**Description**

This package provides a number of methods for creating and augmenting Latin Hypercube Samples. For a complete list of functions, use library(help="lhs").

**Author(s)**

Rob Carnell

**See Also**

| randomLHS, geneticLHS, improvedLHS, maximinLHS, and optimumLHS to generate Latin Hypercube Samples. optAugmentLHS, optSeededLHS, and augmentLHS to modify and augment existing designs. |

**augmentLHS**

**Augment a Latin Hypercube Design**

**Description**

Augments an existing Latin Hypercube Sample, adding points to the design, while maintaining the latin properties of the design.

**Usage**

augmentLHS(1hs, m=1)

**Arguments**

<table>
<thead>
<tr>
<th>1hs</th>
<th>The Latin Hypercube Design to which points are to be added</th>
</tr>
</thead>
<tbody>
<tr>
<td>m</td>
<td>The number of additional points to add to matrix 1hs</td>
</tr>
</tbody>
</table>

**Details**

Augments an existing Latin Hypercube Sample, adding points to the design, while maintaining the latin properties of the design. Augmentation is performed in a random manner.

The algorithm used by this function has the following steps. First, create a new matrix to hold the candidate points after the design has been re-partitioned into \((n + m)^2\) cells, where \(n\) is number of points in the original 1hs matrix. Then randomly sweep through each column (1...k) in the repartitioned design to find the missing cells. For each column (variable), randomly search for an empty row, generate a random value that fits in that row, record the value in the new matrix. The new matrix can contain more filled cells than \(m\) unless \(m = 2n\), in which case the new matrix will
contain exactly \( m \) filled cells. Finally, keep only the first \( m \) rows of the new matrix. It is guaranteed to have \( m \) full rows in the new matrix. The deleted rows are partially full. The additional candidate points are selected randomly due to the random search for empty cells.

**Value**

An \( n \) by \( k \) Latin Hypercube Sample matrix with values uniformly distributed on \([0,1]\)

**Author(s)**

Rob Carnell

**References**

**See Also**

**Examples**

```r
a <- randomLHS(4,3)
a
augmentLHS(a, 2)
```

---

**geneticLHS**  
*Latin Hypercube Sampling with a Genetic Algorithm*

**Description**

Draws a Latin Hypercube Sample from a set of uniform distributions for use in creating a Latin Hypercube Design. This function attempts to optimize the sample with respect to the S optimality criterion through a genetic type algorithm.

**Usage**

```r
geneticLHS(n=10, k=2, pop=100, gen=4, pMut=.1, criterium="S", verbose=FALSE)
```

**Arguments**

- \( n \): The number of partitions (simulations or design points)
- \( k \): The number of replications (variables)
- \( pop \): The number of designs in the initial population
- \( gen \): The number of generations over which the algorithm is applied
Details

Latin hypercube sampling (LHS) was developed to generate a distribution of collections of parameter values from a multidimensional distribution. A square grid containing possible sample points is a Latin square iff there is only one sample in each row and each column. A Latin hypercube is the generalisation of this concept to an arbitrary number of dimensions. When sampling a function of \( k \) variables, the range of each variable is divided into \( n \) equally probable intervals. \( n \) sample points are then drawn such that a Latin Hypercube is created. Latin Hypercube sampling generates more efficient estimates of desired parameters than simple Monte Carlo sampling.

This program generates a Latin Hypercube Sample by creating random permutations of the first \( n \) integers in each of \( k \) columns and then transforming those integers into \( n \) sections of a standard uniform distribution. Random values are then sampled from within each of the \( n \) sections. Once the sample is generated, the uniform sample from a column can be transformed to any distribution by using the quantile functions, e.g. \( \text{qnorm()} \). Different columns can have different distributions.

S-optimality seeks to maximize the mean distance from each design point to all the other points in the design, so the points are as spread out as possible.

