Package ‘maptools’
August 24, 2020

Version 1.0-2
Date 2020-08-12
Title Tools for Handling Spatial Objects
Encoding UTF-8
Depends R (>= 2.10), sp (>= 1.0-11)
Imports foreign (>= 0.8), methods, grid, lattice, stats, utils, grDevices
Suggests rgeos (>= 0.1-8), spatstat (>= 1.60), PBSmapping, maps, RColorBrewer, raster, polyclip, spatstat.utils, plotrix
Enhances gpclib
Description Set of tools for manipulating geographic data. It includes binary access to ‘GSHHG’ shoreline files. The package also provides interface wrappers for exchanging spatial objects with packages such as ‘PBSmapping’, ‘spatstat’, ‘maps’, and others.
License GPL (>= 2)
URL http://maptools.r-forge.r-project.org/, http://r-forge.r-project.org/projects/maptools/

Description

Functions to convert between spatstat raster format im and sps SpatialGridDataFrame as well as one-way conversion from rasters rasterLayer to im. S4-style as() coercion can be used between im and SpatialGridDataFrame objects.
Usage

as.im.SpatialGridDataFrame(from)
as.SpatialGridDataFrame.im(from)
as.im.RasterLayer(from, factor.col.name = NULL)

Arguments

from     object to coerce from
factor.col.name     column name of levels(from) to be treated as a factor; if NULL defaults to last column of from. Ignored if from is not a raster with factor values.

Details

A SpatialGridDataFrame object may contain several columns of data such that several values are associated with each grid cell. In contrast an im object can only contain a single variable value for each cell. In as.im.SpatialGridDataFrame() the first data column is used. To convert another column to im format simply extract this column first as shown in the example below.

Methods

coerce signature(from = "SpatialGridDataFrame",to = "im")
coerce signature(from = "im",to = "SpatialGridDataFrame")

Warning

In spatstat all spatial objects are assumed to be planar. This means that spatstat is not designed to work directly with geographic (longitude and latitude) coordinates. If a sp object is declared to have geographic (unprojected) coordinates maptools refuses to convert directly to spatstat format. Rather, these should be projected first using e.g. spTransform. If you know what you are doing, and really want to force coercion, you can overwrite the proj4string of the sp object with NA, proj4string(x) <-CRS(NA), which will fool the system to think that the data is in local planar coordinates. This is probably not a good idea!

Description

Convert an object of class SpatialLines or SpatialLinesDataFrame (from package sp), representing a collection of polygonal lines, into an object of class linnet (from package spatstat), representing a network.

Usage

as.linnet.SpatialLines(X, ..., fuse = TRUE)

## S4 method for signature 'SpatialLines,linnet'
coerce(from, to = "linnet", strict = TRUE)

## S4 method for signature 'SpatialLinesDataFrame,linnet'
coerce(from, to = "linnet",
       strict = TRUE)

Arguments

X, from Object of class SpatialLines or SpatialLinesDataFrame to be converted.
to output object of class “linnet”.
strict logical flag. If TRUE, the returned object must be strictly from the target class.
... Ignored.
fuse Logical value indicating whether to join different curves which have a common vertex.

Details

This function converts an object of class SpatialLines or SpatialLinesDataFrame into an object of class linnet. It is not a method for the spatstat generic function as.linnet, but like other S4 coercion functions for sp classes to spatstat classes, it may be called directly as a function.

An object of class SpatialLines or SpatialLinesDataFrame (from package sp) represents a list of lists of the coordinates of lines, such as a list of all roads in a city. An object of class linnet in the spatstat package represents a linear network, such as a road network.

If fuse=FALSE, each “Line” object in X will be treated as if it were disconnected from the others. The result is a network that consists of many disconnected sub-networks, equivalent to the list of “Line” objects.

If fuse=TRUE (the default), the code will search for identical pairs of vertices occurring in different “Line” objects, and will treat them as identical vertices, effectively joining the two “Line” objects at this common vertex.

If X belongs to class SpatialLinesDataFrame, the associated columns of data in the auxiliary data frame slot(X,"data") will be copied to the output as the marks attached to the line segments of the network. See the Examples.

Value

An object of class linnet.

  print(max(vertexdegree(L0)))
}
if (run) {
  ## extract data associated with each network segment
  head(marks(as.psp(L)))
}
if (run) {
  fname <- file.path(dname, "fylk-val-ll.shp")
  fylk <- readShapeSpatial(fname, proj4string=CRS("+proj=longlat +ellps=WGS84"))
  is.projected(fylk)
}
if (run) {
  try(L <- as(fylk, "linnet"))
}

Description

Functions to convert between spatstat observation window (owin) format and various sp formats. S4-style as() coercion can be used as well.
Usage

as.owin.SpatialPolygons(W, ..., fatal)
as.owin.SpatialGridDataFrame(W, ..., fatal)
as.owin.SpatialPixelsDataFrame(W, ..., fatal)
as.SpatialPolygons.owin(x)

Arguments

W SpatialPolygons object to coerce to owin
x owin object to coerce to SpatialPolygons format
... ignored
fatal formal coercion argument; ignored

Details

An observation window in spatstat defines a planar region. It is typically used to represent a sampling region. It comes in three different formats: a simple rectangle, a polygon (vector format) or a binary mask (TRUE/FALSE grid; raster format). These can all be coerced to polygonal form internally in spatstat and then converted to SpatialPolygons, which is what as.SpatialPolygons.owin() does. For objects of class SpatialPolygons (and SpatialPolygonsDataFrame) the sp polygons are simply extracted and cast into spatstats polygon format inside the owin object. For SpatialPixelsDataFrame and SpatialGridDataFrame the grid is extracted and cast into spatstats mask format inside the owin object. In all cases any data apart from the spatial region itself are discarded.

Methods

coerce signature(from = "SpatialPolygons",to = "owin")
coerce signature(from = "SpatialPixelsDataFrame",to = "owin")
coerce signature(from = "SpatialGridDataFrame",to = "owin")
coerce signature(from = "owin",to = "SpatialPolygons")

Warning

In spatstat all spatial objects are assumed to be planar. This means that spatstat is not designed to work directly with geographic (longitude and latitude) coordinates. If a sp object is declared to have geographic (unprojected) coordinates maptools refuses to convert directly to spatstat format. Rather, these should be projected first using e.g. spTransform. If you know what you are doing, and really want to force coercion, you can overwrite the proj4string of the sp object with an empty string, proj4string(x) <- "", which will fool the system to think that the data is in local planar coordinates. This is probably not a good idea!

Note

When coercing a SpatialPolygons object to an owin object, full topology checking is enabled by default. To avoid checking, set spatstat.options(checkpolygons=FALSE) (from spatstat (1.14-6)). To perform the checking later, owinpolycheck(W,verbose=TRUE).
as.ppp

Coercion between sp objects and spatstat ppp objects

Description

Functions to convert between \texttt{spatstat} planar point pattern (\texttt{ppp}) format and \texttt{sp} \texttt{SpatialPoints} and \texttt{SpatialPointsDataFrame} as well as one-way conversion from \texttt{SpatialGridDataFrame} to \texttt{ppp}. S4-style \texttt{as()} coercion can be used as well.
Usage

as.ppp.SpatialPoints(X)
as.ppp.SpatialPointsDataFrame(X)
as.SpatialPoints.ppp(from)
as.SpatialPointsDataFrame.ppp(from)
as.SpatialGridDataFrame.ppp(from)

Arguments

from, X  object to coerce from

Details

The main conversion is between sps SpatialPoints/SpatialPointsDataFrame and spatstats ppp. Conversion between SpatialGridDataFrame and ppp should rarely be used; using as.owin.SpatialGridDataFrame is more transparent.

Methods

coerce  signature(from = "SpatialPoints", to = "ppp")
coerce  signature(from = "SpatialPointsDataFrame", to = "ppp")
coerce  signature(from = "ppp", to = "SpatialGridDataFrame")
coerce  signature(from = "ppp", to = "SpatialPointsDataFrame")
coerce  signature(from = "ppp", to = "SpatialPoints")

Warning

In spatstat all spatial objects are assumed to be planar. This means that spatstat is not designed to work directly with geographic (longitude and latitude) coordinates. If a sp object is declared to have geographic (unprojected) coordinates maptools refuses to convert directly to spatstat format. Rather, these should be projected first using e.g. spTransform. If you know what you are doing, and really want to force coercion, you can overwrite the proj4string of the sp object with NA, proj4string(x) <- CRS(NA), which will fool the system to think that the data is in local planar coordinates. This is probably not a good idea!

Note

The ppp format requires an observation window which is the sampling region. The sp formats contain no such information and by default the bounding box of the points is simply used. This is almost never the correct thing to do! Rather, information about the sampling region should be converted into spatstats owin format and assigned as the observation window. Usually conversion from ppp to sp format simply discards the owin. However, as.SpatialGridDataFrame.ppp actually first discards the points(!), second checks that the corresponding owin is in a grid format (matrix of TRUE/FALSE for inside/outside sampling region), and finally converts the TRUE/FALSE grid to a SpatialGridDataFrame.

Examples

run <- FALSE
if (require(spatstat, quietly=TRUE)) run <- TRUE
if (run) {
## Convert SpatialPointsDataFrame into a marked ppp
data(meuse)
coordinates(meuse) = ~x+y
meuse_ppp <- as(meuse, "ppp")
meuse_ppp # Window is the bounding rectangle
}
if (run) {
plot(meuse_ppp, which.marks = "zinc")
}
if (run) {
## Convert SpatialPoints into an unmarked ppp
meuse2 <- as(meuse, "SpatialPoints")
as(meuse2, "ppp")
}
if (run) {
## Get sampling region in grid format and assign it as observation window
data(meuse.grid)
gridded(meuse.grid) = ~x+y
mg_owin <- as(meuse.grid, "owin")
Window(meuse_ppp) <- mg_owin
meuse_ppp # Window is now a binary image mask (TRUE/FALSE grid)
}
if (run) {
plot(meuse_ppp, which.marks = "zinc")
}
if (run) {
## Convert marked ppp back to SpatialPointsDataFrame
rev_ppp_SPDF <- as.SpatialPointsDataFrame.ppp(meuse_ppp)
summary(rev_ppp_SPDF)
}
if (run) {
## Convert marked ppp back to SpatialPoints (discarding marks)
rev_ppp_SP <- as.SpatialPoints.ppp(meuse_ppp)
summary(rev_ppp_SP)
}
if (run) {
## Convert marked ppp back to SpatialGridDataFrame (extracting the window grid)
rev_ppp_SGDF <- as.SpatialGridDataFrame.ppp(meuse_ppp)
summary(rev_ppp_SGDF)
}

Coercion between sp objects and spatstat psp objects
Description

Functions to convert between \texttt{spatstat} planar segment pattern (psp) format and various \texttt{sp} line formats. S4-style \texttt{as()} coercion can be used as well.

Usage

\begin{verbatim}
as.psp.Line(from, ..., window=NULL, marks=NULL, fatal)
as.psp.Lines(from, ..., window=NULL, marks=NULL, fatal)
as.psp.SpatialLines(from, ..., window=NULL, marks=NULL, characterMarks = FALSE, fatal)
as.psp.SpatialLinesDataFrame(from, ..., window=NULL, marks=NULL, fatal)
as.SpatialLines.psp(from)
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{from} object to coerce from
  \item \texttt{...} ignored
  \item \texttt{window} window of class \texttt{owin} as defined in the \texttt{spatstat} package
  \item \texttt{marks} marks as defined in the \texttt{spatstat} package
  \item \texttt{characterMarks} default FALSE, if TRUE, do not convert NULL marks to factor from character
  \item \texttt{fatal} formal coercion argument; ignored
\end{itemize}

Methods

\begin{verbatim}
coerce signature(from = "Line",to = "psp")
coerce signature(from = "Lines",to = "psp")
coerce signature(from = "SpatialLines",to = "psp")
coerce signature(from = "SpatialLinesDataFrame",to = "psp")
coerce signature(from = "psp",to = "SpatialLines")
\end{verbatim}

Warning

In \texttt{spatstat} all spatial objects are assumed to be planar. This means that \texttt{spatstat} is not designed to work directly with geographic (longitude and latitude) coordinates. If a \texttt{sp} object is declared to have geographic (unprojected) coordinates \texttt{maptools} refuses to convert directly to \texttt{spatstat} format. Rather, these should be projected first using e.g. \texttt{spTransform}. If you know what you are doing, and really want to force coercion, you can overwrite the \texttt{proj4string} of the \texttt{sp} object with \texttt{NA}, \texttt{proj4string(x) <- CRS(NA)}, which will fool the system to think that the data is in local planar coordinates. This is probably not a good idea!

as.SpatialPolygons.tess

Coercion of spatstat tess object to sp SpatialPolygons object

Description

This function coerces spatstat tessellation objects of class tess to sps SpatialPolygons class. S4-style as() coercion works as well.

