Package ‘lubridate’

November 6, 2022

**Type**  Package

**Title**  Make Dealing with Dates a Little Easier

**Version**  1.9.0

**Maintainer**  Vitalie Spinu <spinuvit@gmail.com>

**Description**  Functions to work with date-times and time-spans: fast and user friendly parsing of date-time data, extraction and updating of components of a date-time (years, months, days, hours, minutes, and seconds), algebraic manipulation on date-time and time-span objects.

The 'lubridate' package has a consistent and memorable syntax that makes working with dates easy and fun.

**License**  GPL (>= 2)

**URL**  https://lubridate.tidyverse.org,
https://github.com/tidyverse/lubridate

**BugReports**  https://github.com/tidyverse/lubridate/issues

**Depends**  methods, timechange (>= 0.1.1), R (>= 3.2)

**Imports**  generics

**Suggests**  covr, knitr, markdown, testthat (>= 2.1.0), vctrs (>= 0.5.0)

**Enhances**  chron, data.table, timeDate, tis, zoo

**VignetteBuilder**  knitr

**Config/Needs/website**  tidyverse/tidytemplate

**Config/testthat/edition**  3

**Encoding**  UTF-8

**LazyData**  true

**RoxygenNote**  7.2.1

**SystemRequirements**  C++11, A system with zoneinfo data (e.g. /usr/share/zoneinfo). On Windows the zoneinfo included with R is used.

Index 75
**am**

*Does date time occur in the am or pm?*

**Description**

Does date time occur in the am or pm?

**Usage**

\[
\text{am}(x) \\
\text{pm}(x)
\]

**Arguments**

\[
x \quad \text{a date-time object}
\]

**Value**

TRUE or FALSE depending on whether x occurs in the am or pm

**Examples**

\[
x <- \text{ymd("2012-03-26")} \\
\text{am}(x) \\
\text{pm}(x)
\]

---

**as.duration**

*Change an object to a duration*

**Description**

as.duration changes Interval, Period and numeric class objects to Duration objects. Numeric objects are changed to Duration objects with the seconds unit equal to the numeric value.

**Usage**

\[
\text{as.duration}(x, \ldots)
\]

**Arguments**

\[
x \quad \text{Object to be coerced to a duration} \\
\ldots \quad \text{Parameters passed to other methods. Currently unused.}
\]
Details

Durations are exact time measurements, whereas periods are relative time measurements. See Period. The length of a period depends on when it occurs. Hence, a one to one mapping does not exist between durations and periods. When used with a period object, as.duration provides an inexact estimate of the length of the period; each time unit is assigned its most common number of seconds. A period of one month is converted to 2628000 seconds (approximately 30.42 days). This ensures that 12 months will sum to 365 days, or one normal year. For an exact transformation, first transform the period to an interval with as.interval().

Value

A duration object

See Also

Duration, duration()

Examples

```r
span <- interval(ymd("2009-01-01"), ymd("2009-08-01"))  # interval
as.duration(span)
as.duration(10)  # numeric
dur <- duration(hours = 10, minutes = 6)
as.numeric(dur, "hours")
as.numeric(dur, "minutes")
```

---

**as.interval**

*Change an object to an interval*

Description

as.interval changes difftime, Duration, Period and numeric class objects to intervals that begin at the specified date-time. Numeric objects are first coerced to timespans equal to the numeric value in seconds.

Usage

```r
as.interval(x, start, ...)
```

Arguments

- `x` a duration, difftime, period, or numeric object that describes the length of the interval
- `start` a POSIXt or Date object that describes when the interval begins
- `...` additional arguments to pass to as.interval
Details

as.interval can be used to create accurate transformations between Period objects, which measure
time spans in variable length units, and Duration objects, which measure timespans as an exact
number of seconds. A start date-time must be supplied to make the conversion. Lubridate uses
this start date to look up how many seconds each variable length unit (e.g. month, year) lasted for
during the time span described. See as.duration(), as.peri0d().

Value

an interval object

See Also

interval()

Examples

diff <- make_difftime(days = 31) # difftime
as.interval(diff, ymd("2009-01-01"))
as.interval(diff, ymd("2009-02-01"))

dur <- duration(days = 31) # duration
as.interval(dur, ymd("2009-01-01"))
as.interval(dur, ymd("2009-02-01"))

per <- period(months = 1) # period
as.interval(per, ymd("2009-01-01"))
as.interval(per, ymd("2009-02-01"))
as.interval(3600, ymd("2009-01-01")) # numeric

as.period

Change an object to a period

Description

as.period changes Interval, Duration, difftime and numeric class objects to Period class objects with
the specified units.

Usage

as.period(x, unit, ...)
Arguments

- **x**: an interval, difftime, or numeric object
- **unit**: A character string that specifies which time units to build period in. `unit` is only implemented for the `as.period.numeric` method and the `as.period.interval` method. For `as.period.interval`, `as.period` will convert intervals to units no larger than the specified unit.
- **...**: additional arguments to pass to `as.period`

Details

Users must specify which time units to measure the period in. The exact length of each time unit in a period will depend on when it occurs. See `Period` and `period()`. The choice of units is not trivial; units that are normally equal may differ in length depending on when the time period occurs. For example, when a leap second occurs one minute is longer than 60 seconds.

Because periods do not have a fixed length, they cannot be accurately converted to and from `Duration` objects. Duration objects measure time spans in exact numbers of seconds, see `Duration`. Hence, a one to one mapping does not exist between durations and periods. When used with a `Duration` object, `as.period` provides an inexact estimate; the duration is broken into time units based on the most common lengths of time units, in seconds. Because the length of months are particularly variable, a period with a months unit cannot be coerced from a duration object. For an exact transformation, first transform the duration to an interval with `as.interval()`.

Coercing an interval to a period may cause surprising behavior if you request periods with small units. A leap year is 366 days long, but one year long. Such an interval will convert to 366 days when unit is set to days and 1 year when unit is set to years. Adding 366 days to a date will often give a different result than adding one year. Daylight savings is the one exception where this does not apply. Interval lengths are calculated on the UTC timeline, which does not use daylight savings. Hence, periods converted with seconds or minutes will not reflect the actual variation in seconds and minutes that occurs due to daylight savings. These periods will show the "naive" change in seconds and minutes that is suggested by the differences in clock time. See the examples below.

Value

- a period object

See Also

- `Period`, `period()`

Examples

```r
span <- interval(ymd_hms("2009-01-01 00:00:00"), ymd_hms("2010-02-02 01:01:01")) # interval
as.period(span)
as.period(span, unit = "day")
"397d 1H 1M 1S"
leap <- interval(ymd("2016-01-01"), ymd("2017-01-01"))
as.period(leap, unit = "days")
as.period(leap, unit = "years")
dst <- interval(
```
```r
ymd("2016-11-06", tz = "America/Chicago"),
ymd("2016-11-07", tz = "America/Chicago")
)
# as.period(dst, unit = "seconds")
as.period(dst, unit = "hours")
per <- period(hours = 10, minutes = 6)
as.numeric(per, "hours")
as.numeric(per, "minutes")
```

---

**as_date**  
*Convert an object to a date or date-time*

**Description**  
Convert an object to a date or date-time

**Usage**

```r
as_date(x, ...)
```

```r
## S4 method for signature 'ANY'
as_date(x, ...)
```

```r
## S4 method for signature 'POSIXt'
as_date(x, tz = NULL)
```

```r
## S4 method for signature 'numeric'
as_date(x, origin = lubridate::origin)
```

```r
## S4 method for signature 'character'
as_date(x, tz = NULL, format = NULL)
as_datetime(x, ...)
```

```r
## S4 method for signature 'ANY'
as_datetime(x, tz = lubridate::tz(x))
```

```r
## S4 method for signature 'POSIXt'
as_datetime(x, tz = lubridate::tz(x))
```

```r
## S4 method for signature 'numeric'
as_datetime(x, origin = lubridate::origin, tz = "UTC")
```

```r
## S4 method for signature 'character'
as_datetime(x, tz = "UTC", format = NULL)
```

```r
## S4 method for signature 'Date'
as_datetime(x, tz = "UTC")
```
as_date

Arguments

x  a vector of POSIXt, numeric or character objects
...
  further arguments to be passed to specific methods (see above).
tz  a time zone name (default: time zone of the POSIXt object x). See OlsonNames().
origin  a Date object, or something which can be coerced by as.Date(origin, ...) to such an object (default: the Unix epoch of "1970-01-01"). Note that in this instance, x is assumed to reflect the number of days since origin at "UTC".
format  format argument for character methods. When supplied parsing is performed by parse_date_time(x, orders = formats, exact = TRUE). Thus, multiple formats are supported and are tried in turn.

Value

a vector of Date objects corresponding to x.

Compare to base R

These are drop in replacements for as.Date() and as.POSIXct(), with a few tweaks to make them work more intuitively.

• Called on a POSIXct object, as_date() uses the tzone attribute of the object to return the same date as indicated by the printed representation of the object. This differs from as.Date, which ignores the attribute and uses only the tz argument to as.Date() ("UTC" by default).
• Both functions provide a default origin argument for numeric vectors.
• Both functions will generate NAs for invalid date format. Valid formats are those described by ISO8601 standard. A warning message will provide a count of the elements that were not converted.
• as_datetime() defaults to using UTC.

Examples

dt_utc <- ymd_hms("2010-08-03 00:50:50")
dt_europe <- ymd_hms("2010-08-03 00:50:50", tz = "Europe/London")
c(as_date(dt_utc), as.Date(dt_utc))
c(as_date(dt_europe), as.Date(dt_europe))
## need not supply origin
as_date(10)
## Will replace invalid date format with NA
dt_wrong <- c("2009-09-29", "2012-11-29", "2015-29-12")
as_date(dt_wrong)
Cyclic encoding of date-times

Description

Encode a date-time object into a cyclic coordinate system in which the distances between two pairs of dates separated by the same time duration are the same.

Usage

cyclic_encoding(
  x,
  periods,
  encoders = c("sin", "cos"),
  week_start = getOption("lubridate.week.start", 7)
)

Arguments

- **x**: a date-time object
- **periods**: a character vector of periods. Follows same specification as `period` and `floor_date` functions.
- **encoders**: names of functions to produce the encoding. Defaults to "sin" and "cos". Names of any predefined functions accepting a numeric input are allowed.
- **week_start**: week start day (Default is 7, Sunday. Set `lubridate.week.start` to override). Full or abbreviated names of the days of the week can be in English or as provided by the current locale.

Details

Machine learning models don’t know that December 31st and January 1st are close in our human calendar sense. cyclic_encoding makes it obvious to the machine learner that two calendar dates are close by mapping the dates onto the circle.

Value

a numeric matrix with number of columns equal length(periods) * length(types).

Examples

times <- ymd_hms("2019-01-01 00:00:00") + hours(0:23)
cyclic_encoding(times, c("day", "week", "month"))
plot(cyclic_encoding(times, "1d"))
plot(cyclic_encoding(times, "2d"), xlim = c(-1, 1))
plot(cyclic_encoding(times, "4d"), xlim = c(-1, 1))
**date**

*Get/set date component of a date-time*

**Description**

Date-time must be a POSIXct, POSIXlt, Date, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, and its objects.

**Usage**

date(x)

date(x) <- value

**Arguments**

- **x**
  a date-time object

- **value**
  an object for which the date() function is defined

**Details**

date() does not yet support years before 0 C.E. Also date() is not defined for Period objects.

**Value**

the date of x as a Date

**Base compatibility**

date() can be called without any arguments to return a string representing the current date-time. This provides compatibility with base: date() which it overrides.

**Examples**

```r
x <- ymd_hms("2012-03-26 23:12:13", tz = "America/New_York")
date(x)
as.Date(x) # by default as.Date assumes you want to know the date in UTC
as.Date(x, tz = "America/New_York")
date(x) <- as.Date("2000-01-02")
x
```
DateTimeUpdate

Changes the components of a date object

Description

update.Date() and update.POSIXt() return a date with the specified elements updated. Elements not specified will be left unaltered. update.Date and update.POSIXt do not add the specified values to the existing date, they substitute them for the appropriate parts of the existing date.

