes that trigger a sequence of colors from light to dark, such as "blues", or "distinct" to maximize color separation.

- **end_pal**: If specified, then generate a color continuum that begins at `pal` and ends at `end_pal`.

- **n**: Number of colors to display.

- **h**: Beginning HCL hue, 0 to 360.

- **h2**: Ending HCL hue, 0 to 360. Defaults to a value close to 360. Requires `in_order` to be `FALSE`.

- **c**: Value of HCL chroma (saturation). Respective default values for qualitative, sequential, and divergent scales are 60, c(35,75), and 50.
getColors

1 Value of HCL luminance (brightness). Respective default values for qualitative, sequential, and divergent scales are 50, \(c(80,25)\), and \(c(40,70)\).

trans Transparency factor of the area of each slice from 0, no transparency to 1, full transparency.

in_order If TRUE, orders the colors in order of their HCL hue values, the default for a "wheel". Otherwise maximizes the difference between adjacent colors hues to prepare for inclusion in visualizations with qualitative, discrete color scales.

fixup R parameter name. If TRUE, then HCL values outside of the displayable RGB color space are transformed to fit into that space so as to display.

power Power for generating a sequential or divergent HCL scale (via colorspace package) for potentially non-linear changes in chroma and luminance across the scale. Default for sequential is 1 and for divergent 0.75.

shape Default is a "rectangle", or specify a "wheel".

radius Size of wheel. Not applicable to the rectangular shape.

border Color of the borders of each slice. Set to "off" or "transparent" to turn off.

main Title.

labels If TRUE, then displayed. For HCL qualitative scale, default is TRUE, otherwise FALSE.

labels_cex Character expansion factor of labels relative to 1.

lty Line type of the border.

output Default to evaluate if function call at top level, so produce text and graphics output, or embedded in another function call, so do not produce that output. If set to "on", then do output. If set to "off" then do not do output.

quiet If set to TRUE, no list of colors. Can change system default with style function.

... Other parameter values

Details

I. HCL COLORS

Generate a palette of colors according to the parameter pal in the form of a character string vector of their names, and also as a color wheel if not called from another function. The default value (for all but grayscale or white color themes) of pal is "colors", which generates a qualitative palette of the specified number, \(n\), of discrete HCL colors at the same chroma and luminance, respective default values of 60 and 50. With constant chroma and luminance the HCL color space provides a palette of colors with the same gray-scale intensities if desaturated. That means no brightness bias for viewing different colors that represent different areas, such as in a bar chart of two variables, or a pie chart. The primary qualification is that the HCL color space is not in a one-to-one correspondence with the RGB color space of computer monitors, so some HCL colors are approximated (with the default setting of the fixup parameter set to TRUE).

For "colors", the default, the hue values and associated colors are expressed as HEX and RGB values. The first 12 generated discrete colors are blue (240), brown (60), green (120), red (0),
There are various color names defined in 30 degree increments around the HCL color wheel. Visualize the color wheel with the lessR function `getColors`, specifically the function call `getColors(shape="wheel")`. Visualize sequential color scales for each of the colors below with the lessR function `showPalettes`.

<table>
<thead>
<tr>
<th>colors</th>

<td>h</td>
<td>330</td>
</tr>
<tr>
<td>&quot;grays&quot;</td>
<td>c</td>
<td>0</td>
</tr>
</tbody>
</table>

The predefined color name can be provided as the first argument of the function call, that is, the value of `pal`, or the corresponding value of `h` (or `c` for gray scale) can be specified. The specifications are equivalent. To specify a divergent color scale, provide both the value of `pal` as the beginning value and the value of `end_pal` as the last value, such that both values are one of the
pre-specified color ranges. In either situation, of sequential or divergent color scales, custom values of \( c \) and \( l \) can be provided.

III. SPECIFIED COLORS
The third possibility is to generate a color wheel from a specified set of color values. Set the value of \( \text{pal} \) according to the vector of these values. Specify the values with R color names (see the lessR function \texttt{showColors}), RGB values according to the \texttt{rgb} function or from related R color space functions such as \texttt{hcl}, or as hexadecimal codes.

IV. OTHER INCLUDED COLOR PALETTES
The following palettes are from the viridis package: "viridis", "cividis", "magma", "inferno", "plasma".
Movie director Wes Anderson is known for his innovative color themes in his movies, which feature a combination of pastel colors and bold primary colors. The following palettes are from the wesander-son package, based on the colors from his movies: "BottleRocket1", "BottleRocket2", "Rushmore1", "Rushmore", "Royall", "Royal2", "Zissou1", "Darjeeling1", "Darjeeling2", "Chevalier1", "FantasticFox1", "Moonrise1", "Moonrise2", "Moonrise3", "Cavalcanti1", "GrandBudapest1", "GrandBudapest2", "IsleofDogs1", "IsleofDogs2". The generation of the corresponding palettes are with type set to "continuous" to generalize to palettes of any length. Note that this package is suggested, which means to use the package for the first time you will be prompted to install the package.

The palette "distinct" specifies a sequence of 20 colors manually chosen for the distinctiveness. The first five colors are from the qualitative sequence of \texttt{hcl} colors with \( c=90 \) and \( l=50 \). To maximise color separation, the remaining 15 colors do not satisfy constance levels of \( c \) and \( l \). Use such as for plotting with a by variable with up to 20 levels.

FUNCTION USAGE
Use the function on its own, in which case the color rectangle/wheel visualization is generated as are the color values. The vector of color values may be saved in its own R object as the output of the function call. Or, use the function to set colors for other parameter values in other function calls. See the examples.

Value
Colors are invisibly returned as a character string vector.

Description

The lessR (Help()) function was a kind of mini-vignette. Now that R provides these, the Help() function is removed, replaced by the more extensive and informative vignettes. For a list of all vignettes, enter vignette(package="lessR").

Usage

Help(topic=NULL)

Arguments

- topic: ... Removed ...

Description

Abbreviation: hs

From the standard R function hist, plots a frequency histogram with default colors, including background color and grid lines plus an option for a relative frequency and/or cumulative histogram, as well as summary statistics and a table that provides the bins, midpoints, counts, proportions, cumulative counts and cumulative proportions. Bins can be selected several different ways besides the default, including specifying just the bin width and/or the bin start. Also provides improved error diagnostics and feedback for the user on how to correct the problem when the bins do not contain all of the specified data.

If a set of multiple variables is provided, including an entire data frame, then each numeric variable in that set of variables is analyzed, with the option to write the resulting histograms to separate pdf files. The related CountAll function does the same for all variables in the set of variables, histograms for continuous variables and bar charts for categorical variables. Specifying a by1 or by2 variable implements Trellis graphics.

When output is assigned into an object, such as h in h <- hs(Y), can assess the pieces of output for later analysis. A primary such analysis is knitr for dynamic report generation from a generated R markdown file according to the Rmd option in which interpretative R output is embedded in documents. See value below.

Usage

hs(...)
A categorical variable called a conditioning variable that activates **Trellis graphics**, from the lattice package, to provide a separate scatterplot (panel) of numeric primary variables x and y for each level of the variable.

A second conditioning variable to generate Trellis plots jointly conditioned on both the by1 and by2 variables, with by2 as the row variable, which yields a scatterplot (panel) for each cross-classification of the levels of numeric x and y variables.

Optional specification for the number of rows in the layout of a multi-panel display with Trellis graphics. Need not specify ncols.

Optional specification for the number of columns in the layout a multi-panel display with Trellis graphics. Need not specify n_row If set to 1, then the strip that labels each group is moved to the left of each plot instead of the top.

Lattice parameter for the aspect ratio of the panels, defined as height divided by width. The default value is "fill" to have the panels expand to occupy as much space as possible. Set to 1 for square panels. Set to "xy" to specify a ratio calculated to "bank" to 45 degrees, that is, with the line slope approximately 45 degrees.

Optional specified starting value of the bins.

Optional specified bin width, which can be specified with or without a bin_start value.

Optional specified value that is within the last bin, so the actual endpoint of the last bin may be larger than the specified value.

The method for calculating the bins, or an explicit specification of the bins, such as with the standard R seq function or other options provided by the hist function that include the default "Sturges" plus "Scott" and "FD". Not applicable and so not allowed if density is TRUE.

Color theme for this analysis. Make persistent across analyses with style.

Fill color of the bars. Can explicitly choose "grays" or "hcl" colors, or pre-specified R color schemes "rainbow", "terrain", and "heat". Can also provide pre-defined color ranges "blues", "reds" and "greens", as well as custom colors, such as generated by getColors. Default is bar_color from the lessR style function.

Border color of the bars, can be a vector to customize the color for each bar. Default is bar_color from the lessR style function.

Transparency factor of the area of each slice. Default is trans_bar_fill from the lessR style function.

Replaces standard R labels options, which has multiple definitions in R. Specifies to display the count of each bin.

The color of the superimposed, regular histogram when cumulate="both".

Specify a cumulative histogram. The value of "on" displays the cumulative histogram, with default of "off". The value of "both" superimposes the regular
Histogram

`histogram`. 

- **xlab**: Label for x-axis. Defaults to variable name unless variable labels are present, the defaults to also include the corresponding variable label. Can style with the `lessR` `style` function.

- **ylab**: Label for y-axis. Defaults to Frequency or Proportion. Can style with the `lessR` `style` function.

- **main**: Label for the title of the graph. Can set size with `main_cex` and color with `main_color` from the `lessR` `style` function.

- **sub**: Sub-title of graph, below xlab.

- **lab_adj**: Two-element vector – x-axis label, y-axis label – adjusts the position of the axis labels in approximate inches. + values move the labels away from plot edge. Not applicable to Trellis graphics.

- **margin_adj**: Four-element vector – top, right, bottom and left – adjusts the margins of the plotted figure in approximate inches. + values move the corresponding margin away from plot edge. Not applicable to Trellis graphics.

- **rotate_x**: Degrees that the x-axis values are rotated, usually to accommodate longer values, typically used in conjunction with `offset`. Can set persistently with the `lessR` `style` function.

- **rotate_y**: Degrees that the y-axis values are rotated. Can set persistently with the `lessR` `style` function.

- **offset**: The amount of spacing between the axis values and the axis. Default is 0.5. Larger values such as 1.0 are used to create space for the label when longer axis value names are rotated. Can set persistently with the `lessR` `style` function.

- **scale_x**: If specified, a vector of three values that define the numerical values of the x-axis: starting, ending and number of intervals, within the bounds of plot region.

- **scale_y**: Applies to the y-axis. See `scale_x`.

- **density**: If TRUE, plot the smoothed kernel density estimate.

- **dn.hist**: When density is TRUE, plot a histogram behind the density curve.

- **bw**: Bandwidth of kernel density estimation. Initial value is “nrd0”, but unless specified, then may be iterated upward to create a smoother curve.

- **type**: Type of density curve plotted. By default, the general density is plotted, though can request the normal density and both densities.

- **color_gen**: Color of the general density curve.

- **color_nrm**: Color of the normal curve.

- **fill_hist**: Fill color for the histogram behind density curve, defaults to a light gray.

- **fill_nrm**: Fill color for the estimated normal curve, with a partially transparent blue as the default, and transparent for the gray theme.

- **fill_gen**: Fill color for the estimated general density curve, with a partially transparent light red as the default, and a light transparent gray for the gray theme.
Histogram

x.pt  Value of the point on the x-axis for which to draw a unit interval around illustrating the corresponding area under the general density curve. Only applies when requesting type=general.

y.axis  Specifies if the y-axis, the density axis, should be included.

rug  If TRUE, add a rug plot, a direct display of density in the form of a narrow band beneath the density curve.

color_rug  Color of the rug ticks.

size_rug  Line width of the rug ticks.

add  **Draw one or more objects**, text or a geometric figures, on the plot. Possible values are any text to be written, the first argument, which is "text", or, to indicate a figure, "rect" (rectangle), "line", "arrow", "v.line" (vertical line), and "h.line" (horizontal line). The value "means" is short-hand for vertical and horizontal lines at the respective means. Does not apply to Trellis graphics. Customize with parameters such as add_fill and add_color from the style function.

x1  First x coordinate to be considered for each object. All coordinates vary from -1 to 1.

y1  First y coordinate to be considered for each object.

x2  Second x coordinate to be considered for each object. Only used for "rect", "line" and arrow.

y2  Second y coordinate to be considered for each object. Only used for "rect", "line" and arrow.

eval_df  Determines if to check for existing data frame and specified variables. By default is TRUE unless the shiny package is loaded then set to FALSE so that Shiny will run. Needs to be set to FALSE if using the pipe %>% notation.

digits_d  Number of significant digits for each of the displayed summary statistics.

quiet  If set to TRUE, no text output. Can change system default with style function.

do_plot  If TRUE, the default, then generate the plot.

width  Width of the plot window in inches, defaults to 4.5.

height  Height of the plot window in inches, defaults to 4.5.

pdf  If TRUE, graphics are to be redirected to a pdf file.

fun_call  Function call. Used with knitr to pass the function call when obtained from the abbreviated function call hs.

...  Other parameter values for graphics as defined processed by hist and par for general graphics, xlim and ylim for setting the range of the x and y-axes
cex.main for the size of the title
col.main for the color of the title
cex for the size of the axis value labels
col.lab for the color of the axis labels
Details

OVERVIEW
Results are based on the standard R `hist` function to calculate and plot a histogram, or a multi-panel display of histograms with Trellis graphics, plus the additional provided color capabilities, a relative frequency histogram, summary statistics and outlier analysis. The freq option from the standard R `hist` function has no effect as it is always set to FALSE in each internal call to `hist`. To plot densities, use the lessR function `Density`.

VARIABLES and TRELLIS PLOTS
At a minimum there is one primary variable, x, which results in a single histogram. Trellis graphics, from Deepayan Sarkar’s lattice package, may be implemented in which multiple panels are displayed according to the levels of one or two categorical variables, called conditioning variables. A variable specified with by1 is a conditioning variable that results in a Trellis plot, the histogram of x produced at each level of the by1 variable. Inclusion of a second conditioning variable, by2, results in a separate histogram for each combination of cross-classified values of both by1 and by2.

DATA
The data may either be a vector from the global environment, the user’s workspace, as illustrated in the examples below, or one or more variable’s in a data frame, or a complete data frame. The default input data frame is d. Can specify the source data frame name with the data option. If multiple variables are specified, only the numerical variables in the list of variables are analyzed. The variables in the data frame are referenced directly by their names, that is, no need to invoke the standard R mechanisms of the `d$name` notation, the `with` function or the `attach` function. If the name of the vector in the global environment and of a variable in the input data frame are the same, the vector is analyzed.

To obtain a histogram of each numerical variable in the d data frame, use `Histogram()`. Or, for a data frame with a different name, insert the name between the parentheses. To analyze a subset of the variables in a data frame, specify the list with either a : or the c function, such as m01:m03 or c(m01,m02,m03).

The rows parameter subsets rows (cases) of the input data frame according to a logical expression. Use the standard R operators for logical statements as described in Logic such as & for and, | for or and ! for not, and use the standard R relational operators as described in Comparison such as == for logical equality != for not equals, and > for greater than. See the Examples.

COLORS
Individual colors in the plot can be manipulated with options such as color_bars for the color of the histogram bars. A color theme for all the colors can be chosen for a specific plot with the colors option with the lessR function `style`. The default color theme is lightbronze, but a gray scale is available with "gray", and other themes are available as explained in `style`, such as "red" and "green". Use the option style(sub_theme="black") for a black background and partial transparency of plotted colors.

For the color options, such as fill, the value of "off" is the same as "transparent".

Set fill to a single color or a color range, of which there are many possibilities. For "hues" colors of the same chroma and luminance set fill to multiple colors all with the same saturation and brightness. Also available are the pre-specified R color schemes "rainbow", "terrain", and "heat". Can also provide pre-defined color ranges "blues", "reds" and "greens", or generate custom colors, such as from the lessR function `getColors`.

VARIABLE LABELS
If variable labels exist, then the corresponding variable label is by default listed as the label for the horizontal axis and on the text output. For more information, see Read.

**ONLY VARIABLES ARE REFERENCED**
The referenced variable in a lessR function can only be a variable name (or list of variable names). This referenced variable must exist in either the referenced data frame, such as the default d, or in the user’s workspace, more formally called the global environment. That is, expressions cannot be directly evaluated. For example:

````
> Histogram(rnorm(50)) # does NOT work
```

Instead, do the following:

````
> Y <- rnorm(50) # create vector Y in user workspace
> Histogram(Y)  # directly reference Y
```

**ERROR DETECTION**
A somewhat relatively common error by beginning users of the base R `hist` function may encounter is to manually specify a sequence of bins with the `seq` function that does not fully span the range of specified data values. The result is a rather cryptic error message and program termination. Here, Histogram detects this problem before attempting to generate the histogram with `hist`, and then informs the user of the problem with a more detailed and explanatory error message. Moreover, the entire range of bins need not be specified to customize the bins. Instead, just a bin width need be specified, `bin_width`, and/or a value that begins the first bin, `bin_start`. If a starting value is specified without a bin width, the default Sturges method provides the bin width.

**PDF OUTPUT**
To obtain pdf output, use the pdf option, perhaps with the optional width and height options. These files are written to the default working directory, which can be explicitly specified with the R `setwd` function.

**Value**
The output can optionally be saved into an R object, otherwise it simply appears in the console. Two different types of components are provided: the pieces of readable output, and a variety of statistics. The readable output are character strings such as tables amenable for display. The statistics are numerical values amenable for further analysis. The motivation of these types of output is to facilitate R markdown documents, as the name of each piece, preceded by the name of the saved object and a $, can be inserted into the R–Mark down document (see examples), interspersed with explanation and interpretation.

**READABLE OUTPUT**
out_suggest: Suggestions for other similar analyses
out_summary: Summary statistics
out_freq: Frequency distribution
out_outliers: Outlier analysis

**STATISTICS**
bin_width: Bin width
n.bins: Number of bins
breaks: Breaks of the bins
mids: Bin midpoints
Counts: Bin counts
prop: Bin proportion
Cumulate: Bin cumulative counts
cprop: Bin cumulative proportion

Assign Variable Labels [Superseded by VariableLabels]

Description

Deprecated, replaced by VariableLabels. Display a variable label for output, either text output at the console or graphics, such as a title on a graph. To return a variable label generally applies to standard R functions such that the functions can access lessR variable labels. Or, the variable name and label can be listed on the standard output. To assign a variable label, invoke the value option and assign the output to a specified data frame.

Usage

label(x, value=NULL, data=d)

Arguments

x The variable for which to obtain the corresponding variable label.
value If assigned, then the specified data frame is updated with this assigned label.
data Data frame that contains the variable of interest. The output of the function is assigned to this data frame.

Details

Standard R does not provide for variable labels, but lessR does. Read the labels with the lessR Read function, as explained in the corresponding documentation. Individual variable labels can also be assigned with this function. Not all variables need have a label, and the variables with their corresponding labels can be listed or assigned in any order.

The function provides two different modes. The first mode is to return the variable name and label for an existing variable label. One such use is to provide the function as an argument to an existing R function call to access a lessR variable label. For example, use the function as the argument for main in graphics output, where main is the title of the graph. This mode is triggered by not invoking the value option.

The second mode is to assign a variable label to an existing variable. Invoke this mode by specifying a variable label with the value option. The function accesses the entire specified data frame, and then modifies the specified variable label. As such, assign the output of the function to the data frame of interest, such as the default d. One use of this function is to add a variable label to a data frame that contains a new variable created by a transformation of the existing variables.

Value

The specified value of value is returned.

Author(s)

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)
Description

Abbreviation: lc

Plots a line chart, the values of the variable ordered according to their order in the data frame. Usually this ordering would be an ordering according to time, which yields a run chart. The default run chart provides the index, that is, sequential position, of each value of the variable from 1 to the last value. Optionally dates can be provided so that a time-series plot is produced.

For data of one variable exhibiting little trend, the center line is provided for the generation of a run chart, plotting the values of a variable in order of occurrence over time. When the center line, the median by default, is plotted, the analyses of the number and composition of the individual runs, number of consecutive values above or below the center line, is also displayed. Also, the defaults change for each of the types of plots. The intent is to rely on the default values for a relatively sophisticated plot, particularly when compared to the default values of the standard R plot function called with a single variable.

If the provided object to analyze is a set of multiple variables, including an entire data frame, then each non-numeric variable in the data frame is analyzed and the results written to a pdf file in the current working directory. The name of each output pdf file that contains a bar chart and its path are specified in the output.
Usage

```
LineChart(x, data=d, rows=NULL,
    n_cat=getOption("n_cat"), type=NULL,
    line_color=getOption("pt_color"), area=NULL,
    shape_pts=21, lab_cex=1.0, axis_cex=0.75,
    axis_text_color=getOption("axis_x_text_color"),
    rotate_x=0, rotate_y=0, offset=.5,
    xy_ticks=TRUE, line_width=1,
    xlab=NULL, ylab=NULL, main=NULL, sub=NULL, cex=NULL,
    time_start=NULL, time_by=NULL, time_reverse=FALSE,
    center_line=c("default", "mean", "median", "zero", "off"),
    show_runs=FALSE, eval_df=NULL, quiet=getOption("quiet"),
    width=6, height=6, pdf=FALSE,
    ...
)
```

Arguments

- **x**: Variable(s) to analyze. Can be a single numerical variable, either within a data frame or as a vector in the user's workspace, or multiple variables in a data frame such as designated with the `c` function, or an entire data frame. If not specified, then defaults to all numerical variables in the specified data frame, `d` by default.

- **data**: Optional data frame that contains the variable(s) of interest, default is `d`.

- **rows**: A logical expression that specifies a subset of rows of the data frame to analyze.

- **n_cat**: For the analysis of multiple variables, such as a data frame, specifies the largest number of unique values of variable of a numeric data type for which the variable will be analyzed as a categorical. Default is 0.

- **type**: Character string that indicates the type of plot, either "p" for points, "l" for line, or "b" for both. The default is "b" for both points and lines.

- **line_color**: Color of the plotted line.

- **area**: Color of area under the plotted line segments, which by default is not applied, equivalent to a color of "transparent".

- **shape_pts**: The standard plot character, with values defined in `help(points)`. The default value is 21, a circle with both a border and filled area, specified here as `color` and `fill`. `fill` defaults to `color`.

- **lab_cex**: Scale magnification factor for axis labels.
axis_cex  Scale magnification factor, which by defaults displays the axis values to be smaller than the axis labels.

axis_text_color  Color of the font used to label the axis values.

rotate_x  Degrees that the x-axis values are rotated, usually to accommodate longer values, typically used in conjunction with offset.

rotate_y  Degrees that the y-axis values are rotated.

offset  The amount of spacing between the axis values and the axis. Default is 0.5. Larger values such as 1.0 are used to create space for the label when longer axis value names are rotated.

xy_ticks  Flag that indicates if tick marks and associated values on the axes are to be displayed.

line_width  Width of the line segments.

xlab  Label for x-axis. For two variables specified, x and y, if xlab not specified, then the label becomes the name of the corresponding variable. If xy_ticks is FALSE, then no label is displayed. If no y variable is specified, then xlab is set to Index unless xlab has been specified.

ylab  Label for y-axis. If not specified, then the label becomes the name of the corresponding variable. If xy_ticks is FALSE, then no label displayed.

main  Label for the title of the graph. If the corresponding variable labels exist, then the title is set by default from the corresponding variable labels.

sub  Sub-title of graph, below xlab.

cex  Magnification factor for any displayed points, with default of cex=1.0.

time_start  Optional starting date for first data value. Format must be "%Y-%m-%d" or "%Y/%m/%d". If using with x.reverse, the first date is after the data are reverse sorted. Not needed if data are a time series with ts function.

time_by  Accompanies the time_start specification, the interval to increment the date for each sequential data value. A character string, containing one of "day", "week", "month" or "year". This string can optionally be preceded by a positive or negative integer and a space, or followed by "s", as specified in seq.Date. Not needed if data are a time series.

time_reverse  When TRUE, reverse the ordering of the dates, particularly when the data are listed such that first row of data is the newest. Accompanies the time_start specification.

center_line  Plots a dashed line through the middle of a run chart. The two possible values for the line are "mean" and "median". Provides a centerline for the "median" by default when the values randomly vary about the mean. A value of "zero" specifies the center line should go through zero.

show_runs  If TRUE, display the individual runs in the run analysis.

eval_df  Determines if to check for existing data frame and specified variables. By default is TRUE unless the shiny package is loaded then set to FALSE so that Shiny will run. Needs to be set to FALSE if using the pipe %>% notation.

quiet  If set to TRUE, no text output. Can change system default with style function.
Details
OVERVIEW
The line chart is based on the standard R function `plot` when called with only a single variable.

