Package ‘maps’

June 8, 2017

Title Draw Geographical Maps
Version 3.2.0
Date 2017-06-07
Author Original S code by Richard A. Becker and Allan R. Wilks.
        R version by Ray Brownrigg.
        Enhancements by Thomas P Minka and Alex Deckmyn.
Description Display of maps. Projection code and larger maps are in
        separate packages ('mapproj' and 'mapdata').
Depends R (>= 2.14.0)
Imports graphics, utils
LazyData yes
Suggests mapproj (>= 1.2-0), mapdata (>= 2.2-4), sp, maptools
License GPL-2
Maintainer Alex Deckmyn <alex.deckmyn@meteo.be>
NeedsCompilation yes
Repository CRAN
Date/Publication 2017-06-08 05:00:14 UTC

area.map

Description

Computes the areas of regions in a projected map.

Usage

area.map(m, regions = ".", sqmi=TRUE, ...)

Arguments

m
regions
sqmi
...
Details

The area of each matching region in the map is computed, and regions which match the same element of regions have their areas combined. Each region is assumed planar, with vertices specified by the x and y components of the map object.

The correct use of this function is to first use `map` to create polygons and project the coordinates onto a plane, then apply `area.map` to compute the area of the projected regions. If the projection is area-preserving (such as `albers`), then these areas will match the area on the globe, up to a constant. To get an absolute area in square miles, the `sqmi` option will scale the result, depending on the projection.

The coordinates from `map` are affected by its `resolution` argument, so use `resolution=0` for the most accurate areas.

Value

a named vector of region areas.

NOTE

The `sqmi` option assumes the coordinates have been projected with the `mapproject` function.

Author(s)

Tom Minka

See Also

`area.polygon, apply.polygon`

Examples

```r
# because the projection is rectangular, these are not true areas on the globe.
m = map("state", fill = TRUE, plot = FALSE)
area.map(m)
area.map(m, ".*dakota")
area.map(m, c("North Dakota", "South Dakota"))

if(require(mapproj)) {
  # true areas on the globe
  m = map("state", proj="bonne", param=45, fill=TRUE, plot=FALSE)
  # North Dakota is listed as 70,704 square miles
  area.map(m, "North Dakota")
}
```
**canada.cities** *Database of Canadian cities*

**Description**

This database is of Canadian cities of population greater than about 1,000. Also included are province capitals of any population size.

**Format**

A list with 6 components, namely "name", "country.etc", "pop", "lat", "long", and "capital", containing the city name, the province abbreviation, approximate population (as at January 2006), latitude, longitude and capital status indication (0 for non-capital, 1 for capital, 2 for provincial capital).

**NOTE**

Some of the city names may be out of date. Please send any corrections to the package maintainer.

**See Also**

map.cities

---

**county** *United States County Map*

**Description**

This database produces a map of the counties of the United States mainland generated from US Department of the Census data (see the reference).

**Usage**

data(countyMapEnv)

**Format**

The data file is merely a character string which specifies the name of an environment variable which contains the base location of the binary files used by the map drawing functions. This environment variable (R_MAP_DATA_DIR for the datasets in the maps package) is set at package load time if it does not already exist. Hence setting the environment variable before loading the package can override the default location of the binary datasets.
References

map.

Examples

map('county', 'iowa', fill = TRUE, col = palette())

---

### county.fips

| county.fips | FIPS county codes for US County Map |

Description

A database matching FIPS codes to maps package county and state names.

Usage

data(county.fips)

Format

A list with 2 components, namely "fips" and "polyname", containing the FIPS number and respective state or county polygon name. Note that "fips" is represented as an integer, so any leading zero (which is part of the fips code) is not shown by default.

See Also

state.fips
Description

This france database comes from the NUTS III (Tertiary Administrative Units of the European Community) database of the United Nations Environment Programme (UNEP) GRID-Geneva data sets. These were prepared around 1989, and so may be somewhat out of date.

Users of data sets supplied through UNEP/GRID are requested to incorporate in output products and reports acknowledgements to the originator of the data and to the fact that they were acquired through UNEP/GRID. Appropriate wording may be "UNESCO (1987) through UNEP/GRID-Geneva".

Usage

data(francemapEnv)

Format

The data file is merely a character string which specifies the name of an environment variable which contains the base location of the binary files used by the map drawing functions. This environment variable (R_MAP_DATA_DIR for the datasets in the maps package) is set at package load time if it does not already exist. Hence setting the environment variable before loading the package can override the default location of the binary datasets.

map

Examples

map('france', fill = TRUE, col = 1:10)
identify.map

Identify regions on a map

Description
Identifies the map regions clicked by the user.