Usage

as.SpatialPolygons.tess(x)
Arguments

x

spatstat object of class tess to coerce from

Methods

coerce signature(from = "tess", to = "SpatialPolygons")

Author(s)

Edzer Pebesma <edzer.pebesma@uni-muenster.de>, Roger Bivand

Examples

run <- FALSE
if (require(spatstat, quietly=TRUE)) run <- TRUE
if (run) {
  A <- tess(xgrid=0:4, ygrid=0:4)
  A_sp <- as(A, "SpatialPolygons")
  plot(A_sp)
  text(coordinates(A_sp), labels=row.names(A_sp), cex=0.6)
}

CCmaps  Conditioned choropleth maps

Description

Conditioned choropleth maps permit the conditioning of a map of a variable on the values of one or two other variables coded as factors or shingles. This function uses spplot after constructing multiple subsets of the variable of interest defined by the intervals given by the conditioning variables.

Usage

CCmaps(obj, zcol = NULL, cvar = NULL, cvar.names = NULL, ..., names.attr,
       scales = list(draw = FALSE), xlab = NULL, ylab = NULL,
       aspect = mapasp(obj, xlim, ylim), sp.layout = NULL, xlim = bbox(obj)[1, ],
       ylim = bbox(obj)[2, ])

Arguments

obj  object of class SpatialPolygonsDataFrame
zcol single variable name as string
cvar a list of one or two conditioning variables, which should be of class factor or shingle
cvar.names names for conditioning variables, if not given, the names of the variables in the cvar list
... other arguments passed to spplot and levelplot
names.attr  names to use in panel, if different from zcol names
scales  scales argument to be passed to Lattice plots; use list(draw = TRUE) to draw axes scales
xlab  label for x-axis
ylab  label for y-axis
aspect  aspect ratio for spatial axes; defaults to "iso" (one unit on the x-axis equals one unit on the y-axis) but may be set to more suitable values if the data are e.g. if coordinates are latitude/longitude
sp.layout  NULL or list; see spplot
xlim  numeric; x-axis limits
ylim  numeric; y-axis limits

Value
The function returns a SpatialPolygonsDataFrame object with the zcol variable and the partitions of the cvars list variables invisibly.

CCmaps(nc.sids, "ft.SID74", list("Nonwhite_births"=sh_nw4), col.regions=colorRampPalette(c("yellow1", "brown3"))(20), main="Transformed SIDS rates 1974-8")
```
checkPolygonsHoles  

Description

The function checks holes in Polygons objects. Use of the rgeos package functions is preferred, and if rgeos is available, they will be used automatically. In this case, member Polygon objects are checked against each other for containment, and the returned Polygons object has component hole slots set appropriately. In addition, the output Polygons object may be provided with a comment string, encoding the external and internal rings. For gpclib use, see details below.

Usage

checkPolygonsHoles(x, properly=TRUE, avoidGEOS=FALSE, useSTRtree=FALSE)
gpclibPermitStatus()  
gpclibPermit()  
rgeosStatus()

Arguments

x  
An Polygons object as defined in package sp

properly  
default TRUE, use gContainsProperly rather than gContains

avoidGEOS  
default FALSE; if TRUE force use of gpclib even when rgeos is available

useSTRtree  
default FALSE, if TRUE, use rgeos STRtree in checking holes, which is much faster, but uses a lot of memory and does not release it on completion (work in progress)

Details

If the gpclib package is used, an intersection between a gpc.poly object with one or more polygon contours and its bounding box is used to set the hole flag. The function will set single polygon contours to hole=FALSE, and if multiple polygon contours are holes, will set them TRUE. The gpclibPermit function is used to choose to permit the use of gpclib if installed, and gpclibPermitStatus reports its status. The licence for gpclib is not Free or Open Source and explicitly forbids commercial use. See library(help=gpclib).

Value

An Polygons object re-created from the input object.

  p11 <- Polygon(cbind(x=c(24.25, 24.25, 25.75, 25.75, 24.25),
                        y=c(24.25, 25.75, 25.75, 24.25, 24.25))) # H
  p12 <- Polygon(cbind(x=c(24.5, 24.5, 25.5, 25.5, 24.5),
                        y=c(24.5, 25.5, 25.5, 24.5, 24.5))) # I
  p13 <- Polygon(cbind(x=c(24.75, 24.75, 25.25, 25.25, 24.75),
                        y=c(24.75, 25.25, 25.25, 24.75, 24.75)))
```
ContourLines2SLDF

Converter functions to build SpatialLinesDataFrame objects

Description

These functions show how to build converters to SpatialLinesDataFrame objects: ArcObj2SLDF from the list returned by the get.arcdata function in the RArcInfo package; ContourLines2SLDF from the list returned by the contourLines function in the graphics package (here the data frame is just the contour levels, with one Lines object made up of at least one Line object per level); and MapGen2SL reads a file in "Mapgen" format into a SpatialLines object.

Usage

ArcObj2SLDF(arc, proj4string=CRS(as.character(NA)), IDs)
ContourLines2SLDF(cL, proj4string=CRS(as.character(NA)))
MapGen2SL(file, proj4string=CRS(as.character(NA)))

Arguments

arc a list returned by the get.arcdata function in the RArcInfo package
IDs vector of unique character identifiers; if not given, suitable defaults will be used, and the same values inserted as data slot row names
cL a list returned by the contourLines function in the graphics package
proj4string Object of class "CRS": see CRS-class
file filename of a file containing a Mapgen line data set

Value

A SpatialLinesDataFrame object
Note

Coastlines of varying resolution may be chosen online and downloaded in "Mapgen" text format from https://www.ngdc.noaa.gov/mgg/shorelines/shorelines.html, most conveniently using the interactive selection tool, but please note the 500,000 point limit on downloads, which is easy to exceed.

#res <- arcobj2SLDF(arc)
#plot(res)
#invisible(title(""))
res <- ContourLines2SLDF(contourLines(volcano))
plot(res, col=terrain.colors(nrow(as(res, "data.frame"))))
title("Volcano contours as SpatialLines")
```

dotsInPolys

Put dots in polygons

Description

Make point coordinates for a dot density map

Usage

dotsInPolys(pl, x, f = "random", offset, compatible = FALSE)

Arguments

- `pl`: an object of class SpatialPolygons or SpatialPolygonsDataFrame
- `x`: integer vector of counts of same length as `pl` for dots
- `f`: type of sampling used to place points in polygons, either "random" or "regular"
- `offset`: for regular sampling only: the offset (position) of the regular grid; if not set, `c(0.5, 0.5)`, that is the returned grid is not random
compatible  what to return, if TRUE a a list of matrices of point coordinates, one matrix for each member of pl, if false a SpatialPointsDataFrame with polygon ID values

Details

With f="random", the dots are placed in the polygon at random, f="regular" - in a grid pattern (number of dots not guaranteed to be the same as the count). When the polygon is made up of more than one part, the dots will be placed in proportion to the relative areas of the clockwise rings (anticlockwise are taken as holes). From maptools release 0.5-2, correction is made for holes in the placing of the dots, but depends on hole values being correctly set, which they often are not.

Value

If compatible=TRUE, the function returns a list of matrices of point coordinates, one matrix for each member of pl. If x[i] is zero, the list element is NULL, and can be tested when plotting - see the examples. If compatible=FALSE (default), it returns a SpatialPointsDataFrame with polygon ID values as the only column in the data slot.

Note

Waller and Gotway (2004) Applied Spatial Statistics for Public Health Data (Wiley, Hoboken, NJ) explicitly warn that care is needed in plotting and interpreting dot density maps (pp. 81-83)

Examples

```r
nc_SP <- readShapePoly(system.file("shapes/sids.shp", package="maptools")[[1]],
                      proj4string=CRS("+proj=longlat +ellps=clrk66"))
## Not run:
pls <- slot(nc_SP, "polygons")
pls_new <- lapply(pls, checkPolygonsHoles)
nc_SP <- SpatialPolygonsDataFrame(SpatialPolygons(pls_new,
                      proj4string=CRS(proj4string(nc_SP))), data=as(nc_SP, "data.frame"))
## End(Not run)
try1 <- dotsInPolys(nc_SP, as.integer(nc_SP$SID74))
plot(nc_SP, axes=TRUE)
plot(try1, add=TRUE, pch=18, col="red")
try2 <- dotsInPolys(nc_SP, as.integer(nc_SP$SID74), f="regular")
plot(nc_SP, axes=TRUE)
plot(try2, add=TRUE, pch=18, col="red")
```
elide-methods

Methods for Function elide in Package ‘maptools’

Description

Methods for function elide to translate and disguise coordinate placing in the real world.

Usage

elide(obj, ...)

Arguments

obj object to be elided

... other arguments:
  bb if NULL, uses bounding box of object, otherwise the given bounding box
  shift values to shift the coordinates of the input object; this is made ineffective by the scale argument
  reflect reverse coordinate axes
  scale if NULL, coordinates not scaled; if TRUE, the longer dimension is scaled to lie within [0,1] and aspect maintained; if a scalar, the output range of [0,1] is multiplied by scale
  flip translate coordinates on the main diagonal
  rotate default 0, rotate angle degrees clockwise around center
  center default NULL, if not NULL, the rotation center, numeric of length two
  unitsq logical, default FALSE, if TRUE and scale TRUE, impose unit square bounding box (currently only points)

Value

The methods return objects of the input class object with elided coordinates; the coordinate reference system is not set. Note that if the input coordinates or centroids are in the data slot data.frame of the input object, they should be removed before the use of these methods, otherwise they will betray the input positions.

Methods

obj = "SpatialPoints" elides object
obj = "SpatialPointsDataFrame" elides object
obj = "SpatialLines" elides object
obj = "SpatialLinesDataFrame" elides object
obj = "SpatialPolygons" elides object
obj = "SpatialPolygonsDataFrame" elides object
Note

Rotation code kindly contributed by Don MacQueen

Examples

```r
data(meuse)
coordinates(meuse) <- c("x", "y")
proj4string(meuse) <- CRS("+init=epsg:28992")
data(meuse.riv)
river_polygon <- Polygons(list(Polygon(meuse.riv)), ID="meuse")
rivers <- SpatialPolygons(list(river_polygon))
proj4string(rivers) <- CRS("+init=epsg:28992")
rivers1 <- elide(rivers, reflect=c(TRUE, TRUE), scale=TRUE)
meuse1 <- elide(meuse, bb=bbox(rivers), reflect=c(TRUE, TRUE), scale=TRUE)
opar <- par(mfrow=c(1,2))
plot(rivers, axes=TRUE)
plot(meuse, add=TRUE)
plot(rivers1, axes=TRUE)
plot(meuse1, add=TRUE)
par(opar)
meuse1 <- elide(meuse, shift=c(10000, -10000))
bbox(meuse)
bbox(meuse1)
rivers1 <- elide(rivers, shift=c(10000, -10000))
bbox(rivers)
bbox(rivers1)
meuse1 <- elide(meuse, rotate=-30, center=apply(bbox(meuse), 1, mean))
bbox(meuse)
bbox(meuse1)
plot(meuse1, axes=TRUE)
```

---

gcDestination

Find destination in geographical coordinates

Description

Find the destination in geographical coordinates at distance dist and for the given bearing from the starting point given by lon and lat.

Usage