The values on the horizontal axis of the line chart are automatically generated. The default is the index variable, the ordinal position of each data value, in which case this version of the line chart is a run chart. Or, dates on the horizontal axis can be specified from the specified starting date given by `x.start` and the accompanying increment as given by `x.by`, in which case the line chart is typically referred to as a time series chart.

If the data values randomly vary about the mean, the default is to plot the mean as the center line of the graph, otherwise the default is to ignore the center line. The default plot type for the line chart is `type="b"`, for both points and the corresponding connected line segments. The size of the points is automatically reduced according to the number of points plotted, and the `cex` option can override the computed default. If the area below the plotted values is specified to be filled in with color, then the default line type changes to `type="l"`.

DATA
The data may either be a vector from the global environment, the user’s workspace, as illustrated in the examples below, or one or more variable’s in a data frame, or a complete data frame. The default input data frame is `d`. Can specify the source data frame name with the `data` option. If multiple variables are specified, only the numerical variables in the list of variables are analyzed.

The variables in the data frame are referenced directly by their names, that is, no need to invoke the standard R mechanisms of the `d$name` notation, the `with` function or the `attach` function. If the name of the vector in the global environment and of a variable in the input data frame are the same, the vector is analyzed.

The `rows` parameter subsets rows (cases) of the input data frame according to a logical expression. Use the standard R operators for logical statements as described in `Logic` such as `&` for and, `|` for or and `!` for not, and use the standard R relational operators as described in `Comparison` such as `==` for logical equality, `!=` for not equals, and `>` for greater than.

COLORS
Individual colors in the plot can be manipulated with options such as `color`. A color theme for all the colors can be chosen for a specific plot with the `colors` option with the `lessR` function `style`. The default color theme is `dodgerblue`, but a gray scale is available with "gray", and other themes are available as explained in `style`, such as "red" and "green". Use the option `style(sub_theme="black")` for a black background and partial transparency of plotted colors.

For the color options, such as `grid_color`, the value of "off" is the same as "transparent".

VARIABLE LABELS
Although standard R does not provide for variable labels, `lessR` does, obtained from the `Read` function. If the variable labels exist, then the corresponding variable label is by default listed as the label for the horizontal axis and on the text output. For more information, see `Read`. 
PDF OUTPUT
To obtain pdf output, use the pdf option, perhaps with the optional width and height options. These files are written to the default working directory, which can be explicitly specified with the R setwd function.

ONLY VARIABLES ARE REFERENCED
The referenced variable in a lessR function can only be a variable name (or list of variable names). This referenced variable must exist in either the referenced data frame, such as the default d, or in the user’s workspace, more formally called the global environment. That is, expressions cannot be directly evaluated. For example:

> LineChart(rnorm(50)) # does NOT work

Instead, do the following:

> Y <- rnorm(50)  # create vector Y in user workspace
> LineChart(Y)    # directly reference Y

Author(s)
David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

# LineChart in gray scale, then back to default theme
style("gray")
LineChart(Y)
style()

# customize run chart with LineChart options
style(panel_fill="mintcream", color="sienna3")
LineChart(Y, line_width=2, area="slategray3", center_line="median")
style()  # reset style

# customize run chart with R par parameters
# 24 is the R value for a half-triangle pointing up

```r
lc(Y, xlab="My xaxis", ylab="My yaxis", main="My Best Title",
    cex.main=1.5, font.main=3, ylim=c(-4,4), shape_pts=24)
```

# generate steadily increasing values
# get a variable named A in the user workspace
A <- sort(rexp(50))
# default line chart
LineChart(A)
# line chart with border around plotted values
LineChart(A, area="off")
# time series chart, i.e., with dates, and filled area
# with option label for the x-axis
LineChart(A, time_start="2000/09/01", time_by="3 months")
# time series chart from a time series object
y.ts <- ts(A, start=c(2000, 9), frequency=4)
LineChart(y.ts)

# LineChart with built-in data set
LineChart(breaks, data=warpbreaks)

# Line charts for all numeric variables in a data frame
LineChart()

# Line charts for all specified numeric variables in a list of variables
# e.g., use the combine or c function to specify a list of variables
LineChart(c(X,Y))

---

Logit

**Logit Regression Analysis**

**Description**

Abbreviation: lr

Based directly on the standard R `glm` function with `family="binomial"`, automatically provides a logit regression analysis with graphics from a single, simple function call with many default settings, each of which can be re-specified. By default the data exists as a data frame with the default name of `d`, such as data read by the `lessR Read` function. Specify the model in the function call according to an R `formula`, that is, the response variable followed by a tilde, followed by the list of predictor variables, each pair separated by a plus sign. The response variable is either a factor with two levels or a numeric variable with values only of 0 and 1.

Default output includes the inferential analysis of the estimated coefficients and model, sorted residuals and Cook’s Distance, and sorted fitted values for existing data or new data. For a single predictor variable model, the scatterplot of the data with plotted logit function is provided.

Can also be called from the more general `model` function.
Usage

Logit(my_formula, data=d, rows=NULL,
     digits_d=4, text_width=120,

     brief=getOption("brief"),

     res_rows=NULL, res_sort=c("cooks","rstudent","dffits","off"),
     pred=TRUE, pred_all=FALSE, prob_cut=0.5, cooks_cut=1,

     X1_new=NULL, X2_new=NULL, X3_new=NULL, X4_new=NULL,
     X5_new=NULL, X6_new=NULL,

     pdf_file=NULL, width=5, height=5, ...) 

lr(...) 

Arguments 

my_formula Standard R formula for specifying a model. For example, for a response variable named Y and two predictor variables, X1 and X2, specify the corresponding linear model as Y ~ X1 + X2.

data The default name of the data frame that contains the data for analysis is d, otherwise explicitly specify.

rows A logical expression that specifies a subset of rows of the data frame to analyze.

digits_d For the Basic Analysis, it provides the number of decimal digits. For the rest of the output, it is a suggestion only.

text_width Width of the text output at the console.

brief If set to TRUE, reduced text output. Can change system default with style function.

res_rows Default is 25, which lists the first 25 rows of data sorted by the specified sort criterion. To turn this option off, specify a value of 0. To see the output for all observations, specify a value of "all".

res_sort Default is "cooks", for specifying Cook's distance as the sort criterion for the display of the rows of data and associated residuals. Other values are "rstudent" for Studentized residuals, and "off" to not provide the analysis.

pred Default is TRUE, which, produces confidence and prediction intervals for each row, or selected rows, of data.

pred_all Default is FALSE, which produces prediction intervals only for the first, middle and last five rows of data.

prob_cut Probability threshold for classifying an observation into the reference group (1) or not (0). Can be a vector, in which case the forecasts and first confusion matrix are for a threshold of 0.5, then the specified values.
The purpose of Logit is to combine the following function calls into one, as well as provide ancillary analyses such as as graphics, organizing output into tables and sorting to assist interpretation of the output. The basic analysis successively invokes several standard R functions beginning with the standard R function for estimation of the logit model, `glm` with `family="binomial"`. The output of the analysis is stored in the object `lm.out`, available for further analysis in the R environment upon completion of the Logit function. By default automatically provides the analyses from the standard R functions, `summary`, `confint` and `anova`, with some of the standard output modified and enhanced. The residual analysis invokes `fitted`, `resid`, `rstudent`, and `cooks.distance` functions. The option for prediction intervals calls the standard generic R function `predict`.

The default analysis provides the model’s parameter estimates and corresponding hypothesis tests and confidence intervals, goodness of fit indices, the ANOVA table, analysis of residuals and influence as well as the fitted value and standard error for each observation in the model.

DATA
The name d is by default provided by the `Read` function included in this package for reading and displaying information about the data in preparation for analysis. If all the variables in the model are not in the same data frame, the analysis will not be complete. The data frame does not need to be attached, just specified by name with the `data` option if the name is not the default d.
The `rows` parameter subsets rows (cases) of the input data frame according to a logical expression. Use the standard R operators for logical statements as described in `Logic` such as & for and, | for or and ! for not, and use the standard R relational operators as described in `Comparison` such as == for logical equality != for not equals, and > for greater than. See the Examples.

**GRAPHICS**
For models with a single predictor variable, a scatter plot of the data is produced, which also includes the fitted values. As with the density histogram plot of the residuals and the scatterplot of the fitted values and residuals, the scatterplot includes a colored background with grid lines. If more than a single predictor variable, then a scatter plot matrix is produced.

**FORECASTS**
Fitted and forecasted values are listed for all rows of data if the number of rows is less than 25 or if `pred_all=TRUE`. If only some of the rows are listed, sorted by the fitted value, the first and last four rows of data are listed. Also the 4 rows immediately around the fitted value of 0.5 are listed.

**RESIDUAL ANALYSIS**
By default the residual analysis lists the data and fitted value for each observation as well as the residual, Studentized residual, Cook’s distance and dffits, with the first 20 observations listed and sorted by Cook’s distance. The residual displayed is the actual difference between fitted and observed, that is, with the setting in the `residuals` of type="response". The `res_sort` option provides for sorting by the Studentized residuals or not sorting at all. The `res_rows` option provides for listing these rows of data and computed statistics statistics for any specified number of observations (rows). To turn off the analysis of residuals, specify `res_rows=0`.

**INVOKED R OPTIONS**
The `options` function is called to turn off the stars for different significance levels (show.signif.stars=FALSE), to turn off scientific notation for the output (scipen=30), and to set the width of the text output at the console to 120 characters. The later option can be re-specified with the `text_width` option. After `reg` is finished with a normal termination, the options are re-set to their values before the `reg` function began executing.

**COLORS**
The default color theme is dodgerblue, but a gray scale is available with "gray", and other themes are available as explained in `style`, such as "red" and "green". Use the option `style(sub_theme="black")` for a black background and partial transparency of plotted colors.

**Value**
Following the standard R function `glm`, invisibly returns an object of `class` inheriting from "glm" which inherits from the `class"lm"`. Particularly useful for comparing nested models. Assign the output of Logit for a model to an object. Then for a nested model. Then use the `anova` function to compare the models as shown in the examples below.

```

---

**Merge**

**Merge Two Data Frames Horizontally or Vertically**

**Description**

Abbreviation: mrg

A horizontal merge combines data frames horizontally, that is, adds variables (columns) to an existing data frame, such as with a common shared ID field. Performs the horizontal merge based directly on the standard R `merge` function. The vertical merge is based on the `rbind` function in which the two data frames have the same variables but different cases (rows), so the rows build vertically, stacked on top of each other.
The advantages of this lessR function is that it provides a single function for merging data frames, adds text output to the standard R functions that provide feedback regarding properties of the merge, and provides more detailed and presumably more useful error messages.

Usage

```
Merge(data1, data2, by=NULL, quiet=getOption("quiet"), ...)  
mrg(...)  
```

Arguments

- **data1**: The name of the first data frame from which to create the merged data frame.
- **data2**: The name of the second data frame from which to create the merged data frame.
- **by**: If a variable specified, then signals a horizontal merge with the ID field by which the data frames are merged as an inner join, that is, only rows of data are retained that both match on the ID. Specify "rows" to merge vertically.
- **quiet**: If set to TRUE, no text output. Can change system default with style function.
- **...**: Additional arguments available in the base R `merge` function such as all.x=TRUE for an left outer join, which retains all rows of the first data frame even if not matched by a row in the second data table. Specify a right outer join with all.y=TRUE and a full outer join, in which all records from both data frames are retained, with all=TRUE.

Details

`Merge` creates a merged data frame from two input data frames. If by is specified the merge is horizontal. That is the variables in the second input data frame are presumed different from the variables in the first input data frame. The merged data frame is the combination of variables from both input data frames, with the rows aligned by the value of by, an ID field common to both data frames. The result is a natural join, a specific instance of an inner join in which merging occurs according a common variable.

Invoke `merge` parameters all.x, all.y, and all, set to TRUE for the corresponding condition. These parameters set, respectively, a left-outer join, right-outer join, and a outer join in which all records from both data frames are retained regardless if a matching row in the other data frame.

Set by to "rows" for a vertical merge. The variables are presumed the same in each input data frame. The merged data frame consists of the rows of both input data frames. The rows of the first data frame are stacked upon the rows of the second data frame.

Guidance and feedback regarding the merge are provided by default. The first five lines of each of the input data frames are listed before the merge operation, followed by the first five lines of the output data frame.

Value

The merged data frame is returned, usually assigned the name of d as in the examples below. This is the default name for the data frame input into the lessR data analysis functions.

merge, rbind.

Examples

# Horizontal
#--------
# Read("Employee", quiet=TRUE)
d <- 1:4, .(Years, Gender, Dept, Salary)]
Emp1b <- d[1:4, .(JobSat, Plan)]
# horizontal merge
d <- Merge(Emp1a, Emp1b, by="row.names")
# suppress output to console
d <- Merge(Emp1a, Emp1b, by="row.names", quiet=TRUE)

# Vertical
#--------
# Read("Employee", quiet=TRUE)
d <- 1:4,
Emp2a <- d[7:10,]
# vertical merge
d <- Merge(Emp2a, Emp2b, by="rows")

Model

Regression Analysis, ANOVA or t-test

Description

Abbreviation: model, model_brief

Automatically selects and then provides an analysis of a linear model: OLS regression, Logistic regression, ANOVA, or a t-test depending on the proprieties of the data. Comprehensive regression analysis with graphics from a single, simple function call with many default settings, each of which can be re-specified. By default the data exists as a data frame with the default name of d, such as data read by the lessR read function. Specify the model in the function call according to an R formula, that is, the response variable followed by a tilde, followed by the list of predictor variables, each pair separated by a plus sign.

Usage

Model(my_formula, data=d, brief=getOption("brief"), xlab=NULL, ...)

model_brief(..., brief=TRUE)

model(...)
Arguments

my_formula  Standard R formula for specifying a model. For example, for a response variable named Y and two predictor variables, X1 and X2, specify the corresponding linear model as Y ~ X1 + X2.
data  The default name of the data frame that contains the data for analysis is d, otherwise explicitly specify.
brief  If set to TRUE, reduced text output. Can change system default with style function.
xlab  x-axis label, defaults to variable name, or, if present, variable label.
...  Other parameter values for R functions such as lm which provide the core computations.

Details

OVERVIEW
The purpose of Model is to combine many standard R function calls into one, as well as provide ancillary analyses such as as graphics, organizing output into tables and sorting to assist interpretation of the output, all from a single function. Currently the supported models are OLS regression, ANOVA and the t-test. For more details of each of these methods, see the lessR functions Regression, Logit, ANOVA and ttest, respectively, which, in turn are based on many standard R functions.

All invocations of the model function are based on the standard R formula.

Ybin <- cut(Y, breaks=2, labels=FALSE)
# instead, if read data with the Read function
# then the result is the data frame called d
d <- round(data.frame(X1, X2, Y, Ybin),2)
rm(Y); rm(Ybin); rm(X1); rm(X2)

# One-predictor regression
# Provide all default analyses including scatterplot etc.
Model(Y ~ X1)
# alternate form
model(Y ~ X1)
# Multiple regression model
# Provide all default analyses
Model(Y ~ X1 + X2)

# Logit analysis
# Y is binary, 0 or 1
d <- Recode(Ybin, old=c(1,2), new=c(0,1), quiet=TRUE)
Model(Ybin ~ X1)

# t-test
Model(breaks ~ wool, data=warpbreaks)

# ANOVA analysis
# from another data frame other than the default \code{d}
# breaks is numerical, wool and tension are categorical
Model(breaks ~ wool + tension, data=warpbreaks)

---

**Nest**

*Nest the Values of an Integer or Factor Variable*

**Description**

Abbreviation: nt

A nested model has a subset of predictor variables from the corresponding full model. Compare a nested linear model with a full model to evaluate the effectiveness of the predictor variables deleted from the full model to define the nested model.

**Usage**

Nest(y, nested_model, full_model, method=c("lm", "logit"),
data=d, digits_d=NULL, ...)

nt(...)  

**Arguments**

- **y**  
  Response variable.
- **nested_model**  
  Predictor variables in the nested model.
- **full_model**  
  Predictor variables in either the full model, or just those that added to the reduced model to derive the full model.
- **method**  
  Do a least squares analysis, ls, the default, or set to logit.
- **data**  
  The name of the data frame from which to create the subset, which is d by default.
- **digits_d**  
  Number of decimal digits, set by default to at least 2 or the largest number of digits in the values of the response variable plus 1.
- **...**  
  The specified arguments.
Details

Use the standard R function `anova` function to compare a nested model with a corresponding full model. By default, compare models estimated with ordinary least squares from the R function `lm`, or compare models estimated with logistic regression from the R function `glm` with `family="binomial"`. For the logistic analysis, the `anova` analysis is with `test="Chisq"`.

To insure that the same data are analyzed for both models, the fit for the full model is first obtained. Then the data frame that is returned by this analysis is input into the analysis for the nested model. This guarantees that any cases with missing data values missing for the full analysis will have been deleted for the nested analysis. Otherwise rows of data could be retained for the nested analysis that were dropped for the full analysis because of missing data values for the deleted predictor variables. This method also guarantees that cases are not deleted because data was missing on variables not included in full analysis.

Value

The output can optionally be returned and saved into an R object, otherwise it simply appears at the console. The components of this object are redesigned in lessR version 3.3 into (a) pieces of text that form the readable output and (b) a variety of statistics. The readable output are character strings such as tables amenable for viewing and interpretation. The statistics are numerical values amenable for further analysis, such as to be referenced in a subsequent R markdown document. The motivation of these three types of output is to facilitate R markdown documents, as the name of each piece, preceded by the name of the saved object followed by a \$, can be inserted into the R markdown document (see examples).

**TEXT OUTPUT**

`out_models`: The specification of the two models compared
`out_anova`: Analysis of variance or, for logit, analysis of deviance

**STATISTICS**

`fun_call`: Function call that generated the analysis
`anova_tested`: Term that is tested
`anova_residual`: Residual df, and either ss and ms or deviance for logit
`anova_total`: For logit, total df and deviance

Although not typically needed for analysis, if the output is assigned to an object named, for example, `n`, then the complete contents of the object can be viewed directly with the `unclass` function, here as `unclass(n)`. Invoking the `class` function on the saved object reveals a class of `out_all`. The class of each of the text pieces of output is out.

Nest(Reading, c(Absent), c(Verbal, Income))

# compare logistic models, save results into an object
# define the full model by adding just the variables
# not found in the reduced model
d <- Read("BodyMeas")
n <- Nest(Gender, c(Weight, Hips, Hand, Shoe),
c(Height, Waist, Chest), method="logit")
# view the results
n
# see the names of the available output components
names(n)
```

### PieChart

#### Description

**Abbreviation:** pc

Plots a pie chart of a categorical variable (x). The default chart is a doughnut or ring version of a pie chart, that is, a hole in the middle of the pie. Either directly enter the corresponding numerical value (y) or have the numerical variable be the tabulated counts for the frequency of occurrence for each value of the categorical variable. Also displays the frequency table for the variable with the corresponding chi-square inferential analysis. Real numbers can also be entered directly.

