Package ‘lifecycle’

November 7, 2023

Title Manage the Life Cycle of your Package Functions

Version 1.0.4

Description Manage the life cycle of your exported functions with shared conventions, documentation badges, and user-friendly deprecation warnings.

License MIT + file LICENSE

BugReports https://github.com/r-lib/lifecycle/issues

Depends R (>= 3.6)

Imports cli (>= 3.4.0), glue, rlang (>= 1.1.0)

Suggests covr, crayon, knitr, lintr, rmarkdown, testthat (>= 3.0.1), tibble, tidyverse, tools, vctrs, withr

VignetteBuilder knitr

Config/Needs/website tidyverse/tidytemplate, usethis

Config/testthat/edition 3

Encoding UTF-8

RoxygenNote 7.2.1

NeedsCompilation no

R topics documented:

- badge ................................................. 2
- deprecated ........................................... 3
To include lifecycle badges in your documentation:

1. Call `usethis::use_lifecycle()` to copy the badge images into the `man/` folder of your package.
2. Call `lifecycle::badge()` inside R backticks to insert a lifecycle badge:

   ```r
   # 'r lifecycle::badge("experimental")'
   # 'r lifecycle::badge("deprecated")'
   # 'r lifecycle::badge("superseded")'
   ```

   If the deprecated feature is a function, a good place for this badge is at the top of the topic description. If it is an argument, you can put the badge in the argument description.

   The badge is displayed as an image in the HTML version of the documentation and as text otherwise.

   `lifecycle::badge()` is run by `roxygen` at build time so you don’t need to add `lifecycle` to `Imports:` just to use the badges. However, it’s still good practice to add to `Suggests:` so that it will be available to package developers.

Usage

`badge(stage)`

Arguments

- `stage` A lifecycle stage as a string. Must be one of "experimental", "stable", "superseded", or "deprecated".

Value

An `Rd` expression describing the lifecycle stage.
Badges

- [Experimental] lifecycle::badge("experimental")
- [Stable] lifecycle::badge("stable")
- [Superseded] lifecycle::badge("superseded")
- [Deprecated] lifecycle::badge("deprecated")

The meaning of these stages is described in vignette("stages").

---

deprecated

Mark an argument as deprecated

Description

Signal deprecated argument by using self-documenting sentinel deprecated() as default argument. Test whether the caller has supplied the argument with is_present().

Usage

```r
deprecated()

is_present(arg)
```

Arguments

- `arg` A deprecated() function argument.

Magical defaults

We recommend importing lifecycle::deprecated() in your namespace and use it without the namespace qualifier.

In general, we advise against such magical defaults, i.e. defaults that cannot be evaluated by the user. In the case of deprecated(), the trade-off is worth it because the meaning of this default is obvious and there is no reason for the user to call deprecated() themselves.

Examples

```r
foobar_adder <- function(foo, bar, baz = deprecated()) {
  # Check if user has supplied `baz` instead of `bar`
  if (lifecycle::is_present(baz)) {
    # Signal the deprecation to the user
    deprecate_warn("1.0.0", "foo::bar_adder(baz = )", "foo::bar_adder(bar = )")

    # Deal with the deprecated argument for compatibility
    bar <- baz
  }
}
```
foo + bar
}

foobar_adder(1, 2)
foobar_adder(1, baz = 2)

---

**deprecate_soft**  
*Deprecate functions and arguments*

**Description**

These functions provide three levels of verbosity for deprecated functions. Learn how to use them in vignette("communicate").

- **deprecate_soft()** warns only if the deprecated function is called directly, i.e. a user is calling a function they wrote in the global environment or a developer is calling it in their package. It does not warn when called indirectly, i.e. the deprecation comes from code that you don’t control.
- **deprecate_warn()** warns unconditionally.
- **deprecate_stop()** fails unconditionally.

Warnings are only issued once every 8 hours to avoid overwhelming the user. Control with `options(lifecycle_verbosity)`.