Usage

```r
## S3 method for class 'POSIXt'
update(
  object,
  ..., 
  roll_dst = c("NA", "post"),
  week_start = getOption("lubridate.week.start", 7),
  roll = NULL,
  simple = NULL
)
```

Arguments

- **object**: a date-time object
- **...**: named arguments: years, months, ydays, wdays, mdays, days, hours, minutes, seconds, tzs (time zone component)
- **roll_dst**: is a string vector of length one or two. When two values are supplied they specify how to roll date-times when they fall into "skipped" and "repeated" DST transitions respectively. Singleton strings is replicated to the length of two. Possible values are:
  * `pre` - Use the time before the transition boundary.
  * `boundary` - Use the time exactly at the boundary transition.
  * `post` - Use the time after the boundary transition.
  * `NA` - Produce NAs when the resulting time falls inside the problematic interval.

For example `roll_dst = c("pre", "NA")` indicates that for repeated intervals return the time in the earlier interval and for skipped intervals return NA.

- **week_start**: week start day (Default is 7, Sunday. Set lubridate.week.start to override). Full or abbreviated names of the days of the week can be in English or as provided by the current locale.
- **simple, roll**: deprecated

Value

a date object with the requested elements updated. The object will retain its original class unless an element is updated which the original class does not support. In this case, the date returned will be a POSIXlt date object.
**date_decimal**

*Converts a decimal to a date*

### Description

Converts a decimal to a date

### Usage

```r
date_decimal(decimal, tz = "UTC")
```

### Arguments

- **decimal**: a numeric object
- **tz**: the time zone required

### Value

A POSIXct object, whose year corresponds to the integer part of decimal. The months, days, hours, minutes and seconds elements are picked so the date-time will accurately represent the fraction of the year expressed by decimal.

### Examples

```r
date <- ymd("2009-02-10")
decimal <- decimal_date(date) # 2009.11
date_decimal(decimal) # "2009-02-10 UTC"
```

---

**Examples**

```r
date <- ymd("2009-02-10")
update(date, year = 2010, month = 1, mday = 1)
update(date, year = 2010, month = 13, mday = 1)
update(date, minute = 10, second = 3)
```
Description

Get/set days component of a date-time

Usage

day(x)

mday(x)

wday(
  x,
  label = FALSE,
  abbr = TRUE,
  week_start = getOption("lubridate.week.start", 7),
  locale = Sys.getlocale("LC_TIME")
)

day(x) <- value

mday(x) <- value

qday(x) <- value

qday(x) <- value

wday(x, week_start = getOption("lubridate.week.start", 7)) <- value

yday(x) <- value

Arguments

x        a POSIXct, POSIXlt, Date, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, or fts object.
label    logical. Only available for wday. TRUE will display the day of the week as an ordered factor of character strings, such as "Sunday." FALSE will display the day of the week as a number.
abbr     logical. Only available for wday. FALSE will display the day of the week as an ordered factor of character strings, such as "Sunday." TRUE will display an
days_in_month

abbreviated version of the label, such as "Sun". abbr is disregarded if label = FALSE.

week_start
day on which week starts following ISO conventions - 1 means Monday, 7 means Sunday (default). When label = TRUE, this will be the first level of the returned factor. You can set lubridate.week.start option to control this parameter globally.

locale
locale to use for day names. Default to current locale.

value
(for wday<-) a numeric or a string giving the name of the day in the current locale or in English. Can be abbreviated. When a string, the value of week_start is ignored.

Details

mday() and yday() return the day of the month and day of the year respectively. day() and day<-( ) are aliases for mday() and mday<-( ).

Value

wday() returns the day of the week as a decimal number or an ordered factor if label is TRUE.

Examples

x <- as.Date("2009-09-02")
wday(x) # 4

wday(ymd(080101))
wday(ymd(080101), label = TRUE, abbr = FALSE)
wday(ymd(080101), label = TRUE, abbr = TRUE)
wday(ymd(080101) + days(-2:4), label = TRUE, abbr = TRUE)

x <- as.Date("2009-09-02")
yday(x) # 245
mday(x) # 2
yday(x) <- 1 # "2009-01-01"
yday(x) <- 366 # "2010-01-01"
mday(x) > 3

days_in_month

Get the number of days in the month of a date-time

Description

Date-time must be a POSIXct, POSIXlt, Date, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, and its objects.

Usage

days_in_month(x)
decimal_date

Converts a date to a decimal of its year

Arguments

date

a date-time object

Value

An integer of the number of days in the month component of the date-time object.

dst

Get daylight savings time indicator of a date-time

Description

Date-time must be a POSIXct, POSIXlt, Date, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, and fts objects.

Usage

dst(x)

Arguments

x

a date-time object
Details

A date-time’s daylight savings flag can not be set because it depends on the date-time’s year, month, day, and hour values.

Value

A logical. TRUE if DST is in force, FALSE if not, NA if unknown.

Examples

x <- ymd("2012-03-26")
dst(x)

duration Create a duration object.

Description

duration() creates a duration object with the specified values. Entries for different units are cumulative. Durations display as the number of seconds in a time span. When this number is large, durations also display an estimate in larger units, however, the underlying object is always recorded as a fixed number of seconds. For display and creation purposes, units are converted to seconds using their most common lengths in seconds. Minutes = 60 seconds, hours = 3600 seconds, days = 86400 seconds, weeks = 604800. Units larger than weeks are not used due to their variability.

Usage

duration(num = NULL, units = "seconds", ...)
dseconds(x = 1)
dminutes(x = 1)
dhours(x = 1)
ddays(x = 1)
dweeks(x = 1)
dmonths(x = 1)
dyears(x = 1)
dmilliseconds(x = 1)
dmicroseconds(x = 1)
Arguments

num the number or a character vector of time units. In string representation all unambiguous name units and abbreviations and ISO 8601 formats are supported; 'm' stands for month and 'M' for minutes unless ISO 8601 "P" modifier is present (see examples). Fractional units are supported.

units a character string that specifies the type of units that num refers to. When num is character, this argument is ignored.

... a list of time units to be included in the duration and their amounts. Seconds, minutes, hours, days, weeks, months and years are supported. Durations of months and years assume that year consists of 365.25 days.

x numeric value of the number of units to be contained in the duration.

Details

Durations record the exact number of seconds in a time span. They measure the exact passage of time but do not always align with measurements made in larger units of time such as hours, months and years. This is because the length of larger time units can be affected by conventions such as leap years and Daylight Savings Time. Base R provides a second class for measuring durations, the difftime class.

Duration objects can be easily created with the helper functions `dweeks()`, `ddays()`, `dminutes()`, `dseconds()`. These objects can be added to and subtracted to date-times to create a user interface similar to object oriented programming.

Value

a duration object

See Also

`as.duration()` `Duration`

Examples

```r
### Separate period and units vectors

duration(90, "seconds")
duration(1.5, "minutes")
duration(-1, "days")

### Units as arguments
```
### Parsing

duration("2M 1sec")
duration("2hours 2minutes 1second")
duration("2d 2H 2M 2S")
# Missing numerals default to 1. Repeated units are added up.
duration("day day")

### ISO 8601 parsing

duration("P3Y6M4DT12H30M5S")
duration("P23DT23H") # M stands for months
duration("10DT10M") # M stands for minutes
duration("P23DT60H 20min 100 sec") # mixing ISO and lubridate style parsing

# Comparison with characters (from v1.6.0)
duration("day 2 sec") > "day 1sec"

## ELEMENTARY CONSTRUCTORS:

dseconds(1)
dminutes(3.5)

\[ x <- \text{ymd("2009-08-03", tz = "America/Chicago")} \]
\[ x + \text{ddays(1)} + \text{dhours(6)} + \text{dminutes(30)} \]
\[ x + \text{ddays(100)} - \text{dhours(8)} \]

\[ \text{class(as.Date("2009-08-09")] + \text{ddays(1)}) \] # retains Date class
\[ \text{as.Date("2009-08-09")] + \text{dhours(12)} \]
\[ \text{class(as.Date("2009-08-09")] + \text{dhours(12)}) \]
# converts to POSIXt class to accommodate time units

dweeks(1) - ddays(7)
c(1:3) * dhours(1)

# compare DST handling to durations
boundary <- ymd_hms("2009-03-08 01:59:59", tz = "America/Chicago")
boundary + \text{days(1)} # period
boundary + \text{ddays(1)} # duration
\[ \text{is.duration(as.Date("2009-08-03")}) \] # FALSE
\[ \text{is.duration(duration(\text{days = 12.4})}) \] # TRUE
Duration-class

Description

Duration is an S4 class that extends the Timespan class. Durations record the exact number of seconds in a time span. They measure the exact passage of time but do not always align with measurements made in larger units of time such as hours, months and years. This is because the exact length of larger time units can be affected by conventions such as leap years and Daylight Savings Time.

Details

Durations provide a method for measuring generalized timespans when we wish to treat time as a mathematical quantity that increases in a uniform, monotone manner along a continuous numberline. They allow exact comparisons with other durations. See Period for an alternative way to measure timespans that better preserves clock times.

Durations class objects have one slot: .Data, a numeric object equal to the number of seconds in the duration.

fit_to_timeline

Fit a POSIXlt date-time to the timeline

Description

The POSIXlt format allows you to create instants that do not exist in real life due to daylight savings time and other conventions. fit_to_timeline matches POSIXlt date-times to a real times. If an instant does not exist, fit to timeline will replace it with an NA. If an instant does exist, but has been paired with an incorrect timezone/daylight savings time combination, fit_to_timeline returns the instant with the correct combination.

Usage

fit_to_timeline(lt, class = "POSIXct", simple = FALSE)

Arguments

- `lt`: a POSIXlt date-time object.
- `class`: a character string that describes what type of object to return, POSIXlt or POSIXct. Defaults to POSIXct. This is an optimization to avoid needless conversions.
- `simple`: if TRUE, lubridate makes no attempt to detect meaningless time-dates or to correct time zones. No NAs are produced and the most meaningful valid dates are returned instead. See examples.
Value

a POSIXct or POSIXlt object that contains no illusory date-times

Examples

```r
## Not run:

tricky <- structure(list(
  sec = c(5, 0, 0, -1),
  min = c(0L, 5L, 5L, 0L),
  hour = c(2L, 0L, 2L, 2L),
  mday = c(4L, 4L, 14L, 4L),
  mon = c(10L, 10L, 2L, 10L),
  year = c(112L, 112L, 110L, 112L),
  wday = c(0L, 0L, 0L, 0L),
  yday = c(308L, 308L, 72L, 308L),
  isdst = c(1L, 0L, 0L, 1L)
),
.Names = c(
  "sec", "min", "hour", "mday", "mon",
  "year", "wday", "yday", "isdst"
),
class = c("POSIXlt", "POSIXt"),
tzone = c("America/Chicago", "CST", "CDT")
),
tricky
## [1] "2012-11-04 02:00:00 CDT" Doesn't exist because clocks "fall back" to 1:00 CST
## [2] "2012-11-04 00:05:00 CST" Times are still CDT, not CST at this instant
## [3] "2010-03-14 02:00:00 CDT" DST gap
## [4] "2012-11-04 01:59:59 CDT" Does exist, but has deceptive internal structure

fit_to_timeline(tricky)
## Returns:
## [1] "2012-11-04 02:00:00 CST" instant paired with correct tz & DST combination
## [2] "2012-11-04 00:05:00 CST" instant paired with correct tz & DST combination
## [3] NA - fake time changed to NA (compare to as.POSIXct(tricky))
## [4] "2012-11-04 01:59:59 CDT" -real instant, left as is

fit_to_timeline(tricky, simple = TRUE)
## Returns valid time-dates by extrapolating CDT and CST zones:
## [1] "2012-11-04 01:00:05 CST" "2012-11-04 01:05:00 CDT"
## [3] "2010-03-14 03:05:00 CDT" "2012-11-04 01:59:59 CDT"

## End(Not run)
```

---

**force_tz**  
*Replace time zone to create new date-time*
force_tz returns the date-time that has the same clock time as input time, but in the new time zone. force_tzs is the parallel version of force_tz, meaning that every element from time argument is matched with the corresponding time zone in tzones argument.