#### Usage

```r
PieChart(x, y=NULL, data=d, rows=NULL,
  radius=1, hole=0.65, hole_fill=getOption("panel_fill"),
  fill=NULL, color="lightgray",
  trans=getOption("trans_bar_fill"),
  density=NULL, angle=45,
  lty="solid", lwd=1, edges=200,
  clockwise=FALSE, init_angle=ifelse (clockwise, 90, 0),
)```
values=getOption("values"),
values_color=getOption("values_color"),
values_size=getOption("values_size"),
values_digits=getOption("values_digits"),
values_position=getOption("values_position"),
main=NULL, main_cex=1.2, labels_cex=0.9, cex,
add=NULL, x1=NULL, y1=NULL, x2=NULL, y2=NULL,
eval_df=NULL, quiet=getOption("quiet"),
width=6.5, height=6, pdf_file=NULL,
...)

pc(...)  

Arguments

x For each level of this categorical variable, x, display the frequencies as slices of a pie.
y Numeric variable that sets the area of each slice of the pie. If not specified, then its value is the frequency of each category of x, automatically tabulated.
data Optional data frame that contains the variable(s) of interest, default is d.
rows A logical expression that specifies a subset of rows of the data frame to analyze.

radius The pie is drawn in a box with sides that range from -1 to 1, so the maximum value of the radius without truncating the pie is 1.

hole The proportion of the radius that defines the inner hole for what is called a doughnut or hole plot. To show the full pie, set to FALSE or the value of 0.

hole_fill Fill color of the hole, which by default is the same color as panel_fill as set by the color theme or individually with the style function.

fill Specified color of each slice. Default is the discrete scale with, with fixed chroma (50) and luminance (75) for unbiased comparison across colors, for all color themes except "gray" and "white", with default gray scale. Can explicitly choose "grays" or "hues", or pre-specified R color schemes "rainbow", "terrain", and "heat". Or, set to the name of y to map the values of bar fill, specified as (count) if tabulated from the data. Can also provide pre-defined color ranges "blues", "reds" and "greens", as well as custom colors, such as generated by getColors.

color Border color of sides and the pie, can be a vector to customize the color for each slice. Default is bar_color from the lessR style function.

trans Transparency factor of the area of each slice. Default is trans_bar_fill from the lessR style function.
<table>
<thead>
<tr>
<th>density</th>
<th>Density of shading lines, in lines per inch. Default value is NULL, that is, no shading lines.</th>
</tr>
</thead>
<tbody>
<tr>
<td>angle</td>
<td>Angle of shading lines in degrees.</td>

<td>Character expansion factor of title relative to 1.</td>
</tr>
<tr>
<td>labels_cex</td>
<td>Character expansion factor of labels relative to 1. No labels if set to 0.</td>
</tr>
<tr>
<td>cex</td>
<td>General character expansion factor for default values of main_cex, labels_cex, and values_size. Useful for adjustment of text for larger or smaller images.</td>
</tr>
<tr>
<td>add</td>
<td><strong>Draw one or more objects</strong>, text or a geometric figures, on the plot. Possible values are any text to be written, the first argument, which is &quot;text&quot;, or, to indicate a figure, &quot;rect&quot; (rectangle), &quot;line&quot;, &quot;arrow&quot;, &quot;v.line&quot; (vertical line), and &quot;h.line&quot; (horizontal line). The value &quot;means&quot; is short-hand for vertical and horizontal lines at the respective means. Does not apply to Trellis graphics. Customize with parameters such as fill and color from the style function.</td>
</tr>
</tbody>
</table>
PieChart

x1  First x coordinate to be considered for each object. All coordinates vary from -1 to 1.
y1  First y coordinate to be considered for each object.
x2  Second x coordinate to be considered for each object. Only used for "rect", "line" and arrow.
y2  Second y coordinate to be considered for each object. Only used for "rect", "line" and arrow.
eval_df  Determines if to check for existing data frame and specified variables. By default is TRUE unless the shiny package is loaded then set to FALSE so that Shiny will run. Needs to be set to FALSE if using the pipe %>% notation.
quiet  If set to TRUE, no text output. Can change system default with style function.
width  Width of the plot window in inches, defaults to 4.5.
height  Height of the plot window in inches, defaults to 4.5.
pdf_file  Name of the pdf file to if graphics to be redirected to a pdf file.
...

Other parameter values for graphics as defined processed by pie and par for general graphics, which includes radius of the pie, and color_main for the title of the graph.

Details

OVERVIEW
Plot a pie chart with default colors, presumably with a relatively small number of values for each variable. By default, colors are selected for the slices, background and grid lines, all of which can be customized. The basic computations of the chart are provided with the standard R functions pie and chisq.test and the lessR function chisq.test. A minor modification of the original pie code provides for the hole in the middle of the pie, the default doughnut or ring chart.

DATA
The data may either be a vector from the global environment, the user’s workspace, as illustrated in the examples below, or one or more variable’s in a data frame, or a complete data frame. The default input data frame is d. Can specify the source data frame name with the data option. If multiple variables are specified, only the numerical variables in the list of variables are analyzed. The variables in the data frame are referenced directly by their names, that is, no need to invoke the standard R mechanisms of the $name notation, the with function or the attach function. If the name of the vector in the global environment and of a variable in the input data frame are the same, the vector is analyzed.

The rows parameter subsets rows (cases) of the input data frame according to a logical expression. Use the standard R operators for logical statements as described in Logic such as & for and, | for or and ! for not, and use the standard R relational operators as described in Comparison such as == for logical equality != for not equals, and > for greater than. See the Examples.

COLORS
Set the default color of the bars by the current color theme according to bar_fill_discrete argument of the function style, which includes the default color theme "colors" that defines a qualitative HCL color scale, or set the bar color with the fill parameter. These parameters reference a specified vector of color specifications, such as generated by the lessR getColors function.
Set fill to a single color or a color palette, of which there are many possibilities. Define a qualitative color palette with "hues" that provides HCL colors of the same chroma (saturation) and luminance (brightness). Also available are the pre-specified R color palettes "rainbow", "terrain", and "heat". Pre-defined sequential and divergent color ranges are available as implicit calls to `getColors`. The full list of pre-defined color ranges (defined in 30 degree increments around the HCL color wheel): "reds", "rusts", "browns", "olives", "greens", "emeralds", "turquoises", "aquas", "blues", "purples", "violets", "magentas", and "grays".

Defines a sequential color scale with single value of fill for a pre-defined palette such as "blues". Or, manually specify colors. For example, for a two-level by variable, could set fill to `c("coral3","seagreen3")`, where the specified colors are not pre-defined color ranges.

For the pre-defined color scales can obtain more control over the obtained color palettes with an explicit call to `getColors` for the argument to fill. Here the value of chroma (c) and luminance (l) can be explicitly manipulated in conjunction with the specification of a pre-defined color range. Or, create a custom color range for any value of hue (h). See `getColors` for more information.

To change the background color, set the "panel_fill" argument of the `style` function. The hole of the pie defaults to that color, which, of course, can also be specified to a different color.

ANNOTATIONS

Use the `add` and related parameters to annotate the plot with text and/or geometric figures. Each object is placed according from one to four corresponding coordinates, the required coordinates to plot that object, as shown in the following table. The values of the coordinates vary from -1 to 1.

<table>
<thead>
<tr>
<th>Value</th>
<th>Object</th>
<th>Required Coordinates</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>text</td>
<td>x1, x2</td>
</tr>
<tr>
<td>&quot;rect&quot;</td>
<td>rectangle</td>
<td>x1, y1, x2, y2</td>
</tr>
<tr>
<td>&quot;line&quot;</td>
<td>line segment</td>
<td>x1, y1, x2, y2</td>
</tr>
<tr>
<td>&quot;arrow&quot;</td>
<td>arrow</td>
<td>x1, y1, x2, y2</td>
</tr>
</tbody>
</table>

The value of `add` specifies the object. For a single object, enter a single value. Then specify the value of the needed corresponding coordinates, as specified in the above table. For multiple placements of that object, specify vectors of corresponding coordinates. To annotate multiple objects, specify multiple values for `add` as a vector. Then list the corresponding coordinates, for up to each of four coordinates, in the order of the objects listed in `add`. See the examples for illustrations.

Can also specify vectors of different properties, such as `add_color`. That is, different objects can be different colors, different transparency levels, etc.

STATISTICS

In addition to the pie chart, descriptive and inferential statistics are presented. First, for integer variables such as counts, the frequency table with proportions is displayed. Second, the corresponding chi-square test is also displayed. For real valued variables read from a data frame, the summary statistics such as the mean are reported.

PDF OUTPUT

Because `lessR` functions generate their own graphics calls, the standard graphic output functions such as `pdf` do not work with the `lessR` graphics functions. Instead, to obtain pdf output, use the
pdf_file option, perhaps with the optional width and height options. These files are written to
the default working directory, which can be explicitly specified with the R setwd function.

ONLY VARIABLES ARE REFERENCED
The referenced variable in a lessR function can only be a variable name. This referenced vari-
able must exist in either the referenced data frame, d by default, or in the user's workspace, more
formally called the global environment. That is, expressions cannot be directly evaluated. For
example:

> PieChart(rnorm(10)) # does NOT work
Instead, do the following:

> Y <- rnorm(10) # create vector Y in user workspace
> PieChart(Y) # directly reference Y

pivot  

Create a Pivot (Summary) Table

Description
Summarize, that is, aggregate, a numerical variable (value) over one or more categorical variables (by). Display the sample size for each cell and provide the possibility to subset rows. Based on the base R function aggregate.

Usage
pivot(data, compute, value, rows_by, cols_by=NULL,
      na_value=FALSE, na_by=FALSE, na_remove=TRUE,
      digits_d=NULL)

Arguments
data  
compute  
value  
rows_by  

Data frame that contains the variables.
The statistic, defined as a function, to aggregate over the combinations of the values of the categorical variables.
Numerical response variable that is aggregated, i.e., summarized across the groups.
Categorical variables that define the groups (cells) listed in the rows of the output long-form data frame, available to input into other data analysis routines. Not used if function to compute is tabulate.
cols_by  Up to two categorical variables that define the groups displayed as columns in a two dimensional table.

na_value  If TRUE, then show cells with the aggregated variable that are missing.

na_by  If TRUE, then show levels of the grouping variables that are missing.

na_remove  Sets base R parameter na.rm, which, if TRUE, removes missing values from the value variables. Otherwise, the aggregation for a cell with missing data returns NA.

digits_d  Number of significant digits for each of the displayed summary statistics.

Details

pivot uses base R aggregate to generate a pivot table (Excel terminology). Express the categorical variables over which to pivot as a vector with the c function.

pivot provides two additional features than aggregate provides. First is a complete missing data analysis. If there is no missing data for the numerical variables that are aggregated, then the cell sizes are included with the aggregated data. If there is such missing data, then the amount of available data is displayed for all values to be aggregated for each cell.

The second is that the data parameter is listed first in the parameter list, which facilitates the use of the pipe operator from the magrittr package. Also, there is a different interface as the by variables are specified as a vector.

Variable ranges in the specification of by are not needed in general. Only a small number of grouping variables generally define the cells for the aggregation.

The following table lists available single summary statistics. The list is not necessarily exhaustive.

The unique function is tabulate, which does not refer to the base R function of that name, but an indicator to just provide cell counts, no other statistics, generalizing the pivot function to cover more cases. Accordingly, the value and by parameters are redundant, so the by parameter is not needed.

These three functions output their values as an R matrix, which then replaces the values of the variable that is aggregated in the resulting output data frame.

Value

Returns a data frame of the aggregated values, unless for two by variables and table_2d is TRUE, when a table is returned.

aggregate.

Examples

library(knitr) # for kable() called from pivot()
d <- Read("Employee", quiet=TRUE)

# parameter values by name
pivot(data=d, compute=mean, value=Salary, rows_by=c(Dept, Gender))

# calculate mean of Years and Salary for each combination of Dept and Gender
# parameter values by position
pivot(d, mean, c(Years, Salary), c(Dept, Gender))

# output as a 2-d table
pivot(d, mean, Salary, Dept, Gender)

# tabulate only
pivot(d, tabulate, c(Dept, Gender))
Description

Abbreviation:
Violin Plot only: vp, ViolinPlot
Box Plot only: bx, BoxPlot
Scatter Plot only: sp, ScatterPlot

A scatterplot displays the values of a distribution, or the relationship between the two distributions in terms of their joint values, as a set of points in an $n$-dimensional coordinate system, in which the coordinates of each point are the values of $n$ variables for a single observation (row of data). From the identical syntax, from any combination of continuous or categorical variables variables $x$ and $y$, Plot($x$) or Plot($x,y$), where $x$ or $y$ can be a vector, by default generates a family of related 1- or 2-variable scatterplots, possibly enhanced, as well as related statistical analyses. A categorical variable is either non-numeric, such as an R factor, or may be defined to consist of a small number of equally spaced integer values. The maximum number of such values to define such an integer variable as categorical is set by the n_cat parameter, with a default value of 0, that is, by default, all variables with numerical values are defined as continuous variables.

Plot is a general function, which produces a wide variety of scatterplots, which, for a single variable, can be in the context of violin plots and box plots, as outlined in the following list. The parameter definitions that follow this list are grouped, with parameters that relate to the same type of plot defined in the same group.

Plot($x,y$): $x$ and $y$ continuous yields traditional scatterplot of two continuous variables
Plot($x,y$): $x$ and $y$ categorical, to solve the over-plot problem, yields a bubble (balloon) scatterplot, the size of each bubble based on the corresponding joint frequency as a replacement for the two dimensional bar chart
Plot($x,y$): $x$ (or $y$) categorical and the other variable continuous, yields a scatterplot with means at each level of the categorical variable
Plot($x,y$): $x$ (or $y$) categorical with unique (ID) values and the other variable continuous, yields a Cleveland dot plot
Plot($X,y$) or Plot($x,Y$): one vector variable defined by several continuous variables, paired with another single continuous variable, yields multiple scatterplots on the same graph
Plot($x$): one continuous variable generates either, a violin/box/scatterplot (VBS plot), introduced here, or a run chart with run=TRUE, or $x$ can be an R time series variable for a time series chart
Plot($x$): one categorical variable yields a 1-dimensional bubble plot to solve the over-plot problem for a more compact replacement of the traditional bar chart
Plot($X$): one vector of continuous variables, with no $y$-variable, results in a scatterplot matrix
Plot($X$): one vector of categorical $x$-variables, with no $y$-variable, generalizes to a matrix of 1-dimensional bubble plots, here called the bubble plot frequency matrix, to replace a series of bar charts

Represent the influence of additional categorical variables with by1 or by2 to generate Trellis plots conditioned on one or two variables from implicit calls to functions from Deepayan Sarkar’s (2009) lattice package. Use by to group multiple variables on the same plot, or on multiple panels if Trellis graphics are activated. For a third variable, which is continuous, specify size for a bubble plot. By default, the values of analysis that generate the plotted points is data, or choose other values to plot, which are statistics computed from the data such as mean.

pl(...) ScatterPlot(...) sp(...) BoxPlot(...) bx(...) ViolinPlot(...) vp(...)

Arguments

x By itself, or with y, by default, a primary variable, that is, plotted by its values mapped to coordinates. The data values can be continuous or categorical, cross-sectional or a time series. If x is sorted, with equal intervals separating the values, or is a time series, then by default plots the points sequentially, joined by line segments. Can specify multiple x-variables or multiple y-variables as vectors, but not both. Can be in a data frame or defined in the global environment.

y An optional second primary variable. Variable with values to be mapped to coordinates of points in the plot on the vertical axis. Can be continuous or categorical. Can be in a data frame or defined in the global environment.

data Optional data frame that contains one or both of x and y. Default data frame is d.

rows A logical expression that specifies a subset of rows of the data frame to analyze.
enhance For a two-variable scatterplot, if TRUE, automatically add the 0.95 data ellipse, labeling of outliers beyond a Mahalanobis distance of 6 from the ellipse center, the best-fitting least squares line of all the data, the best-fitting least squares line of the regular data without the outliers, and a horizontal and vertical line to represent the mean of each of the two variables.

stat Transform data for categorical variable $x$ into a simple table of paired levels of $x$ with numerical values of $y$. Apply specified transformation such as "count" to each of the levels of $x$, and, for a provided numerical variable $y$, transformations such as "mean", sd, etc. The resulting dot plot is analogous to a bar chart.

n_cat Number of categories, specifies the largest number of unique, equally spaced integer values of a variable for which the variable will be analyzed as categorical instead of continuous. Default is 0. Use to specify that such variables are to be analyzed as categorical, a kind of informal R factor.

by A categorical variable to provide a scatterplot for each level of the numeric primary variables $x$ and $y$ on the same plot, a grouping variable. For two-variable
plots, applies to the panels of a **Trellis graphic** if `by1` is specified.

### by1
A categorical variable called a *conditioning variable* that activates Trellis graphics, provided by Deepayan Sarkar’s (2007) lattice package, to provide a separate panel of numeric primary variables `x` and `y` for each level of the variable. Reorder the levels by first converting to a factor variable with `factor` or lessR `factors`.

### by2
A second *conditioning variable* to generate Trellis plots jointly conditioned on both the `by1` and `by2` variables, with `by2` as the row variable, which yields a scatterplot (panel) for each cross-classification of the levels of numeric `x` and `y` variables.

### n_row
Optional specification for the number of rows in the layout of a multi-panel display with Trellis graphics. Specify `n_col` or `n_row`, but not both.

### n_col
Optional specification for the number of columns in the layout of a multi-panel display with Trellis graphics. Specify `n_col` or `n_row`, but not both. If set to 1, then the strip that labels each group locates to the left of each plot instead of the top.

### aspect
Lattice parameter for the aspect ratio of the panels, defined as height divided by width. The default value is "fill" to have the panels expand to occupy as much space as possible. Set to 1 for square panels. Set to "xy" to specify a ratio calculated to "bank" to 45 degrees, that is, with the line slope approximately 45 degrees.

### theme
Color theme for this analysis. Make persistent across analyses with `style`.

### fill
Either fill color of the points or the area under a line chart. Can also set with the lessR function `getColors` to select from a variety of color palettes. For points, default is `pt_fill` and for area under a line chart, `violin_fill`. For a line chart, set to "on" for default color.

### color
Border color of the points or `line_color` for line plot, can be a vector to customize the color for each point or a color range such as "blues" (see `getColors`). Default is `pt_color` from the lessR `style` function.

### trans
Transparency factor of the fill color of each point. Default is `trans_pt_fill` from the lessR `style` function.

### size
When set to a constant, the scaling factor for **standard points** (not bubbles) or a line, with default of 1.0 for points and 2.0 for a line. Set to 0 to not plot the points or lines. When set to a variable, activates a bubble plot with the size of each bubble further determined by the value of `radius`. Applies to the standard two-variable scatterplot as well as to the scatterplot component of the integrated Violin-Box-Scatterplot (VBS) of a single continuous variable.

### size_cut
If `TRUE` (or 1), then for a bubble plot in which the bubble sizes are defined by a `size` variable, show the value of the sizing variable for selected bubbles in the center of the bubbles, unless the bubble is too small. If `FALSE`, no value is displayed. If a number greater than 1, then display the value only for the indicated number of values, such as just the max and min for a setting of 2, the default value when bubbles represent a size variable. Color of the displayed text set by `bubble_text` from the `style` function.
shape

The plot character(s). The default value is a circle with both an color and filled interior, specified with color and fill. Possible values are circle, square, diamond, triup (triangle up), tridown (triangle down), all uppercase and lowercase letters, all digits, and most punctuation characters. The numbers 21 through 25 as defined by the R points function also apply. If plotting levels according to by, then list one shape for each level to be plotted.

means

If the one variable is categorical, expressed as a factor, and the other variable continuous, then if TRUE, by default, plot means with the scatterplot. Also applies to a 1-D scatterplot.

sort_yx

Sort the values of y by the values of x, such as for a Cleveland dot plot, that is, a numeric x-variable paired with a categorical y-variable with unique values. If a y is a vector of two variables, sort by their difference.

segments_y

For one x-variable, draw a line segment from the y-axis to each plotted point, such as for the Cleveland dot plot. For two x-variables, the line segments connect the two points.

segments_x

Draw a line segment from the x-axis for each plotted point.

jitter_x

Randomly perturbs the plotted points of a scatterplot horizontally according to an internally computed formula, or can be explicitly specified.

jitter_y

Randomly perturbs the plotted points of a scatterplot vertically according to an internally computed formula, or can be explicitly specified.

ID

Name of variable to provide the labels for the selected plotted points for outlier identification, row names of data frame by default. To label all the points use the add parameter described later.

ID_size

Size of the plotted labels. Modify text color of the labels with the style function parameter ID_color.

MD_cut

Mahalanobis distance cutoff to define an outlier in a 2-variable scatterplot.

out_cut

Count or proportion of plotted points to label, in order of their distance from the scatterplot center (means), counting down from the more extreme point. For two-variable plots, assess distance from the center with Mahalanobis distance. For VBS plots of a single continuous variable, refers to outliers on each side of the plot.

out_shape

Shape of outlier points in a 2-variable scatterplot or a VBS plot. Modify fill color from the current theme with the style function parameters out_fill and out2_fill.

out_size

Size of outlier points in a 2-variable scatterplot or VBS plot.

vbs_plot

A character string that specifies the components of the integrated Violin-Box-Scatterplot (VBS) of a continuous variable. A "v" in the string indicates a violin plot, a "b" indicates a box plot with flagged outliers, and a "s" indicates a 1-variable scatterplot. Default value is "vbs". The characters can be in any order and upper- or lower-case. Generalize to Trellis plots with the by1 and by2 parameters, but currently only applies to horizontal displays. Modify fill and border colors from the current theme with the style function parameters violin_fill, violin_color, box_fill and box_color.
vbs_size  
Width of the violin plot to the plot area. Make the violin (and also the accompanying box plot) larger or smaller by making the plot area and/or this value larger or smaller.

bw  
Bandwidth for the smoothness of the violin plot. Higher values for smoother plots. Default is to calculate a bandwidth that provides a relative smooth density plot.

bw_iter  
Number of iterations used to modify default R bandwidth to further smooth the obtained density estimate. When set, also displays the iterations and corresponding results.

violin_fill  
Fill color for a violin plot.

box_fill  
Fill color for a box plot.

vbs_pt_fill  
Points in a VBS scatterplot are black by default because the background is the violin, which is based on the current theme color. To use the values for pt_fill and pt_color specified by the style function, set to "default". Or set to any desired color.

vbs_mean  
Show the mean on the box plot with a strip the color of out_fill, which can be changed with the style function.

fences  
If TRUE, draw the inner upper and lower fences as dotted line segments.

k  
IQR multiplier for the basis of calculating the distance of the whiskers of the box plot from the box. Default is Tukey’s setting of 1.5.

box_adj  
Adjust the box and whiskers, and thus outlier detection, for skewness using the medcouple statistic as the robust measure of skewness according to Hubert and Vandervieren (2008).

a, b  
Scaling factors for the adjusted box plot to set the length of the whiskers. If explicitly set, activates box_adj.

radius  
Scaling factor of the bubbles in a bubble plot, which sets the radius of the largest displayed bubble in inches. To activate, either set the value of size to a third variable where the default is 0.10, or for categorical variables, either a factor or an integer variable with the number of unique values less than n_cat, the size of the bubbles represents frequency, with a default of 0.22.

power  
Relative size of the scaling of the bubbles to each other. Default value of 0.5 scales the bubbles so that the area of each bubble is the value of the corresponding sizing variable. Value of 1 scales so the radius of the bubble is the value of the sizing variable, increasing the discrepancy of size between the variables.

low_fill  
For a categorical variable and the resulting bubble plot, or a matrix of these plots, sets a color gradient of the fill color beginning with this color.

hi_fill  
For a categorical variable and the resulting bubble plot, or a matrix of these plots, sets a color gradient of the fill color ending with this color.

smooth  
Smoothed density plot for two numerical variables. By default, set to TRUE for 2500 or more rows of data.

smooth_points  
Number of points superimposed on the density plot in the areas of the lowest density to help identify outliers, which controls how dark are the smoothed points.
Plot

smooth_size  Size of points superimposed on the density plot.
smooth_exp  Exponent of the function that maps the density scale to the color scale.
smooth_bins  Number of bins in both directions for the density estimation.

fit  The best fit line. Default value is "off", with options for non-linear "loess" and for linear least squares, indicated by "lm". If potential outliers are identified according to out_cut, a second (dashed) fit line is displayed calculated without the outliers. Modify the line color from with the style function parameter fit_color, and the line width with fit_lwd.

fit_se  Confidence level for the error band displayed around the line of best fit. On by default at 0.95 if a fit line is specified. Can be a vector to display multiple ranges. Set to 0 to turn off.

ellipse  Confidence level of a data ellipse for a scatterplot of only a single x-variable and a single y-variable according to the contours of the corresponding bivariate normal density function. Can specify the confidence level(s) for a single or vector of numeric values from 0 to 1, to plot one or more specified ellipses. For Trellis graphics, only the maximum level applies with only one ellipse per panel. Modify fill and border colors with the style function parameters ellipse_fill and ellipse_color.

bin  If TRUE, display the default frequency distribution for the text output of the Violin-Box-Scatter (VBS) Plot, or, if values is set to "count", a frequency polygon.
bin_start  Optional specified starting value of the bins for a frequency polygon or for the text output of a Violin-Box-Scatter (VBS) Plot. Also, sets bin to TRUE.
bin_width  Optional specified bin width value. Also, sets bin to TRUE.
bin_end  Optional specified value that is within the last bin, so the actual endpoint of the last bin may be larger than the specified value.
b breaks  The method for calculating the bins, or an explicit specification of the bins, such as with the standard R seq function or other options provided by the hist function. Also, sets bin to TRUE.
cumulate  Specify a cumulative frequency polygon.
run  If set to TRUE, generate a run chart, i.e., line chart, in which points are plotted in the sequential order of occurrence in the data table. By default, the points are connected by line segments to form a run chart. Set by default when the x-values are sorted with equal intervals or a single variable is a time series. Customize the color of the line segments with segments_color with function style.
lwd  Width of the line segments. Set to zero to remove the line segments._area_fill  Parameter fill applies to points if only points and if only a run chart or time series chart, then to area under line segments. But area_fill takes precedence over fill for the area under the line segments, which is needed to provide both fill for points and this area. Like fill, the value of "on" sets the default fill color for points.
area_origin
Origin for the filled area under the time series line. Values less than this value are below the corresponding reference line, values larger are above the line.

center_line
Plots a dashed line through the middle of a run chart. Provides a center line for the "median" by default, when the values randomly vary about the mean. "mean" and "zero" specify that the center line goes through the mean or zero, respectively. Currently does not apply to Trellis plots.

show_runs
If TRUE, display the individual runs in the run analysis. Also, sets run to TRUE.

stack
If TRUE, multiple time plots are stacked on each other, with area set to TRUE by default.

xlab, ylab
Axis label for x-axis or y-axis. If not specified, then the label becomes the name of the corresponding variable label if it exists, or, if not, the variable name. If xy_ticks is FALSE, no ylab is displayed. Customize these and related parameters with parameters such as lab_color from the style function.

main
Label for the title of the graph. If the corresponding variable labels exist, then the title is set by default from the corresponding variable labels.

sub
Sub-title of graph, below xlab.

lab_adj
Two-element vector – x-axis label, y-axis label – adjusts the position of the axis labels in approximate inches. + values move the labels away from plot edge. Not applicable to Trellis graphics.

margin_adj
Four-element vector – top, right, bottom and left – adjusts the margins of the plotted figure in approximate inches. + values move the corresponding margin away from plot edge. Not applicable to Trellis graphics.

rotate_x
Degrees that the axis values for the value labels on the x-axis are rotated, usually to accommodate longer values, typically used in conjunction with offset. When equal 90 the value labels are perpendicular to the x-axis and a different algorithm places the labels so that offset is not needed.

rotate_y
Degrees that the axis values for the value labels on the y-axis are rotated, usually to accommodate longer values, typically used in conjunction with offset.

offset
The amount of spacing between the axis values and the axis. Default is 0.5. Larger values such as 1.0 are used to create space for the label when longer axis value names are rotated.

xy_ticks
Flag that indicates if tick marks and associated axis values on the axes are to be displayed. To rotate the axis values, use rotate_x, rotate_y, and offset from the style function.

value_labels
Labels for the x-axis on the graph to override existing data values, including factor levels. If the variable is a factor and value_labels is not specified (is NULL), then the value_labels are set to the factor levels with each space replaced by a new line character. If x and y-axes have the same scale, they also apply to the y-axis.

label_max
Maximum size of labels for the values of a categorical variable. Not a literal maximum as preserving unique values may require a larger number of characters than specified.
origin_x  Origin of x-axis. Starting value of x, by default the minimum value of x, except when stat is set to "count" or related where the origin is zero by default, but can be modified.

scale_x     If specified, a vector of three values that define the x-axis with numerical values: starting value, ending value, and number of intervals.

scale_y     If specified, a vector of three values that define the y-axis with numerical values: starting value, ending value, and number of intervals.

pad_x       Proportion of padding added to left and right sides of the x-axis, respectively. Value from 0 to 1 for each of the two elements. If only one element specified, value is applied to both sides.

pad_y       Proportion of padding added to bottom and top sides of the y-axis, respectively. Value from 0 to 1 for each of the two elements. If only one element specified, value is applied to both sides.

legend_title Title of the legend for a multiple-variable x or y plot.

add         Draw one or more objects, text or a geometric figures, on the plot. Possible values are any text to be written, the first argument, which is "text", or, "labels" to label each point with the row name, or, "rect" (rectangle), "line", "arrow", "v_line" (vertical line), and "h_line" (horizontal line). The value "means" is short-hand for vertical and horizontal lines at the respective means. Does not apply to Trellis graphics. Customize with parameters such as add_fill and add_color from the style function.

x1          First x-coordinate to be considered for each object, can be "mean_x". Not used for "h_line".

y1          First y-coordinate to be considered for each object, can be "mean_y". Not used for "v_line".

x2          Second x-coordinate to be considered for each object, can be "mean_x". Only used for "rect", "line" and arrow.

y2          Second y-coordinate to be considered for each object, can be "mean_y". Only used for "rect", "line" and arrow.

eval_df     Determines if to check for existing data frame and specified variables. By default is TRUE unless the shiny package is loaded then set to FALSE so that Shiny will run. Needs to be set to FALSE if using the pipe %>% notation.

digits_d    Number of significant digits for each of the displayed summary statistics.

quiet       If set to TRUE, no text output. Can change system default with style function.

do_plot     If TRUE, the default, then generate the plot.

width       Width of the plot window in inches, defaults to 5 except in RStudio to maintain an approximate square plotting area.

height      Height of the plot window in inches, defaults to 4.5 except for 1-D scatterplots and when in RStudio.

df_file     Indicate to direct pdf graphics to the specified name of the pdf file.
fun_call  Function call. Used with knitr to pass the function call when obtained from the abbreviated function call sp.

... Other parameter values for non-Trellis graphics as defined by and processed by standard R functions plot and par, including
xlim and ylim for setting the range of the x and y-axes
cex.main for the size of the title
col.main for the color of the title
cex for the size of the axis value labels
sub and col.sub for a subtitle and its color

Details

VARIABLES and TRELLIS PLOTS
There is at least one primary variable, x, which defines the coordinate system for plotting in terms of the x-axis, the horizontal axis. Plots may also specify a second primary variable, y, which defines the y-axis of the coordinate system. One of these primary variables may be a vector. The simplest plot is from the specification of only one or two primary variables, each as a single variable, which generates a single scatterplot of either one or two variables, necessarily on a single plot, called a panel, defined by a single x-axis and usually a single y-axis.

For numeric primary variables, a single panel may also contain multiple plots of two types. Form the first type from subsets of observations (rows of data) based on values of a categorical variable. Specify this plot with the by parameter, which identifies the grouping variable to generate a scatterplot of the primary variables for each of its levels. The points for each group are plotted with a different shape and/or color. By default, the colors vary, though to maintain the color scheme, if there are only two levels of the grouping variable, the points for one level are filled with the current theme color and the points for the second level are plotted with transparent interiors.

Or, obtain multiple scatterplots on the same panel with multiple numeric x-variables, or multiple y-variables. To obtain this graph, specify one of the primary variables as a vector of multiple variables.

Trellis graphics, from Deepayan Sarkar’s (2009) lattice package, may be implemented in which multiple panels for one numeric x-variable and one numeric y-variable are displayed according to the levels of one or two categorical variables, called conditioning variables. A variable specified with by is a conditioning variable that results in a Trellis plot, the scatterplot of x and y produced at each level of the by1 variable. The inclusion of a second conditioning variable, by2, results in a separate scatterplot panel for each combination of cross-classified values of both by1 and by2. A grouping variable according to by may also be specified, which is then applied to each panel.

Control the panel dimensions and the overall size of the Trellis plot with the following parameters: width and height for the physical dimensions of the plot window, n_row and n_col for the number of rows and columns of panels, and aspect for the ratio of the height to the width of each panel. The plot window is the standard graphics window that displays on the screen, or it can be specified as a pdf file with the pdf_file parameter.

CATEGORICAL VARIABLES
Conceptually, there are continuous variables and categorical variables. Categorical variables have relatively few unique data values. However, categorical variables can be defined with non-numeric values, but also with numeric values, such as responses to a five-point Likert scale from Strongly
Disagree to Strongly Agree, with responses coded 1 to 5. The three by –variables – by1, by2 and by – only apply to graphs created with numeric x and/or y variables, continuous or categorical.

The standard and most general way to define a categorical variable is as an R factor, such as created with the lessR factors function. lessR provides the option to define an integer variable with equally spaced values as categorical based on the value of n_cat, which can be set locally or globally with the style function. For example, for a variable with data values from 5-point Likert scale, a value of n_cat of 5 will define the variable as categorical. The default value is 0. To explicitly analyze the values as categorical, set n_cat to a value larger than 0, at least the size of the number of unique integer values. Can also annotate a graph of the values of an integer categorical variable with value_labels option.

A scatterplot of Likert type data is problematic because there are so few possibilities for points in the scatterplot. For example, for a scatterplot of two five-point Likert response data, there are only 26 possible paired values to plot, so most of the plotted points overlap with others. In this situation, that is, when a single variable or two variables with Likert response scales are specified, a bubble plot is automatically provided, with the size of each point relative to the joint frequency of the paired data values. To request a sunflower plot in lieu of the bubble plot, set the shape to "sunflower".

DATA
The default input data frame is d. Specify another name with the data option. Regardless of its name, the data frame need not be attached to reference the variables directly by its name, that is, no need to invoke the d$name notation. The referenced variables can be in the data frame and/or the user's workspace, the global environment.

The data values themselves can be plotted, or for a single variable, counts or proportions can be plotted on the y-axis. For a categorical x-variable paired with a continuous variable, means and other statistics can be plotted at each level of the x-variable. If x is continuous, it is binned first, with the standard Histogram binning parameters available, such as bin_width, to override default values. The stat parameter sets the values to plot, with data the default. By default, the connecting line segments are provided, so a frequency polygon results. Turn off the lines by setting lwd=0.

The rows parameter subsets rows (cases) of the input data frame according to a logical expression. Use the standard R operators for logical statements as described in Logic such as & for and, | for or and ! for not, and use the standard R relational operators as described in Comparison such as == for logical equality, != for not equals, and > for greater than. See the Examples.

VALUE LABELS
The value labels for each axis can be over-ridden from their values in the data to user supplied values with the value_labels option. This option is particularly useful for Likert-style data coded as integers. Then, for example, a 0 in the data can be mapped into a "Strongly Disagree" on the plot. These value labels apply to integer categorical variables, and also to factor variables. To enhance the readability of the labels on the graph, any blanks in a value label translate into a new line in the resulting plot. Blanks are also transformed as such for the labels of factor variables.

However, the lessR function factors allows for the easy creation of factors, one variable or a vector of variables, in a single statement, and is generally recommended as the method for providing value labels for the variables.

VARIABLE LABELS
Although standard R does not provide for variable labels, lessR can store the labels in the data frame with the data, obtained from the Read function or VariableLabels. If variable labels exist, then the corresponding variable label is by default listed as the label for the corresponding axis and on the text output.
ONE VARIABLE PLOT
The one variable plot of one continuous variable generates either a violin/box/scatterplot (VBS plot), or a run chart with run=TRUE, or x can be an R time series variable for a time series chart. For the box plot, for gray scale output potential outliers are plotted with squares and outliers are plotted with diamonds, otherwise shades of red are used to highlight outliers. The default definition of outliers is based on the standard boxplot rule of values more than 1.5 IQR’s from the box. The definition of outliers may be adjusted (Hubert and Vandervieren, 2008), such that the whiskers are computed from the medcouple index of skewness (Brys, Hubert, & Struyf, 2004).

The plot can also be obtained as a bubble plot of frequencies for a categorical variable.

TWO VARIABLE PLOT
When two variables are specified to plot, by default if the values of the first variable, x, are unsorted, or if there are unequal intervals between adjacent values, or if there is missing data for either variable, a scatterplot is produced from a call to the standard R plot function. By default, sorted values with equal intervals between adjacent values of the first of the two specified variables yields a function plot if there is no missing data for either variable, that is, a call to the standard R plot function with type="l", which connects each adjacent pair of points with a line segment.

Specifying multiple, continuous x-variables against a single y variable, or vice versa, results in multiple plots on the same graph. The color of the points of the second variable is the same as that of the first variable, but with a transparent fill. For more than two x-variables, multiple colors are displayed, one for each x-variable.

BUBBLE PLOT FREQUENCY MATRIX (BPFM)
Multiple categorical variables for x may be specified in the absence of a y variable. A bubble plot results that illustrates the frequency of each response for each of the variables in a common figure in which the x-axis contains all of the unique labels for all of the variables plotted. Each line of information, the bubbles and counts for a single variable, replaces the standard bar chart in a more compact display. Usually the most meaningful when each variable in the matrix has the same response categories, that is, levels, such as for a set of shared Likert scales. The BPFM is considerably condensed presentation of frequencies for a set of variables than are the corresponding bar charts.

SCATTERPLOT MATRIX
A single vector of continuous variables specified as x, with no y-variable, generates a scatterplot matrix of the specified variable. A continuous variable is defined as a numeric variable with more than n_cat unique responses. To force an item with a small number of unique responses, such as from a 5-pt Likert scale, to be treated as continuous, set n_cat to a number lower than 5, such as n_cat=0 in the function call.

The scatterplot matrix is displayed according to the current color theme. Specific colors such as fill, color, etc. can also be provided. The upper triangle shows the correlation coefficient, and the lower triangle each corresponding scatterplot, with, by default, the non-linear loess best fit line. The code fit option can be used to provide the linear least squares line instead, along with the corresponding fit_color for the color of the fit line.

SIZE VARIABLE
A variable specified with size= is a numerical variable that activates a bubble plot in which the size of each bubble is determined by the value of the corresponding value of size, which can be a variable or a constant.

To explicitly vary the shapes, use shape and a list of shape values in the standard R form with the c function to combine a list of values, one specified shape for each group, as shown in the examples.
To explicitly vary the colors, use `fill`, such as with R standard color names. If `fill` is specified without `shape`, then colors are varied, but not shapes. To vary both shapes and colors, specify values for both options, always with one shape or color specified for each level of the `by` variable.

Shapes beyond the standard list of named shapes, such as "circle", are also available as single characters. Any single letter, uppercase or lowercase, any single digit, and the characters "+", "*" and "]" are available, as illustrated in the examples. In the use of `shape`, either use standard named shapes, or individual characters, but not both in a single specification.

**SCATTERPLOT ELLIPSE**

For a scatterplot of two numeric variables, the `ellipse=TRUE` option draws the .95 data ellipse as computed by the `ellipse` function, written by Duncan Murdoch and E. D. Chow, from the `ellipse` package. The axes are automatically lengthened to provide space for the entire ellipse that extends beyond the maximum and minimum data values. The specific level of the ellipse can be specified with a numerical value in the form of a proportion. Multiple numerical values of `ellipse` may also be specified to obtain multiple ellipses.

**BOXPLOTS**

For a single variable the preferred plot is the integrated violin/box/scatter plot or VBS plot. Only the violin or box plot can be obtained with the corresponding aliases `ViolinPlot` and `BoxPlot`, or by setting `vbs_plot` to "v" or "b". To view a box plot of a continuous variable (Y) across the levels of a categorical variable (X), either as part of the full VBS plot, or by itself, there are two possibilities:

1. `Plot(Y,X)` or `BoxPlot(Y, X)`
2. `Plot(Y, by1=X)` or `BoxPlot(Y, by1=X)`

Both styles produce the same information. What differs is the color scheme.

The first possibility places the multiple box plots on a single pane and also, for the default color scheme "colors", displays the sequence of box plots with the default qualitative color palette from the `lessR` function `getColors`. All colors are displayed at the same level of gray-scale saturation and brightness to avoid perceptual bias. `BarChart` and `PieChart` use the same default colors as well.

The second possibility with `by1` produces the different box plots on a separate panel, that is, a Trellis chart. These box plots are displayed with a single hue, the first color, blue, in the default qualitative sequence.

**TIME CHARTS**

Specifying one or more `x`-variables with no `y`-variables, and `run=TRUE` plots the `x`-variables in a run chart. The values of the specified `x`-variable are plotted on the `y`-axis, with Index on the `x`-axis. Index is the ordinal position of each data value, from 1 to the number of values.

If the specified `x`-variable is of type `Date`, or is a time series, a time series plot is generated for each specified variable. If a formal R time-series, univariate or multivariate, specify as the `x`-variable. Or, specify the `x`-variable of type `Date`, and then specify the `y`-variable as one or more time series to plot. The `y`-variable can be formatted as tidy data with all the values in a single column, or as wide-formatted data with the time-series variables in separate columns.

**2-D KERNEL DENSITY**

With `smooth=TRUE`, the R function `smoothScatter` is invoked according to the current color theme. Useful for very large data sets. The `smooth_points` parameter plots points from the regions of the lowest density. The `smooth_bins` parameter specifies the number of bins in both directions for the density estimation. The `smooth_exp` parameter specifies the exponent in the function that maps the density scale to the color scale to allow customization of the intensity of the plotted gradient.
colors. Higher values result in less color saturation, de-emphasizing points from regions of lesser density. These parameters are respectively passed directly to the smoothScatter nrpoints, nbin and transformation parameters. Grid lines are turned off, but can be displayed by setting the grid_color parameter.

COLORS
A color theme for all the colors can be chosen for a specific plot with the colors option with the lessR function style. The default color theme is "lightbronze". A gray scale is available with "gray", and other themes are available as explained in style, such as "sienna" and "darkred". Use the option style(sub_theme="black") for a black background and partial transparency of plotted colors.

Colors can also be changed for individual aspects of a scatterplot as well with the style function. To provide a warmer tone by slightly enhancing red, try a background color such as panel_fill="snow". Obtain a very light gray with panel_fill="gray99". To darken the background gray, try panel_fill="gray97" or lower numbers. See the lessR function showColors, which provides an example of all available named R colors with their RGB values.

For the color options, such as violin_color, the value of "off" is the same as "transparent".

ANNOTATIONS
Use the add and related parameters to annotate the plot with text and/or geometric figures. Each object is placed according from one to four corresponding coordinates, the required coordinates to plot that object, as shown in the following table. x-coordinates may have the value of "mean_x" and y-coordinates may have the value of "mean_y".

<table>
<thead>
<tr>
<th>Value</th>
<th>Object</th>
<th>Required Coordinates</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;text&quot;</td>
<td>text</td>
<td>x1, y1</td>
</tr>
<tr>
<td>&quot;rect&quot;</td>
<td>rectangle</td>
<td>x1, y1, x2, y2</td>
</tr>
<tr>
<td>&quot;line&quot;</td>
<td>line segment</td>
<td>x1, y1, x2, y2</td>
</tr>
<tr>
<td>&quot;arrow&quot;</td>
<td>arrow</td>
<td>x1, y1, x2, y2</td>
</tr>
<tr>
<td>&quot;v_line&quot;</td>
<td>vertical line</td>
<td>x1</td>
</tr>
<tr>
<td>&quot;h_line&quot;</td>
<td>horizontal line</td>
<td>y1</td>
</tr>
<tr>
<td>&quot;means&quot;</td>
<td>horiz, vert lines</td>
<td></td>
</tr>
</tbody>
</table>

The value of add specifies the object. For a single object, enter a single value. Then specify the value of the needed corresponding coordinates, as specified in the above table. For multiple placements of that object, specify vectors of corresponding coordinates. To annotate multiple objects, specify multiple values for add as a vector. Then list the corresponding coordinates, for up to each of four coordinates, in the order of the objects listed in add.

Can also specify vectors of different properties, such as add_color. That is, different objects can be different colors, different transparency levels, etc.

PDF OUTPUT
To obtain pdf output, use the pdf_file option, perhaps with the optional width and height options. These files are written to the default working directory, which can be explicitly specified with the R setwd function.
ADDITIONAL OPTIONS
Commonly used graphical parameters that are available to the standard R function `plot` are also generally available to `Plot`, such as:

- **cex.main, col.lab, font.sub, etc.** Settings for main- and sub-title and axis annotation, see `title` and `par`.
- **main** Title of the graph, see `title`.
- **xlim** The limits of the plot on the x-axis, expressed as c(x1,x2), where x1 and x2 are the limits. Note that x1 > x2 is allowed and leads to a reversed axis.
- **ylim** The limits of the plot on the y-axis.

ONLY VARIABLES ARE REFERENCED
A referenced variable in a lessR function can only be a variable name. This referenced variable must exist in either the referenced data frame, such as the default d, or in the user's workspace, more formally called the global environment. That is, expressions cannot be directly evaluated. For example:

```r
> Plot(rnorm(50),rnorm(50)) # does NOT work
```

Instead, do the following:

```r
> X <- rnorm(50) # create vector X in user workspace
> Y <- rnorm(50) # create vector Y in user workspace
> Plot(X,Y) # directly reference X and Y
```

Value
The output can optionally be saved into an R object, otherwise it simply appears in the console. The output here is just for the outlier analysis of the two-variable scatterplot with continuous variables. The outlier identification must be activated for the analysis, such as from parameter `MD_cut`.

READABLE OUTPUT
codeout_outlier: Mahalanobis Distance of each outlier.

STATISTICS
codeoutliers_indices: Location of the outliers in the x and y vectors.

Display the portions of saved results of an analysis from a `lessR` function into an object, such as for later display at the console or to be integrated into an Rmd analysis, for example from RStudio. This function is usually implicitly accessed by the user simply by entering the name of an output piece into the console or in a Rmd file, such as, such as `r$out_coefs` that results from `r <- reg(Y ~ X)`.

Now just applies to the `lessR` `Regression` function.

### Usage

```r
## S3 method for class 'out'
print(x, ...)
```

### Arguments

- `x`: The piece of output to display, a character vector or a list of character vectors.
- `...`: Other parameter values.

`Regression`

### Examples

```r
# read internal data set
d <- rd("Employee", quiet=TRUE)
# do the summary statistics
s <- ss.brief(Salary)
# print the piece of output, print function is implicit
s$outliers
```

---

Display all text output from a saved list object

Displays all the results saved as an R list into an object from a `lessR` analysis. An example of a saved object is `r` in `r <- reg(Y ~ X)`. The results are displayed at the console or integrated into a knitr analysis, for example from RStudio. This function is usually implicitly accessed by the user simply by entering the name of the saved object at the console or in a knitr file.
Usage

```r
## S3 method for class 'out_all'
print(x, ...)
```

Arguments

- `x`: The list of components to display.
- `...`: Other parameter values

```

---

**prob_norm**

**Compute and Plot Normal Curve Probabilities over an Interval**

Description

Calculate the probability of an interval for a normal distribution with specified mean and standard deviation, providing both the numerical probability and a plot of the interval with the corresponding normal curve.

Usage

```r
prob_norm(lo=NULL, hi=NULL, mu=0, sigma=1, nrm_color="black",
          fill_nrm="grey91", fill_int="slategray3",
          ylab="", y_axis=FALSE, z=TRUE, axis_size=.9,
          pdf_file=NULL, width=5, height=5, ...)
```

```r
prob.norm(...)```

```r
```
Arguments

- **lo**: Lowest value in the interval for which to compute probability.
- **hi**: Highest value in the interval for which to compute probability.
- **mu**: Population mean of normal distribution.
- **sigma**: Population standard deviation of normal distribution.
- **nrm_color**: Color of the border of the normal curve.
- **fill_nrm**: Fill color of the normal curve.
- **fill_int**: Fill color of the interval for which the probability is computed.
- **ylab**: Label for the optional vertical axis.
- **y_axis**: If TRUE, then a vertical axis is included.
- **z**: If TRUE, then include z-values on the horizontal-axis. Set to FALSE if mu=0 and sigma=1.
- **axis_size**: Magnification factor for the axis labels, the value of axis_cex.
- **pdf_file**: Name of the pdf file to which graphics are redirected.
- **width**: Width of the pdf file in inches.
- **height**: Height of the pdf file in inches.
- **...**: Other parameter values for graphics.

Details

Calculate the normal curve probability for the specified interval and normal curve. If there is no upper value of the interval provided, **hi**, then the upper tail probability is provided, that is, from the specified value until positive infinity. If there is no lower value, **lo**, then the lower tail probability is provided. The probability is calculated with `pnorm`.

Author(s)

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

`pnorm, plot`.

Examples

```r
# Mu=0, Sigma=1: Standard normal prob, values between 0 and 2
prob.norm(0, 2)

# Mu=0, Sigma=1: Standard normal prob, values lower than 2
prob.norm(hi=2)

# Mu=0, Sigma=1: Standard normal prob, values larger than 2
prob.norm(lo=2)

# Mu=100, Sigma=15: Change default fill color of plotted interval
prob.norm(lo=115, hi=125, mu=100, sigma=15, fill_int="plum")
```
**prob_tcut**  

*Plot t-distribution Curve and Specified Cutoffs with Normal Curve*

**Description**

Plot a specified t-distribution against the standardized normal curve with the corresponding upper and lower tail cutoffs.

**Usage**

```r
prob_tcut(df, alpha=0.05, digits_d=3, y_axis=FALSE,
          fill="aliceblue", color_tail="palevioletred4",
          nrm_color=gray(.7), color_t=gray(.08),
          pdf_file=NULL, width=5, height=5, ...)

prob.tcut(...)```

**Arguments**

- `df` Degrees of freedom for t-distribution, must be 2 or larger.
- `alpha` Alpha to define the tail cutoff area.
- `digits_d` Number of decimal digits in the output.
- `y_axis` If FALSE, then the y axis is not displayed.
- `fill` Fill color for the interior of the t-distribution curve.
- `color_tail` Color of the tail areas of the t-distribution.
- `nrm_color` Color of the normal curve.
- `color_t` Color of the t-distribution curve.
- `pdf_file` Name of the pdf file to which graphics are redirected.
- `width` Width of the pdf file in inches.
- `height` Height of the pdf file in inches.
- `...` Other parameter values for graphics.

**Details**

Replaces a t-table by providing the corresponding t-cutoff, the critical value based on the corresponding quantile, as well as a plot that illustrates the tail probabilities. Also compare to the standardized normal curve.

prob.tcut(15)

prob_znorm

Plot a Normal Curve with Shaded Intervals by Standard Deviation

Description

Display a normal curve with shading according to the z-score, the number of standard deviations from the mean.

Usage

prob_znorm(mu=0, sigma=1, color_border="gray10", r=.10, g=.34, b=.94, a=.20,
          xlab="", ylab="", main="",
          y_axis=FALSE, z=TRUE, axis_size=.9,
          pdf_file=NULL, width=5, height=5, ...)

prob.znorm(...)  

Arguments

mu  Population mean of normal distribution.
sigma Population standard deviation of normal distribution.
color_border Color of the border of the normal curve.
r  Red component of fill color, from 0 to 1.
g  Green component of fill color, from 0 to 1.
b  Blue component of fill color, from 0 to 1.
a  Alpha component of fill color, that is, the transparency, from 0 to 1.
xlab  Label for the horizontal axis.
ylab  Label for the optional vertical axis.
main  Label for the graph title.
y_axis  If TRUE, then a vertical axis is included.
z  If TRUE, then include z-values on the horizontal-axis. Set to FALSE if mu=0 and sigma=1.
axis_size Magnification factor for the axis labels, the value of axis_cex.
pdf_file Name of the pdf file to which graphics are redirected.
width  Width of the pdf file in inches.
height Height of the pdf file in inches.
...  Other parameter values for graphics.
Details

Provide a normal curve with shading of each interval defined by the number of standard deviations from the mean. The layers are written with transparency, and over-written so that the middle interval is the darkest and the most extreme intervals, beyond three standard deviations from the mean, are the lightest. Specify \( a=0 \) to turn off the colors. Higher values of the alpha channel, as specified by \( a \), yield darker colors. Specify \( a=1 \) for the same solid color for all intervals.

The normal densities are calculated with \texttt{dnorm} and plotted with \texttt{plot}.

