Package ‘logistf’

August 18, 2023

Version 1.26.0
Date 2023-08-18
Title Firth's Bias-Reduced Logistic Regression
Depends R (>= 3.0.0)
Imports mice, mgcv, formula.tools, Matrix
Suggests emmeans (>= 1.4), estimability
Description Fit a logistic regression model using Firth's bias reduction method, equivalent to penalization of the log-likelihood by the Jeffreys prior. Confidence intervals for regression coefficients can be computed by penalized profile likelihood. Firth's method was proposed as ideal solution to the problem of separation in logistic regression, see Heinze and Schemper (2002) <doi:10.1002/sim.1047>. If needed, the bias reduction can be turned off such that ordinary maximum likelihood logistic regression is obtained. Two new modifications of Firth's method, FLIC and FLAC, lead to unbiased predictions and are now available in the package as well, see Puhr et al (2017) <doi:10.1002/sim.7273>.

Description

Fits a binary logistic regression model using Firth’s bias reduction method, and its modifications FLIC and FLAC, which both ensure that the sum of the predicted probabilities equals the number of events. If needed, the bias reduction can be turned off such that ordinary maximum likelihood logistic regression is obtained.

Details

The package logistf provides a comprehensive tool to facilitate the application of Firth’s correction for logistic regression analysis, including its modifications FLIC and FLAC.

The call of the main function of the library follows the structure of the standard functions as lm or glm, requiring a data.frame and a formula for the model specification. The resulting object belongs
to the new class logistf, which includes penalized maximum likelihood (Firth-logistic’- or FL’-type) logistic regression parameters, standard errors, confidence limits, p-values, the value of the maximized penalized log likelihood, the linear predictors, the number of iterations needed to arrive at the maximum and much more. Furthermore, specific methods for the resulting object are supplied. Additionally, a function to plot profiles of the penalized likelihood function and a function to perform penalized likelihood ratio tests have been included.

In explaining the details of the estimation process we follow mainly the description in Heinze & Ploner (2003). In general, maximum likelihood estimates are often prone to small sample bias. To reduce this bias, Firth (1993) suggested to maximize the penalized log likelihood \( \log L(\beta)^* = \log L(\beta) + 1/2 \log |I(\beta)| \), where \( I(\beta) \) is the Fisher information matrix, i.e. minus the second derivative of the log likelihood. Applying this idea to logistic regression, the score function \( U(\beta) \) is replaced by the modified score function \( U(\beta)^* = U(\beta) + a \), where \( a \) has rth entry \( a_r = 0.5trI(\beta)^{-1}[dI(\beta)/d\beta_r], r = 1, ..., k \). Heinze and Schenper (2002) give the explicit formulae for \( I(\beta) \) and \( I(\beta)/d\beta_r \).

In our programs estimation of \( \beta \) can be based on a Newton-Raphson algorithm or on iteratively reweighted least squares. Parameter values are initialized usually with 0, but in general the user can specify arbitrary starting values.

With a starting value of \( \beta^{(0)} \), the penalized maximum likelihood estimate \( \beta \) is obtained iteratively via Newton-Raphson:

\[
\beta^{(s+1)} = \beta^{(s)} + I(\beta^{(s)})^{-1}U(\beta^{(s)})^*
\]

If the penalized log likelihood evaluated at \( \beta^{(s+1)} \) is less than that evaluated at \( \beta^{(s)} \), then \( \beta(s+1) \) is recomputed by step-halving. For each entry \( r \) of \( \beta \) with \( r = 1, ..., k \) the absolute step size \( |\beta_r^{(s+1)} - \beta_r^*| \) is restricted to a maximal allowed value \( \text{maxstep} \). These two means should avoid numerical problems during estimation. The iterative process is continued until the parameter estimates converge, i.e., until three criteria are met: the change in log likelihood is less than \( l\text{conv} \), the maximum absolute element of the score vector is less than \( g\text{conv} \), the maximum absolute change in beta is less than \( x\text{conv} \). \( l\text{conv}, g\text{conv}, x\text{conv} \) can be controlled by \( \text{control=logistf.control}(l\text{conv}=..., g\text{conv}=..., x\text{conv}=...) \).

Computation of profile penalized likelihood confidence intervals for parameters (logistpl) follows the algorithm of Venzon and Moolgavkar (1988). For testing the hypothesis of \( \gamma = \gamma_0 \), let the likelihood ratio statistic

\[
LR = 2[\log L(\gamma, \delta) - \log L(\gamma_0, \delta_{\gamma_0})^*]
\]

where \( (\gamma, \delta) \) is the joint penalized maximum likelihood estimate of \( \beta = (\gamma, \delta) \), and \( \delta_{\gamma_0} \) is the penalized maximum likelihood estimate of \( \delta \) when \( \gamma = \gamma_0 \). The profile penalized likelihood confidence interval is the continuous set of values \( \gamma_0 \) for which \( LR \) does not exceed the \((1 - \alpha)100\)th percentile of the \( \chi_1^2 \)-distribution. The confidence limits can therefore be found iteratively by approximating the penalized log likelihood function in a neighborhood of \( \beta \) by the quadratic function

\[
l(\beta + \delta) = l(\beta) + \delta^T U^* - 0.5\delta^T I\delta
\]

where \( U^* = U(\beta)^* \) and \( -I = -I(\beta) \).

In some situations computation of profile penalized likelihood confidence intervals may be time consuming since the iterative procedure outlined above has to be repeated for the lower and for the upper confidence limits of each of the \( k \) parameters. In other problems one may not be interested
in interval estimation, anyway. In such cases, the user can request computation of Wald confidence intervals and P-values, which are based on the normal approximation of the parameter estimates and do not need any iterative estimation process. Note that from version 1.24.1 on, the variance-covariance matrix is based on the second derivative of the likelihood of the augmented data rather than the original data, which proved to be a better approximation if the user chooses to set a higher value for $\tau$, the penalty strength.