```r
gcDestination(lon, lat, bearing, dist, dist.units = "km", model = NULL, Vincenty = FALSE)
```

Arguments

- `lon` longitude (Eastings) in decimal degrees (either scalar or vector)
- `lat` latitude (Northings) in decimal degrees (either scalar or vector)
The bearing argument may be a vector when lon and lat are scalar, representing a single point.

A matrix of decimal degree coordinates with Eastings in the first column and Northings in the second column.

Eric Archer and Roger Bivand

Examples
data(state)res <- gcDestination(state.center$x, state.center$y, 45, 250, "km")plot(state.center$x, state.center$y, asp=1, pch=16)arrows(state.center$x, state.center$y, res[,1], res[,2], length=0.05)llist <- vector(mode="list", length=length(state.center$x))for (i in seq(along=llist)) llist[[i]] <- gcDestination(state.center$x[i], state.center$y[i], seq(0, 360, 5), 250, "km")plot(state.center$x, state.center$y, asp=1, pch=3)nll <- lapply(llist, lines)
getinfo.shape

Get shapefile header information

Description

Get shapefile header information; the file should be given including its ".shp" extension, and the function will reconstruct the names of the database (dbf) file and the index (shx) file from these.

Usage

getinfo.shape(filen)
## S3 method for class 'shapehead'
print(x, ...)

Arguments

filen name of file with *.shp extension
x a shapehead list as returned by getinfo.shape
... other arguments passed to print

Details

The function calls code from shapelib to read shapefiles, a file format used by ESRI GIS software among others.

Value

The function returns a list of class shapehead.

Author(s)

Roger Bivand <Roger.Bivand@nhh.no>; shapelib by Frank Warmerdam

Examples

res <- getinfo.shape(system.file("shapes/fylk-val.shp", package="maptools")[[1]])
res
str(res)
**getKMLcoordinates**

*Get a list of coordinates out of a KML file*

**Description**

This function parses a KML file to get the content of `<coordinates>` tags and returns a list of matrices representing the longitude-latitude or if `ignoreAltitude` is `FALSE` the longitude-latitude-altitude coordinates of a KML geometry.

**Usage**

```r
getKMLcoordinates(kmlfile, ignoreAltitude=FALSE)
```

**Arguments**

- **kmlfile**: connection object or a character string of the KML file
- **ignoreAltitude**: if set to `TRUE` the altitude values of a KML points will be ignored

**Value**

`coords` is a list of matrices representing the longitude-latitude or if `ignoreAltitude` is `FALSE` the longitude-latitude-altitude coordinates

**Author(s)**

Hans-J. Bibiko

**See Also**

`kmlPolygon`, `kmlLine`

**Examples**

```r
data(wrld_simpl)
## creates a KML file containing the polygons of South Africa (plus hole)
sw <- slot(wrld_simpl[wrld_simpl$NAME=="South Africa", , "polygons"])[[1]]

tf <- tempfile()
kmlPolygon(sw, kmlfile=tf, name="South Africa", col="#df0000aa", lwd=5,
border=4, kmlname="R Test",
kmldescription="This is <b>only</b> a <a href="http://www.r-project.org">R</a> test.")
zz <- getKMLcoordinates(tf, ignoreAltitude=TRUE)
str(zz)
zz <- getKMLcoordinates(system.file("shapes/Testing.kml", package="maptools"))
str(zz)
```
Description

The function sets up metadata in the form of a SpatialGrid object for defining the size and placing of a PNG image overlay in Google Earth. The internal function Sobj_SpatialGrid can also be called to build a grid for arbitrary Spatial* objects.

Usage

GE_SpatialGrid(obj, asp = NA, maxPixels = 600)
Sobj_SpatialGrid(obj, asp=1, maxDim=100, n=NULL)

Arguments

obj a Spatial* object
asp if NA, will be set to the latitude corrected value
maxPixels the maximum dimension of the output PNG
maxDim the maximum dimension of the output grid; ignored if n not NULL
n if not NULL, the minimum number of cells in the returned grid

Details

The function is used together with kmlOverlay to wrap around the opening of a PNG graphics device, plotting code, and the closing of the device. The computed values take account of the adjustment of the actual data bounding box to an integer number of rows and columns in the image file.

The approach may be used as an alternative to writing PNG files from SpatialGrid and SpatialPixel objects in rgdal using writeGDAL, and to writing KML files using writeOGR for vector data objects. The output PNG files are likely to be very much smaller than large vector data KML files, and hinder the retrieval of exact positional information.

Note that the geometries should be in geographical coordinates with datum WGS84 for export to KML.

Value

returns an S3 object of class GE_SG with components:

height Integer raster height for png call
width Integer raster width for png call
SG a SpatialGrid object with the grid topology of the output PNG
asp the aspect value used
xlim xlim taken from SG
ylim ylim taken from SG

## End(Not run)
options(example.ask=opt_exask)
```

Description

How to plot polygons with holes - holes are encoded by coordinates going anticlockwise, and overplotting is avoided by re-ordering the order in which polygons are plotted.

This example is retained for historical interest only, other solutions are present in the sp package.

Usage

data(gpcholes)
Details

"Date: Tue, 11 May 2004 12:54:20 +0900 From: Hisaji ONO To: r-help
I've tried to create a polygon with one hole by gpclib using following example script.
holepoly <- read.polyfile(system.file("poly-ex/hole-poly.txt", package="gpclib"), nohole = FALSE)
area.poly(holepoly) plot(holepoly,poly.args=list(col="red",border="blue"))
And I noticed plot function couldn't draw polygons with holes correctly.
Does anyone know how to solve this situation?"
*(h1pl has reversed the y component of polygon 1, to make its ring direction clockwise, h2pl re-
verses the order of the two polygons in holepoly1@pts)*

Source

Data file included in "gpclib" package.

Examples

data(gpcholes)
opar <- par(mfrow=c(1,2))
plot(SpatialPolygons(list(h2pl)), col="red", pbg="white", border="blue")
plot(SpatialPolygons(list(h1pl)), col="red", pbg="white", border="blue")
par(opar)

gzAzimuth Find azimuth for geographical coordinates

Description

The function finds azimuth values for geographical coordinates given as decimal degrees from the
from coordinates to the to coordinate. In function trackAzimuth, the azimuth values are found
between successive rows of the input coordinate matrix.

Usage

gzAzimuth(from, to, type = "snyder_sphere")
trackAzimuth(track, type="snyder_sphere")

Arguments

from a two column matrix of geographical coordinates given as decimal degrees (longi-
tude first)
track a two column matrix of geographical coordinates given as decimal degrees (longi-
tude first)
to a one row, two column matrix or two element vector of geographical coordinates
given as decimal degrees (longitude first)
type default is "snyder_sphere", otherwise "abdali"; the results should be identi-
cal with slightly less trigonometry in "abdali"
The azimuth is calculated on the sphere, using the formulae given by Snyder (1987, p. 30) and Abdali (1997, p. 17). The examples use data taken from Abdali (p. 17–18). There is a very interesting discussion of the centrality of azimuth-finding in the development of mathematics and mathematical geography in Abdali’s paper. Among others, al-Khwarizmi was an important contributor. As Abdali puts it, “This is a veritable who’s who of medieval science” (p. 3).

Values in decimal degrees - zero is North - of the azimuth from the from coordinates to the to coordinate.

kmlLine

Create and write a KML file on the basis of a given Lines object

Description
The function is used to create and write a KML file on the basis of a given Lines object (a list of Line objects) for the usage in Google Earth resp. Google Maps.

Usage
```r
kmlLine(obj=NULL, kmlfile=NULL, 
   name="R Line", description="", col=NULL, visibility=1, lwd=1, 
   kmlname="", kmldescription="")
```
Arguments

obj  a Lines or SpatialLinesDataFrame object
kmlfile  if not NULL the name as character string of the kml file to be written
name  the name of the KML line
description  the description of the KML line (HTML tags allowed)
col  the stroke color (see also Color Specification) of the KML line
visibility  if set to 1 or TRUE specifies that the KML line should be visible after loading
lwd  the stroke width for the KML line
kmlname  the name of the KML layer
kmldescription  the description of the KML layer (HTML tags allowed)

Details

The function is used to convert a given Lines object (a list of Line objects) or the first Lines object listed in a passed SpatialLinesDataFrame object into KML line(s). If kmlfile is not NULL the result will be written into that file. If kmlfile is NULL the generated KML lines will be returned (see also value).

For a passed Lines object the function generates a <Style> tag whereby its id attribute is set to the passed object’s ID.

Note that the geometries should be in geographical coordinates with datum WGS84.

The resulting KML line will be embedded in <Placemark><MultiGeometry><LineString>.

Value

x is a list with the elements style and content containing the generated lines of the KML file as character vectors if kmlfile is NULL.

y is a list with the elements header and footer representing the KML file’ header resp. footer if obj is NULL.

Color Specification

The following color specifications are allowed: 'red', 2, or as hex code '#RRGGBB' resp. '#RRGGBBAA' for passing the alpha value.

```r
xx <- readShapeSpatial(system.file("shapes/fylk-val-ll.shp", package="maptools")[[1]], proj4string=CRS("+proj=longlat +ellps=WGS84"))
out <- sapply(slot(xx, "lines"), function(x) { kmlLine(x, name=slot(x, "ID"), col="blue", lwd=1.5, description=paste("river:" , slot(x, "ID")) })
```

```r
tf <- tempfile()
kmlFile <- file(tf, "w")
tf
cat(kmlLine(kmlname="R Test", kmldescription="<i>Hello</i">$header, file=kmlFile, sep="\n")
cat(unlist(out["style",]), file=kmlFile, sep="\n")
cat(unlist(out["content",]), file=kmlFile, sep="\n")
cat(kmlLine()$footer, file=kmlFile, sep="\n")
close(kmlFile)
```

---

**kmlLines**

Create and write a KML file on the basis of a given Lines object

**Description**

The function is used to create and write a KML file on the basis of a given Lines object (a list of Line objects) for the usage in Google Earth and Google Maps.

**Usage**

```r
kmlLines(obj=NULL, kmlfile=NULL,
         name="R Lines", description="", col=NULL, visibility=1, lwd=1,
         kmlname="", kmldescription="")
```

**Arguments**

- **obj** a Lines or SpatialLinesDataFrame object
- **kmlfile** if not NULL the name as character string of the kml file to be written
- **name** the name of the KML line
- **description** the description of the KML line (HTML tags allowed)
- **col** the stroke color (see also Color Specification) of the KML line
- **visibility** if set to 1 or TRUE specifies that the KML line should be visible after loading
- **lwd** the stroke width for the KML line
- **kmlname** the name of the KML layer
- **kmldescription** the description of the KML layer (HTML tags allowed)
Details

The function is used to convert a given Lines object (a list of Line objects) or the first Lines object listed in a passed SpatialLinesDataFrame object into KML line(s). If kmlfile is not NULL the result will be written into that file. If kmlfile is NULL the generated KML lines will be returned (see also value). Function no longer uses append greatly improving performance on large objects or lists.

For a passed Lines object the function generates a <Style> tag whereby its id attribute is set to the passed object's ID.

Note that the geometries should be in geographical coordinates with datum WGS84.

The resulting KML line will be embedded in <Placemark><MultiGeometry><LineString>.

Value

x is a list with the elements style and content containing the generated lines of the KML file as character vectors if kmlfile is NULL.

y is a list with the elements header and footer representing the KML file header and footer if obj is NULL.

Color Specification

The following color specifications are allowed: 'red', 2, or as hex code '#RRGGBB' resp. '#RRGGBBAA' for passing the alpha value.

kmlOverlay

Create and write KML file for PNG image overlay

Description

The function is used to create and write a KML file for a PNG image overlay for Google Earth.

Usage

kmlOverlay(obj, kmlfile = NULL, imagefile = NULL, name = "R image")

Arguments

- **obj**: a GE_SG object from GE_SpatialGrid
- **kmlfile**: if not NULL the name of the kml file to be written
- **imagefile**: the name of the PNG file containing the image - this should be either relative (same directory as kml file) or absolute (fully qualified)
- **name**: the name used to describe the image overlay in GE

Details

The function is used together with GE_SpatialGrid to wrap around the opening of a PNG graphics device, plotting code, and the closing of the device. The computed values take account of the adjustment of the actual data bounding box to an integer number of rows and columns in the image file.

The approach may be used as an alternative to writing PNG files from SpatialGrid and SpatialPixel objects in rgdal using writeGDAL, and to writing KML files using writeOGR for vector data objects. The output PNG files are likely to be very much smaller than large vector data KML files, and hinder the retrieval of exact positional information.

Note that the geometries should be in geographical coordinates with datum WGS84.

