Package ‘lgr’

March 20, 2020

Type Package

Title A Fully Featured Logging Framework

Version 0.3.4

Maintainer Stefan Fleck <stefan.b.fleck@gmail.com>

Description A flexible, feature-rich yet light-weight logging framework based on ‘R6’ classes. It supports hierarchical loggers, custom log levels, arbitrary data fields in log events, logging to plaintext, ‘JSON’, (rotating) files, memory buffers, and databases, as well as email and push notifications. For a full list of features with examples please refer to the package vignette.

**AppenderBuffer**

Log to a memory buffer

**Description**

An Appender that Buffers LogEvents in-memory and redirects them to other Appenders once certain conditions are met.

**Usage**

```r
x <- AppenderBuffer$new(threshold = NA_integer_, layout = LayoutFormat$new(fmt = "%L [%t] %m", timestamp_fmt = "%H:%M:%S", colors = getOption("lgr.colors")), appenders = NULL, buffer_size = 1000, flush_threshold = "fatal", flush_on_exit = TRUE, flush_on_rotate = TRUE, should_flush = default_should_flush, filters = NULL)
```

```r
x$add_appender(appender, name = NULL)
```

```r
x$add_filter(filter, name = NULL)
```

```r
x$append(event)
```

```r
x$filter(event)
```

```r
x$flush()
```

```r
x$format(...)  
```

```r
x$format(color = FALSE, ...)
```

```r
x$remove_appender(pos)
```

```r
x$remove_filter(pos)
```

```r
x$set_appenders(x)
```

```r
x$set_buffer_size(x)
```

```r
x$set_filters(filters)
```

```r
x$set_flush_on_exit(x)
```

```r
x$set_flush_on_rotate(x)
```

```r
x$set_flush_threshold(level)
```

```r
x$set_layout(layout)
```

```r
x$set_should_flush(x)
```

```r
x$set_threshold(level)
```

```r
x$show(threshold = NA_integer_, n = 20L)
```

```r
x$appenders  
x$buffer_df
```

```r
x$buffer_dt
```

```r
x$buffer_events
```
Creating a Buffer Appender

The Layout for this Appender is used only to format console output of its $show() method.

Fields

appenders, set_appenders() Like for a Logger. Buffered events will be passed on to these Appenders once a flush is triggered.

flush_on_exit, set_flush_on_exit(x) TRUE or FALSE: Whether the buffer should be flushed when the Appender is garbage collected (i.e., when you close R).

flush_on_rotate, set_flush_on_rotate TRUE or FALSE: Whether the buffer should be flushed when the Buffer is full (i.e., when you close R). Setting this to off can have slightly negative performance impacts.

buffer_size, set_buffer_size(x) integer scalar \( \geq 0 \) Number of LogEvents to buffer.

buffer_events, buffer_df, buffer_dt The contents of the buffer as a list of LogEvents, a data.frame or a data.table.

flush_threshold, set_flush_threshold() integer or character log level. Minimum event level that will trigger flushing of the buffer. This behaviour is implemented through should_flush(), and you can modify that function for different behaviour.

should_flush(event), set_should_flush(x) A function with exactly one argument: event. If the function returns TRUE, flushing of the buffer is triggered. Defaults to flushing if an event of level error or higher is registered.

dt Get the log recorded by this Appender as a data.table with a maximum of buffer_size rows.

data Get the log recorded by this Appender as a data.frame.

threshold, set_threshold(level) character or integer scalar. The minimum log level that triggers this logger. See log_levels.

layout, set_layout(layout) a Layout that will be used for formatting the LogEvents passed to this Appender.

destination The output destination of the Appender in human-readable form (mainly for print output).
AppenderBuffer

filters, set_filters(filters) a list that may contain functions or any R object with a filter() method. These functions must have exactly one argument: event which will get passed the LogEvent when the Filterable’s filter() method is invoked. If all of these functions evaluate to TRUE the LogEvent is passed on. Since LogEvents have reference semantics, filters can also be abused to modify them before they are passed on. Look at the source code of with_log_level() or with_log_value() for examples.

Methods

flush() Manually trigger flushing

add_appender(appender, name = NULL), remove_appender(pos) Add or remove an Appender. Supplying a name is optional but recommended. After adding an Appender with appender$add_appender(AppenderConsole$new(), name = "console") you can refer to it via appender$appenders$console. remove_appender() can remove an Appender by position or name.

flush() Manually trigger flushing of the buffer

show(n, threshold) Show the last n log entries with a log level below threshold. The log entries will be formatted for console output via this Appenders Layout

append(event) Tell the Appender to process a LogEvent event. This method is usually not called by the user, but invoked by a Logger

filter(event) Determine whether the LogEvent x should be passed on to Appenders (TRUE) or not (FALSE). See also the active binding filters

add_filter(filter, name = NULL), remove_filter(pos) Add or remove a filter. When adding a filter an optional name can be specified. remove_filter() can remove by position or name (if one was specified)

Comparison AppenderBuffer and AppenderDt

Both AppenderBuffer and AppenderDt do in memory buffering of events. AppenderBuffer retains a copies of the events it processes and has the ability to pass the buffered events on to other Appenders. AppenderDt converts the events to rows in a data.table and is a bit harder to configure. Used inside loops (several hundred iterations), AppenderDt has much less overhead than AppenderBuffer. For single logging calls and small loops, AppenderBuffer is more performant. This is related to how memory pre-allocation is handled by the appenders.

In short: Use AppenderDt if you want an in-memory log for interactive use, and AppenderBuffer if you actually want to buffer events

LayoutFormat

Other Appenders: AppenderConsole, AppenderDbi, AppenderFileRotating, AppenderFile, AppenderGmail, AppenderJson, AppenderPushbullet, AppenderRjdbc, AppenderSendmail, AppenderSyslog, AppenderTable, Appender
AppenderConsole Log to the console

Description

A simple Appender that outputs to the console. If you have the package crayon installed log levels will be coloured by default (but you can modify this behaviour by passing a custom Layout).

Usage

```r
x <- AppenderConsole$new(threshold = NA_integer_, layout = LayoutFormat$new(fmt = "%L [%t] %m %f", timestamp_fmt = "%H:%M:%OS3", colors = getOption("lgr.colors", list())), filters = NULL)
```

```
x$add_filter(filter, name = NULL)
x$append(event)
x$filter(event)
x$format(color = FALSE, ...)
x$remove_filter(pos)
x$set_filters(filters)
x$set_layout(layout)
x$set_threshold(level)
```

```
x$destination
x$filters
x$layout
x$threshold
```

Creating a New Appender

New Appenders are instantiated with <AppenderSubclass>$new(). For the arguments to new() please refer to the section Fields. You can also modify those fields after the Appender has been created with setters in the form of appender$set_<fieldname>(value)

Fields

- `threshold`, `set_threshold(level)` character or integer scalar. The minimum log level that triggers this logger. See log_levels

- `layout`, `set_layout(layout)` a Layout that will be used for formatting the LogEvents passed to this Appender

- `destination` The output destination of the Appender in human-readable form (mainly for print output)

- `filters`, `set_filters(filters)` a list that may contain functions or any R object with a `filter()` method. These functions must have exactly one argument: `event` which will get
passed the LogEvent when the Filterable’s filter() method is invoked. If all of these functions evaluate to TRUE the LogEvent is passed on. Since LogEvents have reference semantics, filters can also be abused to modify them before they are passed on. Look at the source code of with_log_level() or with_log_value() for examples.

Methods

append(event) Tell the Appender to process a LogEvent event. This method is usually not called by the user, but invoked by a Logger

filter(event) Determine whether the LogEvent x should be passed on to Appenders (TRUE) or not (FALSE). See also the active binding filters

add_filter(filter, name = NULL), remove_filter(pos) Add or remove a filter. When adding a filter an optional name can be specified. remove_filter() can remove by position or name (if one was specified)

LayoutFormat

Other Appenders: AppenderBuffer, AppenderDbi, AppenderFileRotating, AppenderFile, AppenderGmail, AppenderJson, AppenderPushbullet, AppenderRjdbc, AppenderSendmail, AppenderSyslog, AppenderTable, Appender

Examples

# create a new logger with propagate = FALSE to prevent routing to the root # logger. Please look at the section "Logger Hirarchies" in the package # vignette for more info.
lg <- get_logger("test")$set_propagate(FALSE)

lg$add_appender(AppenderConsole$new())
lg$add_appender(AppenderConsole$new(
    layout = LayoutFormat$new("[%t] %c(): [%n] %m", colors = getOption("lgr.colors")))

# Will output the message twice because we attached two console appenders
lg$warn("A test message")
lg$config(NULL) # reset config

Description

Log to a database table with any DBI compatible backend. Please be aware that AppenderDbi does not support case sensitive / quoted column names, and you advised to only use all-lowercase names for custom fields (see ... argument of LogEvent). When appending to a database table all LogEvent values for which a column exists in the target table will be appended, all others are ignored.
Buffered Logging

AppenderDbi does not write directly to the database but to an in memory buffer. With the default settings, this buffer is written to the database whenever the buffer is full (buffer_size, default is 10 LogEvents), whenever a LogEvent with a level of fatal or error is encountered (flush_threshold) or when the Appender is garbage collected (flush_on_exit), i.e. when you close the R session or shortly after you remove the Appender object via rm(). If you want to disable buffering, just set buffer_size to 0.

Usage

```r
x <- AppenderDbi$new(conn, table, threshold = NA_integer_, layout = select_dbi_layout(conn, table), close_on_exit = TRUE, buffer_size = 10, flush_threshold = "error", flush_on_exit = TRUE, flush_on_rotate = TRUE, should_flush = default_should_flush, filters = NULL)
```

```r
x$add_filter(filter, name = NULL)
x$append(event)
x$filter(event)
x$flush()
x$format(color = FALSE, ...)
x$remove_filter(pos)
x$set_buffer_size(x)
x$set_close_on_exit(x)
x$set_conn(conn)
x$set_filters(filters)
x$set_flush_on_exit(x)
x$set_flush_on_rotate(x)
x$set_flush_threshold(level)
x$set_layout(layout)
x$set_should_flush(x)
x$set_threshold(level)
x$show(threshold = NA_integer_, n = 20)
x$show(threshold = NA_integer_, n = 20L)
```

```r
x$buffer_df
x$buffer_dt
x$buffer_events
x$buffer_size
x$close_on_exit
x$col_types
x$conn
x$data
x$destination
x$dt
x$filters
x$flush_on_exit
x$flush_on_rotate
x$flush_threshold
```
Creating a New Appender

An AppenderDbi is linked to a database table via its table argument. If the table does not exist it is created either when the Appender is first instantiated or (more likely) when the first LogEvent would be written to that table. Rather than to rely on this feature, it is recommended that you create the target log table first manually using an SQL CREATE TABLE statement as this is safer and more flexible. See also LayoutDbi.

New Appenders are instantiated with $new(). For the arguments to new() please refer to the section Fields. You can also modify those fields after the Appender has been created with setters in the form of appender$set_<fieldname>(value)

Fields

Note: $data and show() query the data from the remote database and might be slow for very large logs.

close_on_exit, set_close_on_exit() TRUE or FALSE. Close the Database connection when the Logger is removed?

conn, set_conn(conn) a DBI connection

table Name of the target database table

buffer_size, set_buffer_size(x) integer scalar $= 0 Number of LogEvents to buffer.

buffer_events, buffer_df, buffer_dt The contents of the buffer as a list of LogEvents, a data.frame or a data.table.

flush_threshold, set_flush_threshold() integer or character log level. Minimum event level that will trigger flushing of the buffer. This behaviour is implemented through should_flush(), and you can modify that function for different behaviour.

should_flush(event), set_should_flush(x) A function with exactly one arguments: event. If the function returns TRUE, flushing of the buffer is triggered. Defaults to flushing if an event of level error or higher is registered.

dt Get the log recorded by this Appender as a data.table with a maximum of buffer_size rows

data Get the log recorded by this Appender as a data.frame

threshold, set_threshold(level) character or integer scalar. The minimum log level that triggers this logger. See log_levels

layout, set_layout(layout) a Layout that will be used for formatting the LogEvents passed to this Appender
destination The output destination of the Appender in human-readable form (mainly for print output)

filters, set_filters(filters) a list that may contain functions or any R object with a filter() method. These functions must have exactly one argument: event which will get passed the LogEvent when the Filterable's filter() method is invoked. If all of these functions evaluate to TRUE the LogEvent is passed on. Since LogEvents have reference semantics, filters can also be abused to modify them before they are passed on. Look at the source code of with_log_level() or with_log_value() for examples.