Genetic Algorithm:

1. Generate \( \text{pop} \) random Latin hypercube designs of size \( n \) by \( k \)
2. Calculate the S optimality measure of each design
3. Keep the best design in the first position and throw away half of the rest of the population
4. Take a random column out of the best matrix and place it in a random column of each of the other matrices, and take a random column out of each of the other matrices and put it in copies of the best matrix thereby causing the progeny
5. For each of the progeny, cause a genetic mutation \( p\text{Mut} \) percent of the time. The mutation is accomplished by switching two elements in a column

Value

An \( n \) by \( k \) Latin Hypercube Sample matrix with values uniformly distributed on \([0,1]\)

# Example usage
improvedLHS(4, 3, 50, 5, .25)
```

---

### improvedLHS

**Improved Latin Hypercube Sample**

**Description**

Draws a Latin Hypercube Sample from a set of uniform distributions for use in creating a Latin Hypercube Design. This function attempts to optimize the sample with respect to an optimum euclidean distance between design points.

**Usage**

```r
improvedLHS(n, k, dup=1)
```

**Arguments**

- `n`: The number of partitions (simulations or design points)
- `k`: The number of replications (variables)
- `dup`: A factor that determines the number of candidate points used in the search. A multiple of the number of remaining points than can be added.

---

**Details**

Latin hypercube sampling (LHS) was developed to generate a distribution of collections of parameter values from a multidimensional distribution. A square grid containing possible sample points is a Latin square iff there is only one sample in each row and each column. A Latin hypercube is the generalisation of this concept to an arbitrary number of dimensions. When sampling a function of \( k \) variables, the range of each variable is divided into \( n \) equally probable intervals. \( n \) sample points are then drawn such that a Latin Hypercube is created. Latin Hypercube sampling generates more efficient estimates of desired parameters than simple Monte Carlo sampling.

This program generates a Latin Hypercube Sample by creating random permutations of the first \( n \) integers in each of \( k \) columns and then transforming those integers into \( n \) sections of a standard uniform distribution. Random values are then sampled from within each of the \( n \) sections. Once the sample is generated, the uniform sample from a column can be transformed to any distribution by using the quantile functions, e.g. `qnorm()`. Different columns can have different distributions.

This function attempts to optimize the sample with respect to an optimum euclidean distance between design points.

\[
\text{Optimum distance} = \frac{n^{1/k}}
\]
Value

An n by k Latin Hypercube Sample matrix with values uniformly distributed on [0,1]

Author(s)

Rob Carnell

References

This function is based on the MATLAB program written by John Burkardt and modified 16 Feb 2005 http://www.csit.fsu.edu/~burkardt/m_src/ihs/ihs.m

Examples

improvedLHS(4, 3, 2)

maximinLHS

Maximin Latin Hypercube Sample

Description

Draws a Latin Hypercube Sample from a set of uniform distributions for use in creating a Latin Hypercube Design. This function attempts to optimize the sample by maximizing the minimum distance between design points (maximin criteria).

Usage

maximinLHS(n, k, method="build", dup=1, eps=0.05, maxIter=100, optimize.on="grid", debug=FALSE)

Arguments

n The number of partitions (simulations or design points)
k The number of replications (variables)
method build or iterative is the method of LHS creation. build finds the next best point while constructing the LHS. iterative optimizes the resulting sample on [0,1] or sample grid on [1,N]
dup A factor that determines the number of candidate points used in the search. A multiple of the number of remaining points than can be added. This is used when method="build"
maximinLHS

eps The minimum percent change in the minimum distance used in the iterative method
maxIter The maximum number of iterations to use in the iterative method
optimize.on grid or result gives the basis of the optimization. grid optimizes the LHS on the underlying integer grid. result optimizes the resulting sample on [0,1]
debug prints additional information about the process of the optimization

Details

Latin hypercube sampling (LHS) was developed to generate a distribution of collections of parameter values from a multidimensional distribution. A square grid containing possible sample points is a Latin square if there is only one sample in each row and each column. A Latin hypercube is the generalisation of this concept to an arbitrary number of dimensions. When sampling a function of \( k \) variables, the range of each variable is divided into \( n \) equally probable intervals. \( n \) sample points are then drawn such that a Latin Hypercube is created. Latin Hypercube sampling generates more efficient estimates of desired parameters than simple Monte Carlo sampling.

This program generates a Latin Hypercube Sample by creating random permutations of the first \( n \) integers in each of \( k \) columns and then transforming those integers into \( n \) sections of a standard uniform distribution. Random values are then sampled from within each of the \( n \) sections. Once the sample is generated, the uniform sample from a column can be transformed to any distribution by using the quantile functions, e.g. \( \text{qnorm}() \). Different columns can have different distributions.

Here, values are added to the design one by one such that the maximin criteria is satisfied.

Value

An \( n \) by \( k \) Latin Hypercube Sample matrix with values uniformly distributed on [0,1]

optAugmentLHS  

**Optimal Augmented Latin Hypercube Sample**

**Description**

Augments an existing Latin Hypercube Sample, adding points to the design, while maintaining the *latin* properties of the design. This function attempts to add the points to the design in an optimal way.

**Usage**

optAugmentLHS(lhs, m=1, mult=2)

**Arguments**

- *lhs*: The Latin Hypercube Design to which points are to be added
- *m*: The number of additional points to add to matrix *lhs*
- *mult*: *m* *mult* random candidate points will be created.

**Details**

Augments an existing Latin Hypercube Sample, adding points to the design, while maintaining the *latin* properties of the design. This function attempts to add the points to the design in a way that maximizes S optimality.

S-optimality seeks to maximize the mean distance from each design point to all the other points in the design, so the points are as spread out as possible.

**Value**

optimumLHS

**Examples**

