Package ‘lmomPi’

August 15, 2023

License GPL (>= 3)

Title (Precipitation) Frequency Analysis and Variability with L-Moments from ‘lmom’

Type Package

Description It is an extension of 'lmom' R package: ‘pel()’, ‘cdf()’, ‘qua()’ function families are lumped and called from one function per each family respectively in order to create robust automatic tools to fit data with different probability distributions and then to estimate probability values and return periods. The implemented functions are able to manage time series with constant and/or missing values without stopping the execution with error messages. The package also contains tools to calculate several indices based on variability (e.g. ‘SPI’, Standardized Precipitation Index, see <https://climatedataguide.ucar.edu/climate-data/standardized-precipitation-index-spi> and <http://spei.csic.es/>) for multiple time series or spatially gridded values.

Version 0.6.6

cdf

Generic function for cdf...: probability distribution fitting with L-Moments.

Description

These functions compute value(s) of cumulated probability or SPI-like (normal standardize) index from a sample or time series of x.

Usage

```r
cdf(
  para,
  x,
  probability_distribution_attrname = "probability_distrib",
  indices = NULL,
  return.as.spi = FALSE,
  spi.scale = NA,
  distrib = NA,
  ...
)

spi.cdf(x, para, ...)

cdf.spi(x, para, ...)
```

Arguments

- **x**, **para**, ... L-moments and further parameters for cdf... and cdf
- **probability_distribution_attrname** attribute name for probability distribution
- **indices** vector of string working as factors or indices, e.g. the month names or similar. It must be of the same length of x or the length equal to 1 other NULL, if not used. If used, it computes cdf for each factor.
- **return.as.spi** logical parameter. Default is FALSE. If it is TRUE probability value is transformed to a normalized random variable through standard `qnorm`, as for Standard Precipitation Index (SPI) ([https://climatedataguide.ucar.edu/climate-data/standardized-precipitation-index-spi](https://climatedataguide.ucar.edu/climate-data/standardized-precipitation-index-spi)).
- **spi.scale** integer value or NA. If it greater than 1 x is filtered with the sum of a generic element of x and the previous spi.scale-1 ones (e.g. SPI-3, SPI-6, etc.). Default is NA (no filtering) which is equivalent to spi.scale=1.
- **distrib** character string indicating the probability distribution, it can be used in case para has no attributes. Default is NA and distribution info are all passed through para.
Value

A vector of cumulated probability value(s) or SPI-like Gaussianized values. It is a list of vectors in case of several probability parametric distribution functions (i.e. para is a list and length(para)>1).

Examples

# Sample L-moments of Ozone from the airquality data
data(airquality)
lmom <- samlmu(airquality$Ozone, nmom=6)
distrib <- c("exp","gam","gev","glo","gpa","gno","gum","kap",
  "ln3","nor","pe3","wak","wei")
para_list <- pel(distrib=distrib, lmom=lmom)
cdf_list <- cdf(para=para_list, x=airquality$Ozone)
cdf_gam <- cdf(para=para_list$gam, x=airquality$Ozone)
cdf_gam2 <- cdf(para=para_list$gam, x=airquality$Ozone, distrib="gam")
if (any(cdf_gam!=cdf_gam2, na.rm=TRUE)) stop("Any possible errors after 0.6.3 package updates!")

## Comparison with the SPI/SPEI algorithms: 'SPEI::spi' ('SPEI' package)

if (requireNamespace("SPEI", quietly = TRUE)) {
  library(SPEI)
data(wichita)

distrib_wichita <- 'pe3'
spi.scale <- 1

month_wichita <- sprintf("M%02d", wichita$MONTH)
para_wichita <- pel(x=wichita$PRCP, indices=month_wichita, distrib=distrib_wichita, 
  spi.scale=spi.scale)
spi_wichita <- spi.cdf(x=wichita$PRCP, indices=month_wichita, para=para_wichita, 
  spi.scale=spi.scale)
spi_wichita_speipkg <- spi(data=wichita$PRCP, distrib='PearsonIII', scale=spi.scale)
difference <- spi_wichita-spi_wichita_speipkg$fitted
}

Description

This package contains wrapper functions of 'lmom' packages: 
cdf: generic distribution function;
qua: generic quantile function; 
pe3: fitting of probability distribution function through L-moments.