Usage

```r
## S3 method for class 'map'
identify(x, n = 1, index = FALSE, ...)
```

Arguments

- `x`: a map object containing named polygons.
- `n`: the number of clicks to wait for.
- `index`: If TRUE, returns the index of the polygon, rather than its name.
- `...`: additional arguments passed to `identify.default`.

Details
The current algorithm is somewhat crude — selects the region whose centroid is closest to the click. A more sophisticated approach would use `map.where`.

Value
a character vector of length `n`, naming the selected regions.

Author(s)
Tom Minka

See Also

- `identify`, `map.where`

Examples

```r
identify(map("state", fill = TRUE, col = 0))
if(require(mapproj))
  identify(map("world", proj = "lagrange", fill = TRUE, col = 0, wrap=c(-180,180,-90)))
```
iso.expand  Identify countries by ISO 3166 codes (2 or 3 letters) or by Sovereignty.

Description

This data set and the simple look-up functions allow to build lists of countries for the world map.

Usage

iso.expand(a, regex=TRUE)
sov.expand(sov, regex=TRUE)
iso.alpha(x, n=2)

Arguments

a        A vector of ISO codes. All elements should have the same length, either 2 or 3 letters. Not case sensitive.
sov      A vector of country names. The result is a list of all countries that fall under their sovereignty. Case sensitive, must fit completely.
regex    If TRUE (default), the return vector has the same length as the input (a or sov), but the entries may be regular expressions. If FALSE, the result is a vector of polygon names. This may be more readable, but the return vector may be longer than the input.
x        Vector of country names, may include colons.
n        An integer identifying which ISO code is required. Allowed values are 2 and 3.

Details

The ISO 3166-1 standard identifies countries by a 2 and 3 letter codes. iso.expand translates these codes into the country names as used by the world data base. iso.alpha does the reverse. Note that these functions will not work well with the legacy world data base. Some countries have different ISO codes for different regions (e.g. China:Hong Kong has ISO code HK). In such cases, iso.alpha will return the main code, but iso.expand will return a regular expression that excludes some parts.

Value

iso.expand returns vector of country names. When used as input for map it will plot all the countries as identified either by their sovereignty or by ISO codes. If regex=FALSE the length of the vector may be shorter or longer than the input. If regex=TRUE, the results are concatenated in regular expressions. This format is less readable, but can be used as input e.g. for match.map.

iso.alpha always returns a vector of the same length as the input, containing the 2- or 3-letter codes.

NOTE

These functions use regular expressions and the results will often not work well with map(..., exact=TRUE).

match.map,map.text,iso3166

Examples

# France and all its overseas departments, territories etc.
sov.expand("France") # France and all its overseas departments, territories etc.

# Canary Islands are not included in map("Spain")
iso.expand("ES")
map(regions=sov.expand("Spain"))

# draw a map with ISO codes as labels:
wmlower=TRUE,col=8,xlim=c(-10,40),ylim=c(30,60))
# take out islands, but you loose e.g. UK, New Zealand, small island states
nam <- grep("\.",wm$names,inv=TRUE,val=TRUE)
# ad ISO codes as label
map.text(wm,regions=nam,label=iso.alpha(nam),col=2,exact=TRUE)

iso3166

ISO 3166 country codes (2 or 3 letters) and sovereignty.

Description

This data set lists all ISO3166 country codes and the sovereignty for each country in the list. Some entries are regular expressions.

Format

A data frame with 5 columns: "a2", "a3", "name", "mapname", "sovereignty". These contain the 2- and 3-letter ISO code, the official name, the (possibly shorter) name used in the map data base, and the sovereign country.

Details

The ISO 3166-1 standard identifies countries by a 2 and 3 letter codes. This table listst these for all countries on the world map. This data set also serves as basis for the function iso.expand() and its siblings.
NOTE

Some countries have different ISO codes for some regions. To deal with such particular cases, the "mapname" column may sometimes contain (perl-style) regular expressions rather than simply a country name. For instance, "FI" has mapname "Finland(?!:Aland)", because the Aland islands have a different ISO code. Other codes may appear in two rows if certain parts of countries are not written with the main country as base name. Usually, that is for compatibility with the legacy world data base.

italy

<table>
<thead>
<tr>
<th>italy</th>
<th>Italy Map</th>
</tr>
</thead>
</table>

Description

This italy database comes from the NUTS III (Tertiary Administrative Units of the European Community) database of the United Nations Environment Programme (UNEP) GRID-Geneva data sets. These were prepared around 1989, and so may be somewhat out of date.

Users of data sets supplied through UNEP/GRID are requested to incorporate in output products and reports acknowledgements to the originator of the data and to the fact that they were acquired through UNEP/GRID. Appropriate wording may be "UNESCO (1987) through UNEP/GRID-Geneva".