Usage

force_tz(time, tzone = "", ...)  
## Default S3 method:  
force_tz(time, tzone = "", roll_dst = c("NA", "post"), roll = NULL, ...)  

force_tzs(  
  time,  
  tzones,  
  tzone_out = "UTC",  
  roll_dst = c("NA", "post"),  
  roll = NULL  
)

Arguments

time a POSIXct, POSIXlt, Date, chron date-time object, or a data.frame object. When a data.frame all POSIXt elements of a data.frame are processed with force_tz() and new data.frame is returned.

tzone a character string containing the time zone to convert to. R must recognize the name contained in the string as a time zone on your system.

... Parameters passed to other methods.

roll_dst is a string vector of length one or two. When two values are supplied they specify how to roll date-times when they fall into "skipped" and "repeated" DST transitions respectively. Singleton strings is replicated to the length of two. Possible values are:

* `pre` - Use the time before the transition boundary.
* `boundary` - Use the time exactly at the boundary transition.
* `post` - Use the time after the boundary transition.
* `NA` - Produce NAs when the resulting time falls inside the problematic interval.

For example `roll_dst = c("pre", "NA")` indicates that for repeated intervals return the time in the earlier interval and for skipped intervals return NA.

roll deprecated, same as roll_dst parameter.

tzones character vector of timezones to be "enforced" on time time stamps. If time and tzones lengths differ, the smaller one is recycled in accordance with usual R conventions.

tzone_out timezone of the returned date-time vector (for force_tzs).
Details

Although the new date-time has the same clock time (e.g. the same values in the year, month, days, etc. elements) it is a different moment of time than the input date-time.

As R date-time vectors cannot hold elements with non-uniform time zones, `force_tzs` returns a vector with time zone `tzone_out`, UTC by default.

Value

a POSIXct object in the updated time zone

See Also

`with_tz()`, `local_time()`

Examples

```r
x <- ymd_hms("2009-08-07 00:00:01", tz = "America/New_York")
force_tz(x, "UTC")
force_tz(x, "Europe/Amsterdam")

## DST skip:
y <- ymd_hms("2010-03-14 02:05:05 UTC")
force_tz(y, "America/New_York", roll_dst = "NA")
force_tz(y, "America/New_York", roll_dst = "pre")
force_tz(y, "America/New_York", roll_dst = "boundary")
force_tz(y, "America/New_York", roll_dst = "post")

## DST repeat
y <- ymd_hms("2014-11-02 01:35:00", tz = "UTC")
force_tz(y, "America/New_York", roll_dst = "NA")
force_tz(y, "America/New_York", roll_dst = "pre")
force_tz(y, "America/New_York", roll_dst = "boundary")
force_tz(y, "America/New_York", roll_dst = "post")

## DST skipped and repeated
y <- ymd_hms("2010-03-14 02:05:05 UTC", "2014-11-02 01:35:00", tz = "UTC")
force_tz(y, "America/New_York", roll_dst = c("NA", "pre"))
force_tz(y, "America/New_York", roll_dst = c("boundary", "post"))

## Heterogeneous time-zones:
x <- ymd_hms(c("2009-08-07 00:00:01", "2009-08-07 01:02:03"))
force_tzxs(x, tzones = c("America/New_York", "Europe/Amsterdam"))
force_tzxs(x, tzones = c("America/New_York", "Europe/Amsterdam"), tzone_out = "America/New_York")

x <- ymd_hms("2009-08-07 00:00:01")
force_tzxs(x, tzones = c("America/New_York", "Europe/Amsterdam"))
```
Description

Format in ISO8601 character format

Usage

format_ISO8601(x, usetz = FALSE, precision = NULL, ...)

Arguments

x  An object to convert to ISO8601 character format.
usetz Include the time zone in the formatting. If usetz is TRUE, the time zone is
        included. If usetz is "Z", the time is converted to "UTC" and the time zone is
        indicated with "Z" ISO8601 notation.
precision The amount of precision to represent with substrings of "ymdhms", as "y"ear,
             "m"onth, "d"ay, "h"our, "m"inute, and "s"econd. (e.g. "ymdhm" would show
             precision through minutes. When NULL, full precision for the object is shown.
             ...
             Additional arguments to methods.

Value

A character vector of ISO8601-formatted text.

References

Examples

format_ISO8601(as.Date("02-01-2018", format = "%m-%d-%Y"))
format_ISO8601(as.POSIXct("2018-02-01 03:04:05", tz = "EST"), usetz = TRUE)
format_ISO8601(as.POSIXct("2018-02-01 03:04:05", tz = "EST"), precision = "ymdhm")
guess_formats

Guess possible date-times formats from a character vector

Description

Guess possible date-times formats from a character vector.

Usage

```r
guess_formats(
  x,
  orders,
  locale = Sys.getlocale("LC_TIME"),
  preproc_wday = TRUE,
  print_matches = FALSE
)
```

Arguments

- `x`: input vector of date-times.
- `orders`: format orders to look for. See examples.
- `locale`: locale to use. Defaults to the current locale.
- `preproc_wday`: whether to preprocess weekday names. Internal optimization used by `ymd_hms()` family of functions. If `TRUE`, weekdays are substituted with `%a` or `%A` accordingly, so that there is no need to supply this format explicitly.
- `print_matches`: for development purposes mainly. If `TRUE`, prints a matrix of matched templates.

Value

a vector of matched formats

Examples

```r
x <- c('February 20th 1973',
        'February 14, 2004',
        'Sunday, May 1, 2000',
        'Sunday, May 1, 2000',
        'February 14, 04',
        'Feb 20th 73',
        'January 5 1999 at 7pm',
        'Jan 3 2010',
        'Jan 1, 1999',
        'Jan 3 10',
        '01 3 2010',
        '1 3 10',
        '1 13 89',
```
"5/27/1979",
"12/31/99",
"DOB:12/11/00",
"-----------",
'Thu, 1 July 2004 22:30:00',
'Thu, 1st of July 2004 at 22:30:00',
'Thu, 1July 2004 at 22:30:00',
'Thu, 1July2004 22:30:00',
'Thu, 1July04 22:30:00',
'21 Aug 2011, 11:15:34 pm',
"-----------",
"1979-05-27 05:00:59",
"1979-05-27",
"-----------",
"3 Jan 2000",
"17 April 85",
"27/5/1979",
'20 01 89',
'00/13/10',
"-----------",
"14 12 00",
"03:23:22 pm")

guess Formats(x, "bdY")

## m also matches b and B; y also matches Y

guess Formats(x, "mdy", print_matches = TRUE)

## T also matches IMSp order

guess Formats(x, "T", print_matches = TRUE)

## b and B are equivalent and match, both, abreviated and full names

guess Formats(x, c("mdY", "bdY", "Bdy", "bdY", "bdy"), print_matches = TRUE)

guess Formats(x, c("dmy", "dbY", "dBy", "dBY"), print_matches = TRUE)

guess Formats(x, c("dBY HMS", "dbY HMS", "dmyHMS", "BdY H"), print_matches = TRUE)

guess Formats(x, c("ymd HMS"), print_matches = TRUE)

hour

Get/set hours component of a date-time

Description

Date-time must be a POSIXct, POSIXlt, Date, Period, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, and fts objects.
interval

Usage

hour(x)

hour(x) <- value

Arguments

x a date-time object
value numeric value to be assigned to the hour component

Value

the hours element of x as a decimal number

Examples

x <- ymd("2012-03-26")
hour(x)
hour(x) <- 1
hour(x) <- 25
hour(x) > 2

Description

interval() creates an Interval object with the specified start and end dates. If the start date occurs before the end date, the interval will be positive. Otherwise, it will be negative. Character vectors in ISO 8601 format are supported from v1.7.2.

int_start()/int_end() and int_start<-()/int_end<-() are "accessors" and "setters" respectively of the start/end date of an interval.

int_flip() reverses the order of the start date and end date in an interval. The new interval takes place during the same timespan as the original interval, but has the opposite direction.

int_shift() shifts the start and end dates of an interval up or down the timeline by a specified amount. Note that this may change the exact length of the interval if the interval is shifted by a Period object. Intervals shifted by a Duration or difftime object will retain their exact length in seconds.

int_overlaps() tests if two intervals overlap.

int_standardize() ensures all intervals in an interval object are positive. If an interval is not positive, flip it so that it retains its endpoints but becomes positive.

int_aligns() tests if two intervals share an endpoint. The direction of each interval is ignored.

int_align tests whether the earliest or latest moments of each interval occur at the same time.

int_diff() returns the intervals that occur between the elements of a vector of date-times. int_diff() is similar to the POSIXt and Date methods of diff(), but returns an Interval object instead of a difftime object.
Usage

interval(start = NULL, end = NULL, tzone = tz(start))

start %--% end

is.interval(x)

int_start(int)

int_start(int) <- value

int_end(int)

int_end(int) <- value

int_length(int)

int_flip(int)

int_shift(int, by)

int_overlaps(int1, int2)

int_standardize(int)

int_aligns(int1, int2)

int_diff(times)

Arguments

start, end    POSIXt, Date or a character vectors. When start is a character vector and end is NULL, ISO 8601 specification is assumed but with much more permisive lubridate style parsing both for dates and periods (see examples).
tzone         a recognized timezone to display the interval in
x             an R object
int           an interval object
value         interval’s start/end to be assigned to int
by            A period or duration object to shift by (for int_shift)
int1          an Interval object (for int_overlaps(), int_aligns())
int2          an Interval object (for int_overlaps(), int_aligns())
times         A vector of POSIXct, POSIXlt or Date class date-times (for int_diff())

Details

Intervals are time spans bound by two real date-times. Intervals can be accurately converted to either period or duration objects using as.period(), as.duration(). Since an interval is anchored to
a fixed history of time, both the exact number of seconds that passed and the number of variable length time units that occurred during the interval can be calculated.

Value

`interval()` – Interval object.

`int_start()` and `int_end()` return a POSIXct date object when used as an accessor. Nothing when used as a setter.

`int_length()` – numeric length of the interval in seconds. A negative number connotes a negative interval.

`int_flip()` – flipped interval object

`int_shift()` – an Interval object

`int_overlaps()` – logical, TRUE if int1 and int2 overlap by at least one second. FALSE otherwise

`int-aligns()` – logical, TRUE if int1 and int2 begin or end on the same moment. FALSE otherwise

`int_diff()` – interval object that contains the n-1 intervals between the n date-time in times

See Also

`Interval`, `as.interval()`, `%within%`

Examples

```r
interval(ymd(20090201), ymd(20090101))

date1 <- ymd_hms("2009-03-08 01:59:59")
date2 <- ymd_hms("2000-02-29 12:00:00")
interval(date2, date1)
interval(date1, date2)
span <- interval(ymd(20090101), ymd(20090201))

### ISO Intervals

interval("2007-03-01T13:00:00Z/2008-05-11T15:30:00Z")
interval("2007-03-01T13:00:00Z/P1Y2M10DT2H30M")
interval("P1Y2M10DT2H30M/2008-05-11T15:30:00Z")
interval("2008-05-11/P2H30M")

### More permisive parsing (as long as there are no intermittent / characters)
interval("2008 05 11/P2hours 30minutes")
interval("08 05 11/P 2h 30m")

is.interval(period(months = 1, days = 15)) # FALSE
is.interval(interval(ymd(20090801), ymd(20090809))) # TRUE
int <- interval(ymd("2001-01-01"), ymd("2002-01-01"))
int_start(int)
int_start(int) <- ymd("2001-06-01")
int

int <- interval(ymd("2001-01-01"), ymd("2002-01-01"))
```
### Interval-class

**Interval class**

**Description**

Interval is an S4 class that extends the Timespan class. An Interval object records one or more spans of time. Intervals record these timespans as a sequence of seconds that begin at a specified date. Since intervals are anchored to a precise moment of time, they can accurately be converted to Period or Duration class objects. This is because we can observe the length in seconds of each period that begins on a specific date. Contrast this to a generalized period, which may not have a consistent length in seconds (e.g. the number of seconds in a year will change if it is a leap year).