Choosing the Right DBI Layout

Layouts for relational database tables are tricky as they have very strict column types and further restrictions. On top of that implementation details vary between database backends.

To make setting up AppenderDbi as painless as possible, the helper function select_dbi_layout() tries to automatically determine sensible LayoutDbi settings based on conn and - if it exists in the database already - table. If table does not exist in the database and you start logging, a new table will be created with the col_types from layout.

Methods

flush() Manually trigger flushing of the buffer

show(n, threshold) Show the last n log entries with a log level bellow threshold. The log entries will be formatted for console output via this Appenders Layout

append(event) Tell the Appender to process a LogEvent event. This method is usually not called by the user, but invoked by a Logger

filter(event) Determine whether the LogEvent x should be passed on to Appenders (TRUE) or not (FALSE). See also the active binding filters

add_filter(filter, name = NULL), remove_filter(pos) Add or remove a filter. When adding a filter an optional name can be specified. remove_filter() can remove by position or name (if one was specified)

Other Appenders: AppenderBuffer, AppenderConsole, AppenderFileRotating, AppenderFile, AppenderGmail, AppenderJson, AppenderPushbullet, AppenderRjdbc, AppenderSendmail, AppenderSyslog, AppenderTable, Appender
**AppenderDigest**

Abstract class for digests

**Description**

Abstract classes are exported for package developers that want to extend them, they cannot be instantiated directly.

Abstract class for Appenders that transmit digests of several log events at once, for example `AppenderPushbullet`, `AppenderGmail` and `AppenderSendmail`.

**Fields**

- `subject_layout`, `set_layout(subject_layout)` Like `layout`, but used to format the subject/title of the digest. While `layout` is applied to each `LogEvent` of the digest, `subject_layout` is only applied to the last one.

- `buffer_size`, `set_buffer_size(x)` integer scalar $\geq 0$ Number of `LogEvents` to buffer.

- `buffer_events`, `buffer_df`, `buffer_dt` The contents of the buffer as a list of `LogEvents`, a `data.frame` or a `data.table`.

- `flush_threshold`, `set_flush_threshold()` integer or character `log level`. Minimum event level that will trigger flushing of the buffer. This behaviour is implemented through `should_flush()`, and you can modify that function for different behaviour.

- `should_flush(event)`, `set_should_flush(x)` A function with exactly one arguments: `event`. If the function returns `TRUE`, flushing of the buffer is triggered. Defaults to flushing if an event of level `error` or higher is registered.

- `dt` Get the log recorded by this `Appender` as a `data.table` with a maximum of `buffer_size` rows.

- `data` Get the log recorded by this `Appender` as a `data.frame`.

- `threshold`, `set_threshold(level)` character or integer scalar. The minimum log level that triggers this logger. See `log_levels`.

- `layout`, `set_layout(layout)` a `Layout` that will be used for formatting the `LogEvents` passed to this `Appender`.

- `destination` The output destination of the `Appender` in human-readable form (mainly for print output).

- `filters`, `set_filters(filters)` a list that may contain functions or any `R` object with a `filter()` method. These functions must have exactly one argument: `event` which will get passed the `LogEvent` when the `Filterable`’s `filter()` method is invoked. If all of these functions evaluate to `TRUE` the `LogEvent` is passed on. Since `LogEvents` have reference semantics, filters can also be abused to modify them before they are passed on. Look at the source code of `with_log_level()` or `with_log_value()` for examples.
Methods

flush() Manually trigger flushing of the buffer

show(n, threshold) Show the last n log entries with a log level bellow threshold. The log entries will be formatted for console output via this Appenders Layout

append(event) Tell the Appender to process a LogEvent event. This method is usually not called by the user, but invoked by a Logger

filter(event) Determine whether the LogEvent x should be passed on to Appenders (TRUE) or not (FALSE). See also the active binding filters

add_filter(filter, name = NULL), remove_filter(pos) Add or remove a filter. When adding a filter an optional name can be specified. remove_filter() can remove by position or name (if one was specified)

LayoutFormat, LayoutGlue

Other abstract classes: AppenderMail, AppenderMemory, AppenderTable, Filterable

AppenderDt

Log to an in-memory data.table

Description

An Appender that outputs to an in-memory data.table. This kind of Appender is useful for interactive use, and has very little overhead.

Custom Fields

AppenderDt supports custom fields, but they have to be pre-allocated in the prototype argument. Custom fields that are not part of the prototype are discarded. If you want an Appender that retains all custom fields (at the cost of slightly less performance), take a look at AppenderBuffer.

With the default settings, the custom field value is included in the data.table as a list column to store arbitrary R objects (see example). It is recommended to use this feature only TRACE level.

Usage

x <- AppenderDt$new(threshold = NA_integer_, layout = LayoutFormat$new(fmt = "%L [%t] %m %f", timestamp_fmt = "%H:%M:%OS3", colors = getOption("lgr.colors", list())), prototype = data.table::data.table(.id = NA_integer_, level = NA_integer_, timestamp = Sys.time(), logger = NA_character_, caller = NA_character_, msg = NA_character_, .custom = list(list())), buffer_size = 1e+05, filters = NULL)

x$add_filter(filter, name = NULL)
Creating a Data Table Appender

In addition to the usual fields, AppenderDt$new() requires that you supply a buffer_size and a prototype. These determine the structure of the data.table used to store the log this appender creates and cannot be modified anymore after the instantiation of the appender.

The Layout for this Appender is used only to format console output of its $show() method.

**buffer_size** integer scalar. Number of rows of the in-memory data.table

**prototype** A prototype data.table. The prototype must be a data.table with the same columns and column types as the data you want to log. The actual content of the columns is irrelevant.

There are a few columns that have special meaning, based on their name:

- `.id`: integer (mandatory). Must always be the first column and is used internally by the Appender
- `.custom`: list (optional). If present all custom values of the event (that are not already part of the prototype) are stored in this list column.

**Fields**

dt Get the log recorded by this Appender as a data.table with a maximum of buffer_size rows

data Get the log recorded by this Appender as a data.frame

threshold, set_threshold(level) character or integer scalar. The minimum log level that triggers this logger. See log_levels

layout, set_layout(layout) a Layout that will be used for formatting the LogEvents passed to this Appender

destination The output destination of the Appender in human-readable form (mainly for print output)

filters, set_filters(filters) a list that may contain functions or any R object with a filter() method. These functions must have exactly one argument: event which will get
passed the LogEvent when the Filterable’s filter() method is invoked. If all of these func-
tions evaluate to TRUE the LogEvent is passed on. Since LogEvents have reference semantics,
filters can also be abused to modify them before they are passed on. Look at the source code
of with_log_level() or with_log_value() for examples.

Methods

show(n, threshold) Show the last n log entries with a log level bellow threshold. The log
entries will be formatted for console output via this Appenders Layout

append(event) Tell the Appender to process a LogEvent event. This method is usually not called
by the user, but invoked by a Logger

filter(event) Determine whether the LogEvent x should be passed on to Appenders (TRUE) or
not (FALSE). See also the active binding filters

add_filter(filter, name = NULL), remove_filter(pos) Add or remove a filter. When adding
a filter an optional name can be specified. remove_filter() can remove by position or name
(if one was specified)

Comparison AppenderBuffer and AppenderDt

Both AppenderBuffer and AppenderDt do in memory buffering of events. AppenderBuffer retains a
copies of the events it processes and has the ability to pass the buffered events on to other Appenders.
AppenderDt converts the events to rows in a data.table and is a bit harder to configure. Used
inside loops (several hundred iterations), AppenderDt has much less overhead than AppenderBuffer.
For single logging calls and small loops, AppenderBuffer is more performant. This is related to how
memory pre-allocation is handled by the appenders.

In short: Use AppenderDt if you want an in-memory log for interactive use, and AppenderBuffer if
you actually want to buffer events

Examples

lg <- get_logger("test")
lg$configure(list(  
    appenders = list(memory = AppenderBuffer$new()),
    threshold = NA,
    propagate = FALSE # to prevent routing to root logger for this example)
)  
lg$debug("test")
lg$error("test")

# Displaying the log
lg$appenders$memory$data
lg$appenders$memory$show()
show_log(target = lg$appenders$memory)
# If you pass a Logger to show_log(), it looks for the first AppenderDt
# that it can find.
show_log(target = lg)

# Custom fields are stored in the list column .custom by default
lg$info("the iris data frame", caps = LETTERS[1:5])
lg$appenders$memory$data
lg$appenders$memory$data$.custom[[3]]$caps
lg$config(NULL)

## AppenderFile
### Log to a file

**Description**

A simple Appender that outputs to a file in the file system. If you plan to log to text files, consider logging to JSON files and take a look at AppenderJson, which is more or less a shortcut for AppenderFile with LayoutJson and a few extra methods for convenience.

**Usage**

```r
x <- AppenderFile$new(file, threshold = NA_integer_, layout =
  LayoutFormat$new(), filters = NULL)
```

```r
x$add_filter(filter, name = NULL)
x$append(event)
x$filter(event)
x$format(color = FALSE, ...)
x$remove_filter(pos)
x$set_file(file)
x$set_filters(filters)
x$set_layout(layout)
x$set_threshold(level)
x$show(threshold = NA_integer_, n = 20L)
```

```r
x$destination
x$file
x$filters
x$layout
x$threshold
```

**Fields**

- **file**, `set_file(file)` character scalar. Path to the desired log file. If the file does not exist it will be created.

- **threshold**, `set_threshold(level)` character or integer scalar. The minimum log level that triggers this logger. See log_levels
AppenderFile

layout, set_layout(layout) a Layout that will be used for formatting the LogEvents passed to this Appender

destination The output destination of the Appender in human-readable form (mainly for print output)

filters, set_filters(filters) a list that may contain functions or any R object with a filter() method. These functions must have exactly one argument: event which will get passed the LogEvent when the Filterable’s filter() method is invoked. If all of these functions evaluate to TRUE the LogEvent is passed on. Since LogEvents have reference semantics, filters can also be abused to modify them before they are passed on. Look at the source code of with_log_level() or with_log_value() for examples.