Value

- **x**: a character vector containing the generated lines of the kml file

```

**kmlPoints**

Create and write a KML file on the basis of a given Points object

Description

The function is used to create and write a KML file on the basis of a given SpatialPointsDataFrame object for the usage in Google Earth resp. Google Maps.

Usage

```r
kmlPoints(obj=NULL, kmlfile=NULL, kmlname="", kmldescription="",
   name=NULL, description="”,
```

Arguments

- `obj` a SpatialPointsDataFrame object
- `kmlfile` if not NULL the name as character string of the kml file to be written
- `kmlname` the name of the KML layer
- `kmldescription` the description of the KML layer (HTML tags allowed)
- `name` a character vector to be used as names for each KML Placemark
- `description` a character vector to be used as the description for each KML Placemark (HTML tags allowed)
- `icon` a character vector of icon URLs to be used in the style associated with each KML Placemark
Details

The function is used to convert a given SpatialPointsDataFrame object into a series of KML Placemarks, each with a single Point. If kmlfile is not NULL the result will be written into that file. If kmlfile is NULL the generated KML lines will be returned (see also value).

If name=NULL, the <name> tag for each Placemark will be ‘site #’. If a single value is used for name or description, that value will be replicated for each Placemark. If a single value is used for icon, only a single style will be created and that style will be referenced by each Placemark.

Note that the geometries should be in geographical coordinates with datum WGS84.

Value

x is a list with the elements style and content containing the generated lines of the KML file as character vectors if kmlfile is NULL.

y is a list with the elements header and footer representing the KML file’ header resp. footer if obj is NULL.

kmlPolygon

Create and write a KML file on the basis of a given Polygons object

Description

The function is used to create and write a KML file on the basis of a given Polygons object (a list of Polygon objects) for the usage in Google Earth resp. Google Maps.

Usage

kmlPolygon(obj=NULL, kmlfile=NULL,
name="R Polygon", description="", col=NULL, visibility=1, lwd=1, border=1,
kmlname="", kmldescription="")

Arguments

<table>
<thead>
<tr>

<tr>
<td>kmlname</td>
<td>the name of the KML layer</td>
</tr>
<tr>
<td>kmldescription</td>
<td>the description of the KML layer (HTML tags allowed)</td>
</tr>
</tbody>
</table>

Details

The function is used to convert a given Polygons object (a list of Polygon objects) or the first Polygons object listed in a passed SpatialPolygonsDataFrame object into KML polygon. If kmlfile is not NULL the result will be written into that file. If kmlfile is NULL the generated KML lines will be returned (see also value).

The conversion can also handle polygons which are marked as holes inside of the Polygons object if these holes are listed right after that polygon in which these holes appear. That implies that a given plot order set in the Polygons object will not be considered.

For a passed Polygons object the function generates a <Style> tag whereby its id attribute is set to the passed object’s ID.

Note that the geometries should be in geographical coordinates with datum WGS84.

The resulting KML polygon will be embedded in <Placemark><MultiGeometry><Polygon>.
Value

x is a list with the elements style and content containing the generated lines of the KML file as character vectors if kmlfile is NULL.

y is a list with the elements header and footer representing the KML file' header resp. footer if obj is NULL (see second example).

Color Specification

The following color specifications are allowed: 'red', 2, or as hex code '#RRGGBB' resp. '#RRGGBBAA' for passing the alpha value.

cat(kmlPolygon()$footer, file=kmlFile, sep="\n")
close(kmlFile)
kmlPolygons

Create and write a KML file on the basis of a given Polygons object or list of Polygons or SpatialPolygonsDataFrame

Description

The function is used to create and write a KML file on the basis of a given Polygons object (a list of Polygon objects of SpatialPolygonsDataFrame class) for the usage in Google Earth and Google Maps.

Usage

kmlPolygons(obj=NULL, kmlfile=NULL,  
    name="KML Polygons", description="", col=NULL, visibility=1, lwd=1,  
    border="white", kmlname="", kmldescription="")

Arguments

- obj: a Polygons or SpatialPolygonsDataFrame object or list of objects
- kmlfile: if not NULL the name as character string of the kml file to be written to working directory as "NAME.kml"
- name: the name of the KML polygon in Google Earth
- description: the description of the KML polygon displayed in Google Earth or Maps (HTML tags allowed)
- col: the fill color (see also Color Specification) of the KML polygon. If passing a list of Polygons or SpatialPolygonsDataFrame and length(col) is less than length(object) the first color in col will be applied to all objects in the list
- visibility: if set to 1 or TRUE specifies that the KML polygon should be visible after loading
- lwd: the stroke (polygon’s border line) width for the KML polygon
- border: the stroke color (see also Color Specification) for the KML polygon
- kmlname: the name of the KML layer
- kmldescription: the description of the KML layer (HTML tags allowed)

Details

The function is used to convert a given Polygons object (a list of Polygon objects) or the Polygons object listed in a passed SpatialPolygonsDataFrame object into KML polygon. If kmlfile is not NULL the result will be written into that file. If kmlfile is NULL the generated KML lines will be returned (see also value).

The conversion can also handle polygons which are marked as holes inside of the Polygons object if these holes are listed right after that polygon in which these holes appear. That implies that a given plot order set in the Polygons object will not be considered.

For a passed Polygons object the function generates a <Style> tag whereby its id attribute is set to the passed object’s ID.
Note that the geometries should be in geographical coordinates with datum WGS84.
The resulting KML polygon will be embedded in `<Placemark><MultiGeometry><Polygon>`.

**Value**

x is a list with the elements style and content containing the generated lines of the KML file as character vectors if kmlfile is NULL.
y is a list with the elements header and footer representing the KML file’s header resp. footer if obj is NULL (see second example).

**Color Specification**

The following color specifications are allowed: ‘red’, 2, or as hex code ‘#RRGGBB’ resp. ‘#RRGGBBAA’ for passing the alpha value.

leglabs  

Make legend labels

Description

leglabs makes character strings from the same break points. The plot.polylist() function may be used as a generic S3 method.

Usage

```r
leglabs(vec, under="under", over="over", between="-", reverse=FALSE)
```

Arguments

- `vec`: vector of break values
- `under`: character value for under
- `over`: character value for over
- `between`: character value for between
- `reverse`: flag to reverse order of values, you will also need to reorder colours, see example

mappolys <- readShapeSpatial(system.file("shapes/columbus.shp", package="maptools")[[1]], ID="NEIGNO")
brks <- round(quantile(mappolys$CRIME, probs=seq(0,1,0.2)), digits=2)
colours <- c("salmon1", "salmon2", "red3", "brown", "black")
plot(mappolys, col=colours[findInterval(mappolys$CRIME, brks, all.inside=TRUE)])
legend(x=c(5.8, 7.1), y=c(13, 14.5), legend=leglabs(brks), fill=colours, bty="n")
title(main=paste("Columbus OH: residential burglaries and vehicle",
"thefts per thousand households, 1980", sep="\n"))
#legend with reversed order
plot(mappolys, col=colours[findInterval(mappolys$CRIME, brks, all.inside=TRUE)])
legend(x=c(5.8, 7.1), y=c(13, 14.5), legend=leglabs(brks, reverse = TRUE),
fill=rev(colours), bty="n")
title(main=paste("Columbus OH: residential burglaries and vehicle",
"thefts per thousand households, 1980 (reversed legend)", sep="\n"))
```
lineLabel  

Line label placement with spplot and lattice.

Description

The lineLabel function produces and draws text grobs following the paths defined by a list of Line objects. The sp.lineLabel methods use this function to work easily with spplot.

Usage

```r
lineLabel(line, label,
  spar=.6, position = c('above', 'below'),
  textloc = 'constantSlope',
  col = add.text$col,
  alpha = add.text$alpha,
  cex = add.text$cex,
  lineheight = add.text$lineheight,
  font = add.text$font,
  fontfamily = add.text$fontfamily,
  fontface = add.text$fontface,
  lty = add.line$lty,
  lwd = add.line$lwd,
  col.line = add.line$col,
  identifier = 'lineLabel',
  ...
)

sp.lineLabel(object, labels, byid=TRUE,...)

label(object, text, ...)
```

Arguments

- `line`  
a list of Lines.
- `object`  
A Lines or SpatialLines object.
- `label, labels, text`  
a string or expression to be printed following the path of line. The names of labels should match the values of the ID slot of the lines to label. If labels is missing, the ID slot is used instead. The label method is a wrapper function to extract the ID slots and create a suitable character object with the correct names values.
- `byid`  
If TRUE (default) only the longest line of each unique ID value will be labelled.
- `textloc`  
a character or a numeric. It may be 'constantSlope', 'minSlope' or 'maxDepth', or the numeric index of the location. If it is a numeric, its length must coincide with the number of Lines.
lineLabel

spar

smoothing parameter. With values near zero, the label will closely follow the line. Default value is .6. See smooth.spline for details.

position

character string ('above' or 'below') to define where the text must be placed.

col, alpha, cex, lineheight, font, fontfamily, fontface

graphical arguments for the text. See gpar for details.

lty, lwd, col.line

graphical parameters for the line. See gpar for details.

identifier

A character string to identify the grob to be created.

other arguments

Details

Part of the label location code is adapted from panel.levelplot. smooth.spline is used to resample the segment of the line where the label is placed.

Author(s)

Oscar Perpiñán Lamigueiro.

map2SpatialPolygons

Convert map objects to sp classes

Description

These functions may be used to convert map objects returned by the map function in the maps package to suitable objects defined in the sp package. In the examples below, arguments are shown for retrieving first polygons by name, then lines by window.

Usage

map2SpatialPolygons(map, IDs, proj4string = CRS(as.character(NA)), checkHoles=FALSE)
map2SpatialLines(map, IDs=NULL, proj4string = CRS(as.character(NA)))
pruneMap(map, xlim=NULL, ylim=NULL)

Arguments

map  a map object defined in the maps package and returned by the map function
IDs  Unique character ID values for each output Polygons object; the input IDs can be an integer or character vector with duplicates, where the duplicates will be combined as a single output Polygons object
proj4string  Object of class "CRS”; holding a valid proj4 string
checkHoles  default=FALSE, if TRUE call checkPolygonHoles internally to check hole assignment, (by default no polygon objects are holes)
xlim,ylim  limits for pruning a map object - should only be used for lines, because polygons will not be closed

Details

Any zero area output geometries are dropped, and warnings are issued.
map2SpatialPolygons

Value

map2SpatialPolygons returns a SpatialPolygons object and map2SpatialLines returns a SpatialLines object (objects defined in the sp package); pruneMap returns a modified map object defined in the maps package.

Note

As the examples show, retrieval by name should be checked to see whether a window is not also needed: the "norway" polygons include "Norway:Bouvet Island", which is in the South Atlantic. Here, the IDs argument is set uniformly to "Norway" for all the component polygons, so that the output object contains a single Polygons object with multiple component Polygon objects. When retrieving by window, pruning may be needed on lines which are included because they begin within the window; interior=FALSE is used to remove country boundaries in this case.

}
nearestPointOnLine

Get the nearest point on a line to a given point

Description

This function calculates the coordinates of the nearest point on a line to a given point. This function does not work with geographic coordinates.

Usage

nearestPointOnLine(coordsLine, coordsPoint)

Arguments

coordsLine Matrix with coordinates of line vertices. Each row represents a vertex.
coordsPoint A vector representing the X and Y coordinates of the point.

Value

Vector with the X and Y coordinates of the nearest point on a line to the given point.
nearestPointOnSegment

**Author(s)**
German Carrillo

**See Also**

nearestPointOnSegment, snapPointsToLines

**Examples**

```r
coordsLine = cbind(c(1,2,3),c(3,2,2))
coordsPoint = c(1.2,1.5)
nearestPointOnLine(coordsLine, coordsPoint)
```

---

*nearestPointOnSegment*  
Get the nearest point on a segment to a given point

**Description**

This function calculates the coordinates of and the distance to the nearest point on a segment to a given point. This function does not work with geographic coordinates.

**Usage**

```r
nearestPointOnSegment(s, p)
```

**Arguments**

- `s`  
  A matrix representing the coordinates of the segment. The matrix has 2x2 dimension where each row represents one of the end points.

- `p`  
  A vector representing the X and Y coordinates of the point.

**Value**

A vector with three numeric values representing X and Y coordinates of the nearest point on a segment to a given point as well as the distance between both points.

**Author(s)**

German Carrillo

**References**

The function was ported to R based on this code: http://pastebin.com/n9rUuGRh

**See Also**

nearestPointOnLine, snapPointsToLines
Examples

```r
segment = cbind(c(1,2),c(1,1.5))
point = c(1.2,1.5)
nearestPointOnSegment(segment, point)
```

**Description**

When recentering a world map, say to change an "Atlantic" view with longitude range -180 to 180, to a "Pacific" view, with longitude range 0 to 360, polygons crossed by the new offset, here 0/360, need to be clipped into left and right sub.polygons to avoid horizontal scratches across the map. The `nowrapSpatialPolygons` function performs this operation using polygon intersection, and `nowrapRecenter` recenters the output `SpatialPolygons` object.