The adequacy of Wald confidence intervals for parameter estimates can be verified by plotting the profile penalized log likelihood (PPL) function. A symmetric shape of the PPL function allows use of Wald intervals, while an asymmetric shape demands profile penalized likelihood intervals (Heinze & Schemper (2002)). Further documentation can be found in Heinze & Ploner (2004).

The package includes functions to work with multiply imputed data sets, such as generated by the mice package. Results on individual fits can be pooled to obtain point and interval estimates, as well as profile likelihood confidence intervals and likelihood profiles in general (Heinze, Ploner and Beyea, 2013).

Moreover, in the package the modifications FLIC and FLAC have been implemented, which were described in Puhr et al (2017) as solutions to obtain accurate predicted probabilities.

References

**Description**

Compute all the single terms in the scope argument that can be added to or dropped from the model, fit those models and compute a table of the changes in fit.

**Usage**

```r
## S3 method for class 'logistf'
add1(object, scope, data, test = "PLR", ...)
```

**Arguments**

- `object`: A fitted `logistf`, `flic` or `flac` object
- `scope`: The scope of variables considered for adding or dropping. Should be a vector of variable names. Can be left missing; the method will then use all variables in the object’s data slot which are not identified as the response variable.
- `data`: The data frame used to fit the object.
- `test`: The type of test statistic. Currently, only the PLR test (penalized likelihood ratio test) is allowed for logistf fits.
- `...`: Further arguments passed to or from other methods.

**Details**

drop1 and add1 generate a table where for each variable the penalized likelihood ratio chi-squared, the degrees of freedom, and the p-value for dropping/adding this variable are given.

**Value**

A matrix with nvar rows and 3 columns (Chisquared, degrees of freedom, p-value).

**Examples**

```r
data(sex2)
fit<-logistf(data=sex2, case~1, pl=FALSE)
add1(fit, scope=c("dia", "age"), data=sex2)

fit2<-logistf(data=sex2, case~age+oc+dia+vic+vicl+vis)
drop1(fit2, data=sex2)
```
Analysis of Penalized Deviance for \texttt{logistf} Models

Description

This method compares hierarchical and non-hierarchical \texttt{logistf} models using penalized likelihood ratio tests. It replaces the function \texttt{logistftest} of former versions of \texttt{logistf}.

Usage

```r
## S3 method for class 'logistf'
anova(object, fit2, formula, method = "nested", ...)
```

Arguments

- \texttt{object}: A fitted \texttt{logistf} model object
- \texttt{fit2}: Another fitted \texttt{logistf} model object, to be compared with \texttt{object}
- \texttt{formula}: Alternatively to \texttt{fit2}, a formula which specifies terms to omit from the object model fit.
- \texttt{method}: One of \texttt{c("nested","PLR")}. \texttt{nested} is the default for hierarchically nested models, and will compare the penalized likelihood ratio statistics (minus twice the difference between maximized penalized log likelihood and null penalized log likelihood), where the null penalized log likelihood is computed from the same, hierarchically superior model. Note that unlike in maximum likelihood analysis, the null penalized likelihood depends on the penalty (Jeffreys prior) which itself depends on the scope of variables of the hierarchically superior model. \texttt{PLR} compares the difference in penalized likelihood ratio between the two models, where for each model the null penalized likelihood is computed within the scope of variables in that model. For \texttt{PLR}, the models need not be hierarchically nested.
- \dots: Further arguments passed to the method.

Details

Comparing models fitted by penalized methods, one must consider that the penalized likelihoods are not directly comparable, since a penalty is involved. Or in other words, inserting zero for some regression coefficients will not lead to the same penalized likelihood as if the corresponding variables are simply "unknown" to a model. The \texttt{anova} method takes care that the same penalty is used for two hierarchically nested models, and if the models are not hierarchically nested, it will first relate each penalized likelihood to its null penalized likelihood, and only compare the resulting penalized likelihood ratio statistics. The chi-squared approximation for this latter method (PLR) is considered less accurate than that of the nested method. Nevertheless, it is the only way to go for comparison of non-nested models.
backward

Value

An object of class `anova.logistf` with items

- `chisq`  the chisquared statistic for the model comparison
- `df` The degrees of freedom
- `pval` The p-value
- `call` The function call
- `method` The method of comparison (input)
- `model1` The first model
- `model2` The second model which was compared to the first model
- `PLR1` The PLR statistic of the first model
- `PLR2` the PLR statistic of the second model; for the nested method, this will be the drop in chi-squared due to setting the coefficients to zero

Examples

```r
data(sex2)
fit<-logistf(data=sex2, case~age+oc+dia+vic+vicl+vis)

# simultaneous test of variables vic, vicl, vis:
anova(fit, formula=~vic+vicl+vis)

# test versus a simpler model
fit2<-logistf(data=sex2, case~age+oc+dia)
# or: fit2<-update(fit, case~age+oc+dia)
anova(fit, fit2)

# comparison of non-nested models (with different df):
fit3<-logistf(data=sex2, case~age+vic+vicl+vis)
anova(fit2, fit3, method="PLR")
```

Description

These functions provide simple backward elimination/forward selection procedures for logistf models.
Usage

backward(object, ...)

## S3 method for class 'logistf'
backward(
  object,
  scope,
  data,
  steps = 1000,
  slstay = 0.05,
  trace = TRUE,
  printwork = FALSE,
  full.penalty = FALSE,
  ...
)

## S3 method for class 'flic'
backward(
  object,
  scope,
  steps = 1000,
  slstay = 0.05,
  trace = TRUE,
  printwork = FALSE,
  full.penalty = FALSE,
  ...
)

forward(object, ...)

## S3 method for class 'logistf'
forward(
  object,
  scope,
  data,
  steps = 1000,
  slentry = 0.05,
  trace = TRUE,
  printwork = FALSE,
  pl = TRUE,
  ...
)

Arguments

object A fitted logistf model object. To start with an empty model, create a model fit
  with a formula= y~1, pl=FALSE. (Replace y by your response variable.)