Usage

data(italyMapEnv)

Format

The data file is merely a character string which specifies the name of an environment variable which contains the base location of the binary files used by the map drawing functions. This environment variable (R_MAP_DATA_DIR for the datasets in the maps package) is set at package load time if it does not already exist. Hence setting the environment variable before loading the package can override the default location of the binary datasets.

map

Examples

map('italy', fill = TRUE, col = 1:10)

lakes  World lakes database

Description

This database contains a selection of large lakes (and islands within) taken from the Natural Earth 1:50m map, the same data source as the (v3.0) world map. The lake boundaries are consistent with the 'world' database.

Usage

data(lakesMapEnv)

Format

The data file is merely a character string which specifies the name of an environment variable which contains the base location of the binary files used by the map drawing functions. This environment variable (R_MAP_DATA_DIR for the datasets in the maps package) is set at package load time if it does not already exist. Hence setting the environment variable before loading the package can override the default location of the binary datasets.

Source

The data in this data base is derived from the public domain GIS project Natural Earth, the file "ne_50m_lakes". The Natural Earth data set is available from http://www.naturalearthdata.com.

References

Natural Earth project http://www.naturalearthdata.com

See Also

map.

Examples

map('world')
map('lakes', add=TRUE, fill=TRUE, col='white', boundary='black')
Description

This world database comes from a thinned cleaned-up version of the CIA World Data Bank II data and contains approximately 30,000 points representing the world coastlines and national boundaries approximately around 1990.

Usage

data(worldMapEnv)

Format

The data file is merely a character string which specifies the name of an environment variable which contains the base location of the binary files used by the map drawing functions. This environment variable (R_MAP_DATA_DIR for the datasets in the maps package) is set at package load time if it does not already exist. Hence setting the environment variable before loading the package can override the default location of the binary datasets.

During a transition period (maps version 3.0) it is possible to switch to the old legacy map using the function world.legacy(TRUE) or by setting the setting the environment variable R_MAP_DATA_LEGACY=TRUE prior to loading the package.

Source

The CIA World Data Bank II is currently (2015) still available from https://www.evl.uic.edu/pape/data/WDB/.

map, world.legacy.world

Examples

map('legacy_world', fill = TRUE, col = 1:10)
Draw Geographical Maps

Description

Draw lines and polygons as specified by a map database.

Usage

map(database = "world", regions = ",", exact = FALSE, boundary = TRUE, interior = TRUE, projection = ",", parameters = NULL, orientation = NULL, fill = FALSE, col = 1, plot = TRUE, add = FALSE, namesonly = FALSE, xlim = NULL, ylim = NULL, wrap = FALSE, resolution = if (plot) 1 else 0, type = "l", bg = par("bg"), mar = c(4.1, 4.1, par("mar")[3], 0.1), myborder = 0.01, namefield="name", lforce="n", ...)

Arguments

database character string naming a geographical database, a list of x, y, and names obtained from a previous call to map or a spatial object of class SpatialPolygons or SpatialLines. The string choices include a world map, three USA databases (usa, state, county), and more (type help(package='maps') to see the package index). If the required database is in a different package that has not been attached, the string may be started with "packagename::". The location of the map databases may be overridden by setting the R_MAP_DATA_DIR environment variable.

regions character vector that names the polygons to draw. Each database is composed of a collection of polygons, and each polygon has a unique name. When a region is composed of more than one polygon, the individual polygons have the name of the region, followed by a colon and a qualifier, as in michigan:north and michigan:south. Each element of regions is matched against the polygon names in the database and, according to exact, a subset is selected for drawing. The regions may also be defined using (perl) regular expressions. This makes it possible to use 'negative' expressions like "Norway(?!:Svalbard)", which means Norway and all islands except Svalbard. All entries are case insensitive. The default selects all polygons in the database.

exact If TRUE, only exact matches with regions are selected for drawing. If FALSE, each element of regions is matched as a regular expression against the polygon names in the database and all matches are selected for drawing.

boundary If FALSE, boundary segments are not drawn. A boundary segment is a line segment of the map that bounds only one of the polygons to be drawn. This argument is ignored if fill is TRUE.

interior If FALSE, interior segments are not drawn. An interior segment is a line segment of the map that bounds two of the polygons to be drawn. This argument is ignored if fill is TRUE.
projection character string that names a map projection to use. See `mapproject` (in the mapproj library). The default is to use a rectangular projection with the aspect ratio chosen so that longitude and latitude scales are equivalent at the center of the picture.

parameters numeric vector of parameters for use with the projection argument. This argument is optional only in the sense that certain projections do not require additional parameters. If a projection does require additional parameters, these must be given in the parameters argument.