**Usage**

```r
nowrapRecenter(obj, offset = 0, eps = rep(.Machine$double.eps^(1/2.5), 2),
avoidGEOS = FALSE)
```

```r
nowrapSpatialPolygons(obj, offset = 0, eps=rep(.Machine$double.eps^(1/2.5), 2),
avoidGEOS = FALSE)
```

**Arguments**

- `obj` A `SpatialPolygons` object
- `offset` offset from the Greenwich meridian
- `eps` vector of two (left and right) fuzz factors to retract the ring from the offset (2.5 root to accommodate `rgeos` precision rules)
- `avoidGEOS` default FALSE; use `polyclip` or `gpclib` code even if `rgeos` is available

**Value**

A `SpatialPolygons` object

**Author(s)**

Roger Bivand

**See Also**

`recenter-methods`, `nowrapSpatialLines`
Examples

```r
run <- FALSE
if (require(maps)) run <- TRUE
## Not run:
if (run) {
  world <- map("world", fill=TRUE, col="transparent", plot=FALSE)
  worldSpP <- map2SpatialPolygons(world, world$names, CRS("+proj=longlat +ellps=WGS84"))
  worldSpP <- worldSpP[-grep("Antarctica", row.names(worldSpP)),]
  # incomplete polygons
  worldSpP <- worldSpP[-grep("Ghana", row.names(worldSpP)),]
  # self-intersection mouth of Volta
  worldSpP <- worldSpP[-grep("UK:Great Britain", row.names(worldSpP)),]
  # self-intersection Humber estuary
  worldSpPr <- recenter(worldSpP)
  plot(worldSpPr)
  title("Pacific view without polygon splitting")
}
if (run) {
  worldSpPnr <- nowrapRecenter(worldSpP)
  plot(worldSpPnr)
  title("Pacific view with polygon splitting")
}
## End(Not run)
if (!rgeosStatus()) run <- FALSE
if (run) {
  crds <- matrix(c(-1, 1, 1, -1, 50, 50, 52, 52), ncol=2)
  rcrds <- rbind(crds, crds[1,])
  SR <- SpatialPolygons(list(Polygons(list(Polygon(rcrds)), ID="r1")),
    proj4string=CRS("+proj=longlat +ellps=WGS84"))
  bbox(SR)
}
if (run) {
  SRr <- recenter(SR)
  bbox(SRr)
}
if (run) {
  SRnr <- nowrapRecenter(SR)
  bbox(SRnr)
}
```

### Description

When recentering a world map, most often from the "Atlantic" view with longitudes with range -180 to 180, to the "pacific" view with longitudes with range 0 to 360, lines crossing the offset (0 for this conversion) get stretched horizontally. This function breaks Line objects at the offset (usually Greenwich), inserting a very small gap, and reassembling the Line objects created as Lines. The **rgeos** package is required to use this function.
Usage

nowrapSpatialLines(obj, offset = 0, eps = rep(.Machine$double.eps^(1/2.5), 2))

Arguments

obj A Spatial Lines object
offset default 0, untried for other values
eps vector of two fuzz values, both default 2.5 root of double.eps

Value

A Spatial Lines object

Author(s)

Roger Bivand

recenter-methods, nowrapSpatialPolygons

Examples

Sl <- SpatialLines(list(Lines(list(Line(cbind(sin(seq(-4,4,0.4)),
seq(1,21,1)))))), "1"), proj4string=CRS("+proj=longlat +ellps=WGS84"))
summary(Sl)
if (require(rgeos)) {
  nwSL <- nowrapSpatialLines(Sl)
  summary(nwSL)
  if(require(maps)) {
    worldmap <- map("world", plot=FALSE)
    worldmapLines <- map2SpatialLines(worldmap, proj4string=CRS("+proj=longlat +datum=WGS84"))
    bbox(worldmapLines)
    t0 <- nowrapSpatialLines(worldmapLines, offset=180)
    bbox(t0)
  }
}

Description

This function is used in making SpatialPolygons objects from RArcInfo input.

Usage

pal2SpatialPolygons(arc, pal, IDs, dropPoly1=TRUE,
proj4string=CRS(as.character(NA)))
Arguments

IDs Unique character ID values for each output Polygons object; the input IDs can be an integer or character vector with duplicates, where the duplicates will be combined as a single output Polygons object

proj4string Object of class "CRS"; holding a valid proj4 string

arc Object returned by get.arcdata

pal Object returned by get.paldata

dropPoly1 Should the first polygon in the AVC or e00 data be dropped; the first polygon is typically the compound boundary of the whole dataset, and can be detected by looking at the relative lengths of the list components in the second component of pal, which are the numbers of arcs making up the boundary of each polygon

Value

The functions return a SpatialPolygons object

Author(s)

Roger Bivand

Examples

nc1 <- readShapePoly(system.file("shapes/sids.shp", package="maptools")[[1]], ID="FIPS")
plot(nc1)
text(coordinates(nc1), labels=row.names(nc1), cex=0.6)
if(require(maps)){
  ncmap <- map("county", "north carolina", fill=TRUE, col="transparent",
    plot=FALSE)
  IDs <- sapply(strsplit(ncmap$names, ",\[\,\]", function(x) x[2])
  nc2 <- pal2SpatialPolygons(ncmap, IDs)
  plot(nc2)
text(coordinates(nc2), labels=row.names(nc2), cex=0.6)
}
# if(require(RArcInfo)) {
# td <- tempdir()
# tmpcover <- paste(td, "nc", sep="/"")
# if (!file.exists(tmpcover)) e00toavc(system.file("share/co37_d90.e00",
#   package="maptools")[[1]], tmpcover)
# arc <- get.arcdata(td, "nc")
# pal <- get.paldata(td, "nc")
# pat <- get.tabledata(paste(td, "info", sep="/"), "NC.PAT")
# sapply(pal[[2]], function(x) length(x[[1]]))
# IDs <- paste(pat$ST[-1], pat$CO[-1], sep="")
# nc3 <- pal2SpatialPolygons(arc, pal, IDs=IDs)
# plot(nc3)
text(coordinates(nc3), labels=row.names(nc3), cex=0.6)
#}
Label placement with spplot and lattice.

Description
Use optimization routines to find good locations for point labels without overlaps.

Usage

```r
panel.pointLabel(x, y = NULL,
    labels = seq(along = x),
    method = c("SANN", "GA"),
    allowSmallOverlap = FALSE,
    col = add.text$col,
    alpha = add.text$alpha,
    cex = add.text$cex,
    lineheight = add.text$lineheight,
    font = add.text$font,
    fontfamily = add.text$fontfamily,
    fontface = add.text$fontface,
    fill = 'transparent',
    ...)
```

```r
sp.pointLabel(object, labels, ...)
```

Arguments

- `object` A SpatialPoints object.
- `x, y` coordinates for the point labels. See `xy.coords` for details.
- `labels` a character vector or expression.
- `method` the optimization method, either SANN for simulated annealing (the default) or GA for a genetic algorithm.
- `allowSmallOverlap` logical; if TRUE, labels are allowed a small overlap. The overlap allowed is 2% of the diagonal distance of the plot area.
- `col, alpha, cex, lineheight, font, fontfamily, fontface, fill` Graphical arguments. See `gpar` for details
- `...` Additional arguments (currently not processed).

Author(s)

Tom Short wrote `pointLabel` for base graphics. Oscar Perpiñán Lamigueiro modified this function for lattice and spplot.

myCols <- adjustcolor(colorRampPalette(brewer.pal(n=9, "Reds"))(100), .85)
pts <- spsample(meuse.grid, n=15, type="random")
Rauthors <- readLines(file.path(R.home("doc"), "AUTHORS")[9:28])
someAuthors <- Rauthors[seq_along(pts)]

sl1 <- list("sp.points", pts, pch=19, cex=.8, col="midnightblue")
sl2 <- list("sp.pointLabel", pts, label=someAuthors,
            cex=0.7, col="midnightblue",
            fontfamily="Palatino")

spplot(meuse.grid["dist"], col.regions=myCols, sp.layout=list(sl1, sl2))
Description

Use optimization routines to find good locations for point labels without overlaps.

Usage

pointLabel(x, y = NULL, labels = seq(along = x), cex = 1, method = c("SANN", "GA"), allowSmallOverlap = FALSE, trace = FALSE, doPlot = TRUE, ...)

Arguments

x, y as with plot.default, these provide the x and y coordinates for the point labels. Any reasonable way of defining the coordinates is acceptable. See the function xy.coords for details.

labels as with text, a character vector or expression specifying the text to be written. An attempt is made to coerce other language objects (names and calls) to expressions, and vectors and other classed objects to character vectors by as.character.

cex numeric character expansion factor as with text.

method the optimization method, either "SANN" for simulated annealing (the default) or "GA" for a genetic algorithm.

allowSmallOverlap logical; if TRUE, labels are allowed a small overlap. The overlap allowed is 2% of the diagonal distance of the plot area.

trace logical; if TRUE, status updates are given as the optimization algorithms progress.

doPlot logical; if TRUE, the labels are plotted on the existing graph with text.

... arguments passed along to text to specify labeling parameters such as col.

Details

Eight positions are candidates for label placement, either horizontally, vertically, or diagonally offset from the points. The default position for labels is the top right diagonal relative to the point (considered the preferred label position).

With the default settings, simulating annealing solves faster than the genetic algorithm. It is an open question as to which settles into a global optimum the best (both algorithms have parameters that may be tweaked).
The label positioning problem is NP-hard (nondeterministic polynomial-time hard). Placement becomes difficult and slows considerably with large numbers of points. This function places all labels, whether overlaps occur or not. Some placement algorithms remove labels that overlap.

Note that only cex is used to calculate string width and height (using strwidth and strheight), so passing a different font may corrupt the label dimensions. You could get around this by adjusting the font parameters with par prior to running this function.

Value
An xy list giving the x and y positions of the label as would be placed by text(xy, labels).

Examples
n <- 50
x <- rnorm(n)*10
y <- rnorm(n)*10
plot(x, y, col = "red", pch = 20)
pointLabel(x, y, as.character(round(x,5)), offset = 0, cex = .7)

plot(x, y, col = "red", pch = 20)
pointLabel(x, y, expression(over(alpha, beta[123])), offset = 0, cex = .8)
Virtual class "ppp"

Description

Virtual S4 class definition for S3 classes in the spatstat package to allow S4-style coercion to these classes.

Objects from the Class

A virtual Class: No objects may be created from it.

Author(s)

Edzer J. Pebesma

readAsciiGrid

read/write to/from (ESRI) asciigrid format

Description

read/write to/from ESRI asciigrid format; a fuzz factor has been added to writeAsciiGrid to force cell resolution to equality if the difference is less than the square root of machine precision.

Usage

readAsciiGrid(fname, as.image = FALSE, plot.image = FALSE, colname = basename(fname), proj4string = CRS(as.character(NA)), dec=options()$OutDec)
writeAsciiGrid(x, fname, attr = 1, na.value = -9999, dec=options()$OutDec, ...)

Arguments

fname
file name

as.image
logical; if TRUE, a list is returned, ready to be shown with the image command; if FALSE an object of class SpatialGridDataFrame-class is returned

plot.image
logical; if TRUE, an image of the map is plotted

colname
alternative name for data column if not file basename

proj4string
A CRS object setting the projection arguments of the Spatial Grid returned

dec
decimal point character. This should be a character string containing just one single-byte character — see note below.

x
object of class SpatialGridDataFrame
attr attribute column; if missing, the first column is taken; a name or a column number may be given

na.value numeric; value given to missing valued cells in the resulting map

... arguments passed to write.table, which is used to write the numeric data

Value

readAsciiGrid returns the grid map read; either as an object of class \texttt{SpatialGridDataFrame-class} or, if as.image is TRUE, as list with components \texttt{x}, \texttt{y} and \texttt{z}.