**Usage**

```r
deprecate_soft(
  when,  
  what,  
  with = NULL,  
  details = NULL,  
  id = NULL,  
  env = caller_env(),  
  user_env = caller_env(2)
)

deprecate_warn(
  when,  
  what,  
  with = NULL,  
  details = NULL,  
  id = NULL,  
  always = FALSE,  
  env = caller_env(),  
  user_env = caller_env(2)
)

deprecate_stop(when, what, with = NULL, details = NULL, env = caller_env())
```
deprecate_soft

Arguments

- **when**: A string giving the version when the behaviour was deprecated.
- **what**: A string describing what is deprecated:
  - Deprecate a whole function with "foo()".
  - Deprecate an argument with "foo(arg)".
  - Partially deprecate an argument with "foo(arg = 'must be a scalar integer')".
  - Deprecate anything else with a custom message by wrapping it in 1().
You can optionally supply the namespace: "ns::foo()", but this is usually not needed as it will be inferred from the caller environment.
- **with**: An optional string giving a recommended replacement for the deprecated behaviour. This takes the same form as what.
- **details**: In most cases the deprecation message can be automatically generated from with. When it can't, use details to provide a hand-written message. details can either be a single string or a character vector, which will be converted to a bulleted list. By default, info bullets are used. Provide a named vectors to override.
- **id**: The id of the deprecation. A warning is issued only once for each id. Defaults to the generated message, but you should give a unique ID when the message in details is built programmatically and depends on inputs, or when you'd like to deprecate multiple functions but warn only once for all of them.
- **env, user_env**: Pair of environments that define where deprecate_*() was called (used to determine the package name) and where the function called the deprecating function was called (used to determine if deprecate_soft() should message). These are only needed if you're calling deprecate_*() from an internal helper, in which case you should forward env = caller_env() and user_env = caller_env(2).
- **always**: If FALSE, the default, will warn every 8 hours. If TRUE, will always warn in direct usages. Indirect usages keep warning every 8 hours to avoid disrupting users who can’t fix the issue. Only use always = TRUE after at least one release with the default.

Value

- NULL, invisibly.

Conditions

- Deprecation warnings have class lifecycle_warning_deprecated.
- Deprecation errors have class lifecycle_error_deprecated.

See Also

- lifecycle()
Examples

# A deprecated function `foo`:
deprcate_warn("1.0.0", "foo()")

# A deprecated argument `arg`:
deprcate_warn("1.0.0", "foo(arg)")

# A partially deprecated argument `arg`:
deprcate_warn("1.0.0", "foo(arg = 'must be a scalar integer')")

# A deprecated function with a function replacement:
deprcate_warn("1.0.0", "foo()", "bar()")

# A deprecated function with a function replacement from a different package:
deprcate_warn("1.0.0", "foo()", "otherpackage::bar()")

# A deprecated function with custom message:
deprcate_warn(
    when = "1.0.0",
    what = "foo()",
    details = "Please use 'otherpackage::bar(foo = TRUE)' instead"
)

# A deprecated function with custom bulleted list:
deprcate_warn(
    when = "1.0.0",
    what = "foo()",
    details = c(
        x = "This is dangerous",
        i = "Did you mean 'safe_foo()' instead?"
    )
)

---

expect_deprecated

Does expression produce lifecycle warnings or errors?

Description

These functions are equivalent to testthat::expect_warning() and testthat::expect_error() but check specifically for lifecycle warnings or errors.

To test whether a deprecated feature still works without causing a deprecation warning, set the lifecycle_verbosity option to "quiet".

test_that("feature still works", {
    withr::local_options(lifecycle_verbosity = "quiet")
    expect_true(my_deprecated_function())
})
Usage
expect_deprecated(expr, regexp = NULL, ...)

expect_defunct(expr)

Arguments

expr Expression that should produce a lifecycle warning or error.
regexp Optional regular expression matched against the expected warning message.
... Arguments passed on to expect_match

Details

expect_deprecated() sets the lifecycle_verbosity option to "warning" to enforce deprecation warnings which are otherwise only shown once every 8 hours.

last_lifecycle_warnings

Display last deprecation warnings

Description

last_lifecycle_warnings() returns a list of all warnings that occurred during the last top-level R command, along with a backtrace.

Use print(last_lifecycle_warnings(), simplify = level) to control the verbosity of the backtrace. The simplify argument supports one of "branch" (the default), "collapse", and "none" (in increasing order of verbosity).