**Details**

Intervals can be both negative and positive. Negative intervals progress backwards from the start date; positive intervals progress forwards.

Interval class objects have two slots: `Data`, a numeric object equal to the number of seconds in the interval; and `start`, a POSIXct object that specifies the time when the interval starts.
is.Date

Various date utilities

Description

Date() mirrors primitive constructors in base R (double(), character() etc.)

Usage

is.Date(x)

Date(length = 0L)

NA_Date_

Arguments

x an R object

length A non-negative number specifying the desired length. Supplying an argument
of length other than one is an error.

Format

An object of class Date of length 1.

See Also

is.instant(), is.timespan(), is.POSIXt(), POSIXct()

Examples

is.Date(as.Date("2009-08-03")) # TRUE
is.Date(difftime(now() + 5, now())) # FALSE

is.difftime

Is x a difftime object?

Description

Is x a difftime object?

Usage

is.difftime(x)
Arguments
x an R object

Value
TRUE if x is a difftime object, FALSE otherwise.

See Also
is.instant(), is.timespan(), is.interval(), is.period().

Examples
is.difftime(as.Date("2009-08-03")) # FALSE
is.difftime(make_difftime(days = 12.4)) # TRUE

Description
An instant is a specific moment in time. Most common date-time objects (e.g, POSIXct, POSIXlt, and Date objects) are instants.

Usage
is.instant(x)

Arguments
x an R object

Value
TRUE if x is a POSIXct, POSIXlt, or Date object, FALSE otherwise.

See Also
is.timespan(), is.POSIXt(), is.Date()

Examples
is.instant(as.Date("2009-08-03")) # TRUE
is.timepoint(5) # FALSE
is.POSIXt

Various POSIX utilities

Description

POSIXct() mirrors primitive constructors in base R (double(), character() etc.)

Usage

is.POSIXt(x)

is.POSIXlt(x)

is.POSIXct(x)

POSIXct(length = 0L, tz = "UTC")

NA_POSIXct_

Arguments

x an R object

length A non-negative number specifying the desired length. Supplying an argument of length other than one is an error.

tz a timezone (defaults to "utc")

Format

An object of class POSIXct (inherits from POSIXt) of length 1.

Value

TRUE if x is a POSIXct or POSIXlt object, FALSE otherwise.

See Also

is.instant(), is.timespan(), is.Date()

Examples

is.POSIXt(as.Date("2009-08-03"))

is.POSIXt(as.POSIXct("2009-08-03"))
is.timespan  Is x a length of time?

Description

Is x a length of time?

Usage

is.timespan(x)

Arguments

x  an R object

Value

TRUE if x is a period, interval, duration, or difftime object, FALSE otherwise.

See Also

is.instant(), is.duration(), is.difftime(), is.period(), is.interval()

Examples

is.timespan(as.Date("2009-08-03")) # FALSE
is.timespan(duration(second = 1)) # TRUE

lakers  Lakers 2008-2009 basketball data set

Description

This data set contains play by play statistics of each Los Angeles Lakers basketball game in the 2008-2009 season. Data includes the date, opponent, and type of each game (home or away). Each play is described by the time on the game clock when the play was made, the period in which the play was attempted, the type of play, the player and team who made the play, the result of the play, and the location on the court where each play was made.

References

Originally taken from www.basketballgeek.com/data/.
leap_year

Is a year a leap year?

Description
If x is a recognized date-time object, leap_year will return whether x occurs during a leap year. If x is a number, leap_year returns whether it would be a leap year under the Gregorian calendar.

Usage
leap_year(date)

Arguments
date a date-time object or a year

Value
TRUE if x is a leap year, FALSE otherwise

Examples
x <- as.Date("2009-08-02")
leap_year(x) # FALSE
leap_year(2009) # FALSE
leap_year(2008) # TRUE
leap_year(1900) # FALSE
leap_year(2000) # TRUE

local_time
Get local time from a date-time vector.

Description
local_time retrieves day clock time in specified time zones. Computation is vectorized over both dt and tz arguments, the shortest is recycled in accordance with standard R rules.

Usage
local_time(dt, tz = NULL, units = "secs")

Arguments
dt a date-time object.
tz a character vector of timezones for which to compute the local time.
units passed directly to as.difftime().
Examples

```r
x <- ymd_hms(c("2009-08-07 01:02:03", "2009-08-07 10:20:30"))
local_time(x, units = "secs")
local_time(x, units = "hours")
local_time(x, "Europe/Amsterdam")
local_time(x, "Europe/Amsterdam") == local_time(with_tz(x, "Europe/Amsterdam"))

x <- ymd_hms("2009-08-07 01:02:03")
local_time(x, c("America/New_York", "Europe/Amsterdam", "Asia/Shanghai"), unit = "hours")
```

---

### make_datetime

**Efficient creation of date-times from numeric representations**

**Description**

`make_datetime()` is a very fast drop-in replacement for `base::ISOdate()` and `base::ISOdatetime()`. `make_date()` produces objects of class `Date`.

**Usage**

```r
make_datetime(
  year = 1970L,
  month = 1L,
  day = 1L,
  hour = 0L,
  min = 0L,
  sec = 0,
  tz = "UTC"
)
make_date(year = 1970L, month = 1L, day = 1L)
```

**Arguments**

- `year` numeric year
- `month` numeric month
- `day` numeric day
- `hour` numeric hour
- `min` numeric minute
- `sec` numeric second
- `tz` time zone. Defaults to UTC.

**Details**

Input vectors are silently recycled. All inputs except `sec` are silently converted to integer vectors; `sec` can be either integer or double.
Examples

```r
make_datetime(year = 1999, month = 12, day = 22, sec = 10)
make_datetime(year = 1999, month = 12, day = 22, sec = c(10, 11))
```

Description

`make_difftime()` creates a difftime object with the specified number of units. Entries for different units are cumulative. `difftime` displays durations in various units, but these units are estimates given for convenience. The underlying object is always recorded as a fixed number of seconds.

Usage

```r
make_difftime(num = NULL, units = "auto", ...)
```

Arguments

- `num`: Optional number of seconds
- `units`: A character vector that lists the type of units to use for the display of the return value (see examples). If `units` is "auto" (the default) the display units are computed automatically. This might create undesirable effects when converting `difftime` objects to numeric values in data processing.
- `...`: A list of time units to be included in the `difftime` and their amounts. Seconds, minutes, hours, days, and weeks are supported. Normally only one of `num` or `...` are present. If both are present, the `difftime` objects are concatenated.

Details

Conceptually, `difftime` objects are a type of duration. They measure the exact passage of time but do not always align with measurements made in larger units of time such as hours, months and years. This is because the length of larger time units can be affected by conventions such as leap years and Daylight Savings Time. `lubridate` provides a second class for measuring durations, the `Duration` class.

Value

A `difftime` object

See Also

`duration()`, `as.duration()`
Examples

```r
make_difftime(1)
m[1] 1
make_difftime(60)
m[1] 1
make_difftime(3600)
m[1] 1
make_difftime(3600, units = "minute")
# Time difference of 60 mins
make_difftime(second = 90)
m[1] 1.5
make_difftime(minute = 1.5)
m[1] 1.5
make_difftime(second = 3, minute = 1.5, hour = 2, day = 6, week = 1)
# Time difference of 13.08441 days
make_difftime(hour = 1, minute = -60)
# Time difference of 0 secs
make_difftime(day = -1)
# Time difference of -1 days
make_difftime(120, day = -1, units = "minute")
# Time differences in mins
```

---

**minute**  
*Get/set minutes component of a date-time*

Description

Date-time must be a POSIXct, POSIXlt, Date, Period, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, and its objects.

Usage

```r
minute(x)
```

```r
minute(x) <- value
```

Arguments

- `x`: a date-time object
- `value`: numeric value to be assigned

Value

the minutes element of x as a decimal number

Examples

```r
x <- ymd("2012-03-26")
minute(x)
minute(x) <- 1
minute(x) <- 61
minute(x) > 2
```
month

Get/set months component of a date-time

Description

Date-time must be a POSIXct, POSIXlt, Date, Period, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, and fts objects.

Usage

month(x, label = FALSE, abbr = TRUE, locale = Sys.getlocale("LC_TIME"))

month(x) <- value

Arguments

x
  a date-time object

label
  logical. TRUE will display the month as a character string such as "January." FALSE will display the month as a number.

abbr
  logical. FALSE will display the month as a character string label, such as "January". TRUE will display an abbreviated version of the label, such as "Jan". abbr is disregarded if label = FALSE.

locale
  for month, locale to use for month names. Default to current locale.

value
  a numeric object

Value

If label = FALSE: month as number (1-12, 1 = January, 12 = December), otherwise as an ordered factor.

Examples

x <- ymd("2012-03-26")
month(x)
month(x) <- 1
month(x) <- 13
month(x) > 3

month(ymd(080101))
month(ymd(080101), label = TRUE)
month(ymd(080101), label = TRUE, abbr = FALSE)
month(ymd(080101) + months(0:11), label = TRUE)
**ms**

*Parse periods with hour, minute, and second components*

### Description

Transforms a character or numeric vector into a period object with the specified number of hours, minutes, and seconds. `hms()` recognizes all non-numeric characters except `-` as separators (`-` is used for negative durations). After hours, minutes and seconds have been parsed, the remaining input is ignored.

### Usage

```r
ms(..., quiet = FALSE, roll = FALSE)
hm(..., quiet = FALSE, roll = FALSE)
hms(..., quiet = FALSE, roll = FALSE)
```

### Arguments

- `...` a character vector of hour minute second triples
- `quiet` logical. If `TRUE`, function evaluates without displaying customary messages.
- `roll` logical. If `TRUE`, smaller units are rolled over to higher units if they exceed the conventional limit. For example, `hms("01:59:120", roll = TRUE)` produces period "2H 1M 0S".

### Value

a vector of period objects

### See Also

`hm()`, `ms()`

### Examples

```r
ms(c("09:10", "09:02", "1:10"))
ms("7 6")
ms("6.5")
hm(c("09:10", "09:02", "1:10"))
hm("7 6")
hm("6.5")

x <- c("09:10:01", "09:10:02", "09:10:03")
hms(x)

hms("7 6 5", "3:23::2", "2 : 23 : 33", "Finished in 9 hours, 20 min and 4 seconds")
```
**Description**

The current day and time

**Usage**

```r
now(tzone = ")")

today(tzone = ")")
```

**Arguments**

tzone a character vector specifying which time zone you would like the current time in. tzone defaults to your computer’s system timezone. You can retrieve the current time in the Universal Coordinated Time (UTC) with now("UTC").

**Value**

now - the current datetime as a POSIXct object

**Examples**

```r
now()

now("GMT")

now("")

now() == now() # would be TRUE if computer processed both at the same instant

now() < now() # TRUE

now() > now() # FALSE

today()

today("GMT")

today() == today("GMT") # not always true

today() < as.Date("2999-01-01") # TRUE (so far)
```

---

**origin**

1970-01-01 UTC

**Description**

Origin is the date-time for 1970-01-01 UTC in POSIXct format. This date-time is the origin for the numbering system used by POSIXct, POSIXlt, chron, and Date classes.

**Usage**

origin
Format

An object of class POSIXct (inherits from POSIXt) of length 1.