... Further arguments to be passed to methods.
The scope of variables to add/drop from the model. Can be missing for backward, backward will use the terms of the object fit. Alternatively, an arbitrary vector of variable names can be given, to allow that only some of the variables will be competitively selected or dropped. Has to be provided for forward.

data

The data frame used to fit the object.

steps

The number of forward selection/backward elimination steps.

slstay

For backward, the significance level to stay in the model.

trace

If TRUE, protocols selection steps.

printwork

If TRUE, prints each working model that is visited by the selection procedure.

full.penalty

If TRUE penalty is not taken from current model but from start model.

slentry

For forward, the significance level to enter the model.

pl

For forward, computes profile likelihood confidence intervals for the final model if TRUE.

Details

The variable selection is simply performed by repeatedly calling add1 or drop1 methods for logistf, and is based on penalized likelihood ratio test.

Note that selecting among factor variables is not supported. One way to use forward or backward with factor variables is to first convert them into numeric variables (0/1 coded dummy variables, choosing a sensible reference category). Forward and backward will then perform selection on the dummy variables, meaning that it will collapse levels of a factor variable with similar outcomes.

Value

An updated logistf, flic or flac fit with the finally selected model.

Functions

• forward(): Forward Selection

Examples

data(sex2)
fit<-logistf(data=sex2, case=1, pl=FALSE)
fitf<-forward(fit, scope=c("dia", "age"), data=sex2)

fit2<-logistf(data=sex2, case=age+oc+vic+vicl+vis+dia)
fitb<-backward(fit2, data=sex2)
CLIP.confint

Confidence Intervals after Multiple Imputation: Combination of Likelihood Profiles

Description

This function implements the new combination of likelihood profiles (CLIP) method described in Heinze, Ploner and Beyea (2013). This method is useful for computing confidence intervals for parameters after multiple imputation of data sets, if the normality assumption on parameter estimates and consequently the validity of applying Rubin’s rules (pooling of variances) is in doubt. It consists of combining the profile likelihoods into a posterior. The function CLIP.confint searches for those values of a regression coefficient, at which the cumulative distribution function of the posterior is equal to the values specified in the argument ci.level (usually 0.025 and 0.975). The search is performed using R’s optimize function.

Usage

CLIP.confint(
  obj = NULL,
  variable = NULL,
  data,
  firth = TRUE,
  weightvar = NULL,
  control = logistf.control(),
  ci.level = c(0.025, 0.975),
  pvalue = TRUE,
  offset = NULL,
  bound.lo = NULL,
  bound.up = NULL,
  legacy = FALSE
)

Arguments

obj             Either a list of logistf fits (on multiple imputed data sets), or the result of analysis of a mice (multiply imputed) object using with.mids
variable        The variable of interest, for which confidence intervals should be computed. If missing, confidence intervals for all variables will be computed.
data            A list of data set corresponding to the model fits. Can be left blank if obj was obtained with the dataout=TRUE option or if obj was obtained by mice
firth           If TRUE, applies the Firth correction. Should correspond to the entry in obj.
weightvar       An optional weighting variable for each observation.
control         Control parameters for logistf, usually obtained by logistf.control()
ci.level        The two confidence levels for each tail of the posterior distribution.
pvalue          If TRUE, will also compute a P-value from the posterior.
offset          An optional offset variable
bound.lo       Bounds (vector of length 2) for the lower limit. Can be left blank. Use only if
                problems are encountered.
bound.up       Bounds (vector of length 2) for the upper limit. Can be left blank. Use only if
                problems are encountered.
legacy         If TRUE, will use pure R code for all model fitting. Can be slow. Not recom-
                mended.

Details
For each confidence limit, this function performs a binary search to evaluate the combined posterior,
which is obtained by first transforming the imputed-data likelihood profiles into cumulative distri-
bution functions (CDFs), and then averaging the CDFs to obtain the CDF of the posterior. Usually,
the binary search manages to find the confidence intervals very quickly. The number of iterations
(mean and maximum) will be supplied in the output object. Further details on the method can be
found in Heinze, Ploner and Beyea (2013).

Value
An object of class CLIP.confint, with items:

variable       The variable(s) which were analyzed
estimate       The pooled estimate (average over imputations)
ci             The confidence interval(s)
pvalue         The p-value(s)
imputations    The number of imputed datasets
ci.level       The confidence level (input)
bound.lo       The bounds used for finding the lower confidence limit; usually not of interest.
                May be useful for error-tracing.
bound.up       The bounds used for finding the upper confidence limit
iter           The number of iterations (for each variable and each tail)
call           The call object

**CLIP.profile**

**Combine Profile Likelihoods from Imputed-Data Model Fits**

**Description**

This function uses CLIP (combination of likelihood profiles) to compute the pooled profile of the posterior after multiple imputation.

**Usage**

`CLIP.profile(`
- `obj = NULL`,
- `variable`,
- `data`,
- `which`,
- `firth = TRUE`,
- `weightvar`,
- `control = logistf.control()`,
- `offset = NULL`,
- `from = NULL`,
- `to = NULL`,

---

---
Arguments

obj Either a list of logistf fits (on multiple imputed data sets), or the result of analysis of a mice (multiply imputed) object using with.mids.

variable The variable of interest, for which confidence intervals should be computed. If missing, confidence intervals for all variables will be computed.

data A list of data set corresponding to the model fits. Can be left blank if obj was obtained with the dataout=TRUE option or if obj was obtained by mice.

which Alternatively to variable, the argument which allows to specify the variable to compute the profile for as righthand formula, e.g. which=~X.

firth If TRUE, applies the Firth correction. Should correspond to the entry in obj.

weightvar An optional weighting variable for each observation

ccontrol control parameters for logistf, usually obtained by logistf.control()

offset An optional offset variable

from Lowest value for the sequence of values for the regression coefficients for which the profile will be computed. Can be left blank.

to Highest value for the sequence of values for the regression coefficients for which the profile will be computed. Can be left blank.

steps Number of steps for the sequence of values for the regression coefficients for which the profile will be computed.

legacy If TRUE, only R code will be used. Should be avoided.

keep If TRUE, keeps the profiles for each imputed data sets in the output object.