Creating a New Appender

New Appenders are instantiated with <AppenderSubclass>$new(). For the arguments to new() please refer to the section Fields. You can also modify those fields after the Appender has been created with setters in the form of appender$set_<fieldname>(value)

Methods

append(event) Tell the Appender to process a LogEvent event. This method is usually not called by the user, but invoked by a Logger

filter(event) Determine whether the LogEvent x should be passed on to Appenders (TRUE) or not (FALSE). See also the active binding filters

add_filter(filter, name = NULL), remove_filter(pos) Add or remove a filter. When adding a filter an optional name can be specified. remove_filter() can remove by position or name (if one was specified)

AppenderFileRotating

Description

An extension of AppenderFile that rotates logfiles based on certain conditions. Please refer to the documentation of rotor::rotate() for the meanings of the extra arguments

Usage

```
x <- AppenderFileRotating$new(file, threshold = NA_integer_, layout = LayoutFormat$new(), filters = NULL, size = Inf, max_backups = Inf, compression = FALSE, backup_dir = dirname(file), create_file = TRUE)

x <- AppenderFileRotatingDate$new(file, threshold = NA_integer_, layout = LayoutFormat$new(), filters = NULL, age = Inf, size = -1, max_backups = Inf, compression = FALSE, backup_dir = dirname(file), fmt = "%Y-%m-%d", overwrite = FALSE, create_file = TRUE, cache_backups = TRUE)

x <- AppenderFileRotatingTime$new(file, threshold = NA_integer_, layout = LayoutFormat$new(), filters = NULL, age = Inf, size = -1, max_backups = Inf, compression = FALSE, backup_dir = dirname(file), fmt = "%Y-%m-%d--%H-%M-%S", overwrite = FALSE, create_file = TRUE, cache_backups = TRUE)
```

```
x$add_filter(filter, name = NULL)
x$append(event)
x$clone(deep = FALSE)
x$filter(event)
x$format(color = false, ...)
x$format(color = FALSE, ...)
x$prune(max_backups = self$max_backups)
x$remove_filter(pos)
x$rotate(force = FALSE, now = Sys.time())
x$rotate(force = FALSE)
x$set_age(x)
```

lg$info("A test message")

x$create_file
x$destination
x$file
x$filters
x$fmt
x$layout
x$max_backups
x$overwrite
x$size
x$threshold
```

**Fields**

`age`, `size`, `max_backups`, `fmt`, `overwrite`, `compression`, `backup_dir` Please see `rotor::rotate()` for the meaning of these arguments (`fmt` is passed on as `format`).

`cache_backups`, `set_cache_backups(x)` TRUE or FALSE. If TRUE (the default) the list of backups is cached, if FALSE it is read from disk every time this appender triggers. Caching brings a significant speedup for checking whether to rotate or not based on the age of the last backup, but is only safe if there are no other programs/functions (except this appender) interacting with the backups.

`backups` A `data.frame` containing information on path, file size, etc... on the available backups of `file`.

`file`, `set_file(file)` character scalar. Path to the desired log file. If the file does not exist it will be created.

`threshold`, `set_threshold(level)` character or integer scalar. The minimum log level that triggers this logger. See `log_levels`
layout, set_layout(layout) a Layout that will be used for formatting the LogEvents passed to this Appender

destination The output destination of the Appender in human-readable form (mainly for print output)

filters, set_filters(filters) a list that may contain functions or any R object with a filter() method. These functions must have exactly one argument: event which will get passed the LogEvent when the Filterable’s filter() method is invoked. If all of these functions evaluate to TRUE the LogEvent is passed on. Since LogEvents have reference semantics, filters can also be abused to modify them before they are passed on. Look at the source code of with_log_level() or with_log_value() for examples.

Creating a New Appender

New Appenders are instantiated with <AppenderSubclass>$new(). For the arguments to new() please refer to the section Fields. You can also modify those fields after the Appender has been created with setters in the form of appender$set_<fieldname>(value)

Methods

append(event) Tell the Appender to process a LogEvent event. This method is usually not called by the user, but invoked by a Logger

filter(event) Determine whether the LogEvent x should be passed on to Appenders (TRUE) or not (FALSE). See also the active binding filters

add_filter(filter, name = NULL), remove_filter(pos) Add or remove a filter. When adding a filter an optional name can be specified. remove_filter() can remove by position or name (if one was specified)

AppenderGmail  Send emails via gmailr

Description

Send mails via gmailr::send_message(). This Appender keeps an in-memory buffer like AppenderBuffer. If the buffer is flushed, usually because an event of specified magnitude is encountered, all buffered events are concatenated to a single message. The default behaviour is to push the last 30 log events in case a fatal event is encountered.
Usage

```r
x <- AppenderGmail$new(to, threshold = NA_integer_, flush_threshold = "fatal",
layout = LayoutFormat$new(fmt = "%L [%t] %m %f", timestamp_fmt = "%H:%M:%S"),
subject_layout = LayoutFormat$new(fmt = "[LGR] %L: %m"), buffer_size = 30,
from = get_user(), cc = NULL, bcc = NULL, html = FALSE, filters = NULL)

x$add_filter(filter, name = NULL)

x$append(event)

x$filter(event)

x$flush()

x$format(color = FALSE, ...)

x$remove_filter(pos)

x$should_flush

x$subject_layout

x$threshold

x$to
```
Fields

to, from, cc, bcc character vectors.

html, set_html(TRUE or FALSE. Send a html email message? This does currently only formats
the log contents as monospace verbatim text.

subject_layout, set_layout(subject_layout) Like layout, but used to format the subject/title
of the digest. While layout is applied to each LogEvent of the digest, subject_layout is
only applied to the last one.

buffer_size, set_buffer_size(x) integer scalar >= 0 Number of LogEvents to buffer.

buffer_events, buffer_df, buffer_dt The contents of the buffer as a list of LogEvents, a
data.frame or a data.table.

flush_threshold, set_flush_threshold() integer or character log level. Minimum event
level that will trigger flushing of the buffer. This behaviour is implemented through should_flush(),
and you can modify that function for different behaviour.

should_flush(event), set_should_flush(x) A function with exactly one arguments: event.
If the function returns TRUE, flushing of the buffer is triggered. Defaults to flushing if an event
of level error or higher is registered.

dt Get the log recorded by this Appender as a data.table with a maximum of buffer_size rows

data Get the log recorded by this Appender as a data.frame

threshold, set_threshold(level) character or integer scalar. The minimum log level that
triggers this logger. See log_levels

layout, set_layout(layout) a Layout that will be used for formatting the LogEvents passed to
this Appender

destination The output destination of the Appender in human-readable form (mainly for print
output)

filters, set_filters(filters) a list that may contain functions or any R object with a
filter() method. These functions must have exactly one argument: event which will get
passed the LogEvent when the Filterable's filter() method is invoked. If all of these func-
tions evaluate to TRUE the LogEvent is passed on. Since LogEvents have reference semantics,
filters can also be abused to modify them before they are passed on. Look at the source code
of with_log_level() or with_log_value() for examples.

Methods

flush() Manually trigger flushing of the buffer

show(n, threshold) Show the last n log entries with a log level bellow threshold. The log
entries will be formatted for console output via this Appenders Layout

append(event) Tell the Appender to process a LogEvent event. This method is usually not called
by the user, but invoked by a Logger

filter(event) Determine whether the LogEvent x should be passed on to Appenders (TRUE) or
not (FALSE). See also the active binding filters
add_filter(filter, name = NULL), remove_filter(pos) Add or remove a filter. When adding a filter an optional name can be specified. remove_filter() can remove by position or name (if one was specified)

---

**AppenderJson**  
*Log to a JSON file*

**Description**

AppenderJson is a shortcut for AppenderFile with LayoutJson, but comes with an extra method show() and an extra active field data to comfortably access the underlying file.

**Usage**

```r
x <- AppenderFile$new(file, threshold = NA_integer_, layout = LayoutFormat$new(), filters = NULL)
```

```r
x$add_filter(filter, name = NULL)
x$append(event)
x$filter(event)
x$format(color = FALSE, ...)
x$remove_filter(pos)
x$set_file(file)
x$set_filters(filters)
x$set_layout(layout)
x$set_threshold(level)
x$show(threshold = NA_integer_, n = 20L)
```

```r
x$destination
x$file
x$filters
x$layout
x$threshold
```

**Creating a New Appender**

New Appenders are instantiated with <AppenderSubclass>$new(). For the arguments to new() please refer to the section Fields. You can also modify those fields after the Appender has been created with setters in the form of appender$set_<fieldname>(value)
**Fields**

- `file`, `set_file(file)` character scalar. Path to the desired log file. If the file does not exist it will be created.

- `threshold`, `set_threshold(level)` character or integer scalar. The minimum log level that triggers this logger. See `log_levels`

- `layout`, `set_layout(layout)` a Layout that will be used for formatting the LogEvents passed to this Appender

- `destination` The output destination of the Appender in human-readable form (mainly for print output)

- `filters`, `set_filters(filters)` a list that may contain functions or any R object with a `filter()` method. These functions must have exactly one argument: `event` which will get passed the LogEvent when the Filterable’s `filter()` method is invoked. If all of these functions evaluate to `TRUE` the LogEvent is passed on. Since LogEvents have reference semantics, filters can also be abused to modify them before they are passed on. Look at the source code of `with_log_level()` or `with_log_value()` for examples.

- `data` Get the log recorded by this Appender as a data.frame

**Methods**

- `show(n, threshold)` Show the last `n` log entries with a log level bellow `threshold`. The log entries will be formatted as in the source JSON file

- `append(event)` Tell the Appender to process a `LogEvent` event. This method is usually not called by the user, but invoked by a `Logger`

- `filter(event)` Determine whether the LogEvent `x` should be passed on to Appenders (TRUE) or not (FALSE). See also the active binding filters

- `add_filter(filter, name = NULL), remove_filter(pos)` Add or remove a filter. When adding a filter an optional name can be specified. `remove_filter()` can remove by position or name (if one was specified)
AppenderMemory

Abstract class for logging to memory buffers

Description

Abstract classes are exported for package developers that want to extend them, they cannot be instantiated directly.

AppenderMemory is extended by Appenders that retain an in-memory event buffer, such as AppenderBuffer and AppenderPushbullet.

Usage

```r
x <- AppenderMemory$new(layout = Layout$new(), threshold = NA_integer_)

x$add_filter(filter, name = NULL)
x$append(event)
x$filter(event)
x$flush()
x/format(color = FALSE, ...)
x$remove_filter(pos)
x$set_buffer_size(x)
x$set_filters(filters)
x$set_flush_on_exit(x)
x$set_flush_on_rotate(x)
```

LayoutFormat, LayoutJson

Other Appenders: AppenderBuffer, AppenderConsole, AppenderDbi, AppenderFileRotating, AppenderFile, AppenderGmail, AppenderPushbullet, AppenderRjdbc, AppenderSendmail, AppenderSyslog, AppenderTable, Appender

Examples

```r
tf <- tempfile()
lg <- get_logger("test")
  set_appenders(AppenderJson$new(tf))
  set_propagate(FALSE)

  lg$info("A test message")
  lg$info("A test message %s strings", "with format strings", and = "custom_fields")