Examples

origin

Description

parse_date_time() parses an input vector into POSIXct date-time object. It differs from base::strptime() in two respects. First, it allows specification of the order in which the formats occur without the need to include separators and the % prefix. Such a formatting argument is referred to as "order". Second, it allows the user to specify several format-orders to handle heterogeneous date-time character representations.

parse_date_time2() is a fast C parser of numeric orders.

fast_strptime() is a fast C parser of numeric formats only that accepts explicit format arguments, just like base::strptime().

Usage

parse_date_time(
  x,
  orders,
  tz = "UTC",
  truncated = 0,
  quiet = FALSE,
  locale = Sys.getlocale("LC_TIME"),
  select_formats = .select_formats,
  exact = FALSE,
  train = TRUE,
  drop = FALSE
)

parse_date_time2(
  x,
  orders,
  tz = "UTC",
  exact = FALSE,
  lt = FALSE,
  cutoff_2000 = 68L
)

fast_strptime(x, format, tz = "UTC", lt = TRUE, cutoff_2000 = 68L)
Arguments

- **x**: a character or numeric vector of dates
- **orders**: a character vector of date-time formats. Each order string is a series of formatting characters as listed in `base::strptime()` but might not include the "%" prefix. For example, "ymd" will match all the possible dates in year, month, day order. Formatting orders might include arbitrary separators. These are discarded. See details for the implemented formats. If multiple order strings are supplied, they are applied in turn for `parse_date_time2()` and `fast_strptime()`.
- **tz**: a character string that specifies the time zone with which to parse the dates
- **truncated**: integer, number of formats that can be missing. The most common type of irregularity in date-time data is the truncation due to rounding or unavailability of the time stamp. If the truncated parameter is non-zero `parse_date_time()` also checks for truncated formats. For example, if the format order is "ymdHMS" and truncated = 3, `parse_date_time()` will correctly parse incomplete date-times like 2012-06-01 12:23, 2012-06-01 12 and 2012-06-01.

NOTE: The `ymd()` family of functions is based on `base::strptime()` which currently fails to parse `%Y-%m` formats.
- **quiet**: logical. If TRUE, progress messages are not printed, and No formats found error is suppressed and the function simply returns a vector of NAs. This mirrors the behavior of base R functions `base::strptime()` and `base::as.POSIXct()`.
- **locale**: locale to be used, see `locales`. On Linux systems you can use `system("locale -a")` to list all the installed locales.
- **select_formats**: A function to select actual formats for parsing from a set of formats which matched a training subset of x. It receives a named integer vector and returns a character vector of selected formats. Names of the input vector are formats (not orders) that matched the training set. Numeric values are the number of dates (in the training set) that matched the corresponding format. You should use this argument if the default selection method fails to select the formats in the right order. By default the formats with most formatting tokens (%) are selected and %Y counts as 2.5 tokens (so that it has a priority over %y%m formats). See examples.
- **exact**: logical. If TRUE, the orders parameter is interpreted as an exact `base::strptime()` format and no training or guessing are performed (i.e. train, drop parameters are ignored).
- **train**: logical, default TRUE. Whether to train formats on a subset of the input vector. As a result the supplied orders are sorted according to performance on this training set, which commonly results in increased performance. Please note that even when train = FALSE (and exact = FALSE) guessing of the actual formats is still performed on the training set (a pseudo-random subset of the original input vector). This might result in All formats failed to parse error. See notes below.
- **drop**: logical, default FALSE. Whether to drop formats that didn’t match on the training set. If FALSE, unmatched on the training set formats are tried as a last resort at the end of the parsing queue. Applies only when train = TRUE. Setting this
parameter to TRUE might slightly speed up parsing in situations involving many formats. Prior to v1.7.0 this parameter was implicitly TRUE, which resulted in occasional surprising behavior when rare patterns where not present in the training set.

lt logical. If TRUE, returned object is of class POSIXlt, and POSIXct otherwise. For compatibility with base::strptime() the default is TRUE for fast_strptime() and FALSE for parse_date_time2().

cutoff_2000 integer. For y format, two-digit numbers smaller or equal to cutoff_2000 are parsed as though starting with 20, otherwise parsed as though starting with 19. Available only for functions relying on lubridate internal parser.

format a vector of formats. If multiple formats supplied they are applied in turn till success. The formats should include all the separators and each format letter must be prefixed with %, just as in the format argument of base::strptime().

Details
When several format-orders are specified, parse_date_time() selects (guesses) format-orders based on a training subset of the input strings. After guessing the formats are ordered according to the performance on the training set and applied recursively on the entire input vector. You can disable training with train = FALSE.

parse_date_time(), and all derived functions, such as ymd_hms(), ymd(), etc., will drop into fast_strptime() instead of base::strptime() whenever the guessed from the input data formats are all numeric.

The list below contains formats recognized by lubridate. For numeric formats leading 0s are optional. As compared to base::strptime(), some of the formats are new or have been extended for efficiency reasons. These formats are marked with "(*)" below. Fast parsers parse_date_time2() and fast_strptime() accept only formats marked with "(!)".

a Abbreviated weekday name in the current locale. (Also matches full name)
A Full weekday name in the current locale. (Also matches abbreviated name).
    You don’t need to specify a and A formats explicitly. Wday is automatically handled if proc_wday = TRUE
b (!) Abbreviated or full month name in the current locale. The C parser currently understands only English month names.
B (!) Same as b.
d (!) Day of the month as decimal number (01–31 or 0–31)
H (!) Hours as decimal number (00–24 or 0–24).
I (!) Hours as decimal number (01–12 or 1–12).
j Day of year as decimal number (001–366 or 1–366).
q (!*) Quarter (1–4). The quarter month is added to the parsed month if m element is present.
m (!*) Month as decimal number (01–12 or 1–12). For parse_date_time also matches abbreviated and full months names as b and B formats. C parser understands only English month names.
M (!) Minute as decimal number (00–59 or 0–59).
parse_date_time

p (!) AM/PM indicator in the locale. Commonly used in conjunction with I and not with H. But lubridate’s C parser accepts H format as long as hour is not greater than 12. C parser understands only English locale AM/PM indicator.

S (!) Second as decimal number (00–61 or 0–61), allowing for up to two leap-seconds (but POSIX-compliant implementations will ignore leap seconds).

0S Fractional second.

U Week of the year as decimal number (00–53 or 0–53) using Sunday as the first day 1 of the week (and typically with the first Sunday of the year as day 1 of week 1). The US convention.

w Weekday as decimal number (0–6, Sunday is 0).

W Week of the year as decimal number (00–53 or 0–53) using Monday as the first day of week (and typically with the first Monday of the year as day 1 of week 1). The UK convention.

y (!*) Year without century (00–99 or 0–99). In parse_date_time() also matches year with century (Y format).

Y (!) Year with century.

z (!*) ISO8601 signed offset in hours and minutes from UTC. For example -0800, -08:00 or -08, all represent 8 hours behind UTC. This format also matches the Z (Zulu) UTC indicator. Because base::strftime() doesn’t fully support ISO8601 this format is implemented as an union of 4 formats: Ou (Z), Oz (-0800), OO (-08:00) and Oo (-08). You can use these formats as any other but it is rarely necessary. parse_date_time2() and fast_strptime() support all of these formats.

Om (!*) Matches numeric month and English alphabetic months (Both, long and abbreviated forms).

Op (!*) Matches AM/PM English indicator.

r (*) Matches Ip and H orders.

R (*) Matches HM and IMp orders.

T (*) Matches IMSp, HMS, and HMOS orders.

Value

a vector of POSIXct date-time objects

Note

parse_date_time() (and the derivatives ymd(), ymd_hms(), etc.) relies on a sparse guesser that takes at most 501 elements from the supplied character vector in order to identify appropriate formats from the supplied orders. If you get the error All formats failed to parse and you are confident that your vector contains valid dates, you should either set exact argument to TRUE or use functions that don’t perform format guessing (fast_strptime(), parse_date_time2() or base::strftime()).

For performance reasons, when timezone is not UTC, parse_date_time2() and fast_strptime() perform no validity checks for daylight savings time. Thus, if your input string contains an invalid date time which falls into DST gap and lt = TRUE you will get an POSIXlt object with a nonexistent time. If lt = FALSE your time instant will be adjusted to a valid time by adding an hour. See examples. If you want to get NA for invalid date-times use fit_to_timeline() explicitly.

base::strptime(), ymd(), ymd_hms()

Examples

```r
## ** orders are much easier to write **
x <- c("09-01-01", "09-01-02", "09-01-03")
parse_date_time(x, "ymd")
parse_date_time(x, "y m d")
parse_date_time(x, "%Y%m%d")
# "2009-01-01 UTC" "2009-01-02 UTC" "2009-01-03 UTC"

## ** heterogeneous date-times **
x <- c("09-01-01", "090102", "09-01 03", "09-01-03 12:02")
parse_date_time(x, c("ymd", "ymd Hm"))

## ** different ymd orders **
x <- c("2009-01-01", "02022010", "02-02-2010")
parse_date_time(x, c("dmY", "ymd"))
# "2009-01-01 UTC" "2010-02-02 UTC" "2010-02-02 UTC"

## ** truncated time-dates **
parse_date_time(x, "Ymd HMS", truncated = 3)

## ** specifying exact formats and avoiding training and guessing **
parse_date_time(x, c("%m-%d-%y", "%m%d%y", "%m-%d-%Y %H:%M"), exact = TRUE)
parse_date_time(c("/quotesingle.Var12/17/1996 04:00:00","/quotesingle.Var4/18/1950 0130"), c("%m/%d/%Y %I:%M:%S","%m/%d/%Y %H%M"), exact = TRUE)

## ** quarters and partial dates **
parse_date_time(c("2016.2", "2016-04"), orders = "Yq")
parse_date_time(c("2016", "2016-04"), orders = c("Y", "Ym"))

## ** fast parsing **
## Not run:
options(digits.secs = 3)
## random times between 1400 and 3000
tt <- as.character.POSIXct(runif(1000, -17987443200, 32503680000))
tt <- rep.int(tt, 1000)

system.time(out <- as.POSIXct(tt, tz = "UTC"))
system.time(out1 <- ymd_hms(tt)) # constant overhead on long vectors
system.time(out2 <- parse_date_time2(tt, "YmdHMS"))
system.time(out3 <- fast_strptime(tt, "%Y-%m-%d %H:%M:%OS"))

all.equal(out, out1)
all.equal(out, out2)
all.equal(out, out3)

## End(Not run)
```
## ** how to use `select_formats` argument **

By default %Y has precedence:

```r
parse_date_time(c("27-09-13", "27-09-2013"), "dmy")
```

To give priority to %y format, define your own `select_format` function:

```r
my_select <- function(trained, drop=FALSE, ...){
  n_fmts <- nchar(gsub("[^%]", "", names(trained))) + grepl("%y", names(trained)) * 1.5
  names(trained[ which.max(n_fmts) ])
}
```

```r
parse_date_time(c("27-09-13", "27-09-2013"), "dmy", select_formats = my_select)
```

## ** invalid times with "fast" parsing **

```r
parse_date_time("2010-03-14 02:05:06", "YmdHMS", tz = "America/New_York")
parse_date_time2("2010-03-14 02:05:06", "YmdHMS", tz = "America/New_York")
parse_date_time2("2010-03-14 02:05:06", "YmdHMS", tz = "America/New_York", lt = TRUE)
```

---

### period

Create or parse period objects

**Description**

`period()` creates or parses a period object with the specified values.

**Usage**

`period(num = NULL, units = "second", ...)`

* is.period(x)
* seconds(x = 1)
* minutes(x = 1)
* hours(x = 1)
* days(x = 1)
* weeks(x = 1)
* years(x = 1)
* milliseconds(x = 1)
* microseconds(x = 1)
nanoseconds(x = 1)

picoseconds(x = 1)

## S3 method for class 'numeric'
months(x, abbreviate)

Arguments

num a numeric or character vector. A character vector can specify periods in a convenient shorthand format or ISO 8601 specification. All unambiguous name units and abbreviations are supported, "m" stands for months, "M" for minutes unless ISO 8601 "P" modifier is present (see examples). Fractional units are supported but the fractional part is always converted to seconds.

units a character vector that lists the type of units to be used. The units in units are matched to the values in num according to their order. When num is character, this argument is ignored.