Details

While CLIP.confint iterates to find those values at which the CDF of the pooled posterior equals the confidence levels, CLIP.profile will evaluate the whole profile, which enables plotting and evaluating the skewness of the combined and the completed-data profiles. The combined and completed-data profiles are available as cumulative distribution function (CDF) or in the scaling of relative profile likelihood (minus twice the likelihood ratio statistic compared to the maximum). Using a plot method, the pooled posterior can also be displayed as a density.

Value

An object of class CLIP.profile with items:

beta The values of the regression coefficient

cdf The cumulative distribution function of the posterior

profile The profile of the posterior
cdf.matrix  An imputations x steps matrix with the values of the completed-data CDFs for each beta
profile.matrix An imputations x steps matrix with the values of the completed-data profiles for each beta
call The function call

Description

Support for the emmeans package is available. See below for an example of using emmeans::emmeans() with a logistf object.

Examples

data(sex2)
fit<-logistf(case ~ age+oc+vic+vicl+vis+dia, data=sex2)
emmeans::emmeans(fit, ~age+dia)

flac

Description

flac implements Firth’s bias-reduced penalized-likelihood logistic regression with added covariate.

Usage

flac(...)

## Default S3 method:
flac(
  formula,
data,
  model = TRUE,
  control,
  modcontrol,
  weights,
  offset,
  na.action,
  pl = TRUE,
  plconf = NULL,
  ...
)

## S3 method for class 'logistf'
flac(lfobject, data, model = TRUE, ...)

emmeans-logistf

Emmeans support for logistf

emmeans-logistf

Emmeans support for logistf

Description

Support for the emmeans package is available. See below for an example of using emmeans::emmeans() with a logistf object.

Examples

data(sex2)
fit<-logistf(case ~ age+oc+vic+vicl+vis+dia, data=sex2)
emmeans::emmeans(fit, ~age+dia)

flac

FLAC - Firth’s logistic regression with added covariate

Description

flac implements Firth’s bias-reduced penalized-likelihood logistic regression with added covariate.

Usage

flac(...)

## Default S3 method:
flac(
  formula,
data,
  model = TRUE,
  control,
  modcontrol,
  weights,
  offset,
  na.action,
  pl = TRUE,
  plconf = NULL,
  ...
)

## S3 method for class 'logistf'
flac(lfobject, data, model = TRUE, ...)
Arguments

... Further arguments passed to the method or \texttt{logistf}-call.

\texttt{formula} A formula object, with the response on the left of the operator, and the model terms on the right. The response must be a vector with 0 and 1 or \texttt{FALSE} and \texttt{TRUE} for the outcome, where the higher value (1 or \texttt{TRUE}) is modeled.

\texttt{data} A data frame containing the variables in the model.

\texttt{model} If \texttt{TRUE} the corresponding components of the fit are returned.

\texttt{control} Controls iteration parameter. Taken from \texttt{logistf}-object when specified. Otherwise default is \texttt{control= logistf.control(1)}.

\texttt{modcontrol} Controls additional parameter for fitting. Taken from \texttt{logistf}-object when specified. Otherwise default is \texttt{logistf.mod.control(1)}.

\texttt{weights} specifies case weights. Each line of the input data set is multiplied by the corresponding element of weights

\texttt{offset} a priori known component to be included in the linear predictor

\texttt{na.action} a function which indicates what should happen when the data contain NAs

\texttt{pl} Specifies if confidence intervals and tests should be based on the profile penalized log likelihood (\texttt{pl=TRUE}, the default) or on the Wald method (\texttt{pl=FALSE}).

\texttt{plconf} specifies the variables (as vector of their indices) for which profile likelihood confidence intervals should be computed. Default is to compute for all variables.

\texttt{lfobject} A fitted \texttt{logistf} object.

Details

FLAC is a simple modification of Firth’s logistic regression which provides average predicted probabilities equal to the observed proportion of events, while preserving the ability to deal with separation. It has been described by Puhr et al (2017).

The modified score equations to estimate coefficients for Firth’s logistic regression can be interpreted as score equations for ML estimates for an augmented data set. This data set can be created by complementing each original observation $i$ with two pseudo-observations weighted by $h_i/2$ with unchanged covariate values and with response values set to $y = 0$ and $y = 1$ respectively. The basic idea of FLAC is to discriminate between original and pseudo-observations in the alternative formulation of Firth’s estimation as an iterative data augmentation procedure. The following generic methods are available for FLAC’s output object: \texttt{print}, \texttt{summary}, \texttt{coef}, \texttt{confint}, \texttt{anova}, \texttt{extractAIC}, \texttt{add1}, \texttt{drop1}, \texttt{profile}, \texttt{terms}, \texttt{nobs}, \texttt{predict}. Furthermore, forward and backward functions perform convenient variable selection. Note that \texttt{anova}, \texttt{extractAIC}, \texttt{add1}, \texttt{drop1}, forward and backward are based on penalized likelihood ratio tests.

Value

A FLAC object with components:

\texttt{coefficients} The coefficients of the parameter in the fitted model.

\texttt{predict} A vector with the predicted probability of each observation

\texttt{linear.predictors} A vector with the linear predictor of each observation.
The p-values of the specific parameters
The lower confidence limits of the parameter.
The upper confidence limits of the parameter.
The call object.
The significance level: 0.95
The variance-covariance-matrix of the parameters.
A vector of the (penalized) log-likelihood of the restricted and the full models.
The number of observations.
The formula object.
The augmented dataset used
The number of degrees of freedom in the model.
depending on the fitting method ‘Penalized ML’ or Standard ML.} \item{method}{the method in file likelihood’ or ‘Wald’, depending on the argument pl and plconf.
a copy of the control parameters.
a copy of the modcontrol parameters.
the model terms (column names of design matrix).
if requested (the default), the model frame used.

Methods (by class)

• flac(default): With formula and data
• flac(logistf): With logistf object

flic - Firth's logistic regression with intercept correction

Description

flic implements Firth's bias-reduced penalized-likelihood logistic regression with intercept correction.

Usage

flic(...)