  lg$appenders[[1]]$show()
  lg$appenders[[1]]$data

  # cleanup
  lg$config(NULL)
  unlink(tf)
```
Fields

- `buffer_size`, `set_buffer_size(x)` integer scalar $\geq 0$ Number of LogEvents to buffer.
- `buffer_events`, `buffer_df`, `buffer_dt` The contents of the buffer as a list of LogEvents, a data.frame or a data.table.
- `flush_threshold`, `set_flush_threshold()` integer or character log level. Minimum event level that will trigger flushing of the buffer. This behaviour is implemented through `should_flush()`, and you can modify that function for different behaviour.
- `should_flush(event)`, `set_should_flush(x)` A function with exactly one argument: event. If the function returns TRUE, flushing of the buffer is triggered. Defaults to flushing if an event of level error or higher is registered.
- `dt` Get the log recorded by this Appender as a data.table with a maximum of `buffer_size` rows.
- `data` Get the log recorded by this Appender as a data.frame.
- `threshold`, `set_threshold(level)` character or integer scalar. The minimum log level that triggers this logger. See log_levels.
- `layout`, `set_layout(layout)` a Layout that will be used for formatting the LogEvents passed to this Appender.
- `destination` The output destination of the Appender in human-readable form (mainly for print output).
- `filters`, `set_filters(filters)` a list that may contain functions or any R object with a filter() method. These functions must have exactly one argument: event which will get
passed the LogEvent when the Filterable’s filter() method is invoked. If all of these functions evaluate to TRUE the LogEvent is passed on. Since LogEvents have reference semantics, filters can also be abused to modify them before they are passed on. Look at the source code of with_log_level() or with_log_value() for examples.

Methods

flush() Manually trigger flushing of the buffer

show(n, threshold) Show the last n log entries with a log level bellow threshold. The log entries will be formatted for console output via this Appenders Layout

append(event) Tell the Appender to process a LogEvent event. This method is usually not called by the user, but invoked by a Logger

filter(event) Determine whether the LogEvent x should be passed on to Appenders (TRUE) or not (FALSE). See also the active binding filters

add_filter(filter, name = NULL), remove_filter(pos) Add or remove a filter. When adding a filter an optional name can be specified. remove_filter() can remove by position or name (if one was specified)

See Also

LayoutFormat

Other abstract classes: AppenderDigest, AppenderMail, AppenderTable, Filterable

Description

Send push notifications via pushbullet. This Appender keeps an in-memory buffer like AppenderBuffer. If the buffer is flushed, usually because an event of specified magnitude is encountered, all buffered events are concatenated to a single message that is sent to RPushbullet::pbPost(). The default behaviour is to push the last 7 log events in case a fatal event is encountered.

Usage

x <- AppenderPushbullet$new(threshold = NA_integer_, flush_threshold = "fatal", layout = LayoutFormat$new(fmt = "%K %t> %m %f", timestamp_fmt = "%H:%M:%S"), subject_layout = LayoutFormat$new(fmt = "[LGR] %L: %m"), buffer_size = 6, recipients = NULL, email = NULL, channel = NULL, devices = NULL, apikey = NULL, filters = NULL)

x$add_filter(filter, name = NULL)

x$append(event)

x$filter(event)
Fields

apikey, recipients, email, channel, devices See RPushbullet::pbPost()

buffer_size, set_buffer_size(x) integer scalar >= 0 Number of LogEvents to buffer.

buffer_events, buffer_df, buffer_dt The contents of the buffer as a list of LogEvents, a data.frame or a data.table.

flush_threshold, set_flush_threshold() integer or character log level. Minimum event level that will trigger flushing of the buffer. This behaviour is implemented through should_flush(), and you can modify that function for different behaviour.
should_flush(event), set_should_flush(x) A function with exactly one argument: event. If the function returns TRUE, flushing of the buffer is triggered. Defaults to flushing if an event of level error or higher is registered.

dt Get the log recorded by this Appender as a data.table with a maximum of buffer_size rows

data Get the log recorded by this Appender as a data.frame

threshold, set_threshold(level) character or integer scalar. The minimum log level that triggers this logger. See log_levels

layout, set_layout(layout) a Layout that will be used for formatting the LogEvents passed to this Appender

destination The output destination of the Appender in human-readable form (mainly for print output)

filters, set_filters(filters) a list that may contain functions or any R object with a filter() method. These functions must have exactly one argument: event which will get passed the LogEvent when the Filterable’s filter() method is invoked. If all of these functions evaluate to TRUE the LogEvent is passed on. Since LogEvents have reference semantics, filters can also be abused to modify them before they are passed on. Look at the source code of with_log_level() or with_log_value() for examples.

Methods

flush() Manually trigger flushing of the buffer

show(n, threshold) Show the last n log entries with a log level below threshold. The log entries will be formatted for console output via this Appenders Layout

append(event) Tell the Appender to process a LogEvent event. This method is usually not called by the user, but invoked by a Logger

filter(event) Determine whether the LogEvent x should be passed on to Appenders (TRUE) or not (FALSE). See also the active binding filters

add_filter(filter, name = NULL), remove_filter(pos) Add or remove a filter. When adding a filter an optional name can be specified. remove_filter() can remove by position or name (if one was specified)

AppenderRjdbc

Log to databases via RJDBC

Description

Log to a database table with the RJDBC package. RJDBC is only somewhat DBI compliant and does not work with AppenderDbi. I do not recommend using RJDBC if it can be avoided. AppenderRjdbc is only tested for DB2 databases, and it is likely it will not work properly for other databases. Please file a bug report if you encounter any issues.

Usage

x <- AppenderRjdbc$new(conn, table, threshold = NA_integer_, layout = select_dbi_layout(conn, table), close_on_exit = TRUE, buffer_size = 10, flush_threshold = "error", flush_on_exit = TRUE, flush_on_rotate = TRUE, should_flush = default_should_flush, filters = NULL)

x$add_filter(filter, name = NULL)
x$append(event)
x$filter(event)
x$flush()
x$format(color = FALSE, ...)
x$remove_filter(pos)
x$set_buffer_size(x)
x$set_close_on_exit(x)
x$set_conn(conn)
x$set_filters(filters)
x$set_flush_on_exit(x)
x$set_flush_on_rotate(x)
x$set_flush_threshold(level)
x$set_layout(layout)
x$set_should_flush(x)
x$set_threshold(level)
x$show(threshold = NA_integer_, n = 20)
x$show(threshold = NA_integer_, n = 20L)

x$buffer_df
x$buffer_dt
x$buffer_events
x$buffer_size
x$close_on_exit
x$col_types
x$conn
x$data
x$destination
x*dt
x$filters
Fields

$flush_on_exit
$flush_on_rotate
$flush_threshold
$layout
$should_flush
$table
$table_id
$table_name
$threshold

Note: $data and show() query the data from the remote database and might be slow for very large logs.

close_on_exit, set_close_on_exit(TRUE or FALSE. Close the Database connection when the Logger is removed?)

conn, set_conn(conn) a DBI connection

table Name of the target database table

buffer_size, set_buffer_size(x) integer scalar >= 0 Number of LogEvents to buffer.

buffer_events, buffer_df, buffer_dt The contents of the buffer as a list of LogEvents, a data.frame or a data.table.

flush_threshold, set_flush_threshold() integer or character log level. Minimum event level that will trigger flushing of the buffer. This behaviour is implemented through should_flush(), and you can modify that function for different behaviour.

should_flush(event), set_should_flush(x) A function with exactly one argument: event. If the function returns TRUE, flushing of the buffer is triggered. Defaults to flushing if an event of level error or higher is registered.

dt Get the log recorded by this Appender as a data.table with a maximum of buffer_size rows

data Get the log recorded by this Appender as a data.frame

threshold, set_threshold(level) character or integer scalar. The minimum log level that triggers this logger. See log_levels

layout, set_layout(layout) a Layout that will be used for formatting the LogEvents passed to this Appender

destination The output destination of the Appender in human-readable form (mainly for print output)

filters, set_filters(filters) a list that may contain functions or any R object with a filter() method. These functions must have exactly one argument: event which will get passed the LogEvent when the Filterable’s filter() method is invoked. If all of these functions evaluate to TRUE the LogEvent is passed on. Since LogEvents have reference semantics, filters can also be abused to modify them before they are passed on. Look at the source code of with_log_level() or with_log_value() for examples.
Methods

flush() Manually trigger flushing of the buffer

show(n, threshold) Show the last n log entries with a log level below threshold. The log entries will be formatted for console output via this Appenders Layout

append(event) Tell the Appender to process a LogEvent event. This method is usually not called by the user, but invoked by a Logger

filter(event) Determine whether the LogEvent x should be passed on to Appenders (TRUE) or not (FALSE). See also the active binding filters

add_filter(filter, name = NULL), remove_filter(pos) Add or remove a filter. When adding a filter an optional name can be specified. remove_filter() can remove by position or name (if one was specified)

Creating a New Appender

An AppenderDbi is linked to a database table via its table argument. If the table does not exist it is created either when the Appender is first instantiated or (more likely) when the first LogEvent would be written to that table. Rather than to rely on this feature, it is recommended that you create the target log table first manually using an SQL CREATE TABLE statement as this is safer and more flexible. See also LayoutDbi.

New Appenders are instantiated with <AppenderSubclass>$new(). For the arguments to new() please refer to the section Fields. You can also modify those fields after the Appender has been created with setters in the form of appender$set_<fieldname>(value)

Choosing the Right DBI Layout

Layouts for relational database tables are tricky as they have very strict column types and further restrictions. On top of that implementation details vary between database backends.

To make setting up AppenderDbi as painless as possible, the helper function select_dbi_layout() tries to automatically determine sensible LayoutDbi settings based on conn and - if it exists in the database already - table. If table does not exist in the database and you start logging, a new table will be created with the col_types from layout.

Fields

headers, control see sendmailR::sendmail()

to, from, cc, bcc character vectors.

html, set_html() TRUE or FALSE. Send a html email message? This does currently only formats
the log contents as monospace verbatim text.

subject_layout, set_layout(subject_layout) Like layout, but used to format the subject/title
of the digest. While layout is applied to each LogEvent of the digest, subject_layout is
only applied to the last one.

buffer_size, set_buffer_size(x) integer scalar >= 0 Number of LogEvents to buffer.

buffer_events, buffer_df, buffer_dt The contents of the buffer as a list of LogEvents, a
data.frame or a data.table.

flush_threshold, set_flush_threshold() integer or character log level. Minimum event
level that will trigger flushing of the buffer. This behaviour is implemented through should_flush(),
and you can modify that function for different behaviour.

should_flush(event), set_should_flush(x) A function with exactly one arguments: event.
If the function returns TRUE, flushing of the buffer is triggered. Defaults to flushing if an event
of level error or higher is registered.

dt Get the log recorded by this Appender as a data.table with a maximum of buffer_size rows

data Get the log recorded by this Appender as a data.frame

threshold, set_threshold(level) character or integer scalar. The minimum log level that
triggers this logger. See log_levels

layout, set_layout(layout) a Layout that will be used for formatting the LogEvents passed to
this Appender

destination The output destination of the Appender in human-readable form (mainly for print
output)
AppenderSyslog

filters, set_filters(filters) a list that may contain functions or any R object with a filter() method. These functions must have exactly one argument: event which will get passed the LogEvent when the Filterable’s filter() method is invoked. If all of these functions evaluate to TRUE the LogEvent is passed on. Since LogEvents have reference semantics, filters can also be abused to modify them before they are passed on. Look at the source code of with_log_level() or with_log_value() for examples.

Methods

flush() Manually trigger flushing of the buffer

show(n, threshold) Show the last n log entries with a log level bellow threshold. The log entries will be formatted for console output via this Appenders Layout

append(event) Tell the Appender to process a LogEvent event. This method is usually not called by the user, but invoked by a Logger

filter(event) Determine whether the LogEvent x should be passed on to Appenders (TRUE) or not (FALSE). See also the active binding filters

add_filter(filter, name = NULL), remove_filter(pos) Add or remove a filter. When adding a filter an optional name can be specified. remove_filter() can remove by position or name (if one was specified)

Note

The default Layout’s fmt indents each log entry with 3 blanks. This is a workaround so that Microsoft Outlook does not mess up the line breaks.

See Also

LayoutFormat, LayoutGlue

Other Appenders: AppenderBuffer, AppenderConsole, AppenderDbi, AppenderFileRotating, AppenderFile, AppenderGmail, AppenderJson, AppenderPushbullet, AppenderRjdbc, AppenderSyslog, AppenderTable, Appender

AppenderSyslog Log to the POSIX System Log

Description

An Appender that writes to the syslog on supported POSIX platforms. Requires the rsyslog package.
AppenderSyslog

Usage

```r
x <- AppenderSyslog$new(identifier = NULL, threshold = NA_integer_, layout = LayoutFormat$new("%m"), filters = NULL, syslog_levels = c(CRITICAL = "fatal", ERR = "error", WARNING = "warn", INFO = "info", DEBUG = "debug", DEBUG = "trace"))
```

```r
x$add_filter(filter, name = NULL)
x$append(event)
x$filter(event)
x$format(color = FALSE, ...)
x$remove_filter(pos)
x$set_filters(filters)
x$set_identifier(x)
x$set_layout(layout)
x$set_syslog_levels(x)
x$set_threshold(level)
```