... a list of time units to be included in the period and their amounts. Seconds, minutes, hours, days, weeks, months, and years are supported. Normally only one of num or ... are present. If both are present, the periods are concatenated.

x Any R object for is.periods and a numeric value of the number of units for elementary constructors. With the exception of seconds(), x must be an integer.

abbreviate Ignored. For consistency with S3 generic in base namespace.

Details

Within a Period object, time units do not have a fixed length (except for seconds) until they are added to a date-time. The length of each time unit will depend on the date-time to which it is added. For example, a year that begins on 2009-01-01 will be 365 days long. A year that begins on 2012-01-01 will be 366 days long. When math is performed with a period object, each unit is applied separately. How the length of a period is distributed among its units is non-trivial. For example, when leap seconds occur 1 minute is longer than 60 seconds.

Periods track the change in the "clock time" between two date-times. They are measured in common time related units: years, months, days, hours, minutes, and seconds. Each unit except for seconds must be expressed in integer values.

Besides the main constructor and parser period(), period objects can also be created with the specialized functions years(), months(), weeks(), days(), hours(), minutes(), and seconds(). These objects can be added to and subtracted to date-times to create a user interface similar to object oriented programming.

Note: Arithmetic with periods can result in undefined behavior when non-existent dates are involved (such as February 29th in non-leap years). Please see Period for more details and %m+% and add_with_rollback() for alternative operations.

Value

a period object
See Also

Period, period(), `%m%`, add_with_rollback()

Examples

### Separate period and units vectors

```r
period(c(90, 5), c("second", "minute"))
# "5M 90S"
period(-1, "days")
period(c(3, 1, 2, 13, 1), c("second", "minute", "hour", "day", "week"))
period(c(1, -60), c("hour", "minute"))
period(0, "second")
```

### Units as arguments

```r
period(second = 90, minute = 5)
period(day = -1)
period(second = 3, minute = 1, hour = 2, day = 13, week = 1)
period(hour = 1, minute = -60)
period(second = 0)
period(c(1, -60), c("hour", "minute"), hour = c(1, 2), minute = c(3, 4))
```

### Lubridate style parsing

```r
period("2M 1sec")
period("2hours 2minutes 1second")
period("2d 2H 2M 2S")
period("2days 2hours 2mins 2secs")
period("2 days, 2 hours, 2 mins, 2 secs")
# Missing numerals default to 1. Repeated units are added up.
duration("day day")
```

### ISO 8601 parsing

```r
period("P10M23DT23H") # M stands for months
period("T10T10M") # M stands for minutes
period("P3Y6M4DT12H30M5S") # M for both minutes and months
period("P23DT6OH 20min 100 sec") # mixing ISO and lubridate style parsing
```

### Comparison with characters (from v1.6.0)

```r
duration("day 2 sec") > "day 1sec"
```

### Elementary Constructors

```r
x <- ymd("2009-08-03")
x + days(1) + hours(6) + minutes(30)
x + days(100) - hours(8)
class(as.Date("2009-08-09") + days(1)) # retains Date class
```
as.Date("2009-08-09") + hours(12)
class(as.Date("2009-08-09") + hours(12))  # converts to POSIXt class to accommodate time units
years(1) - months(7)
c(1:3) * hours(1)
hours(1:3)

# sequencing
y <- ymd(090101)  # "2009-01-01 CST"
y + months(0:11)

# compare DST handling to durations
boundary <- ymd_hms("2009-03-08 01:59:59", tz = "America/Chicago")
boundary + days(1)  # period
boundary + ddays(1)  # duration
is.period(as.Date("2009-08-03"))  # FALSE
is.period(period(months = 1, days = 15))  # TRUE

---

**period_to_seconds**  
Contrive a period to/from a given number of seconds

**Description**

period_to_seconds() approximately converts a period to seconds assuming there are 365.25 days in a calendar year and 365.25/12 days in a month.

seconds_to_period() create a period that has the maximum number of non-zero elements (days, hours, minutes, seconds). This computation is exact because it doesn’t involve years or months.

**Usage**

period_to_seconds(x)
seconds_to_period(x)

**Arguments**

x  
A numeric object. The number of seconds to coerce into a period.

**Value**

A number (period) that roughly equates to the period (seconds) given.
Pretty Dates

Pretty dates identifies which unit of time the sub-intervals should be measured in to provide approximately n breaks. It then chooses a "pretty" length for the sub-intervals and sets start and endpoints that 1) span the entire range of the data, and 2) allow the breaks to occur on important date-times (i.e. on the hour, on the first of the month, etc.)

Usage

```r
pretty_dates(x, n, ...)
```

Arguments

- `x`: a vector of POSIXct, POSIXlt, Date, or chron date-time objects
- `n`: integer value of the desired number of breaks
- `...`: additional arguments to pass to function

Value

A vector of date-times that can be used as axis tick marks or bin breaks

Examples

```r
x <- seq.Date(as.Date("2009-08-02"), by = "year", length.out = 2)
pretty_dates(x, 12)
```

Quarter

Get the fiscal quarter and semester of a date-time

Description

Quarters divide the year into fourths. Semesters divide the year into halves.

Usage

```r
quarter(
  x,
  type = "quarter",
  fiscal_start = 1,
  with_year = identical(type, "year.quarter")
)
```

```r
semester(x, with_year = FALSE)
```
Arguments

- **x**: a date-time object of class POSIXct, POSIXlt, Date, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, fts or anything else that can be converted with as.POSIXlt

- **type**: the format to be returned for the quarter. Can be one one of "quarter" - return numeric quarter (default), "year.quarter" return fractional numeric year.quarter, "date_first" or "date_last" which return the date at the quarter’s start end end.

- **fiscal_start**: numeric indicating the starting month of a fiscal year.

- **with_year**: logical indicating whether or not to include the quarter or semester's year (deprecated; use the type parameter instead).

Value

numeric or a vector of class POSIXct if type argument is date_first or date_last

Examples

```r
x <- ymd(c("2012-03-26", "2012-05-04", "2012-09-23", "2012-12-31"))
quarter(x)
quarter(x, type = "year.quarter")
quarter(x, type = "year.quarter", fiscal_start = 11)
quarter(x, type = "date_first", fiscal_start = 11)
quarter(x, type = "date_last", fiscal_start = 11)
semester(x)
semester(x, with_year = TRUE)
```

### rollbackward

**Roll backward or forward a date the previous, current or next month**

**Description**

rollbackward() changes a date to the last day of the previous month or to the first day of the month. rollforward() rolls to the last day of the current month or to the first day of the next month. Optionally, the new date can retain the same hour, minute, and second information. rollback() is a synonym for rollbackward().

**Usage**

```r
rollbackward(dates, roll_to_first = FALSE, preserve_hms = TRUE)
rollback(dates, roll_to_first = FALSE, preserve_hms = TRUE)
rollforward(dates, roll_to_first = FALSE, preserve_hms = TRUE)
```
Arguments

dates A POSIXct, POSIXlt or Date class object.
roll_to_first Rollback to the first day of the month instead of the last day of the month
preserve_hms Retains the same hour, minute, and second information? If FALSE, the new date will be at 00:00:00.

Value

A date-time object of class POSIXlt, POSIXct or Date, whose day has been adjusted to the last day of the previous month, or to the first day of the month.

Examples

date <- ymd("2010-03-03")
rollbackward(date)

dates <- date + months(0:2)
rollbackward(dates)

date <- ymd_hms("2010-03-03 12:44:22")
rollbackward(date)
rollbackward(date, roll_to_first = TRUE)
rollbackward(date, preserve_hms = FALSE)
rollbackward(date, roll_to_first = TRUE, preserve_hms = FALSE)

Description

round_date() takes a date-time object and time unit, and rounds it to the nearest value of the specified time unit. For rounding date-times which are exactly halfway between two consecutive units, the convention is to round up. Note that this is in line with the behavior of R’s base::round.POSIXt() function but does not follow the convention of the base base::round() function which "rounds to the even digit", as per IEC 60559.

Rounding to the nearest unit or multiple of a unit is supported. All meaningful specifications in the English language are supported - secs, min, mins, 2 minutes, 3 years etc.

Rounding to fractional seconds is also supported. Please note that rounding to fractions smaller than 1 second can lead to large precision errors due to the floating point representation of the POSIXct objects. See examples.

floor_date() takes a date-time object and rounds it down to the nearest boundary of the specified time unit.

ceiling_date() takes a date-time object and rounds it up to the nearest boundary of the specified time unit.
round_date

Usage

round_date(
  x,
  unit = "second",
  week_start = getOption("lubridate.week.start", 7)
)

floor_date(
  x,
  unit = "seconds",
  week_start = getOption("lubridate.week.start", 7)
)

ceiling_date(
  x,
  unit = "seconds",
  change_on_boundary = NULL,
  week_start = getOption("lubridate.week.start", 7)
)

Arguments

x  a vector of date-time objects

unit  a string, Period object or a date-time object. When a singleton string, it specifies a time unit or a multiple of a unit to be rounded to. Valid base units are second, minute, hour, day, week, month, bimonth, quarter, season, halfyear and year. Arbitrary unique English abbreviations as in the period() constructor are allowed. Rounding to multiples of units (except weeks) is supported. When unit is a Period object, units of the period objects are used. This is equivalent to converting the period object to its string representation and passing as unit argument.

When unit is a date-time object rounding is done to the nearest of the elements in unit. If range of unit vector does not cover the range of x ceiling_date() and floor_date() round to the max(x) and min(x) for elements that fall outside of range(unit).

week_start  week start day (Default is 7, Sunday. Set lubridate.week.start to override). Full or abbreviated names of the days of the week can be in English or as provided by the current locale.

change_on_boundary  if this is NULL (the default), instants on the boundary remain unchanged, but Date objects are rounded up to the next boundary. If this is TRUE, instants on the boundary are rounded up to the next boundary. If this is FALSE, nothing on the boundary is rounded up at all. This was the default for lubridate prior to v1.6.0. See section Rounding Up Date Objects below for more details.
Details

In lubridate, functions that round date-time objects try to preserve the class of the input object whenever possible. This is done by first rounding to an instant, and then converting to the original class as per usual R conventions.

Value

When unit is a string, return a Date object if x is a Date and unit is larger or equal than "day", otherwise a POSIXct object. When unit is a date-time object, return a date-time object of the same class and same time zone as unit.

Rounding Up Date Objects

By default, rounding up Date objects follows 3 steps:

1. Convert to an instant representing lower bound of the Date: 2000-01-01 –> 2000-01-01 00:00:00
2. Round up to the next closest rounding unit boundary. For example, if the rounding unit is month then next closest boundary of 2000-01-01 is 2000-02-01 00:00:00.
   
   The motivation for this is that the "partial" 2000-01-01 is conceptually an interval (2000-01-01 00:00:00 – 2000-01-02 00:00:00) and the day hasn’t started clocking yet at the exact boundary 00:00:00. Thus, it seems wrong to round a day to its lower boundary.
   