Details

The example functions are illustrated making use of CHIRPS rainfall meteorological data taken:
The package-provided datasets shall be only used as example datasets.

The package also contains wrapper functions to calculate several indices based on variability (e.g. 'SPI', Standardized Precipitation Index, see https://climatedataguide.ucar.edu/climate-data/standardized-precipitation-index-spi and http://spei.csic.es) for multiple time series or spatio-temporal gridded values. The function spi.cdf() is compared against SPEI::spi() in SPEI package (https://cran.r-project.org/package=SPEI). The differences in SPI estimation have order of magnitude averagely about 10^-8, due to the different fitting methods implemented in the two packages. (see SPEI::spi() and spi.cdf() for more details).

The development of this package has been sponsored by ACEWATER2 and "Water for Growth and Poverty Reduction in the Mekrou" projects of the Joint Research Centre of the European Commission (https://aquaknow.jrc.ec.europa.eu).

Description

Generic function for pe3...

Usage

pel(distrib = c("exp", "gam", "gev", "glo", "gpa", "gno", "gum", "kap", "ln3", "nor", 
"pe3", "wak", "wei"),
   lmom = NULL,
   probability_distribution_attrname = "probability_distrib",
   x = NULL,

\begin{verbatim}
nmom = 5,
sort.data = TRUE,
ratios = sort.data,
trim = 0,
indices = NULL,
spi.scale = NA,
correction = NULL,
...
}

pel_x(x, ...)

pel_lmom(lmom, ...)

Arguments

\begin{itemize}
\item \texttt{distrib} character string indicating the probability distribution to fit
\item \texttt{lmom, ...} L-moments and further parameters for pel...
\item \texttt{probability_distribution_attrname} attribute name for probability distribution
\item \texttt{x} vector containing sample. It is utilized to calculate L-moments in case \texttt{lmom} is set equal to NULL.
\item \texttt{nmom, sort.data, ratios, trim} arguments for \texttt{samlmu} (\texttt{nmom}=5 by default). They are utilized if argument \texttt{lmom} is \texttt{NULL}.
\item \texttt{indices} optional index or tag character vector of the same length of \texttt{x} used as INDEX for \texttt{tapply}. It is used to fit different probability distribution in one sample time series (e.g. months in a year).
\item \texttt{spi.scale} integer value or \texttt{NA}. If it is greater than 1, \texttt{x} is filtered with the sum of a generic element of \texttt{x} and the previous \texttt{spi.scale}-1 ones (e.g. SPI-3, SPI-6, etc.). Default is \texttt{NA} (no filtering) which is equivalent to \texttt{spi.scale}=1.
\item \texttt{correction} numeric value correction for the 3rd (and higher) L-moment estimation. Default is \texttt{NULL}, generally it is not used. It is used and suggested to be \texttt{10^{-10}} in case of a massive function use with \texttt{lmom}=\texttt{NULL} (e.g. raster cell or zonal statistics).
\end{itemize}

Details

pel_x and pel_lmom are wrapper functions of pel whose first argument is \texttt{x} or \texttt{lmom} respectively.

Value

A numeric vector containing the parameters of the selected probability distribution. It is a list in case of selection of several probability distributions (i.e. \texttt{length(distrib)>1}).

# Sample L-moments of Ozone from the airquality data
data(airquality)
lmom <- samlmu(airquality$Ozone, nmom=6)
distrib <- "gev"
# Fit a GEV distribution
out_gev <- pel(distrib=distrib, lmom=lmom)

distrib <- c("exp","gam","gev","glo","gpa","gno","gum","kap","ln3",
"nor","pe3","wak","wei")
out_list <- pel(distrib=distrib, lmom=lmom)

### qua

**Generic function for qua...: probability distribution fitting with L-Moments**

#### Description

Generic function for qua...: probability distribution fitting with L-Moments

#### Usage

qua(
  para,
  f,
  probability_distribution_attrname = "probability_distrib",
  distrib = NA,
  ...
)

#### Arguments

- **f, para,...**  
  L-moments and further parameters for qua...
- **probability_distribution_attrname**  
  attribute name for probability distribution
- **distrib**  
  character string indicating the probability distribution, it can be used in case para has no attributes. Default is NA and distribution info are all passed through para.
Value

A vector of quantiles. It is a list of vectors of quantiles in case of several probability parametric
distribution functions (i.e. para is a list and length(para)>1).