Note

In ArcGIS 8, it was not in general necessary to set the dec argument; it is not necessary in a mixed environment with ArcView 3.2 (R writes and ArcView reads "."), but inter-operation with ArcGIS 9 requires care because the defaults used by ArcGIS seem to be misleading, and it may be necessary to override what appear to be platform defaults by setting the argument.

writeAsciiGrid(xS, tmpfl)
aXS <- readAsciiGrid(tmpfl)
par <- par(mfrow=c(1,2))
image(xS, main="before export")
image(aXS, main="after import")
par(par)
unlink(tmpfl)
```
Description

The function reads a data frame from an attached GPS using the external program gpsbabel. The columns of the data frame need to be identified by hand because different GPS order NMEA data in different ways, and the columns should be converted to the correct classes by hand. Once the specifics of a particular GPS are identified, and ways of cleaning erroneous locations are found, the conversion of the output data frame into a usable one may be automated.

Usage

readGPS(i = "garmin", f = "usb:", type="w", invisible=TRUE, ...)

Arguments

i
INTYPE: a supported file type, default "garmin"

f
INFILE: the appropriate device interface, default "usb:", on Windows for serial interfaces commonly "com4:" or similar

type
"w" waypoints, or "t" track, or others provided in gpsbabel

invisible
Under Windows, do not open an extra window

... arguments passed through to read.table

Details

The function just wraps: gpsbabel -i INTYPE -f INFILE -o tabsep -F - in system(), and reads the returned character vector of lines into a data frame. On some systems, INFILE may not be readable by ordinary users without extra configuration. The gpsbabel program must be present and on the user's PATH for the function to work. Typically, for a given GPS, the user will have to experiment first to find a set of data-cleaning tricks that work, but from then on they should be repeatable.

Value

A data frame of waypoint values

## End(Not run)

readShapeLines  
---

### Read arc shape files into SpatialLinesDataFrame objects

#### Description

The use of this function is deprecated and it is not being maintained. Use `rgdal::readOGR()` or `sf::st_read()` instead - both of these read the coordinate reference system from the input file, while this deprecated function does not. For writing, use `rgdal::writeOGR()` or `sf::st_write()` instead.

The `readShapeLines` function reads data from an arc/line shapefile into a `SpatialLinesDataFrame` object; the shapefile may be of type polygon, but for just plotting for example coastlines, a `SpatialLines` object is sufficient. The `writeLinesShape` function writes data from a `SpatialLinesDataFrame` object to a shapefile. Note DBF file restrictions in `write.dbf`.

#### Usage

```r
readShapeLines(fn, proj4string=CRS(as.character(NA)), verbose=FALSE,
    repair=FALSE, delete_null_obj=FALSE)
writeLinesShape(x, fn, factor2char = TRUE, max_nchar=254)
```

#### Arguments

- `fn`  
  shapefile layer name, when writing omitting the extensions *.shp, *.shx and *.dbf, which are added in the function
- `proj4string`  
  Object of class CRS; holding a valid proj4 string
- `verbose`  
  default FALSE - report type of shapefile and number of shapes
repair default FALSE: some shapefiles provided by Geolytics Inc. have values of object sizes stored in the *.shx index file that are eight bytes too large, leading the function to try to read past the end of file. If repair=TRUE, an attempt is made to repair the internal values, permitting such files to be read.

delete_null_obj if TRUE, null geometries will be removed together with their data.frame rows

x a SpatialLinesDataFrame object

factor2char logical, default TRUE, convert factor columns to character

max_nchar default 254, may be set to a higher limit and passed through to the DBF writer, please see Details in write.dbf

Details
The shpID values of the shapefile will be used as Lines ID values; when writing shapefiles, the object data slot row.names are added to the DBF file as column SL_ID.

Value
a SpatialLinesDataFrame object

summary(xx)
xxx <- xx[xx$LENGTH > 30000,]
plot(xxx, col="red", add=TRUE)
tmpfl <- paste(tempdir(), "xxline", sep="/"
writeLinesShape(xxx, tmpfl)
getinfo.shape(paste(tmpfl, ".shp", sep=""))
axx <- readShapeLines(tmpfl, proj4string=CRS("+proj=utm +zone=33 +datum=WGS84"))
plot(axx, col="black", lwd=4)
plot(axx, col="yellow", lwd=1, add=TRUE)
unlink(paste(tmpfl, ".*", sep=""))
xx <- readShapeLines(system.file("shapes/sids.shp", package="maptools")[1], proj4string=CRS("+proj=longlat +datum=NAD27"))
plot(xx, col="blue")
readShapePoints

Read points shape files into SpatialPointsDataFrame objects

Description

The use of this function is deprecated and it is not being maintained. Use rgdal::readOGR() or sf::st_read() instead - both of these read the coordinate reference system from the input file, while this deprecated function does not. For writing, use rgdal::writeOGR() or sf::st_write() instead.

The readShapePoints reads data from a points shapefile into a SpatialPointsDataFrame object. The writePointsShape function writes data from a SpatialPointsDataFrame object to a shapefile. Both reading and writing can be carried out for 2D and 3D point coordinates. Note DBF file restrictions in write.dbf.

Usage

readShapePoints(fn, proj4string = CRS(as.character(NA)), verbose = FALSE, repair=FALSE)
writePointsShape(x, fn, factor2char = TRUE, max_nchar=254)

Arguments

fn shapefile layer name, when writing omitting the extensions *.shp, *.shx and *.dbf, which are added in the function
proj4string Object of class CRS; holding a valid proj4 string
verbose default FALSE: some shapefiles provided by Geolytics Inc. have values of object sizes stored in the *.shx index file that are eight bytes too large, leading the function to try to read past the end of file. If repair=TRUE, an attempt is made to repair the internal values, permitting such files to be read.
x a SpatialPointsDataFrame object
factor2char logical, default TRUE, convert factor columns to character
max_nchar default 254, may be set to a higher limit and passed through to the DBF writer, please see Details in write.dbf

Value

a SpatialPointsDataFrame object

Author(s)

Roger Bivand

readShapePoly

Examples

```r
library(maptools)
x <- readShapePoints(system.file("shapes/baltim.shp", package="maptools")[[1]])
plot(x)
summary(x)
x.x <- xx[xx$PRICE < 40,]
tmpfl <- paste(tempdir(), "xxpts", sep="/")
writePointsShape(xxx, tmpfl)
getinfo.shape(paste(tmpfl, ".shp", sep=""))
axx <- readShapePoints(tmpfl)
plot(axx, col="red", add=TRUE)
unlink(paste(tmpfl, ".*", sep=""))
x.x <- readShapePoints(system.file("shapes/pointZ.shp", package="maptools")[[1]])
dimensions(x)
plot(x)
summary(x)
```

Description

The use of this function is deprecated and it is not being maintained. Use `rgdal::readOGR()` or `sf::st_read()` instead - both of these read the coordinate reference system from the input file, while this deprecated function does not. For writing, use `rgdal::writeOGR()` or `sf::st_write()` instead.

The `readShapePoly` reads data from a polygon shapefile into a `SpatialPolygonsDataFrame` object. The `writePolyShape` function writes data from a `SpatialPolygonsDataFrame` object to a shapefile. Note DBF file restrictions in `write.dbf`.

Usage

```r
readShapePoly(fn, IDvar=NULL, proj4string=CRS(as.character(NA)),
              verbose=FALSE, repair=FALSE, force_ring=FALSE, delete_null_obj=FALSE,
              retrieve_ABS_null=FALSE)
writePolyShape(x, fn, factor2char = TRUE, max_nchar=254)
```

Arguments

- **fn**: shapefile layer name, when writing omitting the extensions ".shp", ".shx" and
  ".dbf", which are added in the function
- **IDvar**: a character string: the name of a column in the shapefile DBF containing the ID
  values of the shapes - the values will be converted to a character vector
- **proj4string**: Object of class CRS; holding a valid proj4 string
- **verbose**: default FALSE - report type of shapefile and number of shapes
repair

default FALSE: some shapefiles provided by Geolytics Inc. have values of object sizes stored in the *.shx index file that are eight bytes too large, leading the function to try to read past the end of file. If repair=TRUE, an attempt is made to repair the internal values, permitting such files to be read.

force_ring

if TRUE, close unclosed input rings

delete_null_obj

if TRUE, null geometries will be removed together with their data.frame rows

retrieve_ABS_null

default FALSE, if TRUE and delete\_null\_obj also TRUE, the function will return a data frame containing the data from any null geometries inserted by ABS

x

a SpatialPolygonsDataFrame object

factor2char

logical, default TRUE, convert factor columns to character

max_nchar

default 254, may be set to a higher limit and passed through to the DBF writer, please see Details in write.dbf

Details

If no IDvar argument is given, the shpID values of the shapefile will be used as Polygons ID values; when writing shapefiles, the object data slot row.names are added to the DBF file as column SP\_ID.

Value

a SpatialPolygonsDataFrame object

**readShapeSpatial**  
*Read shape files into Spatial*DataFrame* objects*

**Description**

The use of this function is deprecated and it is not being maintained. Use `rgdal::readOGR()` or `sf::st_read()` instead - both of these read the coordinate reference system from the input file, while this deprecated function does not. For writing, use `rgdal::writeOGR()` or `sf::st_write()` instead.

The `readShapeSpatial` reads data from a shapefile into a `Spatial*DataFrame` object. The `writeSpatialShape` function writes data from a `Spatial*DataFrame` object to a shapefile. Note DBF file restrictions in `write.dbf`.

**Usage**

```r
readShapeSpatial(fn, proj4string=CRS(as.character(NA)),
                 verbose=FALSE, repair=FALSE, IDvar=NULL, force_ring=FALSE,
                 delete_null_obj=FALSE, retrieve_ABS_null=FALSE)
writeSpatialShape(x, fn, factor2char = TRUE, max_nchar=254)
```

**Arguments**

- **fn**  
  shapefile layer name, when writing omitting the extensions *.shp, *.shx and *.dbf, which are added in the function

- **proj4string**  
  Object of class CRS; holding a valid proj4 string

- **verbose**  
  default FALSE - report type of shapefile and number of shapes

- **repair**  
  default FALSE: some shapefiles provided by Geolytics Inc. have values of object sizes stored in the *.shx index file that are eight bytes too large, leading the function to try to read past the end of file. If repair=TRUE, an attempt is made to repair the internal values, permitting such files to be read.

- **IDvar**  
  a character string: the name of a column in the shapefile DBF containing the ID values of the shapes - the values will be converted to a character vector (Polygons only)

- **force_ring**  
  if TRUE, close unclosed input rings (Polygons only)

- **delete_null_obj**  
  if TRUE, null geometries inserted by ABS will be removed together with their data.frame rows (Polygons and Lines)

- **retrieve_ABS_null**  
  default FALSE, if TRUE and delete\_null\_obj also TRUE, the function will return a data frame containing the data from any null geometries inserted by ABS (Polygons only)

- **x**  
  a vector data `Spatial*DataFrame` object

- **factor2char**  
  logical, default TRUE, convert factor columns to character

- **max_nchar**  
  default 254, may be set to a higher limit and passed through to the DBF writer, please see Details in `write.dbf`
Details

If no IDvar argument is given, the shpID values of the shapefile will be used as Polygons ID values; when writing shapefiles, the object data slot row.names are added to the DBF file as column SP\_ID.

Value

a Spatial*DataFrame object of a class corresponding to the input shapefile

getinfo.shape(paste(tmpfl, ".shp", sep=""))
unlink(paste(tmpfl, ".", sep=""))
```
readSplus  Read exported WinBUGS maps

Description

The function permits an exported WinBUGS map to be read into an sp package class SpatialPolygons object.

Usage

readSplus(file, proj4string = CRS(as.character(NA)))

Arguments

file       name of file
proj4string Object of class "CRS": holding a valid proj4 string

Value

readSplus returns a SpatialPolygons object

Note

In the example, taken from the GeoBUGS manual, the smaller part of area1 has a counter-clockwise ring direction in the data, while other rings are clockwise. This implies that it is a hole, and does not get filled. Errant holes may be filled using checkPolygonsHoles. The region labels are stored in the ID slots of the Polygons objects.

Rgshhs  Read GSHHS data into sp object

Description

If the data are polygon data, the function will read GSHHS polygons into SpatialPolygons object for a chosen region, using binary shorelines from Global Self-consistant Hierarchical High-resolution (Shorelines) Geography, release 2.3.0 of February 1, 2014 (http://www.soest.hawaii.edu/pwessel/gshhg/gshhg-bin-2.3.0.zip).

The getRgshhsMap function calls Rgshhs internally to simplify the interface by returning only a SpatialPolygons object rather than a more complex list, and by calling Rgshhs twice either side of longitude 0 degrees for values of "xlim" straddling 0, then merging the polygons retrieved.

If the data are line data, the borders or river lines will be read into a SpatialLines object. The data are provided in integer form as millionths of decimal degrees. Reading of much earlier versions of the GSHHS binary files will fail with an error message. The netCDF GSHHS files distributed with GMT >= 4.2 cannot be read as they are in a very different format.