```r
x$destination
x$filters
x$identifier
x$layout
x$syslog_levels
x$threshold
```

Fields

- **identifier** character scalar. A string identifying the process; if NULL defaults to the logger name.

- **syslog_levels** a named character vector mapping whose names are log levels as understood by `rsyslog::syslog()` and whose values are lgr log levels (either character or numeric)
  - a function that takes a vector of lgr log levels as input and returns a character vector of log levels for `rsyslog::syslog()`.

- **threshold**, `set_threshold(level)` character or integer scalar. The minimum log level that triggers this logger. See `log_levels`

- **layout**, `set_layout(layout)` a Layout that will be used for formatting the LogEvents passed to this Appender

- **destination** The output destination of the Appender in human-readable form (mainly for print output)

- **filters**, `set_filters(filters)` a list that may contain functions or any R object with a `filter()` method. These functions must have exactly one argument: event which will get passed the LogEvent when the Filterable’s `filter()` method is invoked. If all of these functions evaluate to TRUE the LogEvent is passed on. Since LogEvents have reference semantics, filters can also be abused to modify them before they are passed on. Look at the source code of `with_log_level()` or `with_log_value()` for examples.
Creating a New Appender

New Appenders are instantiated with `<AppenderSubclass>$new()`. For the arguments to `new()` please refer to the section Fields. You can also modify those fields after the Appender has been created with setters in the form of `appender$set_<fieldname>(value)

Methods

`append(event)` Tell the Appender to process a LogEvent event. This method is usually not called by the user, but invoked by a Logger

`filter(event)` Determine whether the LogEvent x should be passed on to Appenders (TRUE) or not (FALSE). See also the active binding filters

`add_filter(filter, name = NULL), remove_filter(pos)` Add or remove a filter. When adding a filter an optional name can be specified. `remove_filter()` can remove by position or name (if one was specified)

See Also

`LayoutFormat, LayoutJson`

Other Appenders: `AppenderBuffer, AppenderConsole, AppenderDbi, AppenderFileRotating, AppenderFile, AppenderGmail, AppenderJson, AppenderPushbullet, AppenderRjdbc, AppenderSendmail, AppenderTable, Appender`

Examples

```r
if (requireNamespace("rsyslog", quietly = TRUE)) {
  lg <- get_logger("rsyslog/test")
  lg$add_appender(AppenderSyslog$new(), "syslog")
  lg$info("A test message")

  if (Sys.info()["sysname"] == "Linux"){
    system("journalctl -t 'rsyslog/test'")
  }

  invisible(lg$config(NULL)) # cleanup
}
```

AppenderTable

Abstract class for logging to tabular structures

Description

Abstract classes are exported for package developers that want to extend them, they cannot be instantiated directly.

AppenderTable is extended by Appenders that write to a data source that can be interpreted as tables, (usually a data.frame). Examples are AppenderDbi, AppenderRjdbc and AppenderDt.
as.data.frame.LogEvent

Fields

data  Get the log recorded by this Appender as a data.frame

threshold, set_threshold(level) character or integer scalar. The minimum log level that triggers this logger. See log_levels

layout, set_layout(layout) a Layout that will be used for formatting the LogEvents passed to this Appender

destination The output destination of the Appender in human-readable form (mainly for print output)

filters, set_filters(filters) a list that may contain functions or any R object with a filter() method. These functions must have exactly one argument: event which will get passed the LogEvent when the Filterable’s filter() method is invoked. If all of these functions evaluate to TRUE the LogEvent is passed on. Since LogEvents have reference semantics, filters can also be abused to modify them before they are passed on. Look at the source code of with_log_level() or with_log_value() for examples.

Methods

show(n, threshold) Show the last n log entries with a log level below threshold.

append(event) Tell the Appender to process a LogEvent event. This method is usually not called by the user, but invoked by a Logger

filter(event) Determine whether the LogEvent x should be passed on to Appenders (TRUE) or not (FALSE). See also the active binding filters

add_filter(filter, name = NULL), remove_filter(pos) Add or remove a filter. When adding a filter an optional name can be specified. remove_filter() can remove by position or name (if one was specified)

See Also

Other abstract classes: AppenderDigest, AppenderMail, AppenderMemory, Filterable

Other Appenders: AppenderBuffer, AppenderConsole, AppenderDbi, AppenderFileRotating, AppenderFile, AppenderGmail, AppenderJson, AppenderPushbullet, AppenderRjdbc, AppenderSendmail, AppenderSyslog, Appender

as.data.frame.LogEvent

Coerce LogEvents to Data Frames

Description

Coerce LogEvents to data.frames, data.tables, or tibbles.
Usage

```r
## S3 method for class 'LogEvent'
as.data.frame(x, row.names = NULL, optional = FALSE,
              stringsAsFactors = FALSE, ...)
as.data.table.LogEvent(x, ...)
as_tibble.LogEvent(x, ...)
```

Arguments

- `x`: any R object.
- `row.names`: NULL or a character vector giving the row names for the data frame. Missing values are not allowed.
- `optional`: currently ignored and only included for compatibility.
- `stringsAsFactors`: logical scalar: should character vectors be converted to factors? Defaults to FALSE (as opposed to `base::as.data.frame()`) and is only included for compatibility.
- `...`: passed on to `data.frame()`

See Also

data.table::data.table, tibble::tibble

Examples

```r
lg <- get_logger("test")
lg$info("lorem ipsum")
as.data.frame(lg$last_event)

lg$info("LogEvents can store any custom log values", df = iris)
as.data.frame(lg$last_event)
head(as.data.frame(lg$last_event)$df[[1]])
```

---

**Basic Setup for the Logging System**

Description

A quick and easy way to configure the root logger. This is less powerful than using `lgr$config()` or `lgr$set_*()`, but reduces the most common configurations to a single line of code.
Usage

basic_config(file = NULL, fmt = "%L [%t] %m",
timestamp_fmt = "%Y-%m-%d %H:%M:%OS3", threshold = "info",
appenders = NULL, console = if (is.null(appenders)) "all" else FALSE,
console_fmt = "%L [%t] %m %f",
console_timestamp_fmt = "%H:%M:%OS3", memory = FALSE)

Arguments

file character scalar: If not NULL a AppenderFile will be created that logs to this file. If the filename ends in .jsonl, the Appender will be set up to use the JSON Lines format instead of plain text (see AppenderFile and AppenderJson).

fmt character scalar: Format to use if file is supplied and not a .jsonl file. If NULL it defaults to "%L [%t] %m" (see format.LogEvent)

timestamp_fmt see format.POSIXct()

threshold character or integer scalar. The minimum log level that should be processed by the root logger.

appenders a single Appender or a list thereof.

console logical scalar or a threshold (see above). Add an appender logs to the console (i.e. displays messages in an interactive R session)

console_fmt character scalar: like fmt but used for console output

console_timestamp_fmt character scalar: like timestamp_fmt but used for console output

memory logical scalar. or a threshold (see above). Add an Appender that logs to a memory buffer, see also show_log() and AppenderBuffer

Value

the root Logger (lgr)

Examples

# log to a file
basic_config(file = tempfile())
unlink(lgr$appenders$file$file) # cleanup

basic_config(file = tempfile(fileext = "jsonl"))
unlink(lgr$appenders$file$file) # cleanup

# log debug messages to a memory buffer
basic_config(threshold = "all", memory = "all", console = "info")
lgr$info("an info message")
lgr$debug("a hidden message")
show_log()

# reset to default config
basic_config()
colorize_levels  

**Colorize Levels**

**Description**

Colorize Levels

**Usage**

```r
colorize_levels(x, colors = getOption("lgr.colors", NULL))
```

**Arguments**

- `x` numeric or character levels to be colored. Unlike in many other functions in lgr, character levels are *not* case sensitive in this function and leading/trailing whitespace is ignored to make it more comfortable to use colorize_levels() inside formatting functions.
- `colors` A list of functions that will be used to color the log levels (likely from crayon::crayon).

**Value**

a character vector wit color ANSI codes

**See Also**

Other formatting utils: `label_levels`

**Examples**

```r
cat(colorize_levels(c(100, 200)))
cat(colorize_levels(c("trace", "warn ", "DEBUG")))
```

default_exception_handler  

**Demote an exception to a warning**

**Description**

Throws a timestamped warning instead of stopping the program. This is the default exception handler used by Loggers.

**Usage**

```r
default_exception_handler(e)
```
Arguments

e an error condition object

Value

The warning as character vector

Examples

tryCatch(stop("an error has occurred"), error = default_exception_handler)

---

default_should_flush Default should_flush function

Description

This is the default "should_flush()" trigger function for Appenders that support such a mechanism, such as AppenderBuffer and AppenderDbi. It returns TRUE if the event's level meets or exceeds the Appender's flush_threshold.

Usage

default_should_flush(event)

Arguments

event a LogEvent

Value

TRUE or FALSE

---

EventFilter Event Filters

Description

Filters can be used for the $set_filter() and $add_filter() methods of Appenders and Loggers. You normally do not need to construct a formal EventFilter object, you can just use any function that has the single argument event or any object that has a filter method.
Modifying LogEvents with Filters

Since LogEvents are R6 objects with reference semantics, Filters can also be abused to modify log events before passing them on. lgr comes with a few preset filters that use this property:

FilterInject$new(..., .list) ... and .list can take any number of named R6 objects that will be injected as custom fields into all LogEvents processed by the Appender/Logger that this filter is attached to. See also with_log_value()

FilterForceLevel$new(level) Sets the level of all LogEvents processed by the Appender/Logger that this filter is attached to to level. See also with_log_value()

Accessing Appenders and Loggers from Filters

You can use the special function .obj() to access the calling Logger/Appender from within a filter

Note

The base class for Filters is called EventFilter so that it doesn’t conflict with base::Filter(). The recommended convention for Filter subclasses is to call them FilterSomething and leave out the Event prefix.

Examples

# using filters to modify log events
lg <- get_logger("test")

analyse <- function(){
  lg$add_filter(FilterForceLevel$new("info"), "force")
  lg$add_filter(FilterInject$new(type = "analysis"), "inject")
  on.exit(lg$remove_filter(c("force", "inject")))
  lg$debug("a debug message")
  lg$error("an error")
}
analyse()
lg$error("an error")
lg$config(NULL) # reset config

# using .obj()
lg <- get_logger("test")
f <- function(event) {
  cat("via event$.logger:", event$.logger$threshold, "\n") # works for loggers only
  cat("via .obj(): ", .obj()$threshold, "\n") # works for loggers and appenders
  TRUE
}
lg$add_filter(f)
lg$fatal("test")
lg$config(NULL)
get_caller

### Information About the System

**Description**

get_caller() Tries to determine the calling functions based on where.

**Usage**

```r
get_caller(where = -1L)

get_user(fallback = "unknown user")
```

**Arguments**

- `where` integer scalar (usually negative). Look up that many frames up the call stack
- `fallback` A fallback in case the user name could not be determined

**Value**

a character scalar.

**See Also**

base::sys.call()
whoami::whoami()

**Examples**

```r
foo <- function() get_caller(-1L)
foo()
get_user()
```

---

get_logger

### Get/Create a Logger

**Description**

Get/Create a Logger

**Usage**