## Default S3 method:
flic(
  formula,
  data,
  model = TRUE,
  control,
  modcontrol,
  weights,
  offset,
  na.action,
  ...
)

## S3 method for class 'logistf'
flic(lfobject, model = TRUE, ...)

Arguments

... Further arguments passed to the method or logistf-call.
formula A formula object, with the response on the left of the operator, and the model terms on the right. The response must be a vector with 0 and 1 or FALSE and TRUE for the outcome, where the higher value (1 or TRUE) is modeled.
data If using with formula, a data frame containing the variables in the model.
model If TRUE the corresponding components of the fit are returned.
control Controls iteration parameter. Taken from logistf-object when specified. Otherwise default is control = logistf.control().
modcontrol Controls additional parameter for fitting. Taken from logistf-object when specified. Otherwise default is logistf.mod.control().
weights specifies case weights. Each line of the input data set is multiplied by the corresponding element of weights
offset a priori known component to be included in the linear predictor
na.action a function which indicates what should happen when the data contain NAs
lfobject A fitted logistf object.
Details

FLIC is a simple modification of Firth’s logistic regression which provides average predicted probabilities equal to the observed proportion of events, while preserving the ability to deal with separation.

In general the average predicted probability in Firth’s logistic regression is not equal to the observed proportion of events. Because the determinant of the Fisher-Information matrix is maximized for \( \pi_i = \frac{1}{2} \) it is concluded that Firth’s penalization tends to push the predicted probabilities towards one-half compared with ML-estimation. FLIC first applies Firth’s logistic regression and then corrects the intercept such that the predicted probabilities become unbiased while keeping all other coefficients constant. The following generic methods are available for flic's output object: print, summary, coef, confint, anova, extractAIC, add1, drop1, profile, terms, nobs, predict. Furthermore, forward and backward functions perform convenient variable selection. Note that anova, extractAIC, add1, drop1, forward and backward are based on penalized likelihood ratio tests.

Value

A flic object with components:

- coefficients: The coefficients of the parameter in the fitted model.
- predict: A vector with the predicted probability of each observation.
- linear.predictors: A vector with the linear predictor of each observation.
- var: The variance-covariance-matrix of the parameters.
- prob: The p-values of the specific parameters.
- ci.lower: The lower confidence limits of the parameter.
- ci.upper: The upper confidence limits of the parameter.
- call: The call object.
- alpha: The significance level: 0.95.
- method: depending on the fitting method 'Penalized ML' or Standard ML.
- method.ci: the method in calculating the confidence intervals, i.e. 'profile likelihood' or 'Wald', depending on the argument pl and plconf.
- df: The number of degrees of freedom in the model.
- loglik: A vector of the (penalized) log-likelihood of the restricted and the full models.
- n: The number of observations.
- formula: The formula object.
- control: a copy of the control parameters.
- modcontrol: a copy of the modcontrol parameters.
- terms: the model terms (column names of design matrix).
- model: if requested (the default), the model frame used.

Methods (by class)

- flic(default): With formula and data
- flic(logistf): With logistf object

logistf for Firth’s bias-Reduced penalized-likelihood logistic regression.

Examples

#With formula and data:
data(sex2)
flic(case ~ age + oc + vic + vicl + vis + dia, sex2)

#With a logistf object:
lf <- logistf(formula = case ~ age + oc + vic + vicl + vis + dia, data = sex2)
flic(lf)

Description
Implements Firth’s bias-Reduced penalized-likelihood logistic regression.

Usage

logistf(
  formula,
  data,
  pl = TRUE,
  alpha = 0.05,
  control,
  plcontrol,
  modcontrol,
  firth = TRUE,
  init,
  weights,
  na.action,
  offset,
  plconf = NULL,
  flic = FALSE,
  model = TRUE,
  ...
)

logistf
Firth's Bias-Reduced Logistic Regression
Arguments

**formula**
A formula object, with the response on the left of the operator, and the model terms on the right. The response must be a vector with 0 and 1 or FALSE and TRUE for the outcome, where the higher value (1 or TRUE) is modeled. It is possible to include contrasts, interactions, nested effects, cubic or polynomial splines and all S features as well, e.g. Y ~ X1*X2 + ns(X3, df=4).

**data**
A data.frame where the variables named in the formula can be found, i.e. the variables containing the binary response and the covariates.

**pl**
Specifies if confidence intervals and tests should be based on the profile penalized log likelihood (pl=TRUE, the default) or on the Wald method (pl=FALSE).

**alpha**
The significance level (1-\(\alpha\) the confidence level, 0.05 as default).

**control**
Controls iteration parameter. Default is control= logistf.control()

**plcontrol**
Controls Newton-Raphson iteration for the estimation of the profile likelihood confidence intervals. Default is plcontrol= logistpl.control()

**modcontrol**
Controls additional parameter for fitting. Default is logistf.mod.control()

**firth**
Use of Firth's penalized maximum likelihood (firth=TRUE, default) or the standard maximum likelihood method (firth=FALSE) for the logistic regression. Note that by specifying pl=TRUE and firth=FALSE (and probably a lower number of iterations) one obtains profile likelihood confidence intervals for maximum likelihood logistic regression parameters.

**init**
Specifies the initial values of the coefficients for the fitting algorithm

**weights**
specifies case weights. Each line of the input data set is multiplied by the corresponding element of weights

**na.action**
a function which indicates what should happen when the data contain NAs

**offset**
a priori known component to be included in the linear predictor

**plconf**
specifies the variables (as vector of their indices) for which profile likelihood confidence intervals should be computed. Default is to compute for all variables.