Usage

Rgshhs(fn, xlim = NULL, ylim = NULL, level = 4, minarea = 0, shift = FALSE, verbose = TRUE, no.clip = FALSE, properly=FALSE, avoidGEOS=FALSE, checkPolygons=FALSE)

getRgshhsMap(fn = system.file("share/gshhs_c.b", package="maptools"),
 xlim, ylim, level = 1, shift = TRUE, verbose = TRUE, no.clip = FALSE,
 properly=FALSE, avoidGEOS=FALSE, checkPolygons=FALSE)

Arguments

fn filename or full path to GSHHS 2.3.0 file to be read
xlim longitude limits within 0-360 in most cases, negative longitudes are also found east of the Atlantic, but the Americas are recorded as positive values
ylim latitude limits
level maximum GSHHS level to include, defaults to 4 (everything), setting 1 will only retrieve land, no lakes
minarea minimum area in square km to retrieve, default 0
shift default FALSE, can be used to shift longitudes > 180 degrees to below zero, beware of artefacts involving unhandled polygon splitting at 180 degrees
verbose default TRUE, print progress reports
no.clip default FALSE, if TRUE, do not clip output polygons to bounding box
properly default FALSE, if TRUE use \texttt{gContainsProperly} rather than \texttt{gContains}, here FALSE because clip rectangle touches clipped objects, so they are not properly contained

\texttt{avoidGEOS} default FALSE; if TRUE force use of \texttt{gpclib} even when \texttt{rgeos} is available

\texttt{checkPolygons} default FALSE, if TRUE, check using GEOS, which may re-order the member Polygon objects with respect to the returned polydata data frame rows

\textbf{Details}

The package is distributed with the coarse version of the shoreline data, and much more detailed versions may be downloaded from the referenced websites. The data is of high quality, matching the accuracy of SRTM shorelines for the full dataset (but not for inland waterbodies). In general, users will construct study region SpatialPolygons objects, which can then be exported (for example as a shapefile), or used in other R packages (such as PBSmapping). The largest land polygons take considerable time to clip to the study region, certainly many minutes for an extract from the full resolution data file including Eurasia (with Africa) or the Americas. For this reason, do not give up if nothing seems to be happening after the (verbose) message: "Rgshhs: clipping $<m>$ of $<n>$ polygons ..." appears. Clipping the largest polygons in full resolution also needs a good deal of memory.

\textbf{Value}

for polygon data, a list with the following components:

- \texttt{polydata} data from the headers of the selected GSHHS polygons
- \texttt{belongs} a matrix showing which polygon belongs to (is included in) which polygon, going from the highest level among the selected polygons down to 1 (land); levels are: 1 land, 2 lake, 3 island\_in\_lake, 4 pond\_in\_island\_in\_lake.
- \texttt{new\_belongs} a ragged list of polygon inclusion used for making SP
- \texttt{SP} a SpatialPolygons object; this is the principal output object, and will become the only output object as the package matures

the \texttt{getRgshhsMap} returns only a SpatialPolygons object; for line data, a list with the following component:

- \texttt{SP} a SpatialLines object

\textbf{Note}

A number of steps are taken in this implementation that are unexpected, print messages, and so require explanation. Following the extraction of polygons intersecting the required region, a check is made to see if Antarctica is present. If it is, a new southern border is imposed at the southern ylim value or -90 if no ylim value is given. When clipping polygons seeming to intersect the required region boundary, it can happen that no polygon is left within the region (for example when the boundaries are overlaid, but also because the min/max polygon values in the header may not agree with the polygon itself (one case observed for a lake west of Groningen). The function then reports a null polygon. Another problem occurs when closed polygons are cut up during the finding of intersections between polygons and the required region boundary.

By default, if the rgeos package is available, it is used for topology operations. If it is not available, the gpclib package may be used. Please also note that gpclib has a restricted licence.
snapPointsToLines

Snap a set of points to a set of lines

Description
This function snaps a set of points to a set of lines based on the minimum distance of each point to any of the lines. This function does not work with geographic coordinates.

Usage
snapPointsToLines(points, lines, maxDist=NA, withAttrs = TRUE, idField=NA)
Arguments

points  An object of the class SpatialPoints or SpatialPointsDataFrame.
lines   An object of the class SpatialLines or SpatialLinesDataFrame.
maxDist Numeric value for establishing a maximum distance to avoid snapping points that are farther apart; its default value is NA.
withAttrs Boolean value for preserving (TRUE) or getting rid (FALSE) of the original point attributes. Default: TRUE. This parameter is optional.
idField A string specifying the field which contains each line’s id. This id will be transferred to the snapped points data set to distinguish the line which each point was snapped to.

Value

SpatialPointsDataFrame object as defined by the R package ‘sp’. This object contains the snapped points, therefore all of them lie on the lines.

sp2Mondrian

write map data for Mondrian

Description
The function outputs a SpatialPolygonsDataFrame object to be used by Mondrian

Usage
sp2Mondrian(SP, file, new_format=TRUE)

Arguments
SP a SpatialPolygonsDataFrame object
file file where output is written
new_format default TRUE, creates a text data file and a separate map file; the old format put both data sets in a single file - the map file is named by inserting "MAP\_" into the file= argument after the rightmost directory separator (if any)

Note
At this release, the function writes out a text file with both data and polygon(s) identified as belonging to each row of data.

Author(s)
Patrick Hausmann and Roger Bivand

References

Examples
## Not run:
td <- tempdir()
x <- readShapePoly(system.file("shapes/columbus.shp", package="maptools")[[1]])
sp2Mondrian(xx, file=file.path(td, "columbus1.txt"))
x <- readShapePoly(system.file("shapes/sids.shp", package="maptools")[[1]])
sp2Mondrian(xx, file=file.path(td, "sids1.txt"))

## End(Not run)
sp2tmap

Convert SpatialPolygons object for Stata tmap command

Description

The function converts a SpatialPolygons object for use with the Stata tmap command, by creating a data frame with the required columns.

Usage

sp2tmap(SP)

Arguments

SP a SpatialPolygons object

Value

a data frame with three columns:

\_ID an integer vector of polygon identifiers in numeric order
\_X numeric x coordinate
\_Y numeric y coordinate

and an ID_n attribute with the named polygon identifiers

Author(s)

Roger Bivand

sp2WB

Export SpatialPolygons object as S-Plus map for WinBUGS

Description

The function exports an sp SpatialPolygons object into a S-Plus map format to be import by WinBUGS.

Usage

sp2WB(map, filename, Xscale = 1, Yscale = Xscale, plotorder = FALSE)

Arguments

- map: a SpatialPolygons object
- filename: file where output is written
- Xscale, Yscale: scales to be written in the output file
- plotorder: default=FALSE, if TRUE, export polygons in plotting order

Author(s)

Virgilio Gómez Rubio, partly derived from earlier code by Thomas Jagger

References

Examples

```
xx <- readShapePoly(system.file("shapes/sids.shp", package="maptools")[[1]],
    IDvar="FIPSNO", proj4string=CRS("+proj=longlat +ellps=clrk66"))
plot(xx, border="blue", axes=TRUE, las=1)
if (!file.exists(tf <- tempfile()))
    sp2WB(as(xx, "SpatialPolygons"), filename=tf)
xxx <- readSplus(tf, proj4string=CRS("+proj=longlat +ellps=clrk66"))
all.equal(xxx, as(xx, "SpatialPolygons"), tolerance=.Machine$double.eps^(-1/4),
    check.attributes=FALSE)
```
SpatialLines2PolySet

Convert sp line and polygon objects to PBSmapping PolySet objects

Description

Functions SpatialLines2PolySet and SpatialPolygons2PolySet convert objects of sp classes to PolySet class objects as defined in the PBSmapping package, and PolySet2SpatialLines and PolySet2SpatialPolygons convert in the opposite direction.

Usage

SpatialLines2PolySet(SL)
SpatialPolygons2PolySet(SpP)
PolySet2SpatialLines(PS)
PolySet2SpatialPolygons(PS, close_polys=TRUE)

Arguments

SL a SpatialLines object as defined in the sp package
SpP a SpatialPolygons object as defined in the sp package
PS a PolySet object
close_polys should polygons be closed if open

Value

PolySet objects as defined in the PBSmapping package

Author(s)

Roger Bivand and Andrew Niccolai

See Also

PolySet, MapGen2SL

Examples

```r
if(require(PBSmapping) && require(maps)) {
  nor_coast_lines <- map("world", interior=FALSE, plot=FALSE, xlim=c(4,32), ylim=c(58,72))
  nor_coast_lines <- pruneMap(nor_coast_lines, xlim=c(4,32), ylim=c(58,72))
  nor_coast_lines_sp <- map2SpatialLines(nor_coast_lines,
                                         proj4string=CRS("+proj=longlat +datum=WGS84 +ellps=WGS84"))
  nor_coast_lines_PS <- SpatialLines2PolySet(nor_coast_lines_sp)
```
SpatialLinesMidPoints

**Line midpoints**

**Description**

The function converts SpatialLinesDataFrame to SpatialPointsDataFrame with points at the midpoints of the line segments.

**Usage**

`SpatialLinesMidPoints(sldf)`

**Arguments**

- `sldf` A SpatialLines or SpatialLinesDataFrame object

**Details**

The function builds a SpatialPointsDataFrame from the midpoints of Line objects belonging to Lines objects in an object inheriting from a Spatial Lines object. The output data slot contains an index variable showing which Lines object the midpoints belong to.

**Value**

A SpatialPointsDataFrame object created from the input object.

**Author(s)**

Jonathan Callahan, modified by Roger Bivand
spCbind-methods

Examples

```
x <- readShapeLines(system.file("shapes/fylk-val.shp", package="maptools")[[1]],
    proj4string=CRS("+proj=utm +zone=33 +datum=WGS84"))
plot(x, col="blue")
spdf <- SpatialLinesMidPoints(x)
plot(spdf, col="orange", add=TRUE)
```

spCbind-methods cbind for spatial objects

Description

spCbind provides cbind-like methods for Spatial*DataFrame objects in addition to the $, [<- and [[<- methods already available.

Methods

- `obj = "SpatialPointsDataFrame", x = "data.frame"` cbind a data frame to the data slot of a SpatialPointsDataFrame object
- `obj = "SpatialPointsDataFrame", x = "vector"` cbind a vector to the data slot of a SpatialPointsDataFrame object
- `obj = "SpatialLinesDataFrame", x = "data.frame"` cbind a data frame to the data slot of a SpatialLinesDataFrame object; the data frame argument must have row names set to the Lines ID values, and should be re-ordered first by matching against a shared key column
- `obj = "SpatialLinesDataFrame", x = "vector"` cbind a vector to the data slot of a SpatialLinesDataFrame object
- `obj = "SpatialPolygonsDataFrame", x = "data.frame"` cbind a data frame to the data slot of a SpatialPolygonsDataFrame object; the data frame argument must have row names set to the Polygons ID values, and should be re-ordered first by matching against a shared key column
- `obj = "SpatialPolygonsDataFrame", x = "vector"` cbind a vector to the data slot of a SpatialPolygonsDataFrame object

Author(s)

Roger Bivand

Examples

```r
data(SplashDams)
plot(SplashDams, axes=TRUE)
```

**Description**

`spRbind` provides rbind-like methods for Spatial*DataFrame objects

**Methods**

- `obj = "SpatialPoints", x = "SpatialPoints"` rbind two SpatialPoints objects
- `obj = "SpatialPointsDataFrame", x = "SpatialPointsDataFrame"` rbind two SpatialPointsDataFrame objects
- `obj = "SpatialLines", x = "SpatialLines"` rbind two SpatialLines objects
- `obj = "SpatialLinesDataFrame", x = "SpatialLinesDataFrame"` rbind two SpatialLinesDataFrame objects
- `obj = "SpatialPolygons", x = "SpatialPolygons"` rbind two SpatialPolygons objects
- `obj = "SpatialPolygonsDataFrame", x = "SpatialPolygonsDataFrame"` rbind two SpatialPolygonsDataFrame objects

**Note**

In addition to the `spRbind`-methods, there are also `rbind`-methods for Spatial* objects. The differences are:

1. `spRbind`-methods can bind 2 objects, whereas `rbind`-methods can bind multiple objects
2. some `rbind` can accept objects with duplicated IDs, for all `spRbind`-methods these have to be modified explicitly, e.g. by calling `spChFIDs-methods`

**Author(s)**

Roger Bivand

**state.vbm**

**US State Visibility Based Map**

**Description**

A SpatialPolygonsDataFrame object (for use with the maptools package) to plot a Visibility Based Map.