# distribution for height of American women, mu=65.5, sigma=2.5
prob.znorm(65.5, 2.5, xlab="Height of American Women")

# do a red fill color
prob.znorm(65.5, 2.5, r=.9, xlab="Height of American Women")
```

Description

Abbreviation: \texttt{rd}, \texttt{rd_lbl}, \texttt{codeRead2}

Reads the contents of the specified data file into an R data table, what R calls a data frame. By default the format of the file is detected from its filetype: comma or tab separated value text file from \texttt{.csv}, SPSS data file from \texttt{.sav}, SAS data from from \texttt{.sas7bdat}, or R data file from \texttt{.rda}, and Excel file from \texttt{.xls} or \texttt{.xlsx} using Alexander Walker's \texttt{openxlsx} package. Specify a fixed width formatted text data file to be read with the required \texttt{Rwidths} option. Identify the data file by either browsing for the file on the local computer system with \texttt{Read()} or identify the file with the first argument a character string in the form of a path name or a web URL (except for \texttt{.Rda} files which must be on the local computer system).

Any variable labels in a native SPSS of native R file are automatically included in the data file. See the details section below for more information. Variable labels can also be added and modified individually with the \texttt{lessR} function \texttt{label}, and more comprehensively with the \texttt{VariableLabels} function.
The function provides feedback regarding the data that is read by invoking the `lessR` function `details`. The default brief form of this function invoked by default only lists the input files, the variable name table, and any variable labels.

The `lessR` function `corRead` reads a correlation matrix.

**Usage**

```r
Read(from=NULL, format=NULL, var_labels=FALSE,
       widths=NULL, stringsAsFactors=FALSE,
       missing="", n_mcut=1,
       miss_show=30, miss_zero=FALSE, miss_matrix=FALSE,
       max_lines=30, sheet=1,
       brief=TRUE, quiet=getOption("quiet"),
       fun_call=NULL, ...)
```

```r
rd(...) rd_lbl(..., var_labels=TRUE)
Read2(..., sep=";", dec="",)
```

**Arguments**

- **from** File reference, either omitted to browse for the data file, or (except for .Rda files) a full path name or web URL, included in quotes. A URL begins with `http://`.

- **format** Format of the data in the file, not usually specified because set by default according to the file type of the file to read: `.csv`, `.tsv`, `.txt` read as a text file, `.xls` or `.xlsx` read as an Excel file, `.sav` reads as an SPSS file, which also reads the variable labels if present, `.sas7bdat` reads as a SAS file, and `.rda` reads as a native R data file. If the data file is not identified by one of these file types, then explicitly set by setting to one of the following values: "csv", "tsv", "Excel", "R", "SPSS", or "SAS".

- **var_labels** Set TRUE if reading a csv or Excel file of variable labels into the data frame `l` in which each row consists of a variable name in the first column and the corresponding variable label in the second column, and perhaps units in the third row if using `Regression` function to generate automatic markdown files of discursive text.

- **widths** Specifies the width of the successive columns for fixed width formatted data.

- **stringsAsFactors** Defaults to `FALSE`, so variables with at least one non-numeric data value are read as character strings instead of factors.

- **missing** Missing value code, which by default is literally a missing data value in the data table.
n_mcut  For the missing value analysis, list the row name and number of missing values if the number of missing exceeds or equals this cutoff.

miss_show  For the missing value analysis, the number of rows, one row per observation, that has as many or missing values as n_mcut.

miss_zero  For the missing value analysis, list the variable name or the row name even for values of 0, that is rows with no missing data. By default only variables and rows with missing data are listed.

miss_matrix  For the missing value analysis, if there is any missing data, list a version of the complete data table with a 0 for a non-missing value and a 1 for a missing value.

sep  Character that separates adjacent values in a text file of data.

dec  Character that serves as the decimal separator in a number.

max_lines  Maximum number of lines to list of the data and labels.

sheet  For Excel files, specifies the work sheet to read. The default is the first work sheet.

brief  If TRUE, display only variable names table plus any variable labels.

quiet  If set to TRUE, no text output. Can change the corresponding system default with style function.

fun_call  Function call. Used with Rmd to pass the function call when obtained from the abbreviated function call rd.

...  Other parameter values define with the R read functions, such as the read.table function for text files, with row.names and header.

Details

By default Read reads text data files which are either comma delimited, csv, or tab-delimited data files, native Excel files of type .xls or .xlsx, native R files with file type of .rda, native SAS files with file type .sas7bdat, and native SPSS files with file type .sav. Invoke the widths option to allow for the reading of fixed width formatted data. Calls the lessR function details to provide feedback regarding details of the data frame that was read. By default, variables defined by non-numeric variables are read as character strings. To read as factors specify stringsAsFactors as FALSE, unless all the values of a variable a non-numeric and unique, in which case the variable is classified as a character string.

CREATE csv FILE

One way to create a csv data file is to enter the data into a text editor. A more structured method is to use a worksheet application such as MS Excel, LibreOffice Calc. Place the variable names in the first row of the worksheet. Each column of the worksheet contains the data for the corresponding variable. Each subsequent row contains the data for a specific observation, such as for a person or a company.

All numeric data in the worksheet should be displayed in the General format, so that the only non-digit character for a numeric data value is a decimal point. The General format removes all dollar signs and commas, for example, leaving only the pure number, stripped of these extra characters which R will not properly read as part of a numeric data value.
To create the csv file from a standard worksheet application such as Microsoft Excel or LibreOffice Calc, first convert any numeric data to general format to remove characters such as dollar signs and commas, and then under the File option, do a Save As and choose the csv format.

Call `help(read.table)` to view the other options that can also be implemented from `Read`.

**MECHANICS**
Specify the file as with the `Read` function for reading the data into a data frame. If no arguments are passed to the function, then interactively browse for the file.

Given a csv data file, or tab-delimited text file, read the data into an R data frame called `d` with `Read`. Because `Read` calls the standard R function `read.csv`, which serves as a wrapper for `read.table`, the usual options that work with `read.table`, such as `row.names`, also can be passed through the call to `Read`.

**SPSS DATA**
Relies upon `read.spss` from the `haven` package to read data in the SPSS .sav or .zsav format. If the file has a file type of .sav, that is, the file specification ends in .sav, then the format is automatically set to "SPSS". To invoke this option for a relevant data file of any file type, explicitly specify `format="SPSS"`. Each (usually) integer variable with value labels is converted into two R variables: the original numeric code with the original variable name, and also the corresponding factor with the variable labels named with the original name plus the suffix _.f_. The variable labels are also displayed for copying into a variable label file. See the SPSS section from `vignette("Read")`.

**R DATA**
Relies upon the standard R function `load`. By convention only, data files in native R format have a file type of .rda. To read a native R data file, if the file type is .rda, the format is automatically set to "R". To invoke this option for a relevant data file of any file type, explicitly specify `format="R"`. Create a native R data file by saving the current data frame, usually `d`, with the `lessR` function `Write`.

**Excel DATA**
Relies upon the function `read.xlsx` from Alexander Walker’s `openxlsx` package. Files with a file type of .xlsx are assigned a format of "Excel". The `read.xlsx` parameter `sheet` specifies the ordinal position of the worksheet in the Excel file, with a default value of 1. The `row.names` parameter can only have a value of 1. Dates stored in Excel as an Excel date type are automatically read as an R Date type.

**lessR DATA**
`lessR` has some data sets included with the package: "BodyMeas", "Cars93", "Employee", "Jackets", "Learn", "Mach4", "Reading", and "StockPrice". `Read` reads each such data set by specifying its name, such as `Read("Employee")`. No specificaiton of `format` and no provided filetype, just enter the name of the data set.

**FIXED WIDTH FORMATTED DATA**
Relies upon `read.fwf`. Applies to data files in which the width of the column of data values of a variable is the same for each data value and there is no delimiter to separate adjacent data values. An example is a data file of Likert scale responses from 1 to 5 on a 50 item survey such that the data consist of 50 columns with no spaces or other delimiter to separate adjacent data values. To read this data set, invoke the `widths` option of `read.fwf`.

**MISSING DATA**
By default, `Read` provides a list of each variable and each row with the display of the number of associated missing values, indicated by the standard R missing value code NA. When reading the data, `Read` automatically sets any empty values as missing. Note that this is different from the R
default in `read.table` in which an empty value for character string variables are treated as a regular data value. Any other valid value for any data type can be set to missing as well with the `missing` option. To mimic the standard R default for missing character values, set `missing=NA`.

To not list the variable name or row name of variables or rows without missing data, invoke the `miss_zero=FALSE` option, which can appreciably reduce the amount of output for large data sets. To view the entire data table in terms of 0’s and 1’s for non-missing and missing data, respectively, invoke the `miss_matrix=TRUE` option.

VARIABLE LABELS
Unlike standard R, `lessR` provides for variable labels, which can be provided for some or all of the variables in a data frame. Store the variable labels in a separate data frame. The variable labels file that is read by `Read` consists of one row for each variable for which a variable label is provided. Each row consists of either two columns, the variable name in the first column and the associated variable label in the second column, or three columns with the third column the variable units. Use the units in conjunction for enhanced readability with the automatic markdown generated by the Rmd parameter for the `Regression` function. The format of the file can be csv or xlsx. The data frame `Read` constructs from this input consists of one variable, called `label`, with the variable names as row names.

The `lessR` legacy approach is to store the variable labels directly with the data in the same data frame. The problem with this approach is that any transformations of the data with any function other than `lessR` transformation functions remove the variable labels. The option for reading the variable labels with the `labels` option of `Read` statement is retained for compatibility.

Reading the data from an SPSS file, however, retains the SPSS variable labels as part of the data file. The `lessR` data analysis functions will properly process these variable labels, but any non-`lessR` data transformations will remove the labels from the data frame. To retain the labels, copy them to the 1 data frame with the `VariableLabels` function with the name of the data frame as the sole argument.

The `lessR` functions that provide analysis, such as `Histogram` for a histogram, automatically include the variable labels in their output, such as the title of a graph. Standard R functions can also use these variable labels by invoking the `lessR` function `label`, such as setting `main=label(I4)` to put the variable label for a variable named I4 in the title of a graph.

Value
The read data frame is returned, usually assigned the name of `d` as in the examples below. This is the default name for the data frame input into the `lessR` data analysis functions.

d <- Read("Employee")

# read a data file organized by columns, with a
# 5 column ID field, 2 column Age field
# and 75 single columns of data, no spaces between columns
# name the variables with lessR function: to
# the variable names are Q01, Q02, ..., Q74, Q75
# d <- Read(widths=c(5,2,rep(1,75)), col.names=c("ID", "Age", to("Q", 75)))
```

---

Recode

Recode the Values of an Integer or Factor Variable

Description

Abbreviation: rec

Recodes the values of one or more integer variables in a data frame. The values of the original variable may be overwritten with the recoded values, or the recoded values can be designated to be placed in a new variable, indicated by the new.name option. Valid values may be converted
to missing, and missing values may be converted to valid values. Any existing variable labels are
retained in the recoded data frame.

There is no provision to recode integer values to character strings because that task is best accom-
plished with the standard R \texttt{factor} function.

Usage

\begin{verbatim}
Recode(old_vars, new_vars=NULL, old, new, data=d, quiet=getOption("quiet"), ...)

rec(...)  
\end{verbatim}

Arguments

- **old_vars**: One or more variables to be recoded.
- **new_vars**: Name of the new variable or variables that contain the recoded values, each
  name in quotes. If not provided, then the values of the original variable are
  replaced.
- **old**: The values of the variables that are to be recoded. If the value is "missing" then
  any existing missing values are replaced by the value specified with \texttt{new}.
- **new**: The recoded values, which match one-to-one with the values in \texttt{old}. If the value
  is "missing" then instead any values specified in \texttt{old} are converted to missing.
- **data**: The name of the data frame from which to create the subset, which is \texttt{d} by
  default.
- **quiet**: If set to \texttt{TRUE}, no text output. Can change system default with \texttt{style}
  function.
- **...**: Parameter values.

Details

Specify the values to be recoded with the required \texttt{old} parameter, and the corresponding recoded
values with the required \texttt{new} parameter. Use \texttt{new_vars} to specify the name of the variable that
contains the recoded values. If \texttt{new_vars} is not present, then the values of the original variable are
overwritten with the recoded values.

Not all of the existing values of the variable to be recoded need be specified. Any value not specified
is unchanged in the values of the recoded variable. Unless otherwise specified, missing values are
unchanged. To modify missing values, set \texttt{old="missing"} to covert missing data values to the
specified value data value given in \texttt{new}. Or, set \texttt{new="missing"} to covert the one or more existing
valid data values specified in \texttt{old} to missing data values.

Diagnostic checks are performed before the recode. First, it is verified that the same number of
values exist in the \texttt{old} and \texttt{new} lists of values. Second, it is verified that all of the values specified
to be recoded in fact exist in the original data.

If the levels of a factor were to be recoded with \texttt{Recode}, then the factor attribute would be lost as
the resulting recoded variable would be character strings. Accordingly, this type of transformation
is not allowed, and instead should be accomplished with the \texttt{Transform} and \texttt{factor} functions as
shown in the examples.
Value

The recoded data frame is returned, usually assigned the name of \texttt{d} as in the examples below. This is the default name for the data frame input into the \texttt{lessR} data analysis functions.

Examples

```r
# construct data frame
d <- read.table(text="Severity Description
1 Mild
4 Moderate
3 Moderate
2 Mild
1 Severe", header=TRUE, stringsAsFactors=FALSE)

# recode Severity into a new variable called SevereNew
d <- Recode(Severity, new_vars="SevereNew", old=1:4, new=c(10,20,30,40))

# abbreviated form, replace original with recoded
# another option, the sequence function, to generate list of values
d <- rec(Severity, old=1:4, new=seq(10,40,by=10))

# reverse score four Likert variables: m01, m02, m03, m10
d <- Read("Mach4")
d <- Recode(c(m01:m03,m10), old=0:5, new=5:0)

# convert any 1 for Plan to missing
# use Read to put data into d data frame
# write results to newdata data frame
d <- Read("Employee")
newdata <- Recode(Plan, old=1, new="missing")

# for Years and Salary convert any missing value to 99
d <- Recode(c(Years, Salary), old="missing", new=99)
```

# convert between factors and integers

```
# recode levels of a factor that should remain a factor
# with the Transform and factor functions
# using Recode destroys the factor attribute, converting to
# character strings instead, so Recode does not allow
d <- Read("Employee")
```
d <- Transform(
  Gender=factor(Gender, levels=c("F", "M"), labels=c("Female", "Male"))
)

# recode levels of a factor to convert to integer first by
# converting to integer with Transform and as.numeric
# here Gender has values M and F in the data
# integers start with 1 through the number of levels, can use
# Recode to change this if desired, such as to 0 and 1
d <- Transform(Gender=as.numeric(Gender))
d <- Recode(Gender, old=c(1,2), new=c(0,1))

# recode integer values to levels of a factor with value labels
# with the Transform function instead of Recode
# here Gender has values 0 and 1 in the data
d <- Read("Mach4")
d <- Transform(
  Gender=factor(Gender, levels=c(0,1), labels=c("Male","Female"))
)

# -------------------------------

regPlot Analysis

Description

Following a call to the lessR function Regression, in which the returned values of the function are saved into an object, allows the default plots generated by Regression to be accessed one at a time. The specific motivation for this function is to allow custom placement of the graphs from the regression analysis from within knitr. Usually the graphics=FALSE parameter is set on the call to Regression within knitr to suppress the normal graphic output that leads to the generation of the graphs at the beginning of the knitr output.

Usage

regPlot(out, type, digits_d=NULL, pred.intervals=TRUE,
  res_sort=c("cooks","rstudent","dffits","off"),
  res_rows=NULL, cooks_cut=1, scatter_coef=NULL,
  pdf=FALSE, width=5, height=5, manage.gr=FALSE, ...)

Arguments

out The object returned by the lessR function Regression.

type Type of plot: 1 plots the scatter plot for a single predictor variable, or the scatter plot matrix for multiple predictors. If a single scatter plot, then the confidence and prediction intervals are included. 2 plots the density and histogram of residuals and 3 plots a scatter plot of the residuals with the fitted values.

digits_d For the Basic Analysis, the number of decimal digits, set by default to at least 3 or the largest number of digits in the values of the response variable plus 1.
pred.intervals  If set to FALSE, the scatter plot for a single predictor with the response does not contain prediction and confidence intervals.

res_sort  Default is "cooks", for specifying Cook’s distance as the sort criterion for the display of the rows of data and associated residuals. Other values are "rstudent" for externally Studentized residuals, "dffits" for dffits and "off" to not sort the rows of data.

res_rows  Default is 20, which lists the first 20 rows of data sorted by the specified sort criterion. To disable residuals, specify a value of 0. To see the output for all observations, specify a value of "all".

cooks_cut  Cutoff value of Cook’s Distance at which observations with a larger value are flagged in red and labeled in the resulting scatterplot of Residuals and Fitted Values. Default value is 1.0.

scatter_coef  Display the correlation coefficients in the upper triangle of the scatterplot matrix.

pdf  If TRUE, then graphics are written to pdf files.

width  Width of the pdf file in inches.

height  Height of the pdf file in inches.

manage.gr  Usually leave FALSE. Refers to graphic management of the lessR system.

...  Other parameter values for R function lm which provides the core computations.

Details

OVERVIEW
The ability to separate plots is particularly useful with knitr to break up the output to intersperse comments between the plots. For Plot 1, for single predictor a scatter plot with the regression line and confidence and prediction intervals is produced. Otherwise a scatter plot matrix of all the variables in the models is obtained.

To help assess the validity of the model, Plot 2 is of the distribution of the residuals, histogram and density plots, both general and normal. Plot 3 plots the residuals against the fitted value and also identifies the points with the largest values of Cook’s distance.

lm, Regression
Examples

```r
# read internal data set
d <- rd("Reading", quiet=TRUE)
# do regression analysis, save result into out
reg.out <- reg(Reading ~ Verbal)
# The full output already contains these plots, obtained by
# entering the name of the saved object
reg.out
# Particularly for knitr it is useful to obtain the plots
# separately from the full output
# Get the scatter plot of the data with the regression line
# and prediction and confidence intervals
regPlot(reg.out, 1)

# Can use with multiple regression for the scatter plot matrix
r <- reg(Reading ~ Verbal + Absent + Income)
regPlot(r, 1, scatter_coef=TRUE)
```

Description

Abbreviation: `reg`, `reg.brief`

Provides a regression analysis with extensive output, including graphics, from a single, simple function call with many default settings, each of which can be re-specified. The computations are obtained from the R function `lm` and related R regression functions. The outputs of these functions are re-arranged and collated.

By default the data exists as a data frame with the default name of `d`, or specify explicitly with the `data` option. Specify the model in the function call as an R `formula`, that is, for a basic model, the response variable followed by a tilde, followed by the list of predictor variables, each pair separated by a plus sign, such as `reg(Y ~ X1 + X2)`. Output is generated into distinct segments by topic, organized and displayed in sequence by default. When the output is assigned to an object, such as `r <- reg(Y ~ X)`, the full or partial output can be accessed for later analysis and/or viewing. A primary such analysis is with knitr for dynamic report generation, run from R directly or from within RStudio. The input instructions to knitr are written comments and interpretation with embedded R code, called R-Markdown. Doing a knitr analysis is to "knit" these comments and subsequent output together so that the R output is embedded in the resulting document – either html, pdf or Word – by default with explanation and interpretation. Generate a complete R-Markdown file with filetype (`.Rmd`) from the `.Rmd` option. Simply specify the option with a file name in quotes, then run the Regression analysis to create the markdown file. Open the newly created `.Rmd` file in RStudio and click the knit button to create a formatted document that consists of the statistical results plus interpretative comments. See the sections arguments, value and examples for more information.
Usage

Regression(my_formula, data=d, rows=NULL, kfold=0,
          digits_d=NULL, standardize=FALSE,
          Rmd=NULL, Rmd_browser=TRUE,
          Rmd_format=c("html", "word", "pdf", "odt", "none"),
          Rmd_data=NULL,
          results=getOption("results"), explain=getOption("explain"),
          interpret=getOption("interpret"), document=getOption("document"),
          code=getOption("code"),
          text_width=120, brief=getOption("brief"), show_R=FALSE,
          res_rows=NULL, res_sort=c("cooks", "rstudent", "dffits", "off"),
          pred_rows=NULL, pred_sort=c("predint", "off"),
          subsets=NULL, cooks_cut=1,
          scatter_coef=TRUE, graphics=TRUE, scatter_3D=FALSE,
          X1_new=NULL, X2_new=NULL, X3_new=NULL, X4_new=NULL,
          X5_new=NULL, X6_new=NULL,
          quiet=getOption("quiet"),
          pdf=FALSE, width=6.5, height=6.5, refs=FALSE,
          fun_call=NULL, ...)}
eg(...)

reg.brief(..., brief=TRUE)
reg_brief(..., brief=TRUE)

Arguments

my_formula Standard R formula for specifying a model. For example, for a response variable named Y and two predictor variables, X1 and X2, specify the corresponding linear model as Y ~ X1 + X2.
data The default name of the data frame that contains the data for analysis is d, otherwise explicitly specify. If knitting and rendering the generated R-Markdown for an interpretative output as specified by the Rmd parameter, then this data frame must first be read by the lessR function Read.
rows A logical expression that specifies a subset of rows of the data frame to analyze.
kfold Number of K-fold cross-validations. If conducted, only the cross-validation output shown.
digits_d For the Basic Analysis, it provides the number of decimal digits, set by default to at least 2 or the largest number of digits in the values of the response variable plus 1.
Regression

standardize

Standardize each of the variables in the regression model before conducting the analysis.

Rmd

File name for the automatically generated R Markdown file, if specified. The file type is .Rmd, a simple text file that can be edited with any text editor, including RStudio to generate custom output.

Rmd_browser

If html format for Rmd rendering, then automatically open output in a browser.

Rmd_format

Format of one or more rendered R Markdown file formats, expressed in any combination of uppercase and lowercase letters. Default is "html", with a browser view automatic, or "word", "odt", "pdf" (if LaTeX is available), or "none". Requires pandoc installed, such as from RStudio.

Rmd_data

The default file reference of the data file when running the generated R Markdown file is the last data file as read by Read (with the unabbreviated version of the function name). To refer to a different file to read specify the path name or web URL of the file.

results

By default TRUE. If set to FALSE the results are not provided in the R Markdown document, relying upon the interpretations. Can set globally with style(results=FALSE).

explain

By default TRUE. If set to FALSE the explanations are not provided in the R Markdown document. Can set globally with style(explain=FALSE).

interpret

By default TRUE. If set to FALSE the interpretations of the results are not provided in the R Markdown document. Can set globally with style(interpret=FALSE).

document

By default TRUE. If set to FALSE the R documentation is not provided in the R Markdown file. Can set globally with style(document=FALSE).

code

By default TRUE. If set to FALSE the R code that generates the results is not provided in the R Markdown file. Can set globally with style(code=FALSE).

text_width

Width of the text output at the console.

brief

If set to TRUE, reduced text output. Can change system default with style function.

show_R

Display the R instructions that yielded the lessR output, albeit without the additional formatting of the results such as combining output of different functions into a table.

res_rows

Default is 20, which lists the first 20 rows of data sorted by the specified sort criterion. To disable residuals, specify a value of 0. To see the output for all observations, specify a value of "all".

res_sort

Default is "cooks", for specifying Cook's distance as the sort criterion for the display of the rows of data and associated residuals. Other values are "rstudent" for externally Studentized residuals, "dffits" for dffits and "off" to not sort the rows of data.

pred_rows

Default is 3, which lists prediction intervals only for the first, middle and last 3 rows of data, unless there are 25 or less rows of data when all rows are displayed. To disable prediction intervals, specify a value of 0. To see the output for rows of data, specify a value of "all".
Regression

pred_sort
Default is "predint", which sorts the rows of data and associated intervals by the lower bound of each prediction interval. Turn off this sort by specifying a value of "off".

subsets
Default is to produce the analysis of the fit based on adjusted R-squared for all possible model subsets of size 10 for each number of predictors, from the leaps package. Set to FALSE to turn off. Defaults lists a maximum of the first 50 values. Specify an integer to change the maximum.

cooks_cut
Cutoff value of Cook’s Distance at which observations with a larger value are flagged in red and labeled in the resulting scatterplot of Residuals and Fitted Values. Default value is 1.0.

scatter_coef
Display the correlation coefficients in the upper triangle of the scatterplot matrix.

graphics
Produce graphics. Default is TRUE. In knitr can be useful to set to FALSE so that regPlot can be used to place the graphics within the output file.

scatter_3D
De-activated because car package no longer linked, but if set to TRUE, directions are provided to use the car scatter3d function directly.

X1_new
Values of the first listed numeric predictor variable for which forecasted values and corresponding prediction intervals are calculated.

X2_new
Values of the second listed numeric predictor variable for which forecasted values and corresponding prediction intervals are calculated.

X3_new
Values of the third listed numeric predictor variable for which forecasted values and corresponding prediction intervals are calculated.

X4_new
Values of the fourth listed numeric predictor variable for which forecasted values and corresponding prediction intervals are calculated.

X5_new
Values of the fifth listed numeric predictor variable for which forecasted values and corresponding prediction intervals are calculated.

X6_new
Values of the sixth listed numeric predictor variable for which forecasted values and corresponding prediction intervals are calculated.

quiet
If set to TRUE, no text output. Can change system default with style function.

pdf
If TRUE, then graphics are written to pdf files.

width
Width of the pdf file in inches.

height
Height of the pdf file in inches.

refs
If TRUE, then list the references for R and the packages used from which functions were used to generate the output.

fun_call
Function call. Used internally with knitr to pass the function call when obtained from the abbreviated function call reg. Not usually invoked by the user.

... Other parameter values for R function lm which provides the core computations.
Details

OVERVIEW
The purpose of Regression is to combine the following function calls into one, as well as provide ancillary analyses such as graphics, organizing output into tables and sorting to assist interpretation of the output, as well as generate R Markdown to run through knitr, such as with RStudio, to provide extensive interpretative output.

The basic analysis successively invokes several standard R functions beginning with the standard R function for estimation of a linear model, \texttt{lm}. The output of the analysis of \texttt{lm} is stored in the object \texttt{lm.out}, available for further analysis in the R environment upon completion of the \texttt{Regression} function. By default \texttt{reg} automatically provides the analyses from the standard R functions, \texttt{summary}, \texttt{confint} and \texttt{anova}, with some of the standard output modified and enhanced. The correlation matrix of the model variables is obtained with \texttt{cor} function. The residual analysis invokes \texttt{fitted}, \texttt{resid}, \texttt{rstudent}, and \texttt{cooks.distance} functions. The option for prediction intervals calls the standard R function \texttt{predict}, once with the argument \texttt{interval="confidence"} and once with \texttt{interval="prediction"}. The \texttt{lessR} \texttt{Density} function provides the histogram and density plots for the residuals and the \texttt{ScatterPlot} function provides the scatter plots of the residuals with the fitted values and of the data for the one-predictor model. The \texttt{pairs} function provides the scatterplot matrix of all the variables in the model. Thomas Lumley’s \texttt{leaps} package contains the \texttt{leaps} function that provides the analysis of the fit of all possible model subsets.