```r
get_logger(name, class = Logger, reset = FALSE)

get_logger_glue(name)
```
get_log_levels

Arguments

name a character scalar or vector: The qualified name of the Logger as a hierarchical value.

class An R6ClassGenerator object. Usually Logger or LoggerGlue are the only valid choices.

reset a logical scalar. If TRUE the logger is reset to an unconfigured state. Unlike $config(NULL) this also replaces a LoggerGlue with vanilla Logger. Please note that this will invalidate Logger references created before the reset call (see examples).

Value

a Logger

Examples

lg <- get_logger("log/ger/test")
# equivalent to
lg <- get_logger(c("log", "ger", "test"))
lg$warn("a %s message", "warning")
lg
lg$parent

if (requireNamespace("glue")){
  lg <- get_logger_glue("log/ger")
}
lg$warn("a {.text} message", .text = "warning")

# completely reset 'glue' to an unconfigured vanilla Logger
get_logger("log/ger", reset = TRUE)
# this invalidates references to the Logger
try(lg$info("lg has been invalidated an no longer works"))

# we have to recreate it
lg <- get_logger("log/ger")
lg$info("now all is well again")

get_log_levels Manage Log Levels

Description

Display, add and remove character labels for log levels.
is_filter

Usage

get_log_levels()
add_log_levels(levels)
remove_log_levels(level_names)

Arguments

levels      a named character vector (see examples)
level_names a character vector of the names of the levels to remove

Value

a named character vector of the globally available log levels (add_log_levels() and remove_log_levels() return invisibly).

Default Log Levels

lgr comes with the following predefined log levels that are identical to the log levels of log4j.

<table>
<thead>
<tr>
<th>Level</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>off</td>
<td>A log level of 0/off tells a Logger or Appender to suspend all logging</td>
</tr>
<tr>
<td>100</td>
<td>fatal</td>
<td>Critical error that leads to program abort. Should always indicate a stop() or similar</td>
</tr>
<tr>
<td>200</td>
<td>error</td>
<td>A severe error that does not trigger program abort</td>
</tr>
<tr>
<td>300</td>
<td>warn</td>
<td>A potentially harmful situation, like warning()</td>
</tr>
<tr>
<td>400</td>
<td>info</td>
<td>An informational message on the progress of the application</td>
</tr>
<tr>
<td>500</td>
<td>debug</td>
<td>Finer grained informational messages that are mostly useful for debugging</td>
</tr>
<tr>
<td>600</td>
<td>trace</td>
<td>An even finer grained message than debug</td>
</tr>
<tr>
<td>NA</td>
<td>all</td>
<td>A log level of NA/all tells a Logger or Appender to process all log events</td>
</tr>
</tbody>
</table>

Examples

get_log_levels()
add_log_levels(c(errorish = 250))
get_log_levels()
remove_log_levels("errorish")
get_log_levels()

is_filter

Check if an R Object is a Filter

Description

Check if an R Object is a Filter
Usage

```r
is_filter(x)
```

Arguments

- `x`: any R Object

See Also

- `EventFilter`

---

## label_levels

### Label/Unlabel Log Levels

**Description**

Label/Unlabel Log Levels

**Usage**

```r
label_levels(levels, log_levels = getOption("lgr.log_levels"))
unlabel_levels(labels, log_levels = getOption("lgr.log_levels"))
```

**Arguments**

- `levels`: an integer vector of log levels
- `log_levels`: a named integer vector, should usually not be set manually.
- `labels`: a character vector of log level labels. Please note that log levels are lowercase by default, even if many appenders print them in uppercase.

**Value**

- a character vector for `label_levels()` and an integer vector for `unlabel_levels`

See Also

- `get_log_levels()`

Other formatting utils: `colorize_levels`

**Examples**

```r
x <- label_levels(c(seq(0, 600, by = 100), NA))
print(x)
unlabel_levels(x)
```
Description

LayoutDbi can contain col_types that AppenderDbi can use to create new database tables; however, it is safer and more flexible to set up the log table up manually with an SQL CREATE TABLE statement instead.

Details

The LayoutDbi parameters fmt, timestamp_fmt, colors and pad_levels are only applied for for console output via the $show() method and do not influence database inserts in any way. The inserts are pre-processed by the methods $format_data(), $format_colnames and $format_tablenames.

It does not format LogEvents directly, but their data.table representations (see as.data.table.LogEvent), as well as column- and table names.

Usage

```r
x <- LayoutDbi$new(col_types = NULL, fmt = "%L [%t] %m %f", timestamp_fmt = "%Y-%m-%d %H:%M:%S", colors = getOption("lgr.colors", list()), pad_levels = "right", format_table_name = identity, format_colnames = identity, 
format_data = identity)

x$clone(deep = FALSE)

x/format_event(event)
x$set_col_types(x)

x$set_colors(x)
x$set_fmt(x)

x$set_pad_levels(x)

x$set_timestamp_fmt(x)

x$sql_create_table(table)

x$toString()

x$col_names

x$col_types

x$colors

x$fmt

x$format_colnames

x$format_data

x$format_table_name

x$pad_levels

x$timestamp_fmt
```
Creating a New Layout

Layouts are instantiated with `<LayoutSubclass>$new()`. For a description of the arguments to this function please refer to the Fields section.

Fields

- `col_types` A named character vector of column types supported by the target database. If not `NULL` this is used by `AppenderDbi` or similar Appenders to create a new database table on instantiation of the Appender. If the target database table already exists, `col_types` is not used.

- `col_names` Convenience method to get the names of the `col_types` vector

Methods

- `format_table_name(x)` Format table names before inserting into the database. For example some databases prefer all lowercase names, some uppercase. SQL updates should be case-agnostic, but sadly in practice not all DBI backends behave consistently in this regard

- `format_colnames` Format column names before inserting into the database. See `$format_table_name` for more info

- `format_data` Format the input `data.table` before inserting into the database. Usually this function does nothing, but for example for SQLite it has to apply formatting to the timestamp.

- `col_names` Convenience method to get the names of the `col_types` vector

- `format_event(event)` format a LogEvent

Database Specific Layouts

Different databases have different data types and features. Currently the following `LayoutDbi` subclasses exist that deal with specific databases, but this list is expected to grow as lgr matures:

- `LayoutSqlite`: For SQLite databases
- `LayoutPostgres`: for Postgres databases
- `LayoutMySql`: for MySQL databases
- `LayoutDb2`: for DB2 databases

The utility function `select_dbi_layout()` tries returns the appropriate Layout for a DBI connection, but this does not work for odbc and JDBC connections where you have to specify the layout manually.

See Also

`select_dbi_layout()`, `DBI::DBI`,

Other Layouts: `LayoutFormat`, `LayoutGlue`, `LayoutJson`, `Layout`
Description

Format a LogEvent as human readable text using format.LogEvent(), which provides a quick and easy way to customize log messages. If you need more control and flexibility, consider using LayoutGlue instead.

Usage

```r
x <- LayoutFormat$new(fmt = "%L \[%t\] %m", timestamp_fmt = "%Y-%m-%d %H:%M:%OS3", colors = NULL, pad_levels = "right")
```

x$clone(deep = FALSE)
x$format_event(event)
x$set_colors(x)
x$set_fmt(x)
x$set_pad_levels(x)
x$set_timestamp_fmt(x)
x$toString()

x$colors
x$fmt
x$pad_levels
x$timestamp_fmt

Creating a New LayoutFormat

A new LayoutFormat is instantiated with LayoutFormat$new(). For a description of the arguments to this function please refer to the Fields, and the documentation of format.LogEvent().

Fields

- **fmt** a character scalar containing format tokens. See format.LogEvent().
- **timestamp_fmt** a character scalar. See base::format.POSIXct()
- **colors** a named list of functions passed on on format.LogEvent()
- **pad_levels** right, left or NULL. See format.LogEvent()

Format Tokens

This is the same list of format tokens as for format.LogEvent()

- **%t** The timestamp of the message, formatted according to timestamp_fmt
- **%l** the log level, lowercase character representation
%L the log level, uppercase character representation
%k the log level, first letter of lowercase character representation
%K the log level, first letter of uppercase character representation
%n the log level, integer representation
%p the PID (process ID). Useful when logging code that uses multiple threads.
%c the calling function
%m the log message
%f all custom fields of x in a pseudo-JSON like format that is optimized for human readability and console output
%j all custom fields of x in proper JSON. This requires that you have jsonlite installed and does not support colors as opposed to %f

Methods

format_event(event) format a LogEvent

See Also

Other Layouts: LayoutDbi, LayoutGlue, LayoutJson, Layout

Examples

# setup a dummy LogEvent
event <- LogEvent$new(
  logger = Logger$new("dummy logger"),
  level = 200,
  timestamp = Sys.time(),
  caller = NA_character_,
  msg = "a test message"
)
lo <- LayoutFormat$new()
lo$format_event(event)
Usage

```r
x <- LayoutGlue$new(fmt = "{{pad_right(colorize_levels(toupper(level_name)), 5)}
    [[timestamp]] msg")
```

```r
x$clone(deep = FALSE)
x$format_event(event)
x$set_colors(x)
x$set_fmt(x)
x$toString()
x$fmt
```

Creating a New LayoutGlue

A new LayoutGlue is instantiated with `LayoutGlue$new()`. It takes a single argument `fmt` that is passed on to `glue::glue()` for each LogEvent.

Fields

- `fmt` see `glue::glue()`

Methods

- `format_event(event)` format a LogEvent

See Also

- `lgr` exports a number of formatting utility functions that are useful for layout glue: `colorize_levels()`, `pad_left()`, `pad_right()`.
- Other Layouts: `LayoutDbi`, `LayoutFormat`, `LayoutJson`, `Layout`

Examples

```r
lg <- get_logger("test")
    set_appenders(AppenderConsole$new())
    set_propagate(FALSE)

lg$appenders[[1]]$set_layout(LayoutGlue$new())
lg$fatal("test")
```

# All fields of the LogEvent are available, even custom ones
```r
lg$appenders[[1]]$layout$set_fmt(
    "{{logger$name} (level_name){{(level)}} (caller): {{toupper(msg)}} {{custom: {custom}}}}"
)
lg$fatal("test", custom = "foobar")
lg$config(NULL) # reset logger config
```
Description
Format a LogEvent as JSON

Usage

```r
x <- LayoutJson$new(toJSON_args = list(auto_unbox = TRUE))
x$clone(deep = FALSE)
x$format_event(event)
x$set_toJSON_args(x)
x$toString()
x$toJSON_args
```

Creating a New Layout

Layouts are instantiated with <LayoutSubclass>$new(). For a description of the arguments to this function please refer to the Fields section.

Fields
toJSON_args, set_toJSON_args() a list of values passed on to jsonlite::toJSON()

Methods
format_event(event) format a LogEvent

See Also

`read_json_lines()`, [http://jsonlines.org/](http://jsonlines.org/)

Other Layouts: LayoutDbi, LayoutFormat, LayoutGlue, Layout

Examples

```r
# setup a dummy LogEvent

event <- LogEvent$new(
  logger = Logger$new("dummy logger"),
  level = 200,
  timestamp = Sys.time(),
  caller = NA_character_,
  msg = "a test message",
  custom_field = "LayoutJson can handle arbitrary fields"
)
```
# Default settings show all event fals
lo <- LayoutJson$new()
lo$format_event(event)

---

**LogEvent**

**Events - The Atomic Unit of Logging**

---

### Description

A LogEvent is a single unit of data that should be logged. LogEvents are usually created by a [Logger](#), and then processed by [Appenders](#).

### Usage

```r
x <- LogEvent$new(logger, level = 400, timestamp = Sys.time(), caller = NA, msg = NA, ...)
```

```r
x$clone(deep = FALSE)
```

```r
x$logger
x$caller
x$level
x$level_name
x$logger
x$msg
x$timestamp
x$values
```

### Creating LogEvents / Fields

The arguments to `LogEvent$new()` directly translate to the fields stored in the LogEvent:

- **level** integer: the log_level / priority of the LogEvent
- **timestamp** POSIXct the time when then the LogEvent was created
- **caller** character. The name of the calling function
- **msg** character. A message
- **logger** character scalar. Name of the Logger that created the event (.logger$full_name)
- **user** character scalar. User as set for the Logger that created this event (.logger$user)

... All named arguments in ... will be added to the LogEvent as custom fields. You can store arbitrary R objects in LogEvents this way, but not all Appenders will support them. See [AppenderJson](#) for an Appender that supports custom fields quite naturally.
Usually the above values will be scalars, but (except for "logger") they can also be vectors if they are all of the same length (or scalars that will be recycled). In this case the event will be treated by the Appenders and Layouts as if several separate events.

**Active Bindings**

LogEvents contain some active bindings that make it easier to retrieve commonly used values.

- `level_name` character: the log level/priority of the LogEvent labelled according to `getOption("lgr.log_levels")`
- `values` list: All values stored in the LogEvent (including all custom fields, but not including `event$logger`)
- `logger_name` character scalar: The name of the Logger that created this event, equivalent to `event$logger$name`
- `logger_user` character scalar: The user of the Logger that created this event, equivalent to `event$logger_user`

See Also

`as.data.frame.LogEvent()`

Examples