Usage

last_lifecycle_warnings()

Examples

# These examples are not run because `last_lifecycle_warnings()` does not
# work well within knitr and pkgdown
## Not run:
f <- function() invisible(g())
g <- function() list(h(), i())
h <- function() deprecate_warn("1.0.0", "this()")
i <- function() deprecate_warn("1.0.0", "that()")
f()
# Print all the warnings that occurred during the last command:
last_lifecycle_warnings()

# By default, the backtraces are printed in their simplified form.
# Use `simplify` to control the verbosity:
print(last_lifecycle_warnings(), simplify = "none")

## End(Not run)

pkg_lifecycle_statuses

Lint usages of functions that have a non-stable life cycle.

Description

- `lint_lifecycle` dynamically queries the package documentation for packages for lifecycle annotations and then searches the directory in `path` for usages of those functions.
- `lint_tidyverse_lifecycle` is a convenience function to call `lint_lifecycle` for all the packages in the tidyverse.
- `pkg_lifecycle_statuses` returns a data frame of functions with lifecycle annotations for an installed package.

Usage

pkg_lifecycle_statuses(
  package,
  which = c("superseded", "deprecated", "questioning", "defunct", "experimental",
    "soft-deprecated", "retired")
)

lint_lifecycle(
  packages,
  path = ".",
  pattern = "[.][Rr](md)?",
  which = c("superseded", "deprecated", "questioning", "defunct", "experimental",
    "soft-deprecated", "retired")
)

lint_tidyverse_lifecycle(
  path = ".",
  pattern = "[.][Rr](md)?",
  which = c("superseded", "deprecated", "questioning", "defunct", "experimental",
    "soft-deprecated", "retired")
)
signal\_stage

**Arguments**

- **package** The name of an installed package.
- **which** The lifecycle statuses to retrieve. Include NA if you want to include functions without a specified lifecycle status in the results.
- **packages** One or more installed packages to query for lifecycle statuses.
- **path** The directory path to the files you want to search.
- **pattern** Any files matching this pattern will be searched. The default searches any files ending in .R or .Rmd.

---

**Description**

*[Experimental]*

`signal\_stage()` allows you to signal life cycle stages other than deprecation (for which you should use `deprecate\_warn()` and friends). There is no behaviour associated with this signal, but in the future we will provide tools to log and report on usage of experimental and superseded functions.

**Usage**

```r
signal\_stage(stage, what, with = NULL, env = caller\_env())
```

**Arguments**

- **stage** Life cycle stage, either "experimental" or "superseded".
- **what** String describing what feature the stage applies too, using the same syntax as `deprecate\_warn()`.
- **with** An optional string giving a recommended replacement for a superseded function.
- **env** Environment used to determine where `signal\_stage()` was called, used to determine the package name.

**Examples**

```r
foofy <- function(x, y, z) {
  signal\_stage("experimental", "foofy()")
  x + y / z
}
foofy(1, 2, 3)
```
Description

There are 3 levels of verbosity for deprecated functions: silence, warning, and error. Since the lifecycle package avoids disruptive warnings, the default level of verbosity depends on the lifecycle stage of the deprecated function, on the context of the caller (global environment or testthat unit tests cause more warnings), and whether the warning was already issued (see the help for deprecation functions).

You can control the level of verbosity with the global option lifecycle_verbosity. It can be set to:

- "quiet" to suppress all deprecation messages.
- "default" or NULL to warn once every 8 hours.
- "warning" to warn every time.
- "error" to error instead of warning.

Note that functions calling deprecate_stop() invariably throw errors.

Examples

if (rlang::is_installed("testthat")) {
  library(testthat)

  mytool <- function() {
    deprecate_soft("1.0.0", "mytool()")
    10 * 10
  }

  # Forcing the verbosity level is useful for unit testing. You can
  # force errors to test that the function is indeed deprecated:
  test_that("mytool is deprecated", {
    rlang::local_options(lifecycle_verbosity = "error")
    expect_error(mytool(), class = "defunctError")
  })

  # Or you can enforce silence to safely test that the function
  # still works:
  test_that("mytool still works", {
    rlang::local_options(lifecycle_verbosity = "quiet")
    expect_equal(mytool(), 100)
  })
}