orientation a vector c(latitude, longitude, rotation) describing where the map should be centered and a clockwise rotation (in degrees) about this center.

fill logical flag that says whether to draw lines or fill areas. If FALSE, the lines bounding each region will be drawn (but only once, for interior lines). If TRUE, each region will be filled using colors from the col argument, and bounding lines are drawn by default using par("fg"). To hide the bounding lines, use border=NA (see ...).

col vector of colors. If fill is FALSE, the first color is used for plotting all lines, and any other colors are ignored. Otherwise, the colors are matched one-one with the polygons that get selected by the region argument (and are reused cyclically, if necessary). If fill = TRUE, the default boundary line colour is given by par("fg"). To change this, you can use the border argument (see '...'). A color of NA causes the corresponding region to be deleted from the list of polygons to be drawn. Polygon colors are assigned after polygons are deleted due to values of the xlim and ylim arguments.

plot logical flag that specifies whether plotting should be done. If plot is TRUE the return value of map will not be printed automatically.

add logical flag that specifies whether to add to the current plot. If FALSE, a new plot is begun, and a new coordinate system is set up.

namesonly If TRUE, the return value will be a character vector of the names of the selected polygons. See the Value section below.

xlim two element numeric vector giving a range of longitudes, expressed in degrees, to which drawing should be restricted. Longitude is measured in degrees east of Greenwich, so that, in particular, locations in the USA have negative longitude. If fill = TRUE, polygons selected by region must be entirely inside the xlim range. The default value of this argument spans the entire longitude range of the database.

ylim two element numeric vector giving a range of latitudes, expressed in degrees, to which drawing should be restricted. Latitude is measured in degrees north of the equator, so that, in particular, locations in the USA have positive latitude. If fill = TRUE, polygons selected by region must be entirely inside the ylim range. The default value of this argument spans the entire latitude range of the database.

wrap Boolean or a numeric vector. If TRUE, lines that cross too far across the map (due to a strange projection) are omitted. If wrap is a vector of length 2 or more, it is interpreted as the longitude range to be used for a global map, e.g. c(-180,180) or c(0,360). This wrapping even works when fill=TRUE and is performed before any projection (so the range must always be in degrees).
However, the wrapping is performed after \texttt{xlim}, \texttt{ylim} are applied, so these options should probably never be combined. If there is a third component, this signifies the latitude at which Antarctica will be "closed". The default value is -89.9. Special values are \texttt{NA} (don’t draw Antarctica at all) and \texttt{0} (draw the line at the latitude of the extremal points, not at a fixed lower latitude).

\texttt{resolution} number that specifies the resolution with which to draw the map. Resolution 0 is the full resolution of the database. Otherwise, just before polylines are plotted they are thinned: roughly speaking, successive points on the polyline that are within \texttt{resolution} device pixels of one another are collapsed to a single point (see the Reference for further details). Thinning is not performed if \texttt{plot} = \texttt{FALSE} or when polygons are drawn (\texttt{fill} = \texttt{TRUE} or \texttt{database} is a list of polygons).

\texttt{type} character string that controls drawing of the map. Aside from the default \texttt{type} = \texttt{"1"}, the value \texttt{type} = \texttt{"n"} can be used to set up the coordinate system and projection for a map that will be added to in later calls.

\texttt{bg} background color.

\texttt{mar} margins, as in \texttt{par}. Defaults allow for \texttt{map.axes}().

\texttt{myborder} scalar or vector of length 2 specifying the proportion of the plot to add to the defined or computed limits as borders.

\texttt{namefield} A vector of column names to be used as region name if \texttt{database} is a \texttt{SpatialPolygonsDataFrame}. Ignored in all other cases.

\texttt{lforce} Limit enforcement. Only taken into account if \texttt{xlim} and/or \texttt{ylim} are defined and (for \texttt{"s"} and \texttt{"l"}) a projection is used. Possible values are \texttt{"n"} (none) \texttt{"e"} (exact), \texttt{"s"} (small), \texttt{"l"} (large). If \texttt{lforce} = \texttt{"e"}, map data is restricted exactly to the given limits prior to projection. This option affects the output value of the map, not only the plot window. If \texttt{lforce} = \texttt{"s"}, the four corners defined by \texttt{xlim} and \texttt{ylim} are projected and the plot window is restricted to the largest rectangle inside this region. \texttt{"l"} will result in a larger rectangle that includes the four corners. However, the parts that fall outside the original limits may not be complete (only polygons that partially fall inside the boundaries are included). This will also work with \texttt{fill=TRUE}. In this case the output value of the data is not changed, only the plot window is affected. These options are only useful for some projections.