INPUT DATA FRAME
The name \texttt{d} is by default provided by the \texttt{Read} function included in this package for reading and displaying information about the data in preparation for analysis. If all the variables in the model are not in the same data frame, the analysis will not complete. Specify the name of the data frame for analysis with the \texttt{data} option if the name is not the default \texttt{d}.

The \texttt{rows} parameter subsets rows (cases) of the input data frame according to a logical expression. Use the standard R operators for logical statements as described in \texttt{Logic} such as \& for and, | for or and ! for not, and use the standard R relational operators as described in \texttt{Comparison} such as == for logical equality != for not equals, and > for greater than. See the Examples.

TEXT OUTPUT
The output is produced in pieces by topic (see values below), automatically collated by default in the final output. But the pieces are available for later reference if the output of the function is directed toward an object, such as \texttt{r} in \texttt{r <-reg(Y ~ X)}. This is especially useful if the pieces are accessed within knitr or individual pieces are displayed at the console.

The text output is organized to provide the most relevant information while at the same time minimizing the total amount of output, particularly for analyses with large numbers of observations (rows of data), the display of which is by default restricted to only the most interesting or representative observations in the analyses of the residuals and predicted values. Additional economy can be obtained by invoking the \texttt{brief=TRUE} option, or run \texttt{reg_brief}, which limits the analysis to just the basic analysis of the estimated coefficients and fit, and if \texttt{X1_new}, etc. are requested, the relevant rows of forecasted values:w .

R MARKDOWN
An R–Markdown file ready for knitting and rendering into one of several formats can be obtained by specifying a value for \texttt{Rmd}. For the specified file name, the directory to which the file is written is displayed on the console text output, and the file type .Rmd is automatically appended to the specified name if it is not included in the specification.
To access the same data file for the regression analysis from running Regression from the R console, and that accomplished by knitting the generated R-Markdown, first read the data into R with the lessR Read function. That function stores the name of the last data file read so that it can be accessed via R as the markdown is knit and then rendered into the specified format. The default rendering is to HTML, but other formats can be specified with Rmd_format.

The output from Rmd is conceptually partitioned into five parts: results, explanations of the results, interpretations of the results, documentation of the code, and the code itself. By default all available output is generated but the flags results, explain, interpret, document, code can be set to FALSE to reduce the output. The options can be specified in a specific function all or set globally, such as with options(explain=FALSE). Turning off all five flags leaves just the outline of the potential output and a bare minimum of results.

Both any existing variable labels and variable units are included in the output to the R-Markdown file. Any variable units set as a dollar, are set as USD dollars and cents in the output, displayed with a $.

The default analysis provides as text output to the console the model’s parameter estimates and corresponding hypothesis tests and confidence intervals, goodness of fit indices, the ANOVA table, correlation matrix of the model’s variables, analysis of residuals and influence as well as the confidence and prediction intervals for each observation in the model. Also provided, for multiple regression models, collinearity analysis of the predictor variables and adjusted R-squared for the corresponding models defined by each possible subset of the predictor variables.

**DECIMAL DIGITS**

The number of decimal digits displayed on the output is, by default, the maximum number of decimal digits for all the data values of the response variable. Or, this value can be explicitly specified with the digits_d parameter.

**GRAPHICS OUTPUT**

Three default graphs are provided. When running R by itself, by default the graphs are written to separate graphics windows (which may overlap each other completely, in which case move the top graphics windows). Or, the pdf option may be invoked to save the graphs to a single pdf file called regOut.pdf. Within RStudio the graphs are successively written to the Plots window. Within knitr from RStudio the graphics will all appear by default at the beginning of the output. Or set to graphics=FALSE, and generate them individually with the accompanying function regPlot at the desired location within the file.

1. A histogram of the residuals includes the superimposed normal and general density plots from the Density function included in this lessR package. The overlapping density plots, which both overlap the histogram, are filled with semi-transparent colors to enhance readability.

2. A scatterplot of the residuals with the fitted values is also provided from the ScatterPlot function included in this package. The point corresponding to the largest value of Cook’s distance, regardless of its size, is plotted in red and labeled and the corresponding value of Cook’s distance specified in the subtitle of the plot. Also by default all points with a Cook’s distance value larger than 1.0 are plotted in red, a value that can be specified to any arbitrary value with the cooks_cut option. This scatterplot also includes the lowess curve.

3. For models with a single predictor variable, a scatterplot of the data is produced, which also includes the regression line and corresponding confidence and prediction intervals. As with the density histogram plot of the residuals and the scatterplot of the fitted values and residuals, the scatterplot includes a colored background with grid lines. For multiple regression models, a scatterplot matrix of the variables in the model with the lowess best-fit line of each constituent scatterplot
is produced. If the scatter_coef option is invoked, each scatterplot in the upper-diagonal of the correlation matrix is replaced with its correlation coefficient.

**RESIDUAL ANALYSIS**

By default the residual analysis lists the data and fitted value for each observation as well as the residual, Studentized residual, Cook’s distance and dfits, with the first 20 observations listed and sorted by Cook’s distance. The res_sort option provides for sorting by the Studentized residuals or not sorting at all. The res_rows option provides for listing these rows of data and computed statistics statistics for any specified number of observations (rows). To turn off the analysis of residuals, specify res_rows=0.

**PREDICTION INTERVALS**

The output for the confidence and prediction intervals includes a table with the data and fitted value for each observation, the lower and upper bounds for the confidence interval and the prediction interval, and the wide of the prediction interval. The observations are sorted by the lower bound of each prediction interval. If there are 25 or more observations then the information for only the first three, the middle three and the last three observations is displayed. To turn off the analysis of prediction intervals, specify pred_rows=0, which also removes the corresponding intervals from the scatterplot produced with a model with exactly one predictor variable, yielding just the scatterplot and the regression line.

The data for the default analysis of the prediction intervals is for the values of the predictor variables for each observation, that is, for each row of the data. New values of the predictor variables can be specified for the calculation of the prediction intervals by providing values for the options X1_new for the values of the first listed predictor variable in the model, X2_new for the second listed predictor variable, and so forth for up to five predictor variables, and all predictor variables are numeric. To provide these values, use functions such as seq for specifying a sequence of values and c for specifying a vector of values. For multiple regression models, all combinations of the specified new values for all of the predictor variables are analyzed.

**RELATIONS AMONG THE VARIABLES**

By default the correlation matrix of all the variables in the model is displayed, and, for multiple regression models, collinearity analysis is provided. Also provided are the first 50 models with the largest R squared adjusted from each possible model from an analysis of all possible subsets of the predictor variables. This all subsets analysis requires the leaps function from the leaps package. These contributed packages are automatically loaded if available. To turn off the all possible sets option, set subsets=FALSE.

**INVOKED R OPTIONS**

The options function is called to turn off the stars for different significance levels (show.signif.stars=FALSE), to turn off scientific notation for the output (scipen=30), and to set the width of the text output at the console to 120 characters. The later option can be re-specified with the text_width option. After Regression is finished with a normal termination, the options are re-set to their values before the Regression function began executing.

**COLOR THEME**

A color theme for all the colors can be chosen for a specific plot with the colors option. Or, the color theme can be changed for all subsequent graphical analysis with the lessR function style. The default color theme is lightbronze, but a gray scale is available by removing the bronze background, such as with style(window_fill="white") or with "gray". Other themes are available as explained in style.

**VARIABLE LABELS**
If variable labels exist, then the corresponding variable label is by default listed as the label for the horizontal axis and on the text output. For more information, see Read.

Value

The output can optionally be returned and saved into an R object, otherwise it simply appears at the console. The components of this object are redesigned in lessR version 3.3 into (a) pieces of text that form the readable output and (b) a variety of statistics. The readable output are character strings such as tables amenable for viewing and interpretation. The statistics are numerical values amenable for further analysis, such as to be referenced in a subsequent knitr document. The motivation of these two types of output is to facilitate knitr documents, as the name of each piece, preceded by the name of the saved object followed by a $\$$, can be inserted into the knitr document (see examples).

TEXT OUTPUT
- out_background: variables in the model, rows of data and retained
- out_estimates: estimated coefficients, hypothesis tests and confidence intervals
- out_fit: fit indices; st dev of residuals; R-sq with adj and PRESS versions
- out_anova: analysis of variance
- out_cor: correlations among all variables in the model
- out_collinear: collinearity analysis
- out_subsets: R squared adjusted for all (or many) possible subsets
- out_residuals: residuals
- out_predict: analysis of residuals and influence
- out_ref: references if selected on the Regression function call
- out_Rmd: lists the name and location of the generated Rmd file
- out_plots: list of plots generated if more than one
- out_suggest: list of suggested other analyses

Separated from the rest of the text output are the major headings, which can be not included with custom collations of the output.

out_title_bck: BACKGROUND
out_title_basic: BASIC ANALYSIS
out_title_rel: RELATIONS AMONG THE VARIABLES
out_title_res: ANALYSIS OF RESIDUALS AND INFLUENCE
out_title_pred: FORECASTING ERROR

STATISTICS
- call: function call that generated the analysis
- formula: model formula that specifies the model
- n.vars: number of variables in the model
- n.obs: number of rows of data submitted for analysis
- n.keep: number of rows of data retained in the analysis
- coefficients: estimated regression coefficients
- sterrs: standard errors of the estimated coefficients
- tvalues: t-values of the estimated coefficients for null of 0
- pvalues: p-values from the t-tests of the estimated coefficients
- cilb: lower bound of 95% confidence interval of estimate
- ciub: upper bound of 95% confidence interval of estimate
- anova_model: model df, ss, ms, F-value and p-value
**Regression**

**anova_residual**: residual df, ss and ms  
**anova_total**: total df, ss and ms  
**se**: standard deviation of the residuals  
**resid_range**: 95% range of normally distributed fitted residuals  
**Rsq**: R-squared  
**Rsqadj**: adjusted R-squared  
**PRESS**: PRESS sum of squares  
**RsqPRESS**: PRESS R-squared  
**m_se**: K-fold average of the standard deviation of residuals.  
**m_MSE**: K-fold average of the MSE.  
**m_Rsq**: K-fold average of R-squared.  
**cor**: correlation matrix of all variables in the model  
**tolerances**: tolerance of each predictor variable for collinearity analysis  
**VIF**: variance inflation factor for each predictor variable  
**resid.max**: five largest values of the residuals on which the output is sorted  
**pred_min_max**: Rows with the smallest and largest prediction intervals  
**residuals**: residuals  
**fitted**: fitted values  
**cooks.distance**: Cook’s distance  
**model**: data retained for the analysis  
**terms**: terms specified for the analysis

Although not typically needed for analysis, if the regression output is assigned to an object named, for example, `r`, then the complete contents of the object can be viewed directly with the `unclass` function, here as `unclass(r)`. Invoking the `class` function on the saved object reveals a class of `out_all`. The class of each of the text pieces of output is `out`.

# Indicator (dummy) variable
#d <- Read("Employee", quiet=TRUE)
#reg(Salary ~ Dept)
**View the Upper and Left Corners of a Data Frame**

**Description**

Useful for large data frame. View the top-left corner of the specified data frame and the bottom-right corner of the data frame.

**Usage**

```r
see(data, n_row=min(nrow(data), 5), n_col=min(ncol(data), 8))
```

**Arguments**

- `data` Name of the data frame to view.
- `n_row` Number of rows to view.
- `n_col` Number of columns to view.

**Details**

For the specified number of rows and columns, just view the subset of the data frame in terms of the top-left and the bottom-right.

**Value**

The subset data frame.

**Author(s)**

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

**See Also**

`Extract`

**Examples**

```r
d <- Read("Employee", quiet=TRUE)

# view the default top-left and bottom-right four rows and eight columns
see(d)

# view the top-left two rows and bottom-right four columns
see(d, n_row=2, n_col=2)
```
showColors

Display All Named R Colors and Corresponding rgb Values

Description

For each specified color, displays the color, the name and the associated rgb definition.

Usage

showColors(file="colors.pdf", color=NULL)

Arguments

file Name of pdf file that contains the list of colors with a default of colors.pdf.
color NULL for all colors, otherwise specify a color and all colors which include that color as part of their name are displayed.

Details

Every color name is defined in terms of a red, a green and a blue component. This function lists the rgb definitions for the specified colors, as well as the name and a display of each color. The output should be routed to an external pdf file for storage. The directory and file name of the output file are displayed.

Author(s)

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

Examples

# all colors
#showColors()

# all colors with 'blue' in their name
#showColors(file="theblues.pdf", color="blue")

showPalettes

Display Color Palettes

Description

For each specified set of palettes display each in the set.

Usage

showPalettes(palette="hcl", n=12, border="transparent", file=NULL)
Arguments

- **palette**: Name of the palette.
- **n**: Number of colors per palette with a default of 12.
- **border**: Border between intervals. By default is off.
- **file**: Name of pdf file that contains the list of colors with a default of the name of the palette. Default is name of palette with a .pdf filetype.

Details

Available palettes are "hcl" for sequential palettes for each of 12 hues across the hcl color wheel in 30 degree intervals plus the qualitative scale of different hues and grayscale, "viridis", and "wesanderson".

Author(s)

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

Examples

```r
# all hcl palettes based on each hue from 30 degrees of the color wheel,
# including "colors" and "grays"
# default is 12 colors per palette
#showPalettes()

# viridis palate, simulate continuity
#showPalettes("viridis", n=500, border="off")
```

Description

Show a sequence of confidence intervals, all calculated from repeated samples of simulated data from the same normal population, and show which intervals contain the true population mean.

Usage

```r
simCImean(ns, n, mu=0, sigma=1, cl=0.95, seed=NULL,
    show_data=FALSE, show_title=TRUE,
    miss_only=FALSE, color_hit="gray40", color_miss="red",
    grid="grey90", ylim_bound=NULL, pause=FALSE,
    main=NULL, pdf_file=NULL, width=5, height=5, ...)
```
**Arguments**

- `ns` Number of samples, that is, repetitions of the experiment.
- `n` Size of each sample.
- `mu` Population mean.
- `sigma` Population standard deviation.
- `cl` Confidence level.
- `seed` Default seed is the R default. Enter a positive integer value to obtain a reproducible result, the same result for the same seed.

- `show_data` Plot the data for each sample over the confidence interval.
- `show_title` Place a title on the graph that contains the parameter values.
- `miss_only` For the text output, only display information for samples that missed the mean.
- `color_hit` Color of the confidence intervals that contains the mean.
- `color_miss` Color of the confidence intervals that miss the mean.
- `grid` Color of the grid lines.
- `ylim_bound` Specify the maximum deviation of the mean in either direction for the extent of the vertical axis.
- `pause` Build the graph and the text output, pausing after each confidence interval.
- `main` Title of graph.

- `pdf_file` Name of optional pdf file to which graphics are redirected.
- `width` Width of the pdf file in inches.
- `height` Height of the pdf file in inches.

... Other parameter values.

**Details**

Simulate random normal data and display the resulting confidence intervals, with or without the data overlaid on each confidence interval. Highlight confidence intervals that miss the underlying population mean.

**Author(s)**

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

**Examples**

```r
# 25 confidence intervals with a sample size each of 100
# mu=0, sigma=1, that is, sample from the standard normal
simCImean(25, 100)

# set the seed for a reproducible result with the same seed
```

"simCImean"
simCImean(25, 100, seed=43)

# 25 confidence intervals with a sample size each of 100
# mu=100, sigma=15
# overlay the data over each confidence interval
simCImean(25, 100, mu=100, sigma=15, show_data=TRUE)

---

**Description**

Show the distribution of sample means and relevant summary statistics, such as the 95% range of variation. Provide a plot of both the specified population and the corresponding distribution of sample means.

**Usage**

```r
simCLT(ns, n, p1=0, p2=1, seed=NULL,
        type=c("normal", "uniform", "lognormal", "antinormal"),
        fill="lightsteelblue3", n_display=0, digits_d=3,
        subtitle=TRUE, pop=TRUE,
        main=NULL, pdf=FALSE, width=5, height=5, ...)
```

**Arguments**

- `ns` Number of samples, that is, repetitions of the experiment.
- `n` Size of each sample.
- `p1` First parameter value for the population distribution, the mean, minimum or meanlog for the normal, uniform, and lognormal populations, respectively. Must be 0, the minimum, for the anti-normal distribution.
- `p2` Second parameter value for the population distribution, the standard deviation, maximum or sdlog for the normal, uniform and lognormal populations, respectively. Is the maximum for the anti-normal, usually left at the default value of 1.
- `seed` Default seed is the R default. Enter a positive integer value to obtain a reproducible result, the same result for the same seed.
- `type` The general population distribution.
- `fill` Fill color of the graphs.
- `n_display` Number of samples for which to display the sample mean and data values.
- `digits_d` Number of decimal digits to display on the output.
- `subtitle` If TRUE, then display the specific parameter values of the population or sample, depending on the graph.
simCLT

pop If TRUE, then display the graph of the population from which the data are sampled.
main Title of graph.
pdf Indicator as to if the graphic files should be saved as pdf files instead of directed to the standard graphics windows.
width Width of the pdf file in inches.
height Height of the pdf file in inches.

... Other parameter values for R function lm which provides the core computations.

Details

Provide a plot of both the specified population and the corresponding distribution of sample means. Include descriptive statistics including the 95% range of sampling variation in raw units and standard errors for comparison to the normal distribution. Also provide a few samples of the data and corresponding means.

Four different populations are provided: normal, uniform, lognormal for a skewed distribution, and what is called the anti-normal, the combining of two side-by-side triangular distributions so that most of the values are in the extremes and fewer values are close to the middle.

For the lognormal distribution, increase the skew by increasing the value of p2, which is the population standard deviation.

The anti-normal distribution requires the triangle package. No population mean and standard deviation are provided for the anti-normal distribution, so the 95% range of sampling variable of the sample mean in terms of standard errors is not provided. ** Not activated until the triangle package is updated. **

If the two plots, of the population and sample distributions respectively, are written to pdf files, according to pdf=TRUE, they are named SimPopulation.pdf and SimSample.pdf. Their names and the directory to which they are written are provided as part the console output.

Author(s)

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

Examples

# plot of the standardized normal
# and corresponding sampling distribution with 10000 samples
# each of size 2
simCLT(ns=1000, n=2)

# plot of the uniform dist from 0 to 4
# and corresponding sampling distribution with 10000 samples
# each of size 2
simCLT(ns=1000, n=2, p1=0, p2=4, type="uniform", bin_width=0.01)

# save the population and sample distributions to pdf files
# simCLT(100, 10, pdf=TRUE)
**Description**

Simulate a sequence of coin flips.

**Usage**

```r
simFlips(n, prob=.5, seed=NULL,
         show_title=TRUE, show_flips=TRUE,
         grid="grey90", pause=FALSE,
         main=NULL, pdf_file=NULL, width=5, height=5, ...)
```

**Arguments**

- `n`: Size of each sample, that is, the number of trials or flips.
- `prob`: Probability of a success on any one trial.
- `seed`: Default seed is the R default. Enter a positive integer value to obtain a reproducible result, the same result for the same seed.
- `show_title`: Place a title on the graph that contains the parameter values.
- `show_flips`: Plot the outcome of each flip.
- `grid`: Color of the grid lines.
- `pause`: Build the graph and the text output, pausing after each confidence interval.
- `main`: Title of graph.
- `pdf_file`: Name of the pdf file to which graphics are redirected.
- `width`: Width of the pdf file in inches.
- `height`: Height of the pdf file in inches.
- `...`: Other parameter values.

**Details**

Generate and plot successive values of a Head or a Tail using standard R `rbinom` function.

**Author(s)**

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)
Examples

# 10 flips of a fair coin
simFlips(10, .5)

# set the seed for a reproducible result with the same seed
simFlips(10, .5, seed=43)

Description

Show a sequence of sample means and data, all simulated from the same normal population. Useful for developing an intuition for developing an informal confidence interval, that is, specifying a likely range of values that contain the true population mean, but without a formal probability.

Usage

simMeans(ns, n, mu=0, sigma=1, seed=NULL, show_title=TRUE, show_data=TRUE, max_data=10, grid="grey90", ylim_bound=NULL, pause=FALSE, sort=NULL, set_mu=FALSE, digits_d=2, main=NULL, pdf_file=NULL, width=5, height=5, ...)

Arguments

ns Number of samples, that is, repetitions of the experiment.
n Size of each sample.
mu Population mean.
sigma Population standard deviation.
seed Default seed is the R default. Enter a positive integer value to obtain a reproducible result, the same result for the same seed.
show_title Place a title on the graph that contains the parameter values.
show_data Show the data values on the text output.
max_data Maximum number of data values per sample on the text output.
grid Color of the grid lines.
ylim_bound Specify the maximum deviation of the mean in either direction for the extent of the vertical axis.
pause Build the graph and the text output sample by sample.
sort Sort the output by the means in ascending order. By default is TRUE unless se.mu or pause is TRUE.
set_mu Have the program randomly set \( \mu \) and \( \sigma \), usually to guess the correct value.
digits_d Sort the output by the means in ascending order.
main Title of graph.

pdf_file Name of the pdf file to which graphics are redirected.
width Width of the pdf file in inches.
height Height of the pdf file in inches.
... Other parameter values.

Details

Simulate random normal data and display the resulting sample means, both as text output and graphic output.

If \( \text{pause}=\text{TRUE} \), then the true population values are not revealed as the simulation progresses. These values are saved in the user's workspace and can be revealed by entering their names at the user prompt, \( \mu \) and \( \sigma \).

Author(s)

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

Examples

```
# 8 samples, each with a sample size of 10
# \( \mu=0, \sigma=1 \), that is, sample from the standard normal
simMeans(8, 10)

# 25 sample means with a sample size each of 100
# \( \mu=100, \sigma=15 \)
# pause after each interval and show the data
simMeans(25, 100, mu=100, sigma=15, show_data=FALSE)
```

Description

Abbreviation: srt

Sorts the values of a data frame according to the values of one or more variables contained in the data frame, or the row names. Variable types include numeric and factor variables. Factors are sorted by the ordering of their values, which, by default is alphabetical. Sorting by row names is also possible.
Usage

Sort(data=d, by, direction=NULL, quiet=getOption("quiet"), ...)  
srt(...)  

Arguments

data  The name of the data frame from which to create the subset, which is d by default.
by  One or more variables to be sorted, or just the character string row.names or random.
direction  Default is ascending for all variables listed in by. Or, specify a list of "+" for ascending and "-" for descending, one for each variable to be sorted.
quiet  If set to TRUE, no text output. Can change system default with style function.
...  Parameter values

Details

Sort sorts the rows of a data frame and lists the first five rows of the sorted data frame. Specify the values upon which to base the sort with the required by parameter. If not all sorted variables are sorted in ascending order, then also specify a sequence of "+" for ascending and "-" for descending, respectively, one for each variable to be sorted. If row.names or random is specified, then no other variables can be specified.

A list of consecutive variables can be specified using the colon notation, such as Years:Salary To specify a list of multiple variables, or "+" and "-" signs, or sets of variables, separate each set of variables or each sign by a comma, then invoke the R combine or c function. For example, if three variables are to be sorted, the first two ascending and the last descending, then specify, direction=c("+","+","-").

Sort is based on the standard R function order, though the Sort function allows for the sorting of factors, whereas order does not.

Value

The sorted data frame is returned, usually assigned the name of d as in the examples below. This is the default name for the data frame input into the lessR data analysis functions.

Author(s)

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

order.
Examples

# construct data frame
d <- read.table(text="Severity Description
  1 Mild
  4 Moderate
  3 Moderate
  2 Mild
  1 Severe", header=TRUE)

# sort the data frame called d according to Severity
# in ascending order
d <- Sort(d, Severity)

# abbreviated form, replace original with sorted
d <- srt(d, Severity)

# sort Description in descending order, sort Severity within
# each level of Description in ascending order
d <- Sort(d, c(Description, Severity), direction=c("-", "+"))

# data in a different data frame than d
d <- Read("Employee")
d <- Sort(d, Gender)

# sort by row names in ascending order
d <- Sort(d, row.names)

# randomly re-shuffle the rows of data
d <- Sort(d, random)

---

style

Set the Default Color Theme and Other System Settings

Description

Deprecated Names: set, theme

The color and style attributes of each plot can be set as a general theme, or individually set from the following list of attributes. For convenience, groups of these attributes are specified to define color themes, plus style sub-themes that apply to any theme, with default values: theme="lightbronze" and sub_theme="default". To reset to the default theme: style().