**Usage**

```r
data(state.vbm)
```

**Details**

A SpatialPolygonsDataFrame object (for use with the maptools package) to plot a map of the US states where the sizes of the states have been adjusted to be more equal.

This map can be useful for plotting state data using colors patterns without the larger states dominating and the smallest states being lost.

The original map is copyrighted by Mark Monmonier. Official publications based on this map should acknowledge him. Commercial publications of maps based on this probably need permission from him to use.

**Author(s)**

Greg Snow <greg.snow@imail.org> (of this compilation)

**Source**

The data was converted from the maps library for S-PLUS. S-PLUS uses the map with permission from the author. This version of the data has not received permission from the author (no attempt made, not that it was refused), most of my uses I feel fall under fair use and do not violate copyright, but you will need to decide for yourself and your applications.

sun-methods

Methods for sun ephemerides calculations

Description

Functions for calculating sunrise, sunset, and times of dawn and dusk, with flexibility for the various formal definitions. They use algorithms provided by the National Oceanic & Atmospheric Administration (NOAA).

Usage

```r
# S4 method for signature 'SpatialPoints, POSIXct'
crepuscule(crds, dateTime, solarDep, direction=c("dawn", "dusk"),
           POSIXct.out=FALSE)

# S4 method for signature 'matrix, POSIXct'
crepuscule(crds, dateTime,
           proj4string=CRS("+proj=longlat +datum=WGS84"), solarDep,
           direction=c("dawn", "dusk"), POSIXct.out=FALSE)

# S4 method for signature 'SpatialPoints, POSIXct'
sunriset(crds, dateTime, direction=c("sunrise", "sunset"),
          POSIXct.out=FALSE)

# S4 method for signature 'matrix, POSIXct'
sunriset(crds, dateTime,
          proj4string=CRS("+proj=longlat +datum=WGS84"),
          direction=c("sunrise", "sunset"), POSIXct.out=FALSE)

# S4 method for signature 'SpatialPoints, POSIXct'
solarnoon(crds, dateTime, POSIXct.out=FALSE)

# S4 method for signature 'matrix, POSIXct'
solarnoon(crds, dateTime,
          proj4string=CRS("+proj=longlat +datum=WGS84"),
          POSIXct.out=FALSE)

# S4 method for signature 'SpatialPoints, POSIXct'
solarpos(crds, dateTime, ...)

# S4 method for signature 'matrix, POSIXct'
solarpos(crds, dateTime,
          proj4string=CRS("+proj=longlat +datum=WGS84"), ...)
```

Examples

```r
data(state.vbm)
plot(state.vbm)

tmp <- state.x77[, 'HS Grad']
tmp2 <- cut(tmp, seq(min(tmp), max(tmp), length.out=11),
           include.lowest=TRUE)
plot(state.vbm, col=cm.colors(10)[tmp2])
```
Arguments

**crds**
- a SpatialPoints or matrix object, containing x and y coordinates (in that order).

**dateTime**
- a POSIXct object with the date and time associated to calculate ephemerides for points given in crds.

**solarDep**
- numeric vector with the angle of the sun below the horizon in degrees.

**direction**
- one of "dawn", "dusk", "sunrise", or "sunset", indicating which ephemerides should be calculated.

**POSIXct.out**
- logical indicating whether POSIXct output should be included.

**proj4string**
- string with valid projection string describing the projection of data in crds.

... other arguments passed through.

Details

NOAA used the reference below to develop their Sunrise/Sunset

https://www.esrl.noaa.gov/gmd/grad/solcalc/sunrise.html and Solar Position

https://www.esrl.noaa.gov/gmd/grad/solcalc/azel.html Calculators. The algorithms include corrections for atmospheric refraction effects.

Input can consist of one location and at least one POSIXct times, or one POSIXct time and at least one location. solarDep is recycled as needed.

Do not use the daylight savings time zone string for supplying dateTime, as many OS will not be able to properly set it to standard time when needed.

Value

crepuscule, sunriset, and solarnoon return a numeric vector with the time of day at which the event occurs, expressed as a fraction, if POSIXct.out is FALSE; otherwise they return a data frame with both the fraction and the corresponding POSIXct date and time.

solarpos returns a matrix with the solar azimuth (in degrees from North), and elevation.

Warning

Compared to NOAA’s original Javascript code, the sunrise and sunset estimates from this translation may differ by +/- 1 minute, based on tests using selected locations spanning the globe. This translation does not include calculation of prior or next sunrises/sunsets for locations above the Arctic Circle or below the Antarctic Circle.

Note

NOAA notes that “for latitudes greater than 72 degrees N and S, calculations are accurate to within 10 minutes. For latitudes less than +/- 72 degrees accuracy is approximately one minute.”
Author(s)

Sebastian P. Luque <spluque@gmail.com>, translated from Greg Pelletier's <gpel461@ecy.wa.gov>
VBA code (available from https://ecology.wa.gov/Research-Data/Data-resources/Models-spreadsheets/Modeling-the-environment/Models-tools-for-TMDLs), who in turn translated it from original Javascript code by NOAA (see Details). Roger Bivand <roger.bivand@nhh.no> adapted the code to work with sp classes.

data=data.frame(winter=win))
image(SPDF, axes=TRUE, col=cm.colors(40))
```
symbolsInPolys

Place grids of points over polygons

Description

Place grids of points over polygons with chosen density and/or symbols (suggested by Michael Wolf).

Usage

symbolsInPolys(pl, dens, symb = "+", compatible = FALSE)

Arguments

- **pl**: an object of class SpatialPolygons or SpatialPolygonsDataFrame
- **dens**: number of symbol plotting points per unit area; either a single numerical value for all polygons, or a numeric vector the same length as pl with values for each polygon
- **symb**: plotting symbol; either a single value for all polygons, or a vector the same length as pl with values for each polygon
- **compatible**: what to return, if TRUE a list of matrices of point coordinates, one matrix for each member of pl; each matrix has a symb attribute that can be used for setting the pch argument for plotting. If the count of points for the given density and polygon area is zero, the list element is NULL, and can be tested when plotting - see the examples.

Details

The dots are placed in a grid pattern with the number of points per polygon being polygon area times density (number of dots not guaranteed to be the same as the count). When the polygon is made up of more than one part, the dots will be placed in proportion to the relative areas of the clockwise rings (anticlockwise are taken as holes). From maptools release 0.5-2, correction is made for holes in the placing of the dots, but depends on hole values being correctly set, which they often are not.

Value

The function returns a list of matrices of point coordinates, one matrix for each member of pl; each matrix has a symb attribute that can be used for setting the pch argument for plotting. If the count of points for the given density and polygon area is zero, the list element is NULL, and can be tested when plotting - see the examples.

Note

Extension to plot pixmaps at the plotting points using addlogo() from the pixmap package is left as an exercise for the user.

nc_SP <- SpatialPolygonsDataFrame(SpatialPolygons(pls_new,
                      proj4string=CRS(proj4string(nc_SP))), data=as(nc_SP, "data.frame"))
# End(Not run)
syms <- c("-", "+", "x")
np <- sapply(slot(nc_SP, "polygons"), function(x) length(slot(x, "Polys")))
try1 <- symbolsInPolys(nc_SP, 100, symb=syms[np])
plot(nc_SP, axes=TRUE)
plot(try1, add=TRUE, pch=as.character(try1$symb))
```

thinnedSpatialPoly  Douglas-Peuker line generalization for Spatial Polygons

Description

The function applies the implementation of the Douglas-Peuker algorithm for line generalization or simplification (originally from shapefiles) to objects inheriting from Spatial Polygons. It does not preserve topology, so is suitable for visualisation, but not for the subsequent analysis of the polygon boundaries, as artefacts may be created, and boundaries of neighbouring entities may be generalized differently. If the rgeos package is available, thinnedSpatialPolyGEOS will be used with partial topology preservation instead of the R implementation here by passing arguments through.

Usage

```r
thinnedSpatialPoly(SP, tolerance, minarea=0, topologyPreserve = FALSE,
                    avoidGEOS = FALSE)
```

Arguments

- **SP**: an object inheriting from the SpatialPolygons class
- **tolerance**: the tolerance value in the metric of the input object
- **minarea**: the smallest area of Polygon objects to be retained, ignored if rgeos used
unionSpatialPolygons

Aggregate Polygons in a SpatialPolygons object

Description

The function aggregates Polygons in a SpatialPolygons object, according to the IDs vector specifying which input Polygons belong to which output Polygons; internal boundaries are dissolved using the rgeos package `gUnaryUnion` function. If the rgeos package is not available, and if the gpclib package is available and the user confirms that its restrictive license conditions are met, its `union` function will be used.

topologyPreserve

choose between two rgeos options: logical determining if the algorithm should attempt to preserve the topology (nodes not complete edges) of the original geometry

avoidGEOS

use R DP code even if rgeos is available

Value

An object of the same class as the input object

Note

Warnings reporting: Non-finite label point detected and replaced, reflect the changes in the geometries of the polygons induced by line generalization.

Author(s)

Ben Stabler, Michael Friendly, Roger Bivand

References

Examples

```r
xx <- readShapeSpatial(system.file("shapes/sids.shp", package="maptools")[[1]],
    IDvar="FIPSNO", proj4string=CRS("+proj=longlat +ellps=clrk66"))
object.size(as(xx, "SpatialPolygons"))
xxx <- thinnedSpatialPoly(xx, tolerance=0.05, minarea=0.001)
object.size(as(xxx, "SpatialPolygons"))
par(mfrow=c(2,1))
plot(xx)
plot(xxx)
par(mfrow=c(1,1))
```
unionSpatialPolygons

Usage

unionSpatialPolygons(SpP, IDs, threshold=NULL, avoidGEOS=FALSE, avoidUnaryUnion=FALSE)

Arguments

SpP A SpatialPolygons object as defined in package sp
IDs A vector defining the output Polygons objects, equal in length to the length of the polygons slot of SpRs; it may be character, integer, or factor (try table(factor(IDs)) for a sanity check). It may contain NA values for input objects not included in the union
threshold if not NULL, an area measure below which slivers will be discarded (some polygons have non-identical boundaries, for instance along rivers, generating slivers on union which are artefacts, not real sub-polygons)
avoidGEOS default FALSE; if TRUE force use of gpclib even when GEOS is available
avoidUnaryUnion avoid gUnaryUnion if it is available; not relevant before GEOS 3.3.0

Value

Returns an aggregated SpatialPolygons object named with the aggregated IDs values in their sorting order; see the ID values of the output object to view the order.

Warning

When using GEOS Unary Union, it has been found that some polygons are not dissolved correctly when the absolute values of the coordinates are very small. No work-around is available at present.

Author(s)

Roger Bivand

Examples

if (rgeosStatus()) {
  ncl <- readShapePoly(system.file("shapes/sids.shp", package="maptools")[[1]],
    proj4string=CRS("+proj=longlat +datum=NAD27"))
  lps <- coordinates(ncl)
  ID <- cut(lps[,1], quantile(lps[,1]), include.lowest=TRUE)
  reg4 <- unionSpatialPolygons(ncl, ID)
  row.names(reg4)
}
Description

The object loaded is a SpatialPolygonsDataFrame object containing a slightly modified version of Bjoern Sandvik’s improved version of world\_borders.zip - TM\_WORLD\_BORDERS\_SIMPL-0.2.zip dataset from the Mapping Hacks geodata site. The country Polygons objects and the data slot data frame row numbers have been set to the ISO 3166 three letter codes.

Usage

data(wrld_simpl)

Format

The format is: Formal class 'SpatialPolygonsDataFrame' [package "sp"] with 5 slots; the data clot contains a data.frame with 246 obs. of 11 variables:

FIPS factor of FIPS country codes
ISO2 factor of ISO 2 character country codes
ISO3 factor of ISO 3 character country codes
UN integer vector of UN country codes
NAME Factor of country names
AREA integer vector of area values
POP2005 integer vector of population in 2005
REGION integer vector of region values
SUBREGION integer vector of subregion values
LON numeric vector of longitude label points
LAT numeric vector of latitude label points

The object is in geographical coordinates using the WGS84 datum.

Source

Examples

data(wrld_simpl)
plot(wrld_simpl)