Extra arguments passed to \texttt{polygon} or \texttt{lines}. Of particular interest may be the options \texttt{border} and \texttt{lty} that control the color and line type of the polygon borders when \texttt{fill} = \texttt{TRUE}.

\textbf{Details}

The simplest form of use of this function is:

\texttt{map(mymap)}

where \texttt{mymap} is the returned value from a previous call to \texttt{map}().
If plot = TRUE, a plot is made where the polygons selected from database, through the regions, xlim, and ylim arguments, are outlined (fill is FALSE) or filled (fill is TRUE) with the colors in col.

The return value is a list with x, y, range, and names components. This object can be used as a database for successive calls to map and functions. If fill is FALSE, the x and y vectors are the coordinates of successive polylines, separated by NAs. If fill is TRUE, the x and y vectors have coordinates of successive polygons, again separated by NAs. Thus the return value can be handed directly to lines or polygon, as appropriate.

When namesonly is TRUE, only the names component is returned.

After a call to map for which the projection argument was specified there will be a global variable .Last.projection containing information about the projection used. This will be consulted in subsequent calls to map which use projection = ''.

---

**map.axes**

**Draw Axes on Geographical Maps**

**Description**

Draws a set of axes on an existing map.

**Usage**

map.axes(...)
Arguments

... Extra arguments passed to axis or box.

Side Effects

x- and y-axes are drawn for the currently displayed map. These will display in longitude and latitude (if no projection= has been specified in the map() call).

Examples

map("state")
map.axes(cex.axis=0.8)

map.cities Add Cities to Existing Map

Description

Adds city locations and (optionally) names to an existing map using a specified database.

Usage

map.cities(x = world.cities, country = "", label = NULL, minpop = 0,
maxpop = Inf, capitals = 0, cex = par("cex"), projection = FALSE,
parameters = NULL, orientation = NULL, pch = 1, ...)

Arguments

x Name of database. See world.cities to determine the structure of the database.
country If the string country is specified, limit the displayed cities to be from within the specified country, province or state (depending on how the database has been constructed).
label If TRUE, label all cities. If NULL, the cities will be labelled unless there are 20 or more.
minpop The minimum value of population below which a particular city will not be shown.
maxpop The maximum value of population above which a particular city will not be shown.
capitals Selection of capitals-only display. Capitals may be 1 (country capital), 2 (provincial, state, or regional capital) or 3 (local capital). See world.cities for further information.
cex The value of cex acts to override the current value of character size expansion.
projection Boolean or character value. If FALSE (the default), no projection is assumed, if TRUE, the previous projection is used, otherwise a character string that names a map projection to use. See mapproject (in the mapproj library).
map.cities

parameters numeric vector of parameters for use with the projection argument. This argument is optional only in the sense that certain projections do not require additional parameters. If a projection does require additional parameters, these must be given in the parameters argument.

orientation a vector c(latitude, longitude, rotation) describing where the map should be centered and a clockwise rotation (in degrees) about this center.

pch plotting character to use for marking city location. See points for options.

Further plotting parameters may be specified as for the commands points and text.

Details

The database is searched for all cities matching the specified criteria and fitting within the limits of the plot currently displayed. The default database is of all cities that have a population greater than a certain threshold or which are capital cities of a country or island territory. The threshold varies from country to country, but in general is no higher than about 40,000. The data are available from originally obtained from Stefan Helders’ website http://www.world-gazetteer.com, which now redirects to http://www.populationmondale.com.

There are three supplied databases, world.cities (the default), us.cities and canada.cities. The latter two, which need to be made available by using a 'data()' call, include the state or province name with the city name (thanks to John Woodruff <jpwoodruff@irisinternet.net> for the state and province information).

Note that if the underlying map is "Pacific-centric", i.e. longitudes exceed 180 degrees, and a projection is used, then the map.cities data must be transformed appropriately.

Value

No value is returned from map.cities.

Side Effects

All cities within the boundaries of the plot containing the current map are added to the plot. Note that it is possible that the boundaries of the plot exceed the boundaries of the map requested, and so more cities than were expected might be shown.

world.cities, canada.cities, us.cities

Examples

map("world", "China")
map.cities(country = "China", capitals = 2)
map("state", "New Jersey")
data(us.cities)
map.cities(us.cities, country="NJ")
map.scale

Add Scale to Existing Unprojected Map

Description

Add a scale to an existing map, both as a ratio and a distance gauge.

Usage

map.scale(x, y, relwidth = 0.15, metric = TRUE, ratio = TRUE, ...)

Arguments

x

y

Location of left end of distance gauge. If not specified, this will be taken to be near the lower left corner of the map.

relwidth

Proportion of width of display to be used for the scale. The default is 0.15 (15%).

metric

If TRUE, the distance gauge will be in km, otherwise miles.

ratio

If FALSE, the scale ratio of the map is not displayed.