```r
c <- randomLHS(4, 3)
c
optAugmentLHS(c, 2, 3)
```

---

**Description**

Draws a Latin Hypercube Sample from a set of uniform distributions for use in creating a Latin Hypercube Design. This function uses the Columnwise Pairwise (CP) algorithm to generate an optimal design with respect to the S optimality criterion.

**Usage**

```r
optimumLHS(n=10, k=2, maxSweeps=2, eps=1, verbose=FALSE)
```

**Arguments**

- `n`: The number of partitions (simulations or design points)
- `k`: The number of replications (variables)
- `maxSweeps`: The maximum number of times the CP algorithm is applied to all the columns.
- `eps`: The optimal stopping criterion
- `verbose`: Print informational messages

**Details**

Latin hypercube sampling (LHS) was developed to generate a distribution of collections of parameter values from a multidimensional distribution. A square grid containing possible sample points is a Latin square if there is only one sample in each row and each column. A Latin hypercube is the generalisation of this concept to an arbitrary number of dimensions. When sampling a function of `k` variables, the range of each variable is divided into `n` equally probable intervals. `n` sample points are then drawn such that a Latin Hypercube is created. Latin Hypercube sampling generates more efficient estimates of desired parameters than simple Monte Carlo sampling.

This program generates a Latin Hypercube Sample by creating random permutations of the first `n` integers in each of `k` columns and then transforming those integers into `n` sections of a standard uniform distribution. Random values are then sampled from within each of the `n` sections. Once the sample is generated, the uniform sample from a column can be transformed to any distribution by using the quantile functions, e.g., `qnorm()`. Different columns can have different distributions.

S-optimality seeks to maximize the mean distance from each design point to all the other points in the design, so the points are as spread out as possible.

This function uses the CP algorithm to generate an optimal design with respect to the S optimality criterion.

**Random Latin Hypercube**

**Description**

Draws a Latin Hypercube Sample from a set of uniform distributions for use in creating a Latin Hypercube Design. This sample is taken in a random manner without regard to optimization.

**Usage**

```r
randomLHS(n, k, preserveDraw)
```

**Arguments**

- `n` The number of partitions (simulations or design points)
- `k` The number of replications (variables)
- `preserveDraw` Default:FALSE. Ensures that two subsequent draws with the same `n`, but one with `k` and one with `m` variables (\( k < m \)), will have the same first `k` columns if the seed is the same.
Latin hypercube sampling (LHS) was developed to generate a distribution of collections of parameter values from a multidimensional distribution. A square grid containing possible sample points is a Latin square iff there is only one sample in each row and each column. A Latin hypercube is the generalisation of this concept to an arbitrary number of dimensions.