```r
lg <- get_logger("test")
lg$error("foo bar")

# The last LogEvent produced by a Logger is stored in the last_event field
lg$last_event  # formatted by default
lg$last_event$values  # values stored in the event

# Also contains the Logger that created it as .logger
lg$last_event$logger  # equivalent to
lg$last_event$.logger$name

# This is really a reference to the complete Logger, so the following is
# possible (though nonsensical)
lg$last_event$.logger$last_event$msg
identical(lg, lg$last_event$.logger)
lg$config(NULL)  # reset logger config
```

**Description**

A Logger produces a LogEvent that contains the log message along with metadata (timestamp, calling function) and dispatches it to one or several Appenders which are responsible for the output (console, file, ...) of the event. `lgr` comes with a single pre-configured Logger called the root Logger that can be accessed via `lgr$<...>`. Instantiation of new Loggers is only necessary if you want to take advantage of hierarchical logging as outlined in `vignette("lgr",package = "lgr")`. 
Logger

Usage

# Cannonical way to initialize a new Logger (see "Creating Loggers")
lg <- get_logger("logger")

# R6 constructor (not recommended for productive use)
lg <- Logger$new(name = "(unnamed logger)", appenders = list(), threshold =
  NULL, filters = list(), exception_handler = default_exception_handler,
  propagate = TRUE)

lg$add_appender(appender, name = NULL)
lg$add_filter(filter, name = NULL)
lg$config(cfg, file, text, list)
lg$debug(msg, ..., caller = get_caller(-8L))
lg$error(msg, ..., caller = get_caller(-8L))
lg$fatal(msg, ..., caller = get_caller(-8L))
lg$filter(event)
lg$handle_exception(...)
lg$info(msg, ..., caller = get_caller(-8L))
lg$log(level, msg, ..., timestamp = Sys.time(), caller = get_caller(-7))
lg$remove_appender(pos)
lg$remove_filter(pos)
lg$set_appenders(x)
lg$set_exception_handler(fun)
lg$set_filters(filters)
lg$set_propagate(x)
lg$set_threshold(level)
lg$spawn(name, ...)
lg$trace(msg, ..., caller = get_caller(-8L))
lg$warn(msg, ..., caller = get_caller(-8L))

lg$ancestry
lg$appenders
lg$exception_handler
lg$filters
lg$inherited_appenders
lg$last_event
lg$name
lg$parent
lg$propagate
lg$threshold

Creating Loggers

If you are a package developer you should define a new Logger for each package, but you do
not need to configure it. Usually only the root logger needs to be configured (new Appenders
added/removed, Layouts modified, etc...).
Loggers should never be instantiated directly with Logger$new() but rather via get_logger("name"). If "name" does not exist, a new Logger with that name will be created, otherwise the function returns a Reference to the existing Logger.

The name is potentially a / separated hierarchical value like foo/bar/baz. Loggers further down the hierarchy are children of the loggers above. (This mechanism does not work of the Logger is initialized with Logger$new())

All calls to get_logger() with the same name return the same Logger instance. This means that Logger instances never need to be passed between different parts of an application.

If you just want to log to an additional output (like a log file), you want a new Appender, not a new Logger.

Fields

You can modify the fields of an existing Logger with logger$set_<fieldname>(value) (see examples). Another way to configure loggers is via its $config() method.

appenders, set_appenders(x) A single Appender or a list thereof. Appenders control the output of a Logger. Be aware that a Logger also inherits the Appenders of its ancestors (see vignette("lgr", package = "lgr") for more info about Logger inheritance structures).

threshold, set_threshold(level) character or integer scalar. The minimum log level that triggers this Logger.

exception_handler, set_exception_handler() a function that takes a single argument e. The function used to handle errors that occur during logging. Defaults to demoting errors to warnings.

propagate, set_propagate() TRUE or FALSE. Should LogEvents be passed on to the appenders of the ancestral Loggers?

filters, set_filters(filters) a list that may contain functions or any R object with a filter() method. These functions must have exactly one argument: event which will get passed the LogEvent when the Filterable’s filter() method is invoked. If all of these functions evaluate to TRUE the LogEvent is passed on. Since LogEvents have reference semantics, filters can also be abused to modify them before they are passed on. Look at the source code of with_log_level() or with_log_value() for examples.

Read-Only Bindings

In addition to the active bindings used to access the fields described above, Loggers also have the following additional read-only bindings:

name character scalar. A hierarchical value (separated by "/") that indicates the loggers name and its ancestors. If a logger is created with get_logger() uniqueness of the name is enforced.

ancestry A named logical vector of containing the propagate value of each Logger upper the inheritance tree. The names are the names of the appenders. ancestry is an S3 class with a custom format()/print() method, so if you want to use the plain logical vector use unclass(lg$ancestry)
inherited_appenders  A list of all inherited appenders from ancestral Loggers of the current Logger

last_event  The last LogEvent produced by the current Logger

Methods

fatal(msg, ..., caller = get_caller(-8L)) Logs a message with level fatal on this logger.
If there are unnamed arguments in ..., they will be passed to base::sprintf() along with
message. Named arguments will be passed as custom fields to LogEvent. If there are named
arguments the names must be unique. caller refers to the name of the calling function and if
specified manually must be a character scalar.

error(msg, ..., caller = get_caller(-8L)) Logs a message with level error on this logger.
The arguments are interpreted as for fatal().

warn(msg, ..., caller = get_caller(-8L)) Logs a message with level warn on this logger.
The arguments are interpreted as for fatal().

info(msg, ..., caller = get_caller(-8L)) Logs a message with level info on this logger.
The arguments are interpreted as for fatal().

deploy(msg, ..., caller = get_caller(-8L)) Logs a message with level debug on this logger.
The arguments are interpreted as for fatal().

deploy(level, msg, ..., timestamp, caller) If the level passes the Logger threshold a new
LogEvent with level, msg, timestamp and caller is created. Unnamed arguments in ...
will be combined with msg via base::sprintf(). Named arguments in ... will be passed
on to LogEvent$new() as custom fields. If no unnamed arguments are present, msg will not
be passed to sprintf(), so in that case you do not have to escape "%" characters. If the
new LogEvent passes this Loggers filters, it will be dispatched to the relevant Appenders
and checked against their thresholds and filters.

cfg(c, f, t, l) Load a Logger configuration. cfg can be either

• a special list object with any or all of the the following elements: appenders, threshold,
  filters, propagate, exception_handler,
• the path to a YAML/JSON config file,
• a character scalar containing YAML,
• NULL (to reset the logger config to the default/unconfigured state)

The arguments file, text and list can be used as an alternative to cfg that enforces that the
supplied argument is of the specified type. See logger_config for details.

add_appender(append, name = NULL), remove_appender(pos) Add or remove an Appender.
Supplying a name is optional but recommended. After adding an Appender with logger$add_appender(AppenderConsole$new(),name
= "console") you can refer to it via logger$appenders$console. remove_appender() can
remove an Appender by position or name.

spawn(...) Spawn a child Logger. get_logger("foo/bar")$spawn("baz") is equivalent to
get_logger("foo/bar/baz"), but can be convenient for programmatic use when the name
of the parent Logger is not known.

filter(event) Determine whether the LogEvent x should be passed on to Appenders (TRUE) or
not (FALSE). See also the active binding filters
add_filter(filter, name = NULL), remove_filter(pos) Add or remove a filter. When adding a filter an optional name can be specified. remove_filter() can remove by position or name (if one was specified)

**LoggerGlue**

LoggerGlue uses `glue::glue()` instead of `base::sprintf()` to construct log messages. `glue` is a very well designed package for string interpolation. It makes composing log messages more flexible and comfortable at the price of an additional dependency and slightly less performance than `sprintf()`.

glue() lets you define temporary named variables inside the call. As with the normal Logger, these named arguments get turned into custom fields; however, you can suppress this behaviour by making named argument start with a ".". Please refer to vignette("lgr",package = "lgr") for examples.

**See Also**

`glue`

**Examples**

```r
# lgr::lgr is the root logger that is always available
lgr$info("Today is a good day")
lgr$fatal("This is a serious error")

# Loggers use sprintf() for string formatting by default
lgr$info("Today is %s", Sys.Date())

# If no unnamed \...\ are present, msg is not passed through sprintf()
lgr$fatal("100% bad") # so this works
lgr$fatal("%s%% bad", 100) # if you use unnamed arguments, you must escape %

# You can create new loggers with get_logger()
tf <- tempfile()
lg <- get_logger("mylogger")$set_appenders(AppenderFile$new(tf))

# The new logger passes the log message on to the appenders of its parent
# logger, which is by default the root logger. This is why the following
# writes not only the file 'tf', but also to the console.
lg$fatal("blubb")
readLines(tf)

# This logger's print() method depicts this relationship.
child <- get_logger("lg/child")
print(child)
print(child$name)

# use formatting strings and custom fields
tf2 <- tempfile()
lg$add_appender(AppenderFile$new(tf2, layout = LayoutJson$new()))
lg$info("Not all %s support custom fields", "appenders", type = "test")
```
```r
cat(readLines(tf), sep = "\n")
cat(readLines(tf2), sep = "\n")

# cleanup
unlink(c(tf, tf2))
lg$configure(NULL) # reset logger config

# LoggerGlue
# You can also create a new logger that uses the awesome glue library for
# string formatting instead of sprintf

if (requireNamespace("glue")){

  lg <- get_logger_glue("glue")
  lg$fatal("blah ", "fizz is set to: {fizz}", foo = "bar", fizz = "buzz")
  # prevent creation of custom fields with prefixing a dot
  lg$fatal("blah ", "fizz is set to: {.fizz}", foo = "bar", .fizz = "buzz")

  # completely reset 'glue' to an unconfigured vanilla Logger
  get_logger("glue", reset = TRUE)
}

# Configuring a Logger
lg <- get_logger("test")
lg$configure(NULL) # resets logger to unconfigured state

# With setters
lg$
  set_threshold("error")$
  set_propagate(FALSE)$
  set_appenders(AppenderConsole$new(threshold = "info"))

lg$configure(NULL)

# With a list
lg$configure(list(
  threshold = "error",
  propagate = FALSE,
  appenders = list(AppenderConsole$new(threshold = "info"))
))

lg$configure(NULL) # resets logger to unconfigured state

# Via YAML
cfg <- "
Logger:
  threshold: error
  propagate: false
  appenders:
    AppenderConsole:
      threshold: info
"
logger_config

Description

logger_config() is an S3 constructor for logger_config objects that can be passed to the $config method of a Logger. You can just pass a normal list instead, but using this constructor is a more formal way that includes additional argument checking.

Usage

logger_config(appenders = NULL, threshold = NULL, filters = NULL, exception_handler = NULL, propagate = TRUE)

as_logger_config(x)

## S3 method for class 'list'
as_logger_config(x)

## S3 method for class 'character'
as_logger_config(x)

Arguments

appenders see Logger
threshold see Logger
filters see Logger
exception_handler see Logger
propagate see Logger
x any R object. Especially:

- A character scalar. This can either be the path to a YAML file or a character scalar containing valid YAML
- a list containing the elements appenders, threshold, exception_handler, propagate and filters. See the section Fields in Logger for details.
- a Logger object, to clone its configuration.

Value

a list with the subclass "logger_config"
a logger_config object
logger_tree

Description
Displays a tree structure of all registered Loggers.