   Behavior on the boundary can be changed by setting change_on_boundary to TRUE or FALSE.
3. If the rounding unit is smaller than a day, return the instant from step 2 (POSIXct), otherwise convert to and return a Date object.

base::round()

Examples

```r
## print fractional seconds
options(digits.secs = 6)

x <- ymd_hms("2009-08-03 12:01:59.23")
round_date(x, ".5s")
round_date(x, "sec")
round_date(x, "second")
round_date(x, "minute")
round_date(x, "5 mins")
round_date(x, "hour")
round_date(x, "2 hours")
round_date(x, "day")
round_date(x, "week")
round_date(x, "month")
round_date(x, "bimonth")
round_date(x, "quarter") == round_date(x, "3 months")
round_date(x, "halfyear")
round_date(x, "year")
```
x <- ymd_hms("2009-08-03 12:01:59.23")
floor_date(x, ".1s")
floor_date(x, "second")
floor_date(x, "minute")
floor_date(x, "hour")
floor_date(x, "day")
floor_date(x, "week")
floor_date(x, "month")
floor_date(x, "bimonth")
floor_date(x, "quarter")
floor_date(x, "season")
floor_date(x, "halfyear")
floor_date(x, "year")

x <- ymd_hms("2009-08-03 12:01:59.23")
ceiling_date(x, ".1 sec") # imprecise representation at 0.1 sec !!!
ceiling_date(x, "second")
ceiling_date(x, "minute")
ceiling_date(x, "5 mins")
ceiling_date(x, "hour")
ceiling_date(x, "day")
ceiling_date(x, "week")
ceiling_date(x, "month")
ceiling_date(x, "bimonth") == ceiling_date(x, "2 months")
ceiling_date(x, "quarter")
ceiling_date(x, "season")
ceiling_date(x, "halfyear")
ceiling_date(x, "year")

## Period unit argument
floor_date(x, days(2))
floor_date(x, years(1))

## As of R 3.4.2 POSIXct printing of fractional numbers is wrong
as.POSIXct("2009-08-03 12:01:59.3") ## -> "2009-08-03 12:01:59.2 CEST"
ceiling_date(x, ".1 sec") ## -> "2009-08-03 12:01:59.2 CEST"

## behaviour of `change_on_boundary`
## As per default behaviour 'NULL', instants on the boundary remain the
## same but dates are rounded up
ceiling_date(ymd_hms("2000-01-01 00:00:00"), "month")
ceiling_date(ymd("2000-01-01"), "month")

## If 'TRUE', both instants and dates on the boundary are rounded up
ceiling_date(ymd_hms("2000-01-01 00:00:00"), "month", change_on_boundary = TRUE)
ceiling_date(ymd("2000-01-01"), "month")

## If 'FALSE', both instants and dates on the boundary remain the same
ceiling_date(ymd_hms("2000-01-01 00:00:00"), "month", change_on_boundary = FALSE)
ceiling_date(ymd("2000-01-01"), "month")

x <- ymd_hms("2000-01-01 00:00:00")
ceiling_date(x, "month")
ceiling_date(x, "month", change_on_boundary = TRUE)

## For Date objects first day of the month is not on the
## "boundary". change_on_boundary applies to instants only.
x <- ymd("2000-01-01")
ceiling_date(x, "month")
ceiling_date(x, "month", change_on_boundary = TRUE)

second Get/set seconds component of a date-time

Description

Date-time must be a POSIXct, POSIXlt, Date, Period, chron, yearmon, yearqtr, zoo, zooreg, timeDate, xts, its, ti, jul, timeSeries, and fts objects.

Usage

second(x)

second(x) <- value

Arguments

x a date-time object

value numeric value to be assigned

Value

the seconds element of x as a decimal number

Examples

x <- ymd("2012-03-26")
second(x)
second(x) <- 1
second(x) <- 61
second(x) > 2
Format dates and times based on human-friendly templates

Description

Stamps are just like `format()`, but based on human-friendly templates like "Recorded at 10 am, September 2002" or "Meeting, Sunday May 1, 2000, at 10:20 pm".

Usage

```r
stamp(
  x,
  orders = lubridate_formats,
  locale = Sys.getlocale("LC_TIME"),
  quiet = FALSE,
  exact = FALSE
)

stamp_date(x, locale = Sys.getlocale("LC_TIME"), quiet = FALSE)

stamp_time(x, locale = Sys.getlocale("LC_TIME"), quiet = FALSE)
```

Arguments

- **x**: a character vector of templates.
- **orders**: orders are sequences of formatting characters which might be used for disambiguation. For example "ymd hms", "aym" etc. See `guess_formats()` for a list of available formats.
- **locale**: locale in which `x` is encoded. On Linux-like systems use `locale -a` in the terminal to list available locales.
- **quiet**: whether to output informative messages.
- **exact**: logical. If TRUE, the `orders` parameter is interpreted as an exact `base::strptime()` format and no format guessing is performed.

Details

`stamp()` is a stamping function date-time templates mainly, though it correctly handles all date and time formats as long as they are unambiguous. `stamp_date()`, and `stamp_time()` are the specialized stamps for dates and times (MHS). These function might be useful when the input template is unambiguous and matches both a time and a date format.

Lubridate tries hard to guess the formats, but often a given format can be interpreted in multiple ways. One way to deal with such cases is to provide unambiguous formats like 22/05/81 instead of 10/05/81 for d/m/y format. Another way is to use a more specialized `stamp_date` and `stamp_time`. The core function `stamp()` prioritizes longer date-time formats.
timespan

If \( x \) is a vector of values \texttt{lubridate} will choose the format which "fits" \( x \) the best. Note that longer formats are preferred. If you have "22:23:00 PM" then "HMSp" format will be given priority to shorter "HMS" order which also fits the supplied string.

Finally, you can give desired format order directly as \texttt{orders} argument.

Value

a function to be applied on a vector of dates

See Also

\texttt{guess_formats()}, \texttt{parse_date_time()}, \texttt{strptime()}

Examples

```r
D <- ymd("2010-04-05") - days(1:5)
stamp("March 1, 1999")(D)
sf <- stamp("Created on Sunday, Jan 1, 1999 3:34 pm")
sf(D)
stamp("Jan 01")(D)
stamp("Sunday, May 1, 2000", locale = "C")(D)
```

Description

A time span can be measured in three ways: as a duration, an interval, or a period.

- \texttt{durations} record the exact number of seconds in a time span. They measure the exact passage of time but do not always align with human measurements like hours, months and years.

- \texttt{periods} record the change in the clock time between two date-times. They are measured in human units: years, months, days, hours, minutes, and seconds.

- \texttt{intervals} are time spans bound by two real date-times. Intervals can be accurately converted to periods and durations.
Examples

duration(3690, "seconds")
period(3690, "seconds")
period(second = 30, minute = 1, hour = 1)
interval(ymd_hms(\"2009-08-09 13:01:30\"), ymd_hms(\"2009-08-09 12:00:00\"))

date <- ymd_hms(\"2009-03-08 01:59:59\") # DST boundary
date + days(1)
date + ddays(1)

date2 <- ymd_hms(\"2000-02-29 12:00:00\")
date2 + years(1)
# self corrects to next real day

date3 <- ymd_hms(\"2009-01-31 01:00:00\")
date3 + c(0:11) * months(1)

span <- date2 %--% date # creates interval

date <- ymd_hms(\"2009-01-01 00:00:00\")
date + years(1)
date - days(3) + hours(6)
date + 3 * seconds(10)

months(6) + days(1)

time_length

Compute the exact length of a time span

Description

Compute the exact length of a time span

Usage

time_length(x, unit = "second")

## S4 method for signature 'Interval'
time_length(x, unit = "second")

Arguments

x a duration, period, difftime or interval
unit a character string that specifies with time units to use
Details

When \( x \) is an \texttt{Interval} object and \texttt{unit} are years or months, \texttt{time_length()} takes into account the fact that all months and years don’t have the same number of days.

When \( x \) is a \texttt{Duration}, \texttt{Period} or \texttt{difftime()} object, length in months or years is based on their most common lengths in seconds (see \texttt{timespan()}).

Value

the length of the interval in the specified unit. A negative number connotes a negative interval or duration

See Also

timespan()

Examples

```r
int <- interval(ymd("1980-01-01"), ymd("2014-09-18"))
time_length(int, "week")

# Exact age
time_length(int, "year")

# Age at last anniversary
trunc(time_length(int, "year"))

# Example of difference between intervals and durations
int <- interval(ymd("1900-01-01"), ymd("1999-12-31"))
time_length(int, "year")
time_length(as.duration(int), "year")
```

---

**tz**

Get/set time zone component of a date-time

Description

Conveniently get and set the time zone of a date-time.

tz<- is an alias for force_tz(), which preserves the local time, creating a different instant in time. Use with_tz() if you want keep the instant the same, but change the printed representation.

Usage

```r
tz(x)

tz(x) <- value
```
Arguments

- **x**: A date-time vector, usually of class `POSIXct` or `POSIXlt`.
- **value**: New value of time zone.

Value

A character vector of length 1. An empty string (""") represents your current time zone.
For backward compatibility, the time zone of a date, NA, or character vector is "UTC".

Valid time zones

Time zones are stored in system specific database, so are not guaranteed to be the same on every system (however, they are usually pretty similar unless your system is very out of date). You can see a complete list with `OlsonNames()`.

See Also

See `DateTimeClasses` for a description of the underlying `tzone` attribute.

Examples

```r
x <- y <- ymd_hms("2012-03-26 10:10:00", tz = "UTC")
tz(x)

# Note that setting tz() preserved the clock time, which implies
# that the actual instant in time is changing
tz(y) <- "Pacific/Auckland"
y
x - y

# This is the same as force_tz()
force_tz(x, "Pacific/Auckland")

# Use with_tz() if you want to change the time zone, leave
# the instant in time the same
with_tz(x, "Pacific/Auckland")
```

---

**week**

Get/set weeks component of a date-time

Description

`week()` returns the number of complete seven day periods that have occurred between the date and January 1st, plus one.

`isoweek()` returns the week as it would appear in the ISO 8601 system, which uses a reoccurring leap week.

`epiweek()` is the US CDC version of epidemiological week. It follows same rules as `isoweek()` but starts on Sunday. In other parts of the world the convention is to start epidemiological weeks on Monday, which is the same as `isoweek`. 
**with_tz**  

Get date-time in a different time zone

**Description**

with_tz returns a date-time as it would appear in a different time zone. The actual moment of time measured does not change, just the time zone it is measured in. with_tz defaults to the Universal Coordinated time zone (UTC) when an unrecognized time zone is inputted. See `Sys.timezone()` for more information on how R recognizes time zones.
Usage

with_tz(time, tzone = "", ...)

## Default S3 method:
with_tz(time, tzone = "", ...)

Arguments

time a POSIXct, POSIXlt, Date, chron date-time object or a data.frame object. When
a data.frame all POSIXt elements of a data.frame are processed with with_tz() and
new data.frame is returned.
tzone a character string containing the time zone to convert to. R must recognize the
name contained in the string as a time zone on your system.
...
Parameters passed to other methods.

Value

a POSIXct object in the updated time zone

See Also

force_tz()

Examples

x <- ymd_hms("2009-08-07 00:00:01", tz = "America/New_York")
with_tz(x, "GMT")

---

year Get/set years component of a date-time

Description

Date-time must be a POSIXct, POSIXlt, Date, Period or any other object convertible to POSIXlt.
isoyear() returns years according to the ISO 8601 week calendar.
epiyear() returns years according to the epidemiological week calendars.

Usage

year(x)

year(x) <- value

isoyear(x)

epiyear(x)
Arguments

x          a date-time object
value      a numeric object

Details

year does not yet support years before 0 C.E.

Value

the years element of x as a decimal number

References

https://en.wikipedia.org/wiki/ISO_week_date

Examples

x <- ymd("2012-03-26")
year(x)
year(x) <- 2001
year(x) > 1995

ymd  Parse dates with year, month, and day components

Description

Transforms dates stored in character and numeric vectors to Date or POSIXct objects (see tz argument). These functions recognize arbitrary non-digit separators as well as no separator. As long as the order of formats is correct, these functions will parse dates correctly even when the input vectors contain differently formatted dates. See examples.