... Further plotting parameters may be specified as for the command text().

Details

The scale is calculated from the displayed graph’s plotting parameters, and the latitude of the location at which the distance gauge will be displayed.

Value

The exact calculated scale is returned.

NOTE

This function is meaningful only if no projection= has been specified in the call to map().

Side Effects

A scale is added to the currently displayed map. This takes the form of an approximate 1:n scale (containing 2-3 significant digits), above a distance gauge which is reasonably accurate for the latitude at which it appears. The circumference at the given latitude is interpolated from a radius of 6356.78 km at the pole and 6378.16 km at the equator.

map.axes
**map.text**

**Examples**

```r
map("world", "China")
map.scale()
```

```r
map.text(database, regions = ".", exact = FALSE, labels, cex = 0.75,
add = FALSE, move = FALSE, ...)
```

**Description**

Like `map`, but labels the regions.

**Usage**

```r
map.text(database, regions = ".", exact = FALSE, labels, cex = 0.75,
add = FALSE, move = FALSE, ...)
```

**Arguments**

- `database` character string naming a geographical database, or a list of x, y, and names obtained from a previous call to `map`.
- `regions` character vector that names the polygons to draw.
- `exact` If 'TRUE', only exact matches with 'regions' are selected for drawing.
- `labels` character vector of labels, one for each region selected. Defaults to the names in the database.
- `cex` character expansion factor.
- `add` If FALSE, a map is drawn, then labels placed on top. If TRUE, labels are added to the existing map.
- `move` If TRUE, labels are moved so that they don’t overlap. Requires the mining library (not in CRAN, contact tpminka@media.mit.edu).
- `...` Other arguments are the same as in `map`.

**Value**

If `add = FALSE`, a map is drawn by calling `map`. Then the label for each region is placed at the centroid of the region polygon.

The return value is a map object, as from `map`.

**Author(s)**

Tom Minka

**Examples**

```r
map.text("world", "ira")  # iran and iraq
map.text("state", "penn")
map.text("county", "penn")  # Pennsylvania counties
map.text("county", "new jersey")  # New Jersey counties
```
map.where  Locate points on a map

Description

Returns the region names containing given locations.

Usage

map.where(database = "world", x, y, ...)

Arguments

database  character string naming a geographical database, or a list of x, y, and names. See the documentation for map for more details.

x  vector of longitudes.

y  vector of latitudes.

...  Options for SpatialPolygons2map, only used if database is of type SpatialPolygonsDataFrame.

Value

A list of character strings, naming the map region that each (longitude, latitude) pair falls into.

Note

This function may give erroneous results if the database contains enclaves. For instance, a point in San Marino may also be identified as being in Italy.

in.polygon

Examples

# NYC
map.where("state", -73.8, 41)
# Auckland
map.where("nz", 174.6, -36.92)
# find both in the world
map.where(x = c(174.6, -73.8), y = c(-36.92, 41))
# with a map object:
 m = map("state", "new york", fill = TRUE, plot = FALSE)
map.where(m, -73.8, 41)
**match.map**

---

**Index map regions**

**Description**

Assigns an index to each map region, useful for map coloring.

**Usage**

match.map(database, regions, exact = FALSE, warn = TRUE)

**Arguments**

- **database**: character string naming a geographical database, or a map object. See the documentation for `map` for more details.
- **regions**: a vector of names, or more generally regular expressions to match against the map region names.
- **exact**: If TRUE, only exact matches with regions are considered. Otherwise each element of regions is assumed to be a regular expression. Matches are always case-insensitive.
- **warn**: If TRUE, a warning is printed when an element of regions matches nothing in the map.

**Value**

Returns an integer vector giving an index to each region in the database. The index is the index of the string in regions which matches the region name. Matching is done as in `map`. More specifically, all regions r whose name matches regions[i] will have index i. Unmatched regions will have index NA. Overlapping matches cause an error.

This behavior differs from `pmatch` because a single entry in regions may match several entries in the map.

Examples

```r
# filled map showing Republican vote in 1900
# (figure 6 in the reference)
data(state, package = "datasets")
data(votes.repub)
state.to.map <- match.map("state", state.name)
x <- votes.repub[state.to.map, "1900"]
gray.colors <- function(n) gray(rev(0:(n - 1))/n)
color <- gray.colors(100)[floor(x)]
map("state", fill = TRUE, col = color); map("state", add = TRUE)
```

---

`nz`  
*New Zealand Basic Map*

Description

This database produce a map of New Zealand at a basic level of detail. The “nz” database includes the 3 main Islands and 19 smaller coastal islands.