Usage
logger_tree()

Value
data.frame with subclass "logger_tree"

Symbology
- Unconfigured Loggers are displayed in gray (if your terminal supports colors and you have the package crayon installed).
- If a logger's threshold is set, it is displayed in square brackets next to its name (reminder: if the threshold is not set, it is inherited from next logger up the logger tree).
- If a logger's propagate field is set to FALSE an red hash (#) sign is displayed in front of the logger name, to imply that it does not pass LogEvents up the tree.

Examples
get_logger("fancymodel")
get_logger("fancymodel/shiny")$set propagate(FALSE)

get_logger("fancymodel/shiny/ui")$set appenders(AppenderConsole$new())

get_logger("fancymodel/shiny/server")$set_appenders(list(AppenderConsole$new(), AppenderConsole$new()))$set_threshold("trace")

get_logger("fancymodel/plumber")

if (requireNamespace("cli")){
  print(logger_tree())
}

### pad_right

**Pad Character Vectors**

**Description**

Pad Character Vectors

**Arguments**

- `x`: a character vector
- `width`: integer scalar, target string width
- `pad`: character scalar, the symbol to pad with

**Examples**

- `pad_left("foo", 5)`
- `pad_right("foo", 5, ".")`
- `pad_left(c("foo", "foooooo"), pad = ".")`

### print.Appender

**Print an Appender object**

**Description**

The `print()` method for Loggers displays the most important aspects of the Appender.

**Usage**

```r
## S3 method for class 'Appender'
print(x, color = requireNamespace("crayon", quietly = TRUE), ...)
```

**Arguments**

- `x`: any R Object
- `color`: TRUE or FALSE: Output with color? Requires the Package crayon
- `...`: ignored

**Value**

`print()` returns `x` (invisibly), `format()` returns a character vector.

**Examples**

- `# print most important details of logger
  print(lgr$console)`
## Description

Print or Format Logging Data

## Usage

```r
## S3 method for class 'LogEvent'
print(x, fmt = "%L [%t] %m %f",
    timestamp_fmt = "%Y-%m-%d %H:%M:%S",
    colors = getOption("lgr.colors"),
    log_levels = getOption("lgr.log_levels"), pad_levels = "right", ...)

## S3 method for class 'LogEvent'
format(x, fmt = "%L [%t] %m %f",
    timestamp_fmt = "%Y-%m-%d %H:%M:%S", colors = NULL,
    log_levels = getOption("lgr.log_levels"), pad_levels = "right", ...)
```

## Arguments

- `x`: a `LogEvent` or `lgr_data` Object
- `fmt`: A character scalar that may contain any of the tokens listed below in the section Format Tokens.
- `timestamp_fmt`: see `format.POSIXct()`
- `colors`: A list of functions that will be used to color the log levels (likely from `crayon::crayon`).
- `log_levels`: a named integer vector of log levels.
- `pad_levels`: right, left or NULL. Whether or not to pad the log level names to the same width on the left or right side, or not at all.
- `...`: ignored

## Value

- `x` for `print()` and a character scalar for `format()`

## Format Tokens

- `%t` The timestamp of the message, formatted according to `timestamp_fmt`
- `%l` the log level, lowercase character representation
- `%L` the log level, uppercase character representation
- `%k` the log level, first letter of lowercase character representation
- `%K` the log level, first letter of uppercase character representation
%n the log level, integer representation
%p the PID (process ID). Useful when logging code that uses multiple threads.
%c the calling function
%m the log message
%f all custom fields of x in a pseudo-JSON like format that is optimized for human readability and console output
%j all custom fields of x in proper JSON. This requires that you have jsonlite installed and does not support colors as opposed to %f

Examples

# standard fields can be printed using special tokens
x <- LogEvent$new(
    level = 300, msg = "a test event", caller = "testfun()", logger = lgr
)
print(x)
print(x, fmt = c("%t (%p) %c: %n - %m"))
print(x, colors = NULL)

# custom values
y <- LogEvent$new(
    level = 300, msg = "a gps track", logger = lgr,
    waypoints = 10, location = "Austria"
)

# default output with %f
print(y)

# proper JSON output with %j
if (requireNamespace("jsonlite")){
    print(y, fmt = "%L [%t] %m %j")
}

print.Logger

Print a Logger Object

Description

The print() method for Loggers displays the most important aspects of the Logger.

You can also print just the ancestry of a Logger which can be accessed with with logger$ancestry(). This returns a named character vector whose names correspond to the names of the Loggers logger inherits from. The TRUE/FALSE status of its elements correspond to the propagate values of these Loggers.
Usage

```r
## S3 method for class 'Logger'
print(x, color = requireNamespace("crayon", quietly = TRUE), ...)

## S3 method for class 'Logger'
format(x, color = FALSE, ...)

## S3 method for class 'ancestry'
print(x, color = requireNamespace("crayon", quietly = TRUE), ...)

## S3 method for class 'ancestry'
format(x, color = FALSE, ...)
```

Arguments

- `x`: any R Object
- `color`: TRUE or FALSE: Output with color? Requires the Package `crayon`
- `...`: ignored

Value

- `print()` returns `x` (invisibly), `format()` returns a character vector.

Examples

```r
# print most important details of logger
print(lgr)
# print only the ancestry of a logger
lg <- get_logger("AegonV/Aerys/Rheagar/Aegon")
get_logger("AegonV/Aerys/Rheagar")$set_propagate(FALSE)

print(lg$ancestry)
unclass(lg$ancestry)
```

Description

Print Logger Trees
## Usage

```r
## S3 method for class 'logger_tree'
print(x, color = requireNamespace("crayon", quietly = TRUE), ...)

## S3 method for class 'logger_tree'
format(x, color = FALSE, ...)
```

### Arguments

- **x**
  - a `logger_tree`
- **color**
  - logical scalar. If TRUE terminal output is colorized via the package `crayon`?
- **...**
  - passed on to `cli::tree()`

### Value

- `x` (invisibly)

---

**read_json_lines**

*Read a JSON logfile*

## Description

Read a JSON logfile

## Usage

```r
read_json_lines(file)
```

### Arguments

- **file**
  - character scalar. path to a JSON logfile (one JSON object per line)

### Value

- a `data.frame`

### See Also

- `LayoutJson`
select_dbi_layout  Select Appropriate Database Table Layout

Description

Selects an appropriate Layout for a database table based on a DBI connection and - if it already exists in the database - the table itself.

Usage

```r
select_dbi_layout(conn, table)
```

Arguments

- `conn`: a DBI connection
- `table`: a character scalar. The name of the table to log to.

simple_logging  Simple Logging

Description

lgr provides convenience functions managing the root Logger. These are designed chiefly for interactive use and are less verbose than their R6 method counterparts.

- `threshold()` sets or retrieves the threshold for an Appender or Logger (the minimum level of log messages it processes). It’s target defaults to the root logger. (equivalent to `lgr::lgr$threshold` and `lgr::lgr$set_threshold`)
- `console_threshold()` is a shortcut to set the threshold of the root loggers AppenderConsole, which is usually the only Appender that manages console output for a given R session. (equivalent to `lgr::lgr$appenders$console$threshold` and `lgr::lgr$appenders$console$set_threshold`)
- `add_appender()` and `remove_appender()` add Appenders to Loggers and other Appenders. (equivalent to `lgr::lgr$add_appender` and `lgr::lgr$remove_appender`)
- `show_log()` displays the last n log entries of an Appender (or a Logger with such an Appender attached) with a $show() method. Most, but not all Appenders support this function (try AppenderFile or AppenderBuffer).
- `show_data()` and `show_dt()` work similar to `show_log()`, except that they return the log as data.frame or data.table respectively. Only Appenders that log to formats that can easily be converted to data.frames are supported (try AppenderJson or AppenderBuffer).

The easiest way to try out this features is by adding an AppenderBuffer to the root logger with `basic_config(memory = TRUE)`. 
Usage

log_exception(code, logfun = lgr$fatal, caller = get_caller(-3))

threshold(level, target = lgr::lgr)

console_threshold(level, target = lgr::lgr$appenders$console)

add_appender(appender, name = NULL, target = lgr::lgr)

remove_appender(pos, target = lgr::lgr)

show_log(threshold = NA_integer_, n = 20L, target = lgr::lgr)

show_dt(target = lgr::lgr)

show_data(target = lgr::lgr)

Arguments

code Any R code

logfun a function for processing the log request, usually lgr$info(), lgr$debug(), etc...

caller a character scalar. The name of the calling function

level integer or character scalar: the desired log level

target a Logger or Appender or the name of a Logger as character scalar

appender an Appender

name character scalar. An optional name for the new Appender.

pos integer index or character names of the appenders to remove

threshold character or integer scalar. The minimum log level that should be processed by the root logger.

n integer scalar. Show only the last n log entries that match threshold

Value

threshold() and console_threshold() return the log_level of target as integer (invisibly)

add_appender() and remove_appender() return target.

show_log() prints to the console and returns whatever the target Appender’s $show() method returns, usually a character vector, data.frame or data.table (invisibly).

show_data() always returns a data.frame and show_dt() always returns a data.table.

Examples

add_appender(AppenderConsole$new(), "second_console_appender")
lgr$fatal("Multiple console appenders are a bad idea")
remove_appender("second_console_appender")
suspend_logging

# Define a logger
lg <- get_logger("test")

# Define an appender
lg$add("myAppender")

# Define the appender name
lg$info("Good that we defined an appender name, so it's easy to remove")

# Reconfigure the root logger
basic_config(memory = TRUE)

# Log some messages
lg$info("a log message")
lg$info("another message with data", data = 1:3)

# Use show_log() to show the log
show_log()
show_data()

---

**suspend_logging**  
*Suspend All Logging*

### Description

Completely disable logging for all loggers. This is for example useful for automated test code. `suspend_logging()` globally disables all logging with `lgr` until `unsuspend_logging()` is invoked, while `without_logging()` and `with_logging()` temporarily disable/enable logging.

### Usage

- `suspend_logging()`
- `unsuspend_logging()`
- `without_logging(code)`
- `with_logging(code)`

### Arguments

- **code**  
  Any R code

### Value

- `suspend_logging()` and `unsuspend_logging()` return `NULL` (invisibly), `without_logging()` and `with_logging()` returns whatever code returns.

### Examples

```r
lg <- get_logger("test")

# temporarily disable logging
lg$fatal("foo")

without_logging({

# temporarily enable logging
with_logging({
```

---
use_logger

Setup a Simple Logger for a Package

Description

This gives you a minimal logger with no appenders that you can use inside your package under the name `lg` (e.g. `lg$fatal("test")`). `use_logger()` does not modify any files but only prints code for you to copy and paste.

Usage

```r
use_logger(pkg = desc::desc_get("Package",
                   rprojroot::find_package_root_file("DESCRIPTION"))[[1]])
```

Arguments

- `pkg` character scalar. Name of the package. The default is to try to get the Package name automatically using the packages `rprojroot` and `desc`

Value

- a character scalar containing R code.

Examples

```r
use_logger("testpkg")
```
*with_log_level*

**Inject Values into Logging Calls**

**Description**

`with_log_level` temporarily overrides the log level of all `LogEvents` created by target `Logger`.

**Usage**

```r
with_log_level(level, code, logger = lgr::lgr)

with_log_value(values, code, logger = lgr::lgr)
```

**Arguments**

- **level** integer or character scalar: the desired log level
- **code** Any R code
- **logger** a `Logger` or the name of one (see `get_logger()`). Defaults to the root logger (`lgr::lgr`).
- **values** a named list of values to be injected into the logging calls

**Details**

These functions abuses lgr's filter mechanic to modify LogEvents in-place before they passed on the Appenders. Use with care as they can produce hard to reason about code.

**Value**

whatever code would return

**Examples**

```r
with_log_level("warn", {
    lgr$info("More important than it seems")
    lgr$fatal("Really not so bad")
})

with_log_value(
    list(msg = "overriden msg"), {
        lgr$info("bar")
        lgr$fatal("FOO")
    })
```