Usage

ymd(
  ...,  # Additional arguments
  quiet = FALSE,
  tz = NULL,
  locale = Sys.getlocale("LC_TIME"),
  truncated = 0
)

ydm(
  ...,  # Additional arguments
  quiet = FALSE,
  tz = NULL,
locale = Sys.getlocale("LC_TIME"),
    truncated = 0
)

mdy(
    ..., quiet = FALSE,
    tz = NULL,
    locale = Sys.getlocale("LC_TIME"),
    truncated = 0
)

myd(
    ..., quiet = FALSE,
    tz = NULL,
    locale = Sys.getlocale("LC_TIME"),
    truncated = 0
)

dmy(
    ..., quiet = FALSE,
    tz = NULL,
    locale = Sys.getlocale("LC_TIME"),
    truncated = 0
)

dym(
    ..., quiet = FALSE,
    tz = NULL,
    locale = Sys.getlocale("LC_TIME"),
    truncated = 0
)

yq(..., quiet = FALSE, tz = NULL, locale = Sys.getlocale("LC_TIME"))

ym(..., quiet = FALSE, tz = NULL, locale = Sys.getlocale("LC_TIME"))

my(..., quiet = FALSE, tz = NULL, locale = Sys.getlocale("LC_TIME"))

Arguments

...  a character or numeric vector of suspected dates
quiet logical. If TRUE, function evaluates without displaying customary messages.
tz   Time zone indicator. If NULL (default), a Date object is returned. Otherwise a POSIXct with time zone attribute set to tz.
locale  locale to be used, see locales. On Linux systems you can use `system("locale -a")` to list all the installed locales.

truncated  integer. Number of formats that can be truncated.

Details

In case of heterogeneous date formats, the `ymd()` family guesses formats based on a subset of the input vector. If the input vector contains many missing values or non-date strings, the subset might not contain meaningful dates and the date-time format won’t be guessed resulting in an All formats failed to parse error. In such cases please see `parse_date_time()` for a more flexible parsing interface.

If the truncated parameter is non-zero, the `ymd()` functions also check for truncated formats. For example, `ymd()` with truncated = 2 will also parse incomplete dates like 2012-06 and 2012.

NOTE: The `ymd()` family of functions is based on `parse_date_time()` and thus directly drop to the internal C parser for numeric months, but uses `base::strptime()` for alphabetic months. This implies that some of `base::strptime()`’s limitations are inherited by `lubridate`’s parser. For example, truncated formats (like `%Y-%b`) will not be parsed. Numeric truncated formats (like `%Y-%m`) are handled correctly by `lubridate`’s C parser.

As of version 1.3.0, `lubridate`’s parse functions no longer return a message that displays which format they used to parse their input. You can change this by setting the `lubridate.verbose` option to TRUE with `options(lubridate.verbose = TRUE)`.

Value

a vector of class POSIXct if tz argument is non-NULL or Date if tz is NULL (default)

See Also

`parse_date_time()` for an even more flexible low level mechanism.

Examples

```r
x <- c("09-01-01", "09-01-02", "09-01-03")
ymd(x)

x <- c("2009-01-01", "2009-01-02", "2009-01-03")
ymd(x)

ymd(090101, 90102)
now() > ymd(20090101)
## TRUE
dmy(010210)
dmy(010210)

ymd(x)

yq('2014.2')

## heterogeneous formats in a single vector:
x <- c(20090101, "2009-01-02", "2009 01 03", "2009-1-4", "2009-1, 5", "Created on 2009 1 6", "200901 !!! 07")

ymd(x)

## What lubridate might not handle:
```
## Extremely weird cases when one of the separators is "" and some of the formats are not in double digits might not be parsed correctly:

```r
Not run: ymd("201002-01", "201002-1", "20102-1")
dmy("0312-2010", "312-2010")
## End(Not run)
```

---

**ymd_hms**

*Parse date-times with year, month, and day, hour, minute, and second components.*

### Description

Transform dates stored as character or numeric vectors to POSIXct objects. The `ymd_hms()` family of functions recognizes all non-alphanumeric separators (with the exception of "." if `frac = TRUE`) and correctly handles heterogeneous date-time representations. For more flexibility in treatment of heterogeneous formats, see low level parser `parse_date_time()`.

### Usage

```r
ymd_hms(
  ..., quiet = FALSE,
  tz = "UTC",
  locale = Sys.getlocale("LC_TIME"),
  truncated = 0
)
```

```r
ymd_hm(
  ..., quiet = FALSE,
  tz = "UTC",
  locale = Sys.getlocale("LC_TIME"),
  truncated = 0
)
```

```r
ymd_h(
  ..., quiet = FALSE,
  tz = "UTC",
  locale = Sys.getlocale("LC_TIME"),
  truncated = 0
)
```

```r
dmy_hms(
  ..., quiet = FALSE,
```
ymd_hms

```r
  tz = "UTC",
  locale = Sys.getlocale("LC_TIME"),
  truncated = 0
)

dmy_hm(

  ..., quiet = FALSE,
  tz = "UTC",
  locale = Sys.getlocale("LC_TIME"),
  truncated = 0
)

dmy_h(

  ..., quiet = FALSE,
  tz = "UTC",
  locale = Sys.getlocale("LC_TIME"),
  truncated = 0
)

mdy_hms(

  ..., quiet = FALSE,
  tz = "UTC",
  locale = Sys.getlocale("LC_TIME"),
  truncated = 0
)

mdy_hm(

  ..., quiet = FALSE,
  tz = "UTC",
  locale = Sys.getlocale("LC_TIME"),
  truncated = 0
)

mdy_h(

  ..., quiet = FALSE,
  tz = "UTC",
  locale = Sys.getlocale("LC_TIME"),
  truncated = 0
)

ymd_hms(

  ..., quiet = FALSE,
```

Arguments

... a character vector of dates in year, month, day, hour, minute, second format
quiet logical. If TRUE, function evaluates without displaying customary messages.
tz a character string that specifies which time zone to parse the date with. The string must be a time zone that is recognized by the user's OS.
locale locale to be used, see locales. On Linux systems you can use system("locale -a") to list all the installed locales.
truncated integer, indicating how many formats can be missing. See details.

Details

The ymd_hms() functions automatically assign the Universal Coordinated Time Zone (UTC) to the parsed date. This time zone can be changed with force_tz().

The most common type of irregularity in date-time data is the truncation due to rounding or unavailability of the time stamp. If the truncated parameter is non-zero, the ymd_hms() functions also check for truncated formats. For example, ymd_hms() with truncated = 3 will also parse incomplete dates like 2012-06-01 12:23, 2012-06-01 12 and 2012-06-01. NOTE: The ymd() family of functions is based on base::strptime() which currently fails to parse %y-%m formats.

In case of heterogeneous date formats the ymd_hms() family guesses formats based on a subset of the input vector. If the input vector contains many missing values or non-date strings, the subset might not contain meaningful dates and the date-time format won't be guessed resulting in All formats failed to parse error. In such cases please see parse_date_time() for a more flexible parsing interface.

As of version 1.3.0, lubridate’s parse functions no longer return a message that displays which format they used to parse their input. You can change this by setting the lubridate.verbose option to TRUE with options(lubridate.verbose = TRUE).
ymd_hms

Value

a vector of POSIXct date-time objects

See Also

• ymd(), hms()
• parse_date_time() for the underlying mechanism

Examples

x <- c("2010-04-14-04-35-59", "2010-04-01-12-00-00")
ymd_hms(x)
x <- c("2011-12-31 12:59:59", "2010-01-01 12:00:00")
ymd_hms(x)

## ** heterogeneous formats **
x <- c(20100101120101, "2009-01-02 12-01-02", "2009.01.03 12:01:03",
"2009-1-4 12-1-4", "2009-1, 5 12:1, 5", "200901-08 1201-08",
"2009 arbitrary 1 non-decimal 6 chars 12 in between 1 !!! 6",
"OR collapsed formats: 20090107 120107 (as long as prefixed with zeros)",
"Automatic wday, Thu, detection, 10-01-10 10:01:10 and p format: AM",
"Created on 10-01-11 at 10:01:11 PM")
ymd_hms(x)

## ** fractional seconds **
op <- options(digits.secs=3)

## ** What lubridate might not handle **
## Extremely weird cases when one of the separators is " " and some of the
### Description

Adding months frustrates basic arithmetic because consecutive months have different lengths. With other elements, it is helpful for arithmetic to perform automatic roll over. For example, 12:00:00 + 61 seconds becomes 12:01:01. However, people often prefer that this behavior NOT occur with months. For example, we sometimes want January 31 + 1 month = February 28 and not March 3. `%m+%` performs this type of arithmetic. Date `%m+% months(n)` always returns a date in the nth month after Date. If the new date would usually spill over into the n + 1th month, `%m+%` will return the last day of the nth month (`rollback()`). Date `%m-%` months(n) always returns a date in the nth month before Date.

### Usage

```
e1 %m+% e2
```

```
add_with_rollback(e1, e2, roll_to_first = FALSE, preserve_hms = TRUE)
```

### Arguments

- **e1**: A period or a date-time object of class `POSIXlt`, `POSIXct` or `Date`.
- **e2**: A period or a date-time object of class `POSIXlt`, `POSIXct` or `Date`. Note that one of e1 and e2 must be a period and the other a date-time object.
- **roll_to_first**: rollback to the first day of the month instead of the last day of the previous month (passed to `rollback()`)
- **preserve_hms**: retains the same hour, minute, and second information? If FALSE, the new date will be at 00:00:00 (passed to `rollback()`)

### Details

- `%m+%` and `%m-%` handle periods with components less than a month by first adding/subtracting months and then performing usual arithmetics with smaller units.
- `%m+%` and `%m-%` should be used with caution as they are not one-to-one operations and results for either will be sensitive to the order of operations.

### Value

A date-time object of class `POSIXlt`, `POSIXct` or `Date`
Examples

```r
jan <- ymd_hms("2010-01-31 03:04:05")
jan + months(1:3) # Feb 31 and April 31 returned as NA
# NA "2010-03-31 03:04:05 UTC" NA
jan %m+% months(1:3) # No rollover

leap <- ymd("2012-02-29")
"2012-02-29 UTC"
leap %m+% years(1)
leap %m+% years(-1)
leap %m-% years(1)

x <- ymd_hms("2019-01-29 01:02:03")
add_with_rollback(x, months(1))
add_with_rollback(x, months(1), preserve_hms = FALSE)
add_with_rollback(x, months(1), roll_to_first = TRUE)
add_with_rollback(x, months(1), roll_to_first = TRUE, preserve_hms = FALSE)
```

%within%

Does a date (or interval) fall within an interval?

Description

Check whether a lies within the interval b, inclusive of the endpoints.

Usage

```r
a %within% b
```

Arguments

- `a` An interval or date-time object.
- `b` Either an interval vector, or a list of intervals. If b is an interval (or interval vector) it is recycled to the same length as a. If b is a list of intervals, a is checked if it falls within any of the intervals, i.e. a %within% list(int1, int2) is equivalent to a %within% int1 | a %within% int2.

Value

A logical vector.

Examples

```r
int <- interval(ymd("2001-01-01"), ymd("2002-01-01"))
int2 <- interval(ymd("2001-06-01"), ymd("2002-01-01"))

ymd("2001-05-03") %within% int # TRUE
```
## recycling (carefully note the difference between using a vector of
## intervals and list of intervals for the second argument)
dates <- ymd(c("2014-12-20", "2014-12-30", "2015-01-01", "2015-01-03"))
blackout_vector <- c(
  interval(ymd("2014-12-30"), ymd("2014-12-31")),
  interval(ymd("2014-12-30"), ymd("2015-01-03"))
)
dates %within% blackout_vector

## within ANY of the intervals of a list
dates <- ymd(c("2014-12-20", "2014-12-30", "2015-01-01", "2015-01-03"))
lst <- list(
  interval(ymd("2014-12-30"), ymd("2014-12-31")),
  interval(ymd("2014-12-30"), ymd("2015-01-03"))
)
dates %within% lst

## interval within a list of intervals
int <- interval(
  ymd("2014-12-20", "2014-12-30"),
  ymd("2015-01-01", "2015-01-03"))
int %within% lst