Usage

```r
data(nzMapEnv)
```

Format

The data file is merely a character string which specifies the name of an environment variable which contains the base location of the binary files used by the map drawing functions. This environment variable (R\_MAP\_DATA\_DIR for the datasets in the maps package) is set at package load time if it does not already exist. Hence setting the environment variable before loading the package can override the default location of the binary datasets.

References

See Also

`map`

Examples

```r
map('nz')
map('nz', xlim = c(166, 179), ylim = c(-48, -34))
```
Sample datasets

Description

Datasets used to illustrate map functions.
ozone contains the median of daily maxima ozone concentration in 41 US cities for June 1974 through August 1974. Concentrations are in parts per billion (ppb).
unemp Has population and unemployment percentage for US counties.
votes.repub contains the percentage republican votes in the 1900 election.

Usage

data(ozone)
data(unemp)
data(votes.repub)

References

Smooth out aggregated data

Description

Increases the resolution of data aggregated over map regions, by either smoothing or interpolation. Also fills in missing values.

Usage

smooth.map(m, z, res = 50, span = 1/10, averages = FALSE, type = c("smooth", "interp"), merge = FALSE)

Arguments

m a map object
z a named vector
res a vector of length two, specifying the resolution of the sampling grid in each dimension. If a single number, it is taken as the vertical resolution, with double taken as the horizontal resolution.
span

kernel parameter (larger = smoother). span = Inf is a special case which
invokes the cubic spline kernel. span is automatically scaled by the map size,
and is independent of res.

averages

If TRUE, the values in z are interpreted as averages over the regions. Otherwise
they are interpreted as totals.

type

see details.

merge

If TRUE, a region named in z includes all matching regions in the map (according
to match.map). If FALSE, a region named in z is assumed to refer to exactly one
region on the map.

Details

For type = "smooth", the region totals are first converted into point measurements on the sampling
grid, by dividing the total for a region among all sample points inside it. Then it is a regular kernel
smoothing problem. Note that the region totals are not preserved.

The prediction $z_o$ for location $x_o$ (a vector) is the average of $z$ for nearby sample points:

$$z_o = \frac{\sum_x k(x, x_o)z(x)}{\sum_x k(x, x_o)}$$

$$k(x, x_o) = exp(-\lambda ||x - x_o||^2)$$

$\lambda$ is determined from span. Note that $x_o$ is over the same sampling grid as $x$, but $z_o$ is not necessarily
the same as $z(x_o)$.

For type = "interp", the region totals are preserved by the higher-resolution function. The
function is assumed to come from a Gaussian process with kernel $k$. The measurement $z[r]$ is
assumed to be the sum of the function over the discrete sample points inside region $r$. This leads
to a simple formula for the covariance matrix of $z$ and the cross-covariance between
$z_o$ and $z$. The prediction is the cross-covariance times the inverse covariance times $z$.
Unlike Tobler’s method, the predictions are not constrained to live within the original data range, so there tends to be “ringing”
effects.

See the references for more details.

Value

A data frame with columns x, y, and z giving the smoothed value $z$ for locations (x, y). Currently
the (x, y) values form a grid, but this is not guaranteed in the future.

Author(s)

Tom Minka

References

W.F. Eddy and A. Mockus. An example of the estimation and display of a smoothly varying function
of time and space - the incidence of disease mumps. Journal of the American Society for Information

**Examples**

```r
# compare to the example for match.map
data(state, package = "datasets")
data(votes.repub)
z = votes.repub[, "1980"]
m = map("state", fill = TRUE, plot = FALSE)
# use a small span to fill in, but not smooth, the data
# increase the resolution to get better results
fit = smooth.map(m, z, span = 1/100, merge = TRUE, ave = TRUE)
mat = tapply(fit$z, fit[[1:2]], mean)
gray.colors <- function(n) gray(rev(0:(n - 1))/n)
par(bg = "blue")
filled.contour(mat, color.palette = gray.colors, nlev = 32, asp = 1)
# another way to visualize:
image(mat, col = gray.colors(100))

# for a higher degree of smoothing:
# fit = smooth.map(m, z, merge = TRUE, ave = TRUE)
# interpolation, state averages are preserved:
# fit = smooth.map(m, z, merge = TRUE, ave = TRUE, type = "interp")
```

**Spatial2map**

Read *SpatialPolygons and SpatialLines* objects

**Description**

These functions transform some classes provided by the package sp into a simple list that can be used by map().

**Usage**

```
SpatialPolygons2map(database, namefield=NULL)
SpatialLines2map(database, namefield=NULL)
```

**Arguments**

- `database` A `SpatialPolygons` or `SpatialLines` object.
- `namefield` The name of a data column in `database` to be used for naming the polygons (or lines). If it is a vector of names, these are all used and separated by a colon ":". Not case sensitive. So if the database contains columns that only differ by case, you get a warning and `namefield` is not used at all.