Usage

style(
  theme=c("colors", "lightbronze", "dodgerblue", "darkred", "gray",
     "gold", "darkgreen", "blue", "red", "rose", "green", "purple",
     "sienna", "brown", "orange", "white", "light"),
  sub_theme=c("default", "black", "wsj"),
)
set=NULL, get=FALSE, reset=TRUE,

window_fill=getOption("window_fill"),
panel_fill=getOption("panel_fill"),
panel_color=getOption("panel_color"),
panel_lwd=getOption("panel_lwd"),
panel_lty=getOption("panel_lty"),

width=120, show=FALSE, ...)

set(...)
color  
Color of a line segment such as the border of bar or point. Can explicitly choose  
"grays" or "hues", or pre-specified R color schemes "rainbow", "terrain",  
and "heat". Can also provide pre-defined color ranges "blues", "reds" and  
"greens", as well as custom colors, such as generated by getColors  

bar_color  
Color of the border of a filled region such as a histogram bar.  

bar_color_discrete  
Color of the border of a filled region for values on a qualitative scale.  

bar_color_ordered  
Color of the border of a filled region for values on a quantitative scale, such as a  
histogram bar.  

values  
If not the default value of "off", adds the numerical results to the plot according  
to "%", "prop" or "input", that is, percentages, proportions, or the value from  
which the slices are plotted, such as tabulated counts if y is not specified, or the  
value of y if the plotted values are provided. If any other values parameter is  
specified, default is set to "%".  

values_color  
Color of the plotted text. Could be a vector to specify a unique color for each  
value. If fewer colors are specified than the number of categories, the colors are  
recycled.  

values_size  
Character expansion factor, the size, of the plotted text, for which the default  
value is 0.95.  

values_digits  
Number of decimal digits for which to display the values. Default is 0, round to  
the nearest integer, for "%" and 2 for "prop".  

values_position  
Position of the plotted text. Default is inside the pie, or, if "label", as part of  
the label for each value outside of the pie.  

pt_fill  
Color of a filled plotted point.  

trans_pt_fill  
The transparency of the inner region of a plotted point. Value from 0 to 1, opaque  
to transparent.  

pt_color  
Color of a line or outline of a filled region, such as the border of a plotted point.  

se_fill  
Color of the fill for the standard error plot about a fit line in a scatter plot.  

ellipse_fill  
Color of the fill for an ellipse in a scatter plot.  

ellipse_color  
Color of the border for an ellipse in a scatter plot.  

ellipse_lwd  
Line width of the border for an ellipse in a scatter plot.  

fit_color  
Color of the fit line in a scatter plot.  

fit_lwd  
Width of fit line. By default is 2 for Windows and 1.5 for Mac.  

bubble_text_color  
Color of the displayed text regarding the size of a bubble, either a tabulated  
frequency for categorical variables, or the value of a third variable according to  
size.  

segment_color  
Color of connecting line segments when there are also plotted points, such as in  
a frequency polygon. Default color is color.
ID_color  Color of the text to display the ID labels.
out_fill  For a scatterplot, color of the border of potential outliers, which, for the unadjusted boxplot, are default values 1.5 IQR’s beyond the lower or upper quartile.
out_color  For a scatterplot, color of potential outliers.
out2_fill  For a scatterplot, color of extreme outliers, which, for the unadjusted boxplot, are default values 3 IQR’s beyond the lower or upper quartile.
out2_color  For a scatterplot, color of the border of extreme outliers.

violin_fill  Fill color for a violin plot.
violin_color  Border color for the violin in a violin plot.
box_fill  Fill color for a box plot.
box_color  Border color of a box in a box plot.

axis_color  Color of the axes.
axis_x_color  Color of the x-axis.
axis_y_color  Color of the y-axis.
axis_lwd  Line width of axes.
axis_x_lwd  Line width of horizontal axis.
axis_y_lwd  Line width of vertical axis.
axis_lty  Line type of axes, either "solid", "dashed", "dotted", "dotdash", "longdash", "twodash", or "blank".
axis_x_lty  Line type of horizontal axis.
axis_y_lty  Line type of vertical axis.
axis_cex  Scale magnification factor, which by defaults displays the axis values to be smaller than the axis labels. Provides the functionality of, and can be replaced by, the standard R cex.axis.
axis_x_cex  Scale magnification factor for the x-axis.
axis_y_cex  Scale magnification factor for the y-axis.
axis_text_color  Color of the font used to label the axis values.
axis_x_text_color  Color of the font used to label the x-axis values.
axis_y_text_color  Color of the font used to label the y-axis values.
rotate_x  Degrees that the x-axis values are rotated, usually to accommodate longer values, typically used in conjunction with offset.
rotate_y  Degrees that the y-axis values are rotated.
offset  The spacing between the axis values and the axis. Default is 0.5. Larger values such as 1.0 are used to create space for the label when longer axis value names are rotated.
lab_color  Color of the axis labels.
lab_x_color  Color of the axis labels on the horizontal axis.
lab_y_color  Color of the axis labels on the vertical axis.
lab_cex  Size of labels for x and y axes.
lab_x_cex  Size of labels for x.
lab_y_cex  Size of labels for y.
maint_color  Color of the title.
maint_cex  Size of the title font.

grid_color  Color of the grid lines.
grid_x_color  Color of the grid lines for the x-axis.
grid_y_color  Color of the grid lines for the y-axis.
grid_lwd  Width of grid lines.
grid_x_lwd  Width of vertical grid lines, inherits from grid_lwd.
grid_y_lwd  Width of horizontal grid lines, inherits from grid_lwd.
grid_lty  Line type for grid lines: "solid", "dashed", "dotted", "dotdash", "longdash", or "twodash", or "blank".
grid_x_lty  Line-type of vertical grid lines, inherits from grid_lty.
grid_y_lty  Line-type of horizontal grid lines, inherits from grid_lty.

strip_fill  Fill color for the **strip that labels each panel** in a Trellis plot.
strip_color  Border color for the strip that labels each panel in a Trellis plot.
strip_text_color  Color of the label in each strip of a Trellis plot.

add_fill  Interior fill color of added object. Can explicitly choose "grays" or "hues", or pre-specified R color schemes "rainbow", "terrain", and "heat". Can also provide pre-defined color ranges "blues", "reds" and "greens", as well as custom colors, such as generated by getColors.
add_trans  Transparency level of color or fill, which ever is applicable from 0 (opaque) to 1 (transparent).
add_color  Color of borders and lines of added object.
add_cex  Text expansion factor, relative to 1. As with the following properties, can be a vector for multiple placement or objects.
add_lwd  Line width of added object.
add_lty  Line type of added object. See panel_lty for types.

n_cat  Number of categories that specifies the largest number of unique equally-spaced values of variable of a numeric data type for which the variable will be analyzed as categorical. Applies to ScatterPlot and SummaryStats, and also to the functions such as Histogram when processing multiple graphs.
suggest  If TRUE, then provide suggestions for alternative analyses.
quiet   If TRUE then some functions suppress console output.
brief   If set to TRUE, reduced text output.

results For the R markdown file generated by the Rmd option, show the results.
explain For the R markdown file generated by the Rmd option, explain the results.
interpret For the R markdown file generated by the Rmd option, interpret the results.
document For the R markdown file generated by the Rmd option, documents the code that generated the results.

code For the R markdown file generated by the Rmd option, shows the code that generated the results.

width Maximum width of each line displayed at the console, just accesses the standard R options function for width.
show Option for showing all settings.
...
... Parameter values_

Details

OVERVIEW
Sets the default color palette via the R options statement, as well as the transparency of plotted bars and points and other non-color characteristics such as the color of the grid lines. For convenience, groups of attributes are organized into themes and sub-themes. When the theme is specified, all options are reset to their default values. All other modifications, with individual parameters or grouped parameters as a sub-theme, are cumulative. For example, one sub-theme can be followed by another, as well as the specifications of individual attributes. Calling the function with no arguments sets to the default style.

Available themes:
"lightbronze" [default]
"dodgerblue" [default lessR 3.6.0 and earlier]
"darkred"
"gray"
"gold"
"darkgreen"
"blue"
"red"
"rose"
"green"
"purple"
"sienna"
"brown"
"orange"
"white"
"light"
The "gray" color theme is based on the colors used in Hadley Wickham’s ggplot2 package. The "lightbronze" theme, especially with the wsj sub-theme, is based on Jeffrey Arnold’s wsj theme from his ggthemes package.

SUB-THEMES
"black": Black background of the entire device window with translucent fill colors from the current theme. "wsj": Similar to the wsj theme from the ggthemes package, especially with the theme of "lightbronze". The y-axis is removed with though the value labels retained, the vertical grid is removed, and the horizontal grid is dotted and thicker than the default.

Value

The current settings can optionally be saved into an R object, and then read back at a later time with the set function.

Examples

```r
# some data
d <- rd("Employee", quiet=TRUE)

# gold colors embedded in a black background
style("gold", sub_theme="black")
Plot(Years, Salary, size=0, ellipse=seq(.1,.9,.1))

# three ways to do gray scale
style(window_fill="white")
# 1. gray scale with a light gray background
style("gray")
# 2. gray scale with a dark, almost black, background
style("gray", sub_theme="black")
# 3. mostly black and white
style("white")

# reset style to the default "colors"
```

style()

# set bar fill to qualitative hcl colors
# here also turn off bar borders and set to a mild transparency
Histogram(Salary, fill="greens", color="off")
# same as
# style(bar_fill_ordered="greens", bar_color="off")
# Histogram(Salary)

# set bar fill to 6 blue colors
# for continuous band explicitly call getColors and specify n
# to obtain the full spectrum, such as for analysis of Likert
# scale responses with six possible responses per item
style(bar_fill=getColors("blues", n=6))

# adjust Trellis strip to a dark background
style(strip_fill="gray60", strip_color="gray20",
      strip_text_color=rgb(247,242,230, maxColorValue=255))
Plot(Years, Salary, by1=Gender)

# define a custom style beyond just colors
style(panel_fill="off", panel_color="off",
      window_fill=rgb(247,242,230, maxColorValue=255),
      pt_fill="black", trans=0,
      lab_color="black", axis_text_color="black",
      axis_y_color="off",
      grid_x_color="off", grid_y_color="black", grid_lty="dotted", grid_lwd=1)
hs(Salary)

# save the current theme settings into an R object without changes
# unless set to FALSE, get is always TRUE, for all calls to style
mystyle <- style(get=TRUE)
# ... bunch of changes
# then recall older settings to current theme setting
style(set=mystyle)

# create a gray-scale with a sub-theme of wsj
# save, and then at a later session read back in
grayWSJ <- style("gray", sub_theme="wsj")

# ...
#mystyle <- Read("grayWSJ.rda") # read grayWSJ.rda
#style(set=mystyle)

# all numeric variables with 8 or less unique values and equally spaced
# intervals are analyzed as categorical variables
style(n_cat=8)
Subset

Description

Abbreviation: subs

Based directly on the standard R subset function to only include or exclude specified rows or data, and for specified columns of data. Output provides feedback and guidance regarding the specified subset operations. Rows of data may be randomly extracted, and also with the code provided to generate a hold out validation sample created. The hold out sample is created from the original data frame, usually named d, so the subset data frame must be directed to a data frame with a new name or the data re-read to construct the holdout sample. Any existing variable labels are retained in the subset data frame.

Usage

Subset(rows, columns, data=d, holdout=FALSE, random=0, quiet=getOption("quiet"), ...) 
subs(...)

Arguments

rows Specify the rows, i.e., observations, to be included or deleted, such as with a logical expression or by direct specification of the numbers of the corresponding rows of data.
columns Specify the columns, i.e., variables, to be included or deleted.
data The name of the data frame from which to create the subset, which is d by default.
holdout Create a hold out sample for validation if rows is a proportion or an integer to indicate random extraction of rows of data.
random If an integer or proportion, specifies number of rows to data to randomly extract.
quiet If set to TRUE, no text output. Can change system default with style function.
... The list of variables, each of the form, variable = equation. Each variable can be the name of an existing variable in the data frame or a newly created variable.

Details

Subset creates a subset data frame based on one or more rows of data and one or more variables in the input data frame, and lists the first five rows of the revised data frame. Guidance and feedback regarding the subsets are provided by default. The first five lines of the input data frame are listed before the subset operation, followed by the first five lines of the output data frame.

The argument rows can be a logical expression based on values of the variables, or it can be an integer or proportion to indicate random extraction of rows. An integer specifies the number of rows to retain, and a proportion specifies the corresponding proportion, which is then rounded to an integer. If holdout=TRUE, then the code to create a hold out data frame with a subsequent Subset analysis is also created. Copy and run this code on the original data frame to create the hold out sample.
To indicate retaining an observation, specify at least one variable name and the value of the variable for which to retain the corresponding observations, using two equal signs to indicate the logical equality. If no rows are specified, all rows are retained. Use the base R `row.names` function to identify rows by their row names, as illustrated in the examples below.

To indicate retaining a variable, specify at least one variable name. To specify multiple variables, separate adjacent variables by a comma, and enclose the list within the standard R combine function, `c`. A single variable may be replaced by a range of consecutive variables indicated by a colon, which separates the first and last variables of the range. To delete a variable or variables, put a minus sign, `-`, in front of the `c`.

**Value**

The subset of the data frame is returned, usually assigned the name of `d` as in the examples below. This is the default name for the data frame input into the `lessR` data analysis functions.

`subset`, `factor`.

**Examples**

```r
# construct data frame
d <- read.table(text="Severity Description
  1 Mild
  4 Moderate
  3 Moderate
  2 Mild
  1 Severe",
header=TRUE)
# only include those with a value of Moderate for Description
d <- Subset(rows=Description="Moderate")
# use abbreviation and do not need the rows= for the first argument
d <- subs(Description="Moderate")
# locate, that is, display only, the 2nd and 4th rows of data
Subset(row.names(d)=="2" | row.names(d)=="4")
# retain only the first and fourth rows of data, store in myd
myd <- Subset(c(1,4))
# delete only the first and fourth rows of data, store in myd
myd <- Subset(-c(1,4))
# built-in data table warpbreaks has several levels of wool
# and breaks plus continuous measure tension
# retain only the A level of wool and the L level of tension,
# and the one variable breaks
```
SummaryStats

Summary Statistics for One or Two Variables

Description

Abbreviation: ss, ss.brief

Descriptive or summary statistics for a numeric variable or a factor, one at a time or for all numeric and factor variables in the data frame. For a single variable, there is also an option for summary statistics at each level of a second, usually categorical variable or factor, with a relatively few number of levels. For a numeric variable, output includes the sample mean, standard deviation, skewness, kurtosis, minimum, 1st quartile, median, third quartile and maximum, as well as the number of non-missing and missing values. For a categorical variable, the output includes the table of counts for each value of a factor, the total sample size, and the corresponding proportions.

If the provided object to analyze is a set of multiple variables, including an entire data frame, then each non-numeric variable in the data frame is analyzed and the results written to a pdf file in the current working directory. The name of each output pdf file that contains a bar chart and its path are specified in the output.

When output is assigned into an object, such as s in s <- ss(Y), the pieces of output can be accessed for later analysis. A primary such analysis is knitr for dynamic report generation in which R output embedded in documents See value below.

Usage

SummaryStats(x=NULL, by=NULL, data=d, rows=NULL, n_cat=getOption("n_cat"), digits_d=NULL, brief=getOption("brief"), label_max=20, ...)

ss.brief(..., brief=TRUE)
ss_brief(..., brief=TRUE)
ss(...)

d <- Subset(wool=="A" & tension=="L", columns=breaks, data=warpbreaks)

# delete Years and Salary
d <- Read("Employee", quiet=TRUE)
d <- Subset(columns=-c(Years, Salary))

# locate, display only, a specified row by its row.name
d <- Read("Employee", quiet=TRUE)
Subset(row.names(d)=="Fulton, Scott")

# randomly extract 60% of the data
# generate code to create the hold out sample of the rest
d <- Read("Employee", quiet=TRUE)
mysubset <- Subset(random=.6, holdout=TRUE)
Arguments

- **x**
  Variable(s) to analyze. Can be a single variable, either within a data frame or as a vector in the user’s workspace, or multiple variables in a data frame such as designated with the `c` function, or an entire data frame. If not specified, then defaults to all variables in the specified data frame, `d` by default.

- **by**
  Applies to an analysis of a numeric variable, which is then analyzed at each level of the `by` variable. The variable is coerced to a factor.

- **data**
  Optional data frame that contains the variable of interest, default is `d`.

- **rows**
  A logical expression that specifies a subset of rows of the data frame to analyze.

- **n_cat**
  Specifies the largest number of unique values of variable of a numeric data type for which the variable will be analyzed as a categorical. Default is off, set to 0.

- **digits_d**
  Specifies the number of decimal digits to display in the output.

- **brief**
  If set to `TRUE`, reduced text output. Can change system default with `style` function.

- **label_max**
  Maximum size of labels for the values of a variable. Not a literal maximum as preserving unique values may require a larger number of characters than specified.

- **...**
  Further arguments to be passed to or from methods.

Details

**OVERVIEW**

The `by` option specifies a categorical variable or factor, with a relatively few number of values called levels. The variable of interest is analyzed at each level of the factor.

The `digits_d` parameter specifies the number of decimal digits in the output. It must follow the formula specification when used with the formula version. By default the number of decimal digits displayed for the analysis of a variable is one more than the largest number of decimal digits in the data for that variable.

Reported outliers are based on the boxplot criterion. The determination of an outlier is based on the length of the box, which corresponds, but may not equal exactly, the interquartile range. A value is reported as an outlier if it is more than 1.5 box lengths away from the box.

Skewness is computed with the usual adjusted Fisher-Pearson standardized moment skewness coefficient, the version found in many commercial packages.

The `lessR` function `Read` reads the data from an external csv file into the data frame called `d`. To describe all of the variables in a data frame, invoke `SummaryStats(d)`, or just `SummaryStats()`, which then defaults to the former.

In the analysis of a categorical variable, if there are more than 10 levels then an abbreviated analysis is performed, only reporting the values and the associated frequencies. If all the values are unique, then the user is prompted with a note that perhaps this is actually an ID field which should be specified using the `row.names` option when reading the data.

**DATA**

If the variable is in a data frame, the input data frame has the assumed name of `d`. If this data frame is named something different, then specify the name with the `data` option. Regardless of its name,
the data frame need not be attached to reference the variable directly by its name, that is, no need to invoke the $name notation.

To analyze each variable in the d data frame, use SummaryStats(). Or, for a data frame with a different name, insert the name between the parentheses. To analyze a subset of the variables in a data frame, specify the list with either a : or the c function, such as m01:m03 or c(m01,m02,m03).

VARIABLE LABELS
If variable labels exist, then the corresponding variable label is by default listed as the label for the horizontal axis and on the text output. For more information, see Read.

ONLY VARIABLES ARE REFERENCED
The referenced variable in a lessR function can only be a variable name. This referenced variable must exist in either the referenced data frame, such as the default d, or in the user’s workspace, more formally called the global environment. That is, expressions cannot be directly evaluated. For example:

```r
> SummaryStats(rnorm(50)) # does NOT work
```

Instead, do the following:

```r
> Y <- rnorm(50) # create vector Y in user workspace
> SummaryStats(Y) # directly reference Y
```

Value

The output can optionally be saved into an R object, otherwise it simply appears in the console. Redesigned in lessR version 3.3 to provide two different types of components: the pieces of readable output in character format, and a variety of statistics. The readable output are character strings such as tables amenable for reading. The statistics are numerical values amenable for further analysis. A primary motivation of these two types of output is to facilitate knitr documents, as the name of each piece can be inserted into the knitr document.

If the analysis is of a single numeric variable, the full analysis returns the following statistics: n, miss, mean, sd, skew, kurtosis, min, quartile1, median, quartile3, max, IQR. The brief analysis returns the corresponding subset of the summary statistics. If the analysis is conditioned on a by variable, then nothing is returned except the text output. The pieces of readable output are out_stats and out_outliers.

If the analysis is of a single categorical variable, a list is invisibly returned with two tables, the frequencies and the proportions, respectively named freq and prop. The pieces of readable output are out_title and out_stats.

If two categorical variables are analyzed, then for the full analysis four tables are returned as readable output, but no numerical statistics. The pieces are out_title, out_freq, out_prop, out_colsum, out_rowsum.

Although not typically needed, if the output is assigned to an object named, for example, s, as in s <-ss(Y), then the contents of the object can be viewed directly with the unclass function, here as unclass(s).

SummaryStats(Travel)
Create a Sequence of Numbered Variable Names with a Common Prefix and Width

Description

Generates sequentially numbered variable names, all starting with the same prefix, usually in conjunction with reading data values into R. The advantage over the standard R function `paste0` is that it maintains equal widths of the names, such as `m08` instead of `m8` if some values are `m10` or larger up to `m99`.

Usage

to(prefix, until, from=1, same.size=TRUE)

Arguments

- prefix: Character string that begins each variable name.
- until: Last name in the sequence, the one with the last number.
- from: First name in the sequence, the one with the initial number.
- same.size: If TRUE, pads the beginning of each number for the variable name with leading zeros so that all names are of the same width.

Details

Some data sets, particularly those from surveys, have sequentially numbered variable names, each beginning with the same prefix, such as the first later of the name of a set of related attitude items. This function generates the string of such variable names, generally intended for use in a `read` statement for reading the data and then naming the variables, or for a subsequent assignment of the names with a `names`. Relies upon the R `paste` function.

`paste`.

Examples

```
# generate: "m01" "m02" "m03" "m04" "m05" "m06" "m07" "m08" "m09" "m10"
to("m", 10)

# generate: "m1" "m2" "m3" "m4" "m5" "m6" "m7" "m8" "m9" "m10"
to("m", 10, same.size=FALSE)
# equivalent to standard R function
```
```
paste0("m", 1:10)

# generate a 10 x 10 data frame
d <- data.frame(matrix(rnorm(100), nrow=10))
# name the variables in the data frame
names(d) <- to("m", 10)
```

---

### Transform

**Transform the Values of an Integer or Factor Variable**

#### Description

Abbreviation: `trans`

A wrapper for the base R `transform` function that defaults to the `d` data frame and provides output regarding the specified transformation(s).

#### Usage

```r
Transform(data=d, quiet=getOption("quiet"), ...)
trans(...)
```

#### Arguments

- **data**
  - The name of the data frame from which to create the subset, which is `d` by default.
- **quiet**
  - If set to `TRUE`, no text output. Can change system default with `style` function.
- **...**
  - The list of transformations, each of the form, `variable = equation`. Each variable can be the name of an existing variable in the data frame or a newly created variable.

#### Details

The first five rows of the data frame are listed before the transformation, and the first five values of the transformed variables are listed after the transformation. The default input data frame is `d`.

Guidance and feedback regarding the transformations are provided by default. The first five lines of the input data frame are listed before the transformation, then the specified transformations are listed, followed by the first five lines of the transformed data frame.

Multiple transformations can be defined with a single statement. Note that a newly created transformed variable cannot then be used to define another transformed variable in the same `Transform` statement. Instead, the transformed variable that depends on an earlier created transformed variable must be defined in its own `Transform` statement.

