1 Introduction

*mRMRe* is an R package for parallelized mRMR ensemble feature selection.

1.1 Installation and Settings

*mRMRe* requires that *Rcpp* is installed. These should be installed automatically when you install *mRMRe*. Install *mRMRe* from CRAN or Bioconductor using *biocLite* function.

\[
> \text{install.packages("mRMRe")}
\]

Load *mRMRe* into your current workspace:

\[
> \text{library(mRMRe)}
\]

The mRMRe package allows its users to set the number of threads it will use for computations. One should may consider the following method to avoid crowding computing clusters, or fully utilize them.

\[
> \text{set.thread.count(2)}
\]

Load the example dataset *cgps* into your current workspace:

\[
> \text{data(cgps)}
> \text{data.annot <- data.frame(cgps.annot)}
> \text{data.cgps <- data.frame(cgps.ic50, cgps.ge)}
\]

1.2 Requirements

*mRMRe* has only been tested on Windows and Linux platforms. It requires that the *openMP* C library be installed on the hosts on which the package is intended to run.

2 Measures of Association

2.1 Mutual Information Matrix

mRMRe offers a fully parallelized implementation to compute the Mutual Information Matrix (MIM). The object *data.cgps* should be a dataframe with
samples/observations in rows and features/variables in columns. The method supports the following column types: "numeric" ("integer" or "double"), "ordered factor" and "Surv". Mutual information (MI) between two columns is estimated using a linear approximation based on correlation such that MI is estimated as $I(x,y) = -\frac{1}{2} \ln (1 - \rho(x,y)^2)$, where $I$ and $\rho$ respectively represent the MI and correlation coefficient between features $x$ and $y$. Correlation between continuous variables can be computed using either Pearson’s or Spearman’s estimators, while Cramer’s V and Somers’ $D_{xy}$ index are used for correlation between discrete variables and between continuous variables and survival data, respectively.

```r
> ## Test on a dummy dataset.
> # Create a dummy data set
> library(survival)
> df <- data.frame(
+   "surv1" = Surv(runif(100),
+       sample(0:1, 100, replace = TRUE)),
+   "cont1" = runif(100),
+   "disc1" = factor(sample(1:5, 100, replace = TRUE),
+       ordered = TRUE),
+   "surv2" = Surv(runif(100),
+       sample(0:1, 100, replace = TRUE)),
+   "cont2" = runif(100),
+   "cont3" = runif(100),
+   "surv3" = Surv(runif(100),
+       sample(0:1, 100, replace = TRUE)),
+   "disc2" = factor(sample(1:5, 100, replace = TRUE),
+       ordered = TRUE))
> dd <- mRMR.data(data = df)
> # Show a partial mutual information matrix.
> print(mim(subsetData(dd, 1:4, 1:4)))
```

```
surv1  cont1  disc1  surv2
surv1 0.00000000 0.05889152 0.05889152 Inf
cont1 0.05889152 Inf 0.08699561 NA
disc1 0.05889152 0.08699561 Inf NA
surv2 NA NA NA NA
```
```r
## Test on the 'cgps' dataset, where the variables are all of continuous type.

```r
dd <- mRMR.data(data = data.cgps)
dd <- subsetData(dd, 1:10, 1:10)

# Uses Spearman as correlation estimator
spearman_mim <- mim(dd, continuous_estimator = "spearman")
print(spearman_mim[1:4, 1:4])
```

```
cgps.ic50 geneid_3310 geneid_2978 geneid_6352
cgps.ic50 Inf 0.025796493 0.000900719 0.108915849

geneid_6352 9.249434e-02 0.02740061 5.790450e-02 Inf
```

### 2.2 Correlations

The mRMRe package offers an efficient, stratified and weighted implementation of the major correlation estimators: Cramer’s V, Somers Dxy index (based on the concordance index), Pearson, Spearman correlation coefficients.

```r
# Compute c-index between feature 1 and 2
correlate(cgps.ge[, 1], cgps.ge[, 2], method = "cindex")

# Compute Cramer's V
x <- sample(factor(c("CAT_1", "CAT_2", "CAT_3"),
    ordered = TRUE), 100, replace = TRUE)
y <- sample(factor(c("CAT_1", "CAT_2"),
    ordered = TRUE), 100, replace = TRUE)
correlate(x, y, method = "cramersv")
```
> # Compute Pearson coefficient with random strata and
> # sample weights between features 1 and 2
> strata <- sample(factor(c("STRATUM_1", "STRATUM_2",
+                         "STRATUM_3"),
+                   ordered = TRUE),
+                   nrow(cgps.ge), replace = TRUE)
> weights <- runif(nrow(cgps.ge))
> correlate(cgps.ge[, 1], cgps.ge[, 2], strata = strata,
+           weights = weights, method = "pearson")

3 mRMR Feature Selection

mRMRe offers a highly efficient implementation of the mRMR feature selection [2, 4]. The two crucial aspects of our implementation consists first, in parallelizing the key steps of the algorithm and second, in using a lazy procedure to compute only the part of the MIM that is required during the search for the best set of features (instead of estimating the full MIM).

3.1 Classic mRMR

Here is an example of the classic mRMR feature selection [2].

> dd <- mRMR.data(data = data.cgps)
> mRMR.classic(data = dd, target_indices = c(1),
+              feature_count = 30)

3.2 Ensemble mRMR

> dd <- mRMR.data(data = data.cgps)
> # For mRMR.classic-like results
> mRMR.ensemble(data = dd, target_indices = c(1),
+                solution_count = 1, feature_count = 30)
> # For mRMR.ensemble-like results
> mRMR.ensemble(data = dd, target_indices = c(1),
+                solution_count = 5, feature_count = 30)
4 Causality Inference

The mRMRe package allows one to infer causality through the use of the co-information lattice method [1, 3].

```r
> ensemble <- mRMR.ensemble(data = dd, target_indices = c(1),
+   solution_count = 5,
+   feature_count = 10)
> causality(ensemble)
```

5 Session Info

- R version 3.1.1 (2014-07-10), x86_64-apple-darwin13.1.0
- Base packages: base, datasets, grDevices, graphics, methods, splines, stats, utils
- Other packages: igraph 0.7.0, mRMRe 2.0.5, survival 2.37-7
- Loaded via a namespace (and not attached): tools 3.1.1