**Details**

The 'map' list object only preserves co-ordinates and polygon names. All other information available in the original data is lost.

The option `namefield` is only taken into account if `database` is class `Spatial[]DataFrame`. `namefield` may be a vector of column names, e.g. to get polygons named as 'country:state'.
Value

A list with four components: x, y, names, range, similar to the return value of map(). This data can be used as a database for map(). The lines and polygons are separated by NA.

state.fips

FIPS state codes for US 48 State Map

Description

A database matching FIPS codes to maps package state names.

Usage

data(state.fips)

Format

A list with 6 components, namely "fips", "ssa", "region", "division", "abb" and "polyname", containing the US Census Bureau FIPS, SSA, REGION and DIVISION numbers, the standard state abbreviation and the respective state polygon name. Note that "fips" is represented as an integer, so any leading zero (which is part of the fips code) is not shown by default.

map.

Examples

map('usa')
Description

This updated (2013) world map is imported from the Natural Earth project (the 1:50m resolution version). It replaces a much older version based on the CIA World Data Bank II data. That older version is still included in the package and can be reached as legacy_world.

Usage

data(worldMapEnv)

Format

The data file is merely a character string which specifies the name of an environment variable which contains the base location of the binary files used by the map drawing functions. This environment variable (R_MAP_DATA_DIR_WORLD) is set at package load time if it does not already exist. Hence setting the environment variable before loading the package can override the default location of the binary datasets.

During a transition period (maps version 3.0–1) it is possible to switch to the old legacy map using the function world.legacy(TRUE) or by setting the environment variable R_MAP_DATA_LEGACY=TRUE prior to loading the package.

Details

As of version 3.1, the world database no longer contains any lakes. These have been moved to a separate database called lakes.

Source

Examples

```
# notice how some polygons extend beyond the [-180,180] interval:
map('world', fill = TRUE, col = 1:10)
# if you wrap at [-180,180], you also can get a clean closure of Antarctica
map('world', fill = TRUE, col = 1:10, wrap=c(-180,180))
```

---

**world.cities**

*Database of world cities*

---

**Description**

This database is primarily of world cities of population greater than about 40,000. Also included are capital cities of any population size, and many smaller towns.

**Usage**

```
data(world.cities)
```

**Format**

A list with 6 components, namely "name", "country.etc", "pop", "lat", "long", and "capital", containing the city name, the country name, approximate population (as at January 2006), latitude, longitude and capital status indication (0 for non-capital, 1 for capital, 2 for China Municipalities, and 3 for China Provincial capitals)

**NOTE**

Some of the country names and city names may be out of date. Please send any corrections to the package maintainer.

**See Also**

*map.cities*

---

**world.legacy**

*Legacy world map*

---

**Description**

A function to switch the "world" map to the old (1990) version and back.

**Usage**

```
world.legacy(wl=FALSE)
```
Arguments

wl Set to TRUE to switch to the old world map. Set FALSE to switch back to the new map. In either case, the old legacy map can always be reached as legacy_world.

Details

This function switches the "world" database to the old (1990) version. It is provided temporarily for cases where the new updated world map causes problems. In this way, code may run unchanged and still use the legacy world data base. It is highly recommended, though, to use this possibility only as a last resource. Addressing legacy_world directly or updating code to use the new data base is the recommended option.

The new version is updated to about 2013, so has many new countries that did not exist in 1990 (e.g. in Central and Eastern Europe).

This function may be removed from the maps package in future releases. The legacy world database is also available directly as legacy_world.

See Also

map.world, legacy_world

---

**world2**  
*Pacific Centric Low resolution World Map*

Description

This is an alternative version of the world database based on latitudes [0, 360), which then has the Pacific Ocean in the centre of the map.

Usage

data(world2MapEnv)

Format

The data file is merely a character string which specifies the name of an environment variable which contains the base location of the binary files used by the map drawing functions. This environment variable (R_MAP_DATA_DIR_WORLD for the datasets in the maps package) is set at package load time if it does not already exist. Hence setting the environment variable before loading the package can override the default location of the binary datasets.
NOTE
This data set is in fact largely obsolete. Often the same (more general) result can be obtained by using wrapping:

```r
map("world", wrap=c(0,360))
```
This will also work fine with `fill=TRUE` or any other appropriate longitude interval (e.g. `c(-90,270)`). However, `world2` is useful when setting `xlim` to an interval crossing the 180 meridian.

Source
The Natural Earth data set is available from [http://www.naturalearthdata.com](http://www.naturalearthdata.com).

References