**flic**
If TRUE, intercept is altered such that the predicted probabilities become unbiased while keeping all other coefficients constant (see Puhr et al, 2017)

**model**
If TRUE the corresponding components of the fit are returned.

**...**
Further arguments to be passed to logistf

Details

`logistf` is the main function of the package. It fits a logistic regression model applying Firth’s correction to the likelihood. The following generic methods are available for logistf’s output object:

- print, summary, coef, vcov, confint, anova, extractAIC, add1, drop1, profile, terms, nobs, predict. Furthermore, forward and backward functions perform convenient variable selection. Note that anova, extractAIC, add1, drop1, forward and backward are based on penalized likelihood ratios.
**Value**

The object returned is of the class `logistf` and has the following attributes:

- **coefficients**: the coefficients of the parameter in the fitted model.
- **alpha**: the significance level (1- the confidence level) as specified in the input.
- **terms**: the column names of the design matrix.
- **var**: the variance-covariance-matrix of the parameters.
- **df**: the number of degrees of freedom in the model.
- **loglik**: a vector of the (penalized) log-likelihood of the restricted and the full models.
- **iter**: A vector of the number of iterations needed in the fitting process for the null and full model.
- **n**: the number of observations.
- **y**: the response-vector, i.e. 1 for successes (events) and 0 for failures.
- **formula**: the formula object.
- **call**: the call object.
- **terms**: the model terms (column names of design matrix).
- **linear.predictors**: a vector with the linear predictor of each observation.
- **predict**: a vector with the predicted probability of each observation.
- **hat.diag**: a vector with the diagonal elements of the Hat Matrix.
- **conv**: the convergence status at last iteration: a vector of length 3 with elements: last change in log likelihood, max(abs(score vector)), max change in beta at last iteration.
- **method**: depending on the fitting method 'Penalized ML' or 'Standard ML'.
- **method.ci**: the method in calculating the confidence intervals, i.e. profile likelihood' or 'Wald', depending on the argument pl and plconf.
- **ci.lower**: the lower confidence limits of the parameter.
- **ci.upper**: the upper confidence limits of the parameter.
- **prob**: the p-values of the specific parameters.
- **pl.iter**: only if pl==TRUE: the number of iterations needed for each confidence limit.
- **betahist**: only if pl==TRUE: the complete history of beta estimates for each confidence limit.
- **pl.conv**: only if pl==TRUE: the convergence status (deviation of log likelihood from target value, last maximum change in beta) for each confidence limit.
- **control**: a copy of the control parameters.
- **modcontrol**: a copy of the modcontrol parameters.
- **flic**: logical, is TRUE if intercept was altered such that the predicted probabilities become unbiased while keeping all other coefficients constant. According to input of logistf.
- **model**: if requested (the default), the model frame used.
- **na.action**: information returned by model.frame on the special handling of NAs.

logistf.control

Control Parameters for logistf

Description

Sets parameters for iterations in Firth’s penalized-likelihood logistic regression.

Usage

logistf.control(
  maxit = 25,
  maxhs = 0,
  maxstep = 5,
  lconv = 1e-05,
  gconv = 1e-05,
  xconv = 1e-05,
  collapse = TRUE,
  fit = "NR"
)

Arguments

maxit  The maximum number of iterations
maxhs  The maximum number of step-halvings in one iteration. The increment of the
        beta vector within one iteration is divided by 2 if the new beta leads to a decrease
        in log likelihood.
maxstep  Specifies the maximum step size in the beta vector within one iteration. Set to
         -1 for infinite stepsize.
lconv  Specifies the convergence criterion for the log likelihood.
gconv  Specifies the convergence criterion for the first derivative of the log likelihood
          (the score vector).
xconv  Specifies the convergence criterion for the parameter estimates.
collapse  If TRUE, evaluates all unique combinations of x and y and collapses data set.
fit  Fitting method used. One of Newton-Raphson: "NR" or Iteratively reweighted
      least squares: "IRLS"
logistf.mod.control

Details

logistf.control() is used by logistf and logistftest to set control parameters to default values. Different values can be specified, e.g., by logistf(..., control= logistf.control(maxstep=1)).

Value

- **maxit**: The maximum number of iterations
- **maxhs**: The maximum number of step-halvings in one iteration. The increment of the beta vector within one iteration is divided by 2 if the new beta leads to a decrease in log likelihood.
- **maxstep**: Specifies the maximum step size in the beta vector within one iteration.
- **lconv**: Specifies the convergence criterion for the log likelihood.
- **gconv**: Specifies the convergence criterion for the first derivative of the log likelihood (the score vector).
- **xconv**: Specifies the convergence criterion for the parameter estimates.
- **collapse**: If TRUE, evaluates all unique combinations of x and y and collapses data set.
- **fit**: Fitting method used. One of Newton-Raphson: "NR" or Iteratively reweighted least squares: "IRLS"

Examples

```r
data(sexagg)
fit2<-logistf(case ~ age+oc+vic+vicl+vis+dia, data=sexagg, weights=COUNT,
control=logistf.control(maxstep=1))
summary(fit2)
```

Description

Sets parameters for logistf calls.

Usage

logistf.mod.control(tau = 0.5, terms.fit = NULL)

Arguments

- **tau**: Penalization parameter (default = 0.5)
- **terms.fit**: A numeric vector of terms to fit. Intercept has to be included if needed.
logistftest

Penalized likelihood ratio test

Description

This function performs a penalized likelihood ratio test on some (or all) selected factors. The resulting object is of the class logistftest and includes the information printed by the proper print method.

Usage

logistftest(
    object,
    test,
    values,
    firth = TRUE,
    beta0,
    weights,
    control,
    modcontrol,
    ...
)

Arguments

object A fitted logistf object
test righthand formula of parameters to test (e.g. ~ B + D - 1). As default all parameter apart from the intercept are tested. If the formula includes -1, the intercept is omitted from testing. As alternative to the formula one can give the indexes of the ordered effects to test (a vector of integers). To test only the intercept specify test = ~ - . or test = 1.
values Null hypothesis values, default values are 0. For testing the specific hypothesis B1=1, B4=2, B5=0 we specify test= ~B1+B4+B5-1 and values=c(1, 2, 0).
firth Use of Firth’s (1993) penalized maximum likelihood (firth=TRUE, default) or the standard maximum likelihood method (firth=FALSE) for the logistic regression. Note that by specifying pl=TRUE and firth=FALSE (and probably lower number of iterations) one obtains profile likelihood confidence intervals for maximum likelihood logistic regression parameters.

beta0 Specifies the initial values of the coefficients for the fitting algorithm

weights Case weights

control Controls parameters for iterative fitting

modcontrol Controls additional parameter for fitting. Default is \texttt{modcontrol} of object.