#### Value

The transformed data frame is returned, usually assigned the name of `d` as in the examples below. This is the default name for the data frame input into the `lessR` data analysis functions.
Examples

# construct data frame
d <- read.table(text="Status Severity
1 Mild
4 Moderate
3 Moderate
2 Mild
1 Severe", header=TRUE)

# replace Status with a transformed version
d <- Transform(Status=Status-1)

# abbreviated form
d <- trans(StatusNew=Status-1)

# replace Status with a transformed version
# leave input d unmodified
# save transformed data frame to the created data frame called newdata
newdata <- Transform(Status=Status-1)

# construct data frame
# recode Status into a factor
d <- Transform(Status=factor(Status, labels=c("OK","Hurts","Painful","Yikes")))

# read lessR data set dataEmployee into data frame d
d <- Read("Employee")
# multiple transformations in one statement
# Months is a new variable
# Salary is a new version of the old Salary
# JobSat was read as non-numeric, so as a factor, but is also ordinal
# Plan was read as numeric values 0,1,2, now converted to a factor
d <- Transform(
  Months=Years*12,
  Salary=Salary/1000,
  Plan=factor(Plan,
    levels=c(0,1,2), labels=c("GoodHealth", "YellowCross", "BestCare"))
)
# new variable Months now exists
# if relevant, supply a corresponding variable label
# d <- label(Months, "Months Employed in the Company")
# confirm
db()
# ----------------------------
# transformations with factors
# ----------------------------

# transform a nominal variable to ordinal, re-order the categories
d <- Transform(JobSat=
    factor(JobSat, levels=c("low", "med", "high"), ordered=TRUE))

# recode levels of a factor that should remain a factor
# with the Transform and factor functions
# using Recode destroys the factor attribute, converting to
# character strings instead, so Recode does not allow
d <- Read("Employee")
d <- Transform(
    Gender=factor(Gender, levels=c("F", "M"), labels=c("Female", "Male"))
)

# recode levels of a factor to convert to integer first by
# converting to integer with Transform and as.numeric
# here Gender has values M and F in the data
# integers start with 1 through the number of levels, can use
# Recode to change this if desired, such as to 0 and 1
# Gender is now a factor to illustrate
d <- Transform(Gender=as.numeric(Gender))
d <- Recode(Gender, old=c(1,2), new=c(0,1))

# recode integer values to levels of a factor with value labels
# with the Transform function instead of Recode
# here Gender has values 0 and 1 in the data
d <- Read("Mach4")
d <- Transform(
    Gender=factor(Gender, levels=c(0,1), labels=c("Male","Female"))
)

# ----------------------------

ttest  

Generic Method for t-test and Standardized Mean Difference with Enhanced Graphics

Description

Abbreviation: tt, tt_brief, tt.brief [deprecated]

Provides enhanced output from the standard t.test function applied to the analysis of the mean of a single variable, or the independent groups analysis of the mean difference, from either data or summary statistics. Includes the analysis of a dependent-groups analysis from the data. The data can be in the form of a data frame or separate vectors of data, one for each group. This output includes the basic descriptive statistics, analysis of assumptions and the hypothesis test and confidence interval. For two groups the output also includes the analysis for both with and without the assumption of homogeneous variances, the pooled or within-group standard deviation, and the standardized mean difference or Cohen’s d and its confidence interval.
The output from data for two groups introduces the ODDSMD plot, which displays the Overlapping Density Distributions of the two groups as well as the means, mean difference and Standardized Mean Difference. The plot also includes the results of the descriptive and inferential analyses. For the dependent-groups analysis, a scatter plot of the two groups of data also is produced, which includes the diagonal line through the scatter plot that represents equality, and a line segment for each point in the scatter plot which is the vertical distance from the point to the diagonal line to display the amount of change.

Can also be called from the more general model function.

Usage

```r
ttest(x=NULL, y=NULL, data=d, rows=NULL, paired=FALSE,
      n=NULL, m=NULL, s=NULL, mu=NULL,
      n1=NULL, n2=NULL, m1=NULL, m2=NULL, s1=NULL, s2=NULL,
      Ynm="Y", Xnm="X", X1nm="Group1", X2nm="Group2", xlab=NULL,
      brief=getOption("brief"), digits_d=NULL, conf_level=0.95,
      alternative=c("two_sided", "less", "greater"),
      mmd=NULL, msmd=NULL, Edesired=NULL,
      show_title=TRUE, bw1="bcv", bw2="bcv",
      graph=TRUE, line_chart=FALSE,
      width=5, height=5, pdf_file=NULL, ...)
```

```
tt.brief(...)
tt_brief(...)
tt(...)
```

Arguments

- **x** A formula of the form Y ~ X, where Y is the numeric response variable compared across the two groups, and X is a grouping variable with two levels that define the corresponding groups, or, if the data are submitted in the form of two vectors, the responses for the first group.

- **y** If x is not a formula, the responses for the second group, otherwise NULL.

- **data** Data frame that contains the variable of interest, default is d.

- **rows** A logical expression that specifies a subset of rows of the data frame to analyze.

- **paired** Set to TRUE for a dependent-samples t-test with two data vectors or variables from a data frame, with the difference computed from subtracting the first vector from the second.

- **n** Sample size for one group.

- **m** Sample size for one group.

- **s** Sample size for one group.
mu  Hypothesized mean for one group. If not present, then confidence interval only.
n1  Sample size for first of two groups.
n2  Sample size for second of two groups.
m1  Sample mean for first of two groups.
m2  Sample mean for second of two groups.
s1  Sample standard deviation for first of two groups.
s2  Sample standard deviation for second of two groups.
Ynm Name of response variable.
Xnm Name of predictor variable, the grouping variable or factor with exactly two levels.
X1nm Value of grouping variable, the level that defines the first group.
X2nm Value of grouping variable, the level that defines the second group.
xlab x-axis label, defaults to variable name, or, if present, variable label.
brief If set to TRUE, reduced text output. Can change system default with style function.
digits_d Number of decimal places for which to display numeric values. Suggestion only.
conf_level Confidence level of the interval, expressed as a proportion.
alternative Default is "two_sided". Other values are "less" and "greater".
mmd Minimum Mean Difference of practical importance, the difference of the response variable between two group means. The concept is optional, and only one of mmd and msmd is provided.
msmd For the Standardized Mean Difference, Cohen’s d, the Minimum value of practical importance. The concept is optional, and only one of mmd and msmd is provided.
Edesired The desired margin of error for the needed sample size calculation for a 95% confidence interval, based on Kupper and Hafner (1989).
show_title Show the title on the graph of the density functions for two groups.
bw1 Bandwidth for the computation of the densities for the first group.
bw2 Bandwidth for the computation of the densities for the second group.
graph If TRUE, then display the graph of the overlapping density distributions.
line_chart Plot the run chart for the response variable for each group in the analysis.
pdf_file Name of the pdf file to which the density graph is redirected. Also specifies to save the line charts with pre-assigned names if they are computed.
width Width of the pdf file in inches.
height Height of the pdf file in inches.
... Further arguments to be passed to or from methods.
Details

OVERVIEW
If \( n \) or \( n_1 \) are set to numeric values, then the analysis proceeds from the summary statistics, the sample size and mean and standard deviation of each group. Missing data are counted and then removed for further analysis of the non-missing data values. Otherwise the analysis proceeds from data, which can be in a data frame, by default named \( d \), with a grouping variable and response variable, or in two data vectors, one for each group.

Following the format and syntax of the standard \texttt{t.test} function, to specify the two-group test with a formula, \texttt{formula}, the data must include a variable that has exactly two values, a grouping variable or factor generically referred to as \( X \), and a numerical response variable, generically referred to as \( Y \). The formula is of the form \( Y \sim X \), with the names \( Y \) and \( X \) replaced by the actual variable names specific to a particular analysis. The formula method automatically retrieves the names of the variables and data values for display on the resulting output.

The values of the response variable \( Y \) can be organized into two vectors, the values of \( Y \) for each group in its corresponding vector. When submitting data in this form, the output is enhanced if the actual names of the variables referred to generically as \( X \) and \( Y \), as well as the names of the levels of the factor \( X \), are explicitly provided.

For the output, when computed from the data the two groups are automatically arranged so that the group with the larger mean is listed as the first group. The result is that the resulting mean difference, as well as the standardized mean difference, is always non-negative.

The inferential analysis in the full version provides both homogeneity of variance and the Welch test which does not assume homogeneity of variance. Only a two-sided test is provided. The null hypothesis is a population mean difference of 0.

If computed from the data, the bandwidth parameter controls the smoothness of the estimated density curve. To obtain a smoother curve, increase the bandwidth from the default value.

DATA
If the input data frame is named something different than \( d \), then specify the name with the \texttt{data} option. Regardless of its name, the data frame need not be attached to reference the variable directly by its name without having to invoke the \texttt{d$name} notation.

PRACTICAL IMPORTANCE
The practical importance of the size of the mean difference is addressed when one of two parameter values are supplied, the minimum mean difference of practical importance, \( \text{mmd} \), or the corresponding standardized version, \( \text{msmd} \). The remaining value is calculated and both values are added to the graph and the console output.

DECIMAL DIGITS
The number of decimal digits is determined by default from the largest number of decimal digits of the entered descriptive statistics. The number of decimal digits is then set at that value, plus one more with a minimum of two decimal digits by default. Or, override the default with the \texttt{digits_d} parameter.

VARIABLE LABELS
If variable labels exist, then the corresponding variable label is by default listed as the label for the horizontal axis and on the text output. For more information, see \texttt{Read}.

PDF OUTPUT
To obtain pdf output, use the \texttt{pdf_file} option, perhaps with the optional \texttt{width} and \texttt{height} options.
These files are written to the default working directory, which can be explicitly specified with the R `setwd` function.

Value

Returned value is NULL except for a two-group analysis from a formula. Then the values for the response variable of the two groups are separated and returned invisibly as a list for further analysis as indicated in the examples below. The first group of data values is the group with the largest sample mean.

- `value1`: Value of the grouping variable for the first group.
- `group1`: Data values for the first group.
- `value2`: Value of the grouping variable for the second group.
- `group2`: Data values for the second group.

ttest(Salary, mu=52000)

# just with employees with salaries less than $100,000
ttest(Salary, mu=52000, rows=(Salary < 100000))

# -------------------------------------------------------
# tt for two groups from data stored in two vectors
# -------------------------------------------------------

# create two separate vectors of response variable Y
# the vectors exist are not in a data frame
# their lengths need not be equal
Y1 <- round(rnorm(n=10, mean=50, sd=10),2)
Y2 <- round(rnorm(n=10, mean=60, sd=10),2)

# analyze the two vectors directly
# usually explicitly specify variable names and levels of X
# to enhance the readability of the output
ttest(Y1, Y2, Ynm="MyY", Xnm="MyX", X1nm="Group1", X2nm="Group2")

# dependent groups t-test from vectors in global environment
ttest(Y1, Y2, paired=TRUE)
ttestPower

# dependent groups t-test from variables in data frame d
d <- data.frame(Y1,Y2)
rm(Y1); rm(Y2)
ttest(Y1, Y2, paired=TRUE)
# independent groups t-test from variables (vectors) in a data frame
ttest(Y1, Y2)

# tt from summary statistics
# -------------------------------------------------------
# one group: sample size, mean and sd
# optional variable name added
tt(n=34, m=8.92, s=1.67, Ynm="Time")
# confidence interval and hypothesis test, from descriptive stats
# get rid of the data frame, analysis should still proceed
rm(d)
tt_brief(n=34, m=8.92, s=1.67, mu=9, conf_level=0.90)
# two groups: sample size, mean and sd for each group
# specify the briefer form of the output
tt_brief(n1=19, m1=9.57, s1=1.45, n2=15, m2=8.09, s2=1.59)

### ttestPower

#### Compute a Power Curve for a One or Two Group t-test

**Description**

Abbreviation: ttp

From one or two sample sizes, and either the within-cell (pooled) standard deviation, or one or two separate group standard deviations, generate and calibrate a power curve for either the one-sample t-test or the independent-groups t-test, as well as ancillary statistics. Uses the standard R function `power.t.test` to calculate power and then the `ScatterPlot` function in this package to automatically display the annotated power curve with colors.

For both the one and two-group t-tests, power is calculated from a single sample size and single standard deviation. For the two-sample test, the within-group standard deviation is automatically calculated from the two separate group standard deviations if not provided directly. Similarly, the harmonic mean of two separate sample sizes is calculated if two separate sample sizes are provided.

**Usage**

```r
ttestPower(n=NULL, s=NULL, n1=NULL, n2=NULL, s1=NULL, s2=NULL, mmd=NULL, msmd=NULL, mdp=.8, mu=NULL, pdf_file=NULL, width=5, height=5, ...)
```

ttp(...)
Arguments

- **n**: Sample size for each of the two groups.
- **s**: Within-group, or pooled, standard deviation.
- **n1**: Sample size for Group 1.
- **n2**: Sample size for Group 2.
- **s1**: Sample standard deviation for Group 1.
- **s2**: Sample standard deviation for Group 2.
- **mmd**: Minimum Mean Difference of practical importance, the difference of the response variable between two group means. The concept is optional, and only one of mmd and msmd is provided.
- **msmd**: For the Standardized Mean Difference, Cohen’s d, the Minimum value of practical importance. The concept is optional, and only one of mmd and msmd is provided.
- **mdp**: Minimum Desired Power, the smallest value of power considered to provide sufficient power. Default is 0.8. If changed to 0 then the concept is dropped from the analysis.
- **mu**: Hypothesized mean, of which a provided value triggers a one-sample analysis.
- **pdf_file**: Name of the pdf file to which graphics are redirected.
- **width**: Width of the pdf file in inches.
- **height**: Height of the pdf file in inches.
- **...**: Other parameter values, such as lwd and lab_cex from plot and col.line and col.bg from ScatterPlot.

Details

This function relies upon the standard `power.t.test` function to calibrate and then calculate the power curve according to the relevant non-central t-distribution. The Plot function from this package, which in turn relies upon the standard plot function, plots the power curve. As such, parameters in Plot for controlling the different colors and other aspects of the display are also available, as are many of the more basic parameters in the usual plot function.

Also plotted, if provided, is the minimal meaningful difference, mmd, as well as the minimal desired power, mdp, provided by default. Relevant calculations regarding these values are also displayed at the console. One or both concepts can be deleted from the analysis. Not providing a value mmd implies that the concept will not be considered, and similarly for setting mdp to 0.

Invoke the function with the either the within-group (pooled) standard deviation, s, or the two separate group standard deviations, s1 and s2, from which s is computed. If the separate standard deviations are provided, then also provide the sample sizes, either as a single value of n or as two separate sample sizes, n1 and n2. If separate sample sizes n1 and n2 are entered, their harmonic mean serves as the value of n.

For power analysis of the two-sample t-test, the null hypothesis is a zero population mean difference. For a one-sample test, the null hypothesis is specified, and it is this non-null specification of mu that triggers the one-sample analysis. Only non-directional or two-tailed tests are analyzed.
The effect size that achieves a power of 0.8 is displayed. If a minimal meaningful difference, mmd, is provided, then the associated power is also displayed, as well as the needed sample size to achieve a power of 0.8.

If the function is called with no parameter values, that is, as ttp(), then the values of n1, n2 and sw must already exist before the function call. If they do, these values are used in the power computations.

Examples

# default power curve and colors
ttestPower(n=20, s=5)
# short name
ttp(n=20, s=5)

# default power curve and colors
# plus optional smallest meaningful effect to enhance the analysis
ttestPower(n=20, s=5, mmd=2)

# power curve from both group standard deviations and sample sizes
# also provide the minimum standardized mean difference of
# practical importance to obtain corresponding power
ttestPower(n1=14, n2=27, s1=4, s2=6, mmd=.5)

# power curve for one sample t-test, triggered by non-null mu
ttestPower(n=20, s=5, mu=30, mmd=2)

---

values

List the Values of a Variable

Description

List the values of a variable from the global environment or a data frame.

Usage

values(x, data=d, ...)

Arguments

x Variable for which to construct the histogram and density plots.
data Data frame that contains the variable of interest, default is d.
... Other parameter values for as defined processed by print, including digits.
Details

Provided for listing the values of a variable in an unattached data frame. All lessR functions that access data for analysis from a data frame, such as the default d provided by the Read function that reads the data frame from an external data file, do not require the data frame to be attached. Attaching a data frame can lead to some confusing issues, but one negative of not attaching is that simply listing the name of a variable within the data frame leads to an ‘object not found’ error. The values function provides access to that variable within a data frame just as is true for any other lessR function that accesses data.

The function displays the values of the specified variable with the standard R print function, so parameter values for print can also be passed to values.

Author(s)

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

print

Examples

# generate 10 random normal data values
Y <- rnorm(10)
d <- data.frame(Y)
rm(Y)

# list the values of Y
values(Y)

# variable of interest is in a data frame which is not the default d
# access the breaks variable in the R provided warpbreaks data set
# although data not attached, access the variable directly by its name
data(warpbreaks)
values(breaks, data=warpbreaks)

---

VariableLabels  Create or Display Variable Labels

Description

Assign and/or display variable labels stored in the data frame l. Variable labels enhance output of analyses either as text output at the console or as graphics, such as an axis label on a graph. The variable labels can be assigned individually, or for some or all variables.

NOTE: Mostly deprecated. Can just set var_labels=TRUE on for a call to Read to read a file of variable labels, and assign the output to l. Still needed to pull labels out of data frame from an SPSS read, or to read units to generate Rmd files from Regression.
VariableLabels

Usage

VariableLabels(x, value=NULL, quiet=getOption("quiet"))

Arguments

x
The file reference or character string variable (see examples) from which to obtain the variable labels, or a variable name for which to assign or obtain the corresponding variable label in conjunction with the value parameter. Can also be a data frame from which to extract any existing variable labels.

value
The variable label assigned to a specific variable, otherwise NULL.

quiet
If set to TRUE, no text output. Can change system default with style function.

Details

Unlike standard R, lessR provides for variable labels, here stored in the data frame l. To read the labels from an external file, specify a file reference as the first argument of the function call. Or create a character string of variable names and labels and specify the character string as the first argument to the function call. To assign an individual variable label with this function specify the variable name as the first argument followed by the label in quotes. Not all variables need have a label, and the variables with their corresponding labels can be listed or assigned in any order. If the l data frame is created or modified, the output of the function must be assigned to l, as shown in the following examples.

When all or some of the labels are read, either from the console or an external csv or Excel file, each line of the file contains the variable name and then the associated variable label. The file types of .csv and .xlsx in the file reference listed in the first position of the function call are what trigger the interpretation of the argument as a file reference.

For a file that contains only labels, each row of the file, including the first row, consists of the variable name, a comma if a csv file, and then the label. For the csv form of the file, this is the standard csv format such as obtained with the csv option from a standard worksheet application such as Microsoft Excel or LibreOffice Calc. Not all variables in the data frame that contains the data, usually d, need have a label, and the variables with their corresponding labels can be listed in any order. An example of this file follows for four variables, I1 through I4, and their associated labels.

I2,This instructor presents material in a clear and organized manner.
I4,Overall, this instructor was highly effective in this class.
I1,This instructor has command of the subject.
I3,This instructor relates course materials to real world situations.

If there is a comma in the variable label, then the label needs to be enclosed in quotes.

The lessR functions that provide analysis, such as Histogram for a histogram, automatically include the variable labels in their output, such as the title of a graph. Standard R functions can also use these variable labels by invoking the lessR function label, such as setting main=label(I4) to put the variable label for a variable named I4 in the title of a graph.
Variable units may also be added to the third column of a variable label file. These are used for generating a better natural language text in the generation of R-Markdown files with the Rmd option on supporting functions such as `Regression`. For currency (USD), indicate with unit: dollar.

**Value**

The data frame with the variable labels is returned.

**Author(s)**

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

**See Also**

Read.

**Examples**

```r
# read file and then variable labels from csv files
# 1 <- Read("http://lessRstats.com/data/employee.csv")
# 1 <- VariableLabels("http://lessRstats.com/data/employee_lbl.csv")

# construct and read variable labels from console
lbl <- "
Years, Years of Company Employment
Gender, Male or Female
Dept, Department Employed
Salary, Annual Salary (USD)
JobSat, JobSat with Work Environment
Plan, 1=GoodHealth 2=YellowCross 3=BestCare
"
1 <- VariableLabels(lbl)
1

# add/modify a single variable label
1 <- VariableLabels(Salary, "Annual Salaries in USD")
1

# list the contents of a single variable label
VariableLabels(Salary)

# display all variable labels
VariableLabels()
```
**Write**

*Write the Contents of a Data Frame to an External File*

**Description**

Abbreviation: `wrt`, `wrt_r`, `wrt_x`

Writes the contents of the specified data frame, such as with the default `d`, to the current working directory as either the default `csv` data file, an Excel data table, or a native R data file of the specified data frame. If the write is for a `csv` file, then any variable labels are written to a second `csv` file with "_lbl" appended to the file name. Any variable labels and variable units are automatically included in a native R data file.

**Usage**

```r
Write(to=NULL, data=d, format=c("csv", "R", "Excel"), rowNames=NULL, ExcelTable=FALSE, ExcelColWidth=TRUE, quiet=getOption("quiet"), ...)
wrt(...)
wrt_r(..., format="R")
wrt_x(..., format="Excel")
```

**Arguments**

- **to**
  Name of the output file as a character string, that is, with quotes. If not included in the name, the file type is automatically added to the name, either `.csv` or `.rda`, depending of the value of `format`.

- **data**
  Data frame to be written as an object, that is, no quotes.

- **format**
  Format of file to be written with `.csv` as the default.

- **rowNames**
  Format of file to be written with `.csv` as the default. Set to `TRUE` by default unless writing to Excel or csv file and row names are just the integers from 1 to the number of rows.

- **ExcelTable**
  If `TRUE`, write the Excel file as an Excel table.

- **ExcelColWidth**
  On by default but calculation of column widths for large files takes more time, so option to turn off.

- **quiet**
  If set to `TRUE`, no text output. Can change system default with `style` function.

- **...**
  Other parameter values for `csv` files consistent with the usual `write.table`, including `na=""` to write missing data to a `csv` file as blanks instead of `NA`.

**Details**

Can specify the file name without the file type, which `Write` adds automatically, `.csv` for a comma separated values data file and `.rda` for a native R data file. The default file name is the name of the
data frame to be written. The name of the file that is written, as well as the name of the working
directory into which the file was written, are displayed at the console.

An Excel file is written using functions from Alexander Walker’s openxlsx package.
Write is designed to work in conjunction with the function Read from this package, which reads a
csv, fixed width format, or native SPSS or R data files into the data frame d. Write relies upon the
R functions write.csv and save.

When writing the data frame in native R format, the specified name of the resulting .rda file is
distinct from the name of the data frame as stored within R.

xAnd

Text Processing: Insert and Into a List

Description

Inserts the word and into a vector of words, each a separate character string. Primarily for internal
use in text processing of knitr output. Not usually referenced by the user.
xAnd

Usage
xAnd(x)

Arguments
x The set of character strings for which to insert and.

Details
Input is a vector of character strings, output is a single character string with and inserted if needed.

Author(s)
David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

Examples
xAnd(c("sky", "land", "mountains"))

xNum

Text Processing: Convert a Number to a Word

Description
Converts a number to a word. Primarily for internal use in text processing of knitr output. Not usually referenced by the user.

Usage
xNum(x)

Arguments
x The integer to convert.

Details
Input is an integer, or coerced to integer after rounding. For integers from 0 to 12, output is the single English word. For values larger than 12, or negative, the integer is just converted to character format.

Author(s)
David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

Examples
xNum(5)
xP

*Text Processing: Print Formatted Numbers*

**Description**

Prints numbers nicely formatted, with optional units. Primarily for internal use in text processing of \texttt{knitr} output. Not usually referenced by the user.

**Usage**

\[
xP(x, \text{d=}NULL, \text{unit=}NULL, \text{semi=}FALSE)
\]

**Arguments**

- \texttt{x} The variable.
- \texttt{d} The digits.
- \texttt{unit} Unit of measurement for the variable.
- \texttt{semi} Add a semicolon before the unit to add some horizontal spacing in math mode.

**Details**

Input is numeric, output is formatted text. A special unit is "$", which is added to the front of the number instead of as a trailing descriptor.

**Author(s)**

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

**Examples**

\[
xP(12345678.9, \text{d=}2, \text{unit=}\"\$\")
\]
\[
xP(12345678.9, \text{d=}2, \text{unit=}\"\text{lbs}\")
\]

---

xRow

*Text Processing: Add the Word Row to Case Labels that Could be Numeric*

**Description**

For a vector of row names, if the names can be represented as integers the word Row is added to the beginning of each name in the vector. Primarily for internal use in text processing of \texttt{knitr} output. Not usually referenced by the user.
Usage

xRow(x)

Arguments

x  Vector with names for each value.

Details

Input is a vector of values, output is vector of associated row labels, perhaps with the added word Row.

Author(s)

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

Examples

# The word Row gets added
v <- c(2, 4, 6)
names(v) <- c("1", "2", "3")
xRow(v)

# The word Row does not get added
v <- c(2, 4, 6)
names(v) <- c("Bill", "Tulane", "Hanna")
xRow(v)

xU

Text Processing: Capitalize First Letter of a Word

Description

Capitalize the first letter of a word. Primarily for internal use in text processing of knitr output. Not usually referenced by the user.

Usage

xU(x)

Arguments

x  The character string (word) for which to capitalize the first letter.

Details

Input is a single word. Output is the word with its first letter capitalized.
Author(s)

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

Examples

xU("the")

---

Text Processing: Wrap Words to Create New Lines From a Specified Line

Description

Split a larger line into multiple lines by wrapping words with inserted line feeds. Primarily for internal use in text processing of knitr output. Not usually referenced by the user.

Usage

xW(x, w=90, indent=5)

Arguments

x The character string to split into separate lines.
w Maximum width of each line.
indent Amount of spaces to indent lines after the first line.

Details

Input is a sentence. Output is the sentence word wrapped into multiple lines, each line up to the maximum width.

Author(s)

David W. Gerbing (Portland State University; <gerbing@pdx.edu>)

Examples

xW("The quick brown fox jumped over the lazy do"