Further arguments passed to \texttt{logistf.fit}

Details

This function performs a penalized likelihood ratio test on some (or all) selected factors. The resulting object is of the class \texttt{logistf} and includes the information printed by the proper print method. Further documentation can be found in Heinze & Ploner (2004). In most cases, the functionality of the \texttt{logistf} function is replaced by \texttt{anova.logistf}, which is a more standard way to perform likelihood ratio tests. However, as shown in the example below, \texttt{logistf} provides some specials such as testing against non-zero values. (By the way, \texttt{anova.logistf} calls \texttt{logistf}.

Value

The object returned is of the class \texttt{logistf} and has the following attributes:

- \texttt{testcov} A vector of the fixed values of each covariate; NA stands for a parameter which is not tested.
- \texttt{loglik} A vector of the (penalized) log-likelihood of the full and the restricted models. If the argument beta0 not missing, the full model isn’t evaluated
- \texttt{df} The number of degrees of freedom in the model
- \texttt{prob} The p-value of the test
- \texttt{call} The call object
- \texttt{method} Depending on the fitting method ‘Penalized ML’ or ‘Standard ML’
- \texttt{beta} The coefficients of the restricted solution

Author(s)

Georg Heinze

References

Examples

```r
data(sex2)
fit<-logistf(case ~ age+oc+vic+vicl+vis+dia, data=sex2)
logistftest(fit, test = ~ vic + vicl - 1, values = c(2, 0))
```

---

### logistpl.control

Control Parameters for `logistf` Profile Likelihood Confidence Interval Estimation

**Description**

Sets parameters for modified Newton-Raphson iteration for finding profile likelihood confidence intervals in Firth's penalized likelihood logistic regression.

**Usage**

```r
logistpl.control(
  maxit = 100,
  maxhs = 0,
  maxstep = 5,
  lconv = 1e-05,
  xconv = 1e-05,
  ortho = FALSE,
  pr = FALSE
)
```

**Arguments**

- `maxit` : The maximum number of iterations
- `maxhs` : The maximum number of step-halvings in one iteration. The increment of the beta vector within one iteration is divided by 2 if the new beta leads to a decrease in log likelihood.
- `maxstep` : Specifies the maximum step size in the beta vector within one iteration. Set to -1 for infinite stepsize.
- `lconv` : Specifies the convergence criterion for the log likelihood.
- `xconv` : Specifies the convergence criterion for the parameter estimates.
- `ortho` : Requests orthogonalization of variable for which confidence intervals are computed with respect to other covariates.
- `pr` : Request rotation of the matrix spanned by the covariates.

**Details**

`logistpl.control()` is used by `logistf` to set control parameters to default values when computing profile likelihood confidence intervals. Different values can be specified, e.g., by `logistf(..., control= logistf.control(maxstep=1))`. 
plot.logistf.profile

Value

maxit The maximum number of iterations
maxhs The maximum number of step-halvings in one iteration. The increment of the beta vector within one iteration is divided by 2 if the new beta leads to a decrease in log likelihood.
maxstep Specifies the maximum step size in the beta vector within one iteration.
lconv Specifies the convergence criterion for the log likelihood.
xconv Specifies the convergence criterion for the parameter estimates.
ortho specifies if orthogonalization is requested.
pr specifies if rotation is requested

Author(s)
Georg Heinze

Examples

data(sexagg)
fit2<-logistf(case ~ age+oc+vic+vicl+vis+dia, data=sexagg, weights=COUNT, plcontrol=logistpl.control(maxstep=1))
summary(fit2)

plot.logistf.profile plot Method for logistf Likelihood Profiles

Description
Provides the plot method for objects created by profile.logist or CLIP.profile

Usage

## S3 method for class 'logistf.profile'
plot(
x, type = "profile",
max1 = TRUE,
colmain = "black",
colimp = "gray",
plotmain = T,
ylim = NULL,
...)

plot.logistf.profile

Arguments

x  A profile.logistf object

type  Type of plot: one of c("profile", "cdf", "density")

max1  If type="density", normalizes density to maximum 1

colmain  Color for main profile line

colimp  color for completed-data profile lines (for logistf.profile objects that also carry the CLIP.profile class attribute)

plotmain  if FALSE, suppresses the main profile line (for logistf.profile objects that also carry the CLIP.profile class attribute)

ylim  Limits for the y-axis

...  Further arguments to be passed to plot().

Details

The plot method provides three types of plots (profile, CDF, and density representation of a profile likelihood). For objects generated by CLIP.profile, it also allows to show the completed-data profiles along with the pooled profile.

Value

The function is called for its side effects

Author(s)

Georg Heinze und Meinhard Ploner

predict.flac  Predict Method for flac Fits

Description
Obtains predictions from a fitted flac object.

Usage
## S3 method for class 'flac'
predict(
  object,
  newdata,
  type = c("link", "response", "terms"),
  se.fit = FALSE,
...
)

Arguments
  object            A fitted object of class flac.
  newdata           Optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.
predict.flic

The type of prediction required. The default is on the scale of the linear predictors. The alternative response gives the predicted probabilities. Type terms returns a matrix with the fitted values of each term in the formula on the linear predictor scale.

se.fit
If TRUE (default = FALSE) standard errors are computed.

further arguments passed to or from other methods.

Details
If newdata is omitted the predictions are based on the data used for the fit.

Value
A vector or matrix of predictions.

predict.flic  Predict Method for flic Fits

Description
Obtains predictions from a fitted flic object.

Usage

## S3 method for class 'flic'
predict(
  object,
  newdata,
  type = c("link", "response", "terms"),
  se.fit = FALSE,
  ...
)

Arguments

object  A fitted object of class flic.
newdata  Optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.
type  The type of prediction required. The default is on the scale of the linear predictors. The alternative response gives the predicted probabilities. Type terms returns a matrix with the fitted values of each term in the formula on the linear predictor scale.
se.fit  If TRUE (default = FALSE) standard errors are computed.
...  further arguments passed to or from other methods.
predict.logistf

Details

If newdata is omitted the predictions are based on the data used for the fit.

Value

A vector or matrix of predictions

Usage

## S3 method for class 'logistf'
predict(
  object,
  newdata,
  type = c("link", "response", "terms"),
  flic = FALSE,
  se.fit = FALSE,
  reference,
  na.action = na.pass,
  ...
)

Arguments

object A fitted object of class logistf.
newdata Optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.
type The type of prediction required. The default is on the scale of the linear predictors. The alternative response gives the predicted probabilities. Type terms returns a matrix with the fitted values of each term in the formula on the linear predictor scale.
flic If TRUE(default = FALSE), predictions are computed with intercept correction.
se.fit If TRUE(default = FALSE) standard errors are computed.
reference A named vector of reference values for each variable for type="terms".
na.action Function determining what should be done with missing values in newdata. The default is to predict NA.
... further arguments passed to or from other methods.
Details

If newdata is omitted the predictions are based on the data used for the fit.

Value

A vector or matrix of predictions.

profile.logistf

Compute Profile Penalized Likelihood

Description

Evaluates the profile penalized likelihood of a variable based on a logistf model fit

Usage

```r
## S3 method for class 'logistf'
profile(
fitted,
which,
variable,
steps = 100,
pitch = 0.05,
limits,
alpha = 0.05,
firth = TRUE,
legends = TRUE,
control,
plcontrol,
...
)
```

Arguments

- **fitted**: An object fitted by `logistf`
- **which**: A righthand formula to specify the variable for which the profile should be evaluated, e.g., `which=X`.
- **variable**: Alternatively to which, a variable name can be given, e.g., `variable="X"`
- **steps**: Number of steps in evaluating the profile likelihood
- **pitch**: Alternatively to steps, one may specify the step width in multiples of standard errors
- **limits**: Lower and upper limits of parameter values at which profile likelihood is to be evaluated
- **alpha**: The significance level ($1-\alpha$ the confidence level, 0.05 as default).
profile.logistf

firth      Use of Firth’s penalized maximum likelihood (firth=TRUE, default) or the standard maximum likelihood method (firth=FALSE) for the logistic regression.

legends    legends to be included in the optional plot

control    Controls Newton-Raphson iteration. Default is control= logistf.control(maxstep,maxit, maxhs, lconv, gconv, xconv)

plcontrol  Controls Newton-Raphson iteration for the estimation of the profile likelihood confidence intervals. Default is plcontrol= logistpl.control(maxstep, maxit, maxhs, lconv, xconv, ortho, pr)

...        Further arguments to be passed.

Value

An object of class logistf.profile with the following items:

beta       Parameter values at which likelihood was evaluated
stdbeta    Parameter values divided by standard error
profile    profile likelihood, standardized to 0 at maximum of likelihood. The values in profile are given as minus $\chi^2$
loglik     Unstandardized profile likelihood
signed.root signed root (z) of $\chi^2$ values (negative for values below the maximum likelihood estimate, positive for values above the maximum likelihood estimate)
cdf        profile likelihood expressed as cumulative distribution function, obtained as $\Phi(z)$, where $\Phi$ denotes the standard normal distribution function.

References

Examples

data(sex2)
fit<-logistf(case ~ age+oc+vic+vicl+vis+dia, data=sex2)
plot(profile(fit,variable="dia"))
plot(profile(fit,variable="dia"), "cdf")
plot(profile(fit,variable="dia"), "density")
PVR.confint  

**Pseudo Variance Modification of Rubin’s Rule**

**Description**

The pseudo-variance modification proposed by Heinze, Ploner and Beyea (2013) provides a quick way to adapt Rubin’s rules to situations of a non-normal distribution of a regression coefficient. However, the approximation is less accurate than that of the CLIP method.

**Usage**

```r
PVR.confint(obj, variable, skewbeta = FALSE)
```

**Arguments**

- `obj`: A fitted logisf object
- `variable`: The variable(s) to compute the PVR confidence intervals, either provided as names or as numbers
- `skewbeta`: If TRUE, incorporates information on the skewness of the parameter estimates across the imputed data sets.

**Details**

The pseudo-variance modification computes a lower and an upper pseudo-variance, which are based on the distance between profile likelihood limits and the parameter estimates. These are then plugged into the usual Rubin’s rules method of variance combination.

**Value**

An object of class PVR.confint with items:

- `estimate`: the pooled parameter estimate(s) (the average across completed-data estimates)
- `ci`: the confidence intervals based on the PVR method
- `lower.var`: the lower pseudo-variance(s)
- `upper.var`: the upper pseudo-variance(s)
- `conflev`: the confidence level: this is determined by the confidence level (1-alpha) used in the input fit objects
- `call`: the function call
- `variable`: the variable(s) for which confidence intervals were computed

**Author(s)**

Urinary Tract Infection in American College Students

Description

This data set deals with urinary tract infection in sexually active college women, along with covariate information on age and contraceptive use. The variables are all binary and coded in 1 (condition is present) and 0 (condition is absent).

Usage

sex2
sexagg

Format

sex2: a data.frame containing 239 observations

case  urinary tract infection, the study outcome variable
age   >= 24 years
dia   use of diaphragm
oc    use of oral contraceptive
vic   use of condom
vicl  use of lubricated condom
vis   use of spermicide

Description

This data set deals with urinary tract infection in sexually active college women, along with covariate information on age and contraceptive use. The variables are all binary and coded in 1 (condition is present) and 0 (condition is absent): case (urinary tract infection, the study outcome variable), age (>= 24 years), dia (use of diaphragm), oc (use of oral contraceptive), vic (use of condom), vicl (use of lubricated condom), and vis (use of spermicide).

Usage

sexagg

Format

sexagg: an aggregated data.frame containing 31 observations with case weights (COUNT).

case  urinary tract infection, the study outcome variable
age   >= 24 years
dia   use of diaphragm
oc    use of oral contraceptive
vic   use of condom
vicl  use of lubricated condom
vis   use of spermicide
